

35FS4500-35FS6500-ASILD

Grade 0 safety power system basis chip with CAN flexible data transceiver

Rev. 4 — 5 August 2024

Product data sheet

1 General description

The 35FS4500/35FS6500 SMARTMOS devices are a multi-output, power supply, integrated circuit, including CAN Flexible Data (FD) transceiver, dedicated to harsh automotive and transportation markets requiring high reliability (Grade 0) and high functional safety (fit for ASIL D) performance.

Multiple switching and linear voltage regulators, including low-power mode (32 μ A) are available with various wake-up capabilities. An advanced power management scheme is implemented to maintain high efficiency over a wide range of input voltages (down to 2.7 V) and output current ranges (up to 1.5 A).

The 35FS4500/35FS6500 includes configurable fail-safe/fail silent safety behavior and features, with two fail-safe outputs, becoming a full part of a safety oriented system partitioning, to reach a high integrity safety level (up to ASIL D).

The built-in CAN FD interface fulfills the ISO 11898-2 and -5 standards.

High temperature capability up to $T_A = 150\text{ }^{\circ}\text{C}$ and $T_J = 175\text{ }^{\circ}\text{C}$, compliant with AEC-Q100 Grade 0 automotive qualification.

2 Features

- Battery voltage sensing and MUX output pin
- Highly flexible SMPS pre-regulator, allowing two topologies: non-inverting buck-boost and standard buck
- Family of devices to supply MCU core from 1.0 V to 5.0 V, with SMPS (0.8 A or 1.5 A) or LDO (0.5 A)
- Linear voltage regulator dedicated to auxiliary functions, or to sensor supply (V_{CCA} tracker or independent), 5.0 V or 3.3 V
- Linear voltage regulator dedicated to MCU A/D reference voltage or I/Os supply (V_{CCA}), 5.0 V or 3.3 V
- 3.3 V keep alive memory supply available in low-power mode
- Long duration timer, counting up to 6 months with 1.0 s resolution
- Multiple wake-up sources in low-power mode: CAN, IOs, LDT
- Five configurable I/Os

3 Applications

- T_A up to 150 °C and T_J up to 175 °C
- Drive train electrification (BMS, hybrid EV and HEV, inverter, DCDC, alterno starter)
- Drive train - chassis and safety (active suspension, steering, safety domain gateway)
- Power train (EMS, TCU, gear box)

5 Ordering information

5.1 Part numbers definition

MC35FS c 5 x y z AE/R2

Table 1. Part number breakdown

Code	Option	Variable	Description
c	4 series	V _{CORE} type	Linear
	6 series		DCDC
x	0	V _{CORE} current	0.5 A or 0.8 A
	1		1.5 A
y	0	Functions	none
	1		FS1B
	2		LDT
	3		FS1B, LDT

Table 1. Part number breakdown...continued

Code	Option	Variable	Description
z	N	Physical interface	none
	C		CAN FD

5.2 Part numbers list

Table 2. Orderable part variations

Part number	Temperature (T _A)	Package	FS1B	LDT	VCORE	VCORE type	VKAM on	CAN FD	Notes
MC35FS4500CAE	-40 °C to 150 °C	48-pin LQFP exposed pad	0	0	0.5 A	Linear	by SPI	1	[1]
MC35FS4500NAE			0	0	0.5 A	Linear	by SPI	0

7.2 Pin description

Table 3. 35FS4500/35FS6500 pin definition

A functional description of each pin can be found in [Section 11 "Functional pin description" on page 26](#).

