Backplane Driver

FEATURES

- Typical propagation delay: 2.0ns
- Typical supply current ($-I_{EE}$): 78mA

DESCRIPTION

The 100126 contains nine independent, high-speed buffer gates each with a single input and a single output. The gates are non-inverting. These buffers are useful in bus-oriented systems where buffering is desired. The output transition times are slower to minimize noise when used in a backplane environment.

All unused inputs can be left open due to integrated pull-down resistors.

NOTES:

- The specified limits represent the worst case values for the parameter. Since these worst case values normally occur at the supply voltage and temperature extremes, additional noise immunity can be achieved by decreasing the allowable operating condition ranges.
- Conditions for testing shown in the tables are not necessarily worst case. For worst case testing guidelines, refer to DC Testing, Chapter 1, Section 3.
- The specified limits shown in the DC electrical characteristics table can be met only after thermal equilibrium has been established. Thermal equilibrium is established by applying power for at least 2 minutes, while maintaining transverse airflow of 2.5 meters/sec (500 linear feet/min) over the device, mounted either in a test socket or on a printed circuit board. Test voltage values are given in the DC operating conditions table.
- The device can function down to $V_{EE} = -5.7\text{V}$, allowing operation with either the 10K or the 10KH family. Correction factors can be used to calculate new DC limits for the extended V_{EE} range. For more information, see Chapters 5 and 10, Section 4.