Pin	Symbol	Type	Definition
1	VSUP1	A_IN	Power supply of the device. An external reverse battery protection diode in series is mandatory.
2	VSUP2	A_IN	Second power supply. Protected by the external reverse battery protection diode used for VSUP1. VSUP1 and VSUP2 must be connected together externally.
3	VSENSE	A_IN	Sensing of the battery voltage. Must be connected prior to the reverse battery protection diode.
4	VSUP3	A_IN	Third power supply dedicated to the device supply. Protected by the external reverse battery protection diode used for VSUP1. Must be connected between the reverse protection diode and the input PI filter.
5	or FS1B	D_OUT	Second output of the safety block (active low). The pin is asserted low at start-up and when a fault condition is detected, with a configurable delay or duration versus FS0B output terminal. Open drain structure.
6	GND_COM	GROUND	Dedicated ground for physical layers
7	CAN_5V	A_OUT	Output voltage for the embedded CAN FD interface
8	CANH	A_IN/OUT	CAN output high. If CAN function is not used, this pin must be left open.
9	CANL	A_IN/OUT	CAN output low. If CAN function is not used, this pin must be left open.
10	IO_4	D_IN A_OUT	Can be used as digital input (load dump proof) with wake-up capability or as an output gate driver Digital input: Pin status can be read through the SPI. Can be used to monitor error signals from another IC for safety purposes (when used in conjunction with IO_5). Wake-up capability: Can be selectable to wake-up on edges or levels. Output gate driver: Can drive a logic level low-side NMOS transistor. Controlled by the SPI.
11	IO_5/VKAM	A_IN D_IN A_OUT	Can be used as digital input with wake-up capability or as an analog output providing keep alive memory supply in low-power mode. Analog input: Pin status can be read through the MUX output terminal. Digital input: Pin status can be read through the SPI. Can be used to monitor error signals from another IC for safety purposes (when used in conjunction with IO_4). Wake-up capability: Can be selectable to wake-up on edges or levels. Supply output: Provide keep alive memory supply in low-power mode.
12	IO_0	A_IN D_IN	Can be used as analog or digital input (load dump proof) with wake-up capability (selectable). Analog input: Pin status can be read through the MUX output terminal. Digital input: Pin status can be read through the SPI. Wake-up capability: Can be selectable to wake-up on edges or levels.
13	FCRBM	A_IN	Feedback core resistor bridge monitoring: For safety purposes, this pin is used to monitor the middle point of a redundant resistor bridge connected on V _{CORE} (in parallel to the one used to set the V _{CORE} voltage). If not used, this pin must be connected directly to FB_CORE.

Table 3. 35FS4500/35FS6500 pin definition ...continued

A functional description of each pin can be found in [Section 11 "Functional pin description" on page 26](#).

Pin	Symbol	Type	Definition
14	FS0B	D_OUT	First output of the safety block (active low). The pin is asserted low at start-up and when a fault condition is detected. Open drain structure.
15	DEBUG	D_IN	Debug mode entry input
16	AGND	GROUND	Analog ground connection
17	MUX_OUT	A_OUT	Multiplexed output to be connected to a MCU ADC. Selection of the analog parameter is available at MUX-OUT through the SPI.
18 19	IO_2:3	D_IN	Digital input pin with wake-up capability (logic level compatible) Digital input: Pin status can be read through the SPI. Can be used to monitor FCCU error signals from MCU for safety purposes. Wake-up capability: Can be selectable to wake-up on edges or levels.
20	TXD	D_IN	Transceiver input from the MCU which controls the state of the CAN bus. Internal pull-up to VDDIO. If CAN function is not used, this pin must be left open.
21	RXD	D_OUT	Receiver output which reports the state of the CAN bus to the MCU If CAN function is not used, this pin must be left open.
22	or VPU_FS	A_OUT	Pull-up output for FS1B function
23	NC	N/A	Not connected. Pin must be left open.
24	RSTB	D_OUT	This output is asserted low when the safety block reports a failure. The main function is to reset the MCU. Reset input voltage is also monitored in order to detect external reset and fault condition. Open drain structure.
25	MISO	D_OUT	SPI bus. primary input secondary output
26	MOSI	D_IN	SPI bus. primary output secondary input
27	SCLK	D_IN	SPI Bus. Serial clock
28	NCS	D_IN	Not chip select (active low)
29	INTB	D_OUT	This output pin generates a low pulse when an Interrupt condition occurs. Pulse duration is configurable. Internal pull-up to VDDIO.
30	VDDIO	A_IN	Input voltage for MISO output buffer. Allows voltage compatibility with MCU I/Os.
31	SELECT	D_IN	Hardware selection pin for VAUX and VCCA output voltages
32	FB_CORE	A_IN	VCORE voltage feedback. Input of the error amplifier.
33	COMP_CORE	A_OUT	Compensation network. Output of the error amplifier. For FS4500 series, this pin must be left open (NC).
34	VCORE_SNS	A_IN	VCORE input voltage sense
35	SW_CORE	A_OUT	VCORE output switching point for FS6500 series
	or VCORE	A_OUT	VCORE output voltage for FS4500 series
36	BOOT_CORE	A_IN/OUT	Bootstrap capacitor for VCORE internal NMOS gate drive. For FS4500 series, this pin must be left open (NC).
37	VPRE	A_IN	VPRE input voltage sense
38	VAUX	A_OUT	VAUX output voltage. External PNP ballast transistor. Collector connection
39	VAUX_B	A_OUT	VAUX voltage regulator. External PNP ballast transistor. Base connection

Table 3. 35FS4500/35FS6500 pin definition ...continued

A functional description of each pin can be found in [Section 11 "Functional pin description" on page 26](#).

Pin	Symbol	Type	Definition
40	VAUX_E	A_OUT	VAUX voltage regulator. External PNP ballast transistor. Emitter connection
41	VCCA_E	A_OUT	VCCA voltage regulator. External PNP ballast transistor. Emitter connection
42	VCCA_B	A_OUT	VCCA voltage regulator. External PNP ballast transistor. Base connection
43	VCCA	A_OUT	VCCA output voltage. External PNP ballast transistor. Collector connection
44	GATE_LS	A_OUT	Low-side MOSFET gate drive for non-inverting buck-boost configuration
45	DGND	GROUND	Digital ground connection
46	BOOT_PRE	A_IN/OUT	Bootstrap capacitor for the VPRES internal NMOS gate drive
47	SW_PRE2	A_OUT	Second pre-regulator output switching point
48	SW_PRE1	A_OUT	First pre-regulator output switching point

8 Maximum ratings

Table 4. Maximum ratings

All voltages are with respect to ground, unless otherwise specified. Exceeding these ratings may cause a malfunction or permanent damage to the device.

Symbol	Ratings	Value	Unit	Notes
Electrical ratings				
V _{SUP1/2/3}	DC voltage at power supply pins	-1.0 to 40	V	[1]
V _{SENSE}	DC voltage at battery sense pin (with ext R in series mandatory)	-14 to 40	V	
V _{SW1,2}	DC voltage at SW_PRE1 and SW_PRE2 Pins	-1.0 to 40	V	
V _{PRE}	DC voltage at VPRE Pin	-0.3 to 8	V	
V _{GATE_LS}	DC voltage at Gate_LS pin	-0.3 to 8	V	
V _{BOOT_PRE}	DC voltage at BOOT_PRE pin	-1.0 to 50	V	
V _{SW_CORE}	DC voltage at SW_CORE pin	-1.0 to 8	V	
V _{CORE_SNS}	DC voltage at VCORE_SNS pin	0.0 to 8	V	
V _{BOOT_CORE}	DC voltage at BOOT_CORE pin	0.0 to 15	V	
V _{FB_CORE}	DC voltage at FB_CORE pin	-0.3 to 2.5	V	
V _{COMP_CORE}	DC voltage at COMP_CORE pin	-0.3 to 2.5	V	
V _{FCRBM}	DC voltage at FCRBM pin	-0.3 to 8	V	
V _{AUX_B,E}	DC voltage at VAUX_B, VAUX_E pins	-0.3 to 40	V	
V _{AUX}	DC voltage at VAUX pin	-2.0 to 40	V	
V _{CCA_B,E}	DC voltage at VCCA_B, VCCA_E pins	-0.3 to 8	V	
V _{CCA}	DC voltage at VCCA pin	-0.3 to 8	V	
V _{DDIO}	DC voltage at VDDIO pin	-0.3 to 8	V	
V _{CAN_5V}	DC voltage on CAN_5V pin	-0.3 to 8	V	
V _{PU_FS}	DC voltage at VPU_FS pin	-0.3 to 8	V	
V _{FSxB}	DC voltage at FS0B, FS1B pins (with ext R in series mandatory)	-0.3 to 40	V	
V _{DEBUG}	DC voltage at DEBUG pin	-0.3 to 40	V	
V _{IO_0,4}	DC voltage at IO_0, IO_4 pins (with ext R in series mandatory)	-0.3 to 40	V	
V _{IO_5}	DC voltage at IO_5 pin	-0.3 to 20	V	
V _{KAM}	DC voltage at VKAM pin	-0.3 to 8	V	
V _{DIG}	DC voltage at INTB, RSTB, MISO, MOSI, NCS, SCLK, MUX_OUT, RXD, TXD, IO_2, IO_3 pins	-0.3 to 8	V	
V _{SELECT}	DC voltage at SELECT pin	-0.3 to 8	V	
V _{BUS_CAN}	DC voltage on CANL, CANH pins	-27 to 40	V	
I _{I_SENSE}	V _{SENSE} maximum current capability	-5.0 to 5.0	mA	
I _{IO_0, 4, 5}	IOs maximum current capability (IO_0, IO_4, IO_5)	-5.0 to 5.0	mA	

Grade 0 safety power system basis chip with CAN flexible data transceiver

Table 4. Maximum ratings ...continued

All voltages are with respect to ground, unless otherwise specified. Exceeding these ratings may cause a malfunction or permanent damage to the device.

Symbol	Ratings	Value	Unit	Notes
ESD voltage				
V _{ESD-HBM1}	Human body model (JESD22/A114) – 100 pF, 1.5 kΩ	±2.0	kV	[2]
V _{ESD-HBM2}	• All pins	±4.0	kV	
V _{ESD-HBM3}	• VSUP1,2,3, VSENSE, VAUX, IO_0,4, FS0B, FS1B, DEBUG • CANH, CANL	±6.0	kV	
V _{ESD-CDM1}	Charge device model (JESD22/C101):	±500	V	
V _{ESD-CDM2}	• All pins • Corner pins	±750	V	
System level ESD (gun test)				
• VSUP1, 2, 3, VSENSE, VAUX, IO_0, 4, 5, FS0B, FS1B				
V _{ESD-GUN1}	330 Ω/150 pF unpowered according to IEC61000-4-2	±8.0	kV	
V _{ESD-GUN2}	330 Ω/150 pF unpowered according to OEM CAN, FLexray Conformance	±8.0	kV	
V _{ESD-GUN3}	2.0 kΩ/150 pF unpowered according to ISO10605.2008	±8.0	kV	
V _{ESD-GUN4}	2.0 kΩ/330 pF powered according to ISO10605.2008 • CANH, CANL	±8.0	kV	
V _{ESD-GUN5}	330 Ω/150 pF unpowered according to IEC61000-4-2	±15.0	kV	
V _{ESD-GUN6}	330 Ω/150 pF unpowered according to OEM CAN, FLexray Conformance	±12.0	kV	
V _{ESD-GUN7}	2.0 kΩ/150 pF unpowered according to ISO10605.2008	±15.0	kV	
V _{ESD-GUN8}	2.0 kΩ/330 pF powered according to ISO10605.2008	±12.0	kV	
Thermal ratings				
T _A	Ambient temperature	–40 to 150	°C	
T _J	Junction temperature	–40 to 175	°C	
T _{STG}	Storage temperature	–55 to 150	°C	
Thermal resistance				
R _{θJA}	Thermal resistance junction to ambient	30	°C/W	[3]
R _{θJCTOP}	Thermal resistance junction to case top	23.8	°C/W	[4]
R _{θJCBOTTOM}	Thermal resistance junction to case bottom	0.9	°C/W	[5]

[1] All VSUPs (V_{SUP1/2/3}) must be connected to the same supply (see [Figure 65](#))

[2] Compared to AGND

[3] Per JEDEC JESD51-6 with the board (JESD51-7) horizontal

[4] Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC - 883 Method 1012.1).

[5] Thermal resistance between the die and the solder par on the bottom of the packaged based on simulation without any interface resistance.

9 Static electrical characteristics

Table 5. Static electrical characteristics

$T_A = -40\text{ °C}$ to 150 °C , unless otherwise specified. $V_{SUP} = V_{SUP_UV_L}$ to 36 V, unless otherwise specified. All voltages referenced to ground. When $28\text{ V} < V_{SUP} < 36\text{ V}$, thermal dissipation must be considered (see [Figure 30](#)).

Symbol	Parameter	Min.	Typ.	Max.	Unit	Notes
Power supply						
I_{SUP123}	Power supply current in normal mode	—	—	15.0	mA	
I_{SUP3}	Power supply current for VSUP3 in normal mode	—	3.5	5.0	mA	
I_{SUP_LPOFF1}	Power supply current in LPOFF ($V_{SUP} = 14\text{ V}$ at $T_A = 25\text{ °C}$)	—	32	—	μA	[1]
I_{SUP_LPOFF2}	Power supply current in LPOFF ($V_{SUP} = 18\text{ V}$ at $T_A = 80\text{ °C}$)	—	42	60	μA	
V_{SNS_UV}	Power supply undervoltage warning	7.0	8.0	9.0	V	
$V_{SNS_UV_HYST}$	Power supply undervoltage warning hysteresis	0.1	—	0.52	V	
V_{SUP_IPFF}	I_{PFF} input voltage detection	21	—	27	V	
$V_{SUP_IPFF_HYST}$	I_{PFF} input voltage hysteresis	0.2	—	—	V	
$V_{SUP_UV_7}$	Power supply undervoltage lockout (power-up)	7.0	—	8.2	V	
$V_{SUP_UV_5}$	Power supply undervoltage lockout (power-up)	—	—	5.6	V	
$V_{SUP_UV_L}$	Power supply undervoltage lockout (falling – boost config.)	—	—	2.7	V	
$V_{SUP_UV_L_B}$	Power supply undervoltage lockout (falling – buck config.)	—	—	4.5	V	[2]
$V_{SUP_UV_LPOFF}$	Power supply undervoltage lockout in LPOFF	—	—	4.5	V	[3]
$V_{SUP_UV_HYST}$	Power supply undervoltage lockout hysteresis	—	0.1	—	V	[4]
V_{PRE} voltage pre-regulator						
V_{PRE}	V_{PRE} output voltage					
	• Buck mode ($V_{SUP} > V_{SUP_UV_7}$)	6.25	—	6.75	V	
	• Buck mode ($V_{SUP_UV_7} \geq V_{SUP} \geq 4.5\text{ V}$)	$V_{PRE_UV_4P3}$	$V_{SUP} - R_{DS(on)_PRE} * I_{PRE}$	—	V	
	• Boost mode ($V_{SUP} \geq 2.7\text{ V}$)	6.0	—	7.0	V	
I_{PRE}	V_{PRE} maximum output current capability					
	• Buck or boost with $V_{SUP} > V_{SUP_UV_7}$	2.0	—	—	A	[4]
	• Buck with $V_{SUP_UV_7} \geq V_{SUP} \geq 4.5\text{ V}$	0.5	2.0	—	A	[4]
	• Boost with $V_{SUP_UV_7} \geq V_{SUP} \geq 6.0\text{ V}$	2.0	—	—	A	[4]
	• Boost with $6.0\text{ V} \geq V_{SUP} \geq 4.0\text{ V}$	1.0	—	—	A	[4]
	• Boost with $4.0\text{ V} \geq V_{SUP} \geq 2.7\text{ V}$	0.3	—	—	A	[4]
I_{PRE_LIM1}	SW _{PRE} output current limitation in buck-boost mode ($V_{SUP} \leq 28\text{ V}$)	3.5	—	—	A	
I_{PRE_LIM2}	SW _{PRE} output current limitation in buck mode ($V_{SUP} \leq 28\text{ V}$)	2.5	—	—	A	
I_{PRE_OC}	SW _{PRE} overcurrent detection threshold in buck mode ($V_{SUP} \leq 28\text{ V}$)	4.5	—	—	A	
V_{PRE_UV}	V_{PRE} undervoltage detection threshold (falling)	5.5	—	6.0	V	
$V_{PRE_UV_HYST}$	V_{PRE} undervoltage hysteresis	0.05	—	0.15	V	[5]

Table 5. Static electrical characteristics...continued

$T_A = -40\text{ }^\circ\text{C}$ to $150\text{ }^\circ\text{C}$, unless otherwise specified. $V_{SUP} = V_{SUP_UV_L}$ to 36 V, unless otherwise specified. All voltages referenced to ground. When $28\text{ V} < V_{SUP} < 36\text{ V}$, thermal dissipation must be considered (see [Figure 30](#)).

Symbol	Parameter	Min.	Typ.	Max.	Unit	Notes
$V_{PRE_UV_4P3}$	V_{PRE} shut-off threshold (falling – buck and buck/boost)	4.1	—	4.5	V	
$V_{PRE_UV_4P3_HYST}$	V_{PRE} shut-off hysteresis	0.05	—	0.15	V	[5]
R_{DSON_PRE}	V_{PRE} pass transistor on resistance with $V_{SUP} \leq 28\text{ V}$	—	—	200	m Ω	
L_{IR_VPRE}	V_{PRE} line regulation	—	20	—	mV	[5]
LOR_{VPRE_BUCK}	V_{PRE} load regulation for $C_{OUT_VPRE} = 57\text{ }\mu\text{F}$ • I_{PRE} from 50 mA to 2.0 A - buck mode	—	100	—	mV	[5]
LOR_{VPRE_BOOST}	V_{PRE} load regulation for $C_{OUT_VPRE} = 57\text{ }\mu\text{F}$ • I_{PRE} from 50 mA to 2.0 A - boost mode	—	500	—	mV	[5]
$V_{PRE_LL_H}$ $V_{PRE_LL_L}$	V_{PRE} pulse skipping thresholds	— —	200 180	— —	mV	
T_{WARN_PRE}	V_{PRE} thermal warning threshold	—	125	—	$^\circ\text{C}$	
T_{SD_PRE}	V_{PRE} thermal shutdown threshold	180	—	—	$^\circ\text{C}$	
$T_{SD_PRE_HYST}$	V_{PRE} thermal shutdown hysteresis	—	10	—	$^\circ\text{C}$	[5]
$V_{G_LS_OH}$	LS gate driver high output voltage ($I_{OUT} = 50\text{ mA}$)	$V_{PRE} - 1$	—	V_{PRE}	V	
$V_{G_LS_OL}$	LS gate driver low level ($I_{OUT} = 50\text{ mA}$)	—	—	0.5	V	
I_{G_LS}	LS gate driver current capability	—	300	—	mA	
R_{G_SHORT}	GATE_LS pin short to GND resistance to detect buck mode only	—	—	10	Ω	
V_{core} voltage regulator						
V_{CORE_FB}	V_{CORE} feedback input voltage	0.784	0.8	0.816	V	
I_{PD_CORE}	V_{CORE} internal pull-down current (active when V_{CORE} is enabled)	5.0	12	25	mA	
I_{CORE}	V_{CORE} output current capability in normal mode					
	• 35FS450x	—	—	0.5	A	
	• 35FS650x	—	—	0.8	A	
I_{CORE_LIM}	V_{CORE} output current limitation					
	• 35FS450x	0.55	—	1.7	A	
	• 35FS650x	1.0	—	2.0	A	
	• 35FS651x	1.8	—	2.8	A	
	R_{DSON_CORE}	V_{CORE} pass transistor on resistance	—	—	200	m Ω
$FS65_LOR_{V_{CORE}_1.2}$	V_{CORE} transient load regulation – 1.2 V range $C_{OUT_V_{CORE}} = 40\text{ }\mu\text{F}$, $I_{CORE} = 10\text{ mA}$ to 1.5 A, $dI_{CORE}/dt \leq 2.0\text{ A}/\mu\text{s}$	-60	—	60	mV	[4]
$FS65_LOR_{V_{CORE}_3.3}$	V_{CORE} transient load regulation – 3.3 V range $C_{OUT_V_{CORE}} = 40\text{ }\mu\text{F}$, $I_{CORE} = 10\text{ mA}$ to 1.5 A, $dI_{CORE}/dt \leq 2.0\text{ A}/\mu\text{s}$	-100	—	100	mV	[4]
$FS65_LOR_{V_{CORE}_5}$	V_{CORE} transient load regulation – 5.0 V range $C_{OUT_V_{CORE}} = 20\text{ }\mu\text{F}$, $I_{CORE} = 10\text{ mA}$ to 0.8 A, $dI_{CORE}/dt \leq 2.0\text{ A}/\mu\text{s}$	-150	—	150	mV	[4]
$FS45_LOR_{V_{CORE}_1.2}$	V_{CORE} transient load regulation – 1.2 V range	-60	—	60	mV	[4]

V_{AMUX_REF}	Internal voltage reference	2.462	2.5	2.538	V	
$V_{AMUX_TP_CO}$	Internal temperature sensor coefficient	—	9.9	—	mV/°C	[5]
V_{AMUX_TP}	Temperature sensor MUX_OUT output voltage (at $T_J = 165\text{ }^\circ\text{C}$)	2.08	2.15	2.22	V	
Interrupt						
V_{INTB_OL}	Low output level ($I_{INT} = 2.5\text{ mA}$)	—	—	0.5	V	
R_{PU_INT}	Internal pull-up resistor (connected to VDDIO)	—	10	—	KΩ	
I_{INT_LK}	Input leakage current	—	—	1.0	μA	
Digital interface						
$MISO_H$	High output level on MISO ($I_{MISO} = 1.5\text{ mA}$)	$V_{DDIO} - 0.4$	—	—	V	
$MISO_L$	Low output level on MISO ($I_{MISO} = 2.0\text{ mA}$)	—	—	0.4	V	
I_{MISO}	Tri-state leakage current ($V_{DDIO} = 5.0\text{ V}$)	-5.0	—	5.0	μA	
V_{DDIO}	Supply voltage for MISO output buffer	3.0	—	5.5	V	
I_{VDDIO}	Current consumption on VDDIO	—	1.0	3.0	mA	
SPI_{LK}	SCLK, NCS, MOSI input current	-1.0	—	1.0	μA	
V_{SPI_IH}	SCLK, NCS, MOSI high input threshold	2.0	—	—	V	
V_{SPI_IL}	SCLK, NCS, MOSI low input threshold	—	—	0.8	V	
R_{SPI}	NCS, MOSI internal pull-up (pull-up to VDDIO)	200	400	800	KΩ	
Debug						
V_{DEBUG_IL}	Low input voltage threshold	2.1	2.35	2.8	V	
V_{DEBUG_IH}	High input voltage threshold	4.35	4.6	4.97	V	
I_{DEBUG_LK}	Input leakage current	-10	—	10	μA	

Table 5. Static electrical characteristics...continued

$T_A = -40\text{ }^\circ\text{C}$ to $150\text{ }^\circ\text{C}$, unless otherwise specified. $V_{SUP} = V_{SUP_UV_L}$ to 36 V, unless otherwise specified. All voltages referenced to ground. When $28\text{ V} < V_{SUP} < 36\text{ V}$, thermal dissipation must be considered (see [Figure 30](#)).

Symbol	Parameter	Min.	Typ.	Max.	Unit	Notes
CAN transceiver (FD 2.0 Mbit/s)						
CAN logic input pin (TXD)						
V_{TXD_IH}	TXD high input threshold	$0.7 \times V_{DDIO}$	—	—	V	
V_{TXD_IL}	TXD low input threshold	—	—	$0.3 \times V_{DDIO}$	V	
$TXD_{PULL-UP}$	TXD main device pull-up	20	33	50	k Ω	
TXD_{LK}	TXD input leakage current, $V_{TXD} = V_{DDIO}$	-1.0	—	1.0	μA	
CAN logic output pin (RXD)						
V_{RXD_OL1}	Low level output voltage ($I_{RXD} = 250\text{ }\mu\text{A}$)	—	—	0.4	V	
V_{RXD_OL2}	Low level output voltage ($I_{RXD} = 1.5\text{ mA}$)	—	—	0.9	V	
$VOUT_{HIGH}$	High level output voltage ($I_{RXD} = -250\text{ }\mu\text{A}$, $V_{DDIO} = 3.0\text{ V}$ to 5.5 V)	$V_{DDIO} - 0.4$	—	—	V	
CAN output pins (CANH, CANL)						
$V_{DIFF_COM_MODE}$	Differential input comparator common mode range in normal mode	-20	—	20	V	
V_{IN_DIFF}	Differential input voltage threshold in normal mode	0.5	—	0.9	V	
$V_{DIFF_COM_SLEEP}$	Differential input comparator common mode range in sleep mode	-12	—	12	V	
$V_{IN_DIFF_SLEEP}$	Differential input voltage threshold in sleep mode	0.4	—	1.1	V	
V_{IN_HYST}	Differential input hysteresis (in TX, RX mode)	50	—	—	mV	
R_{IN_CHCL}	CANH, CANL input resistance	5.0	—	50	k Ω	
R_{IN_DIFF}	CAN differential input resistance	10	—	100	k Ω	
R_{IN_SLEEP}	CANH, CANL input resistance device supplied and in CAN sleep mode	5.0	—	50	k Ω	
R_{IN_MATCH}	Input resistance matching	-3.0	—	3.0	%	
V_{CANH}	CANH output voltage ($45\text{ }\Omega < R_{BUS} < 65\text{ }\Omega$)					
	• TX dominant state	2.75	—	4.5	V	
	• TX recessive state	2.0	2.5	3.0	V	
V_{CANL}	CANL output voltage ($45\text{ }\Omega < R_{BUS} < 65\text{ }\Omega$)					
	• TX dominant state	0.5	—	2.25	V	
	• TX recessive state	2.0	2.5	3.0	V	
V_{CAN_SYM}	CAN dominant voltage symmetry ($V_{CANL} + V_{CANH}$)	4.5	5.0	5.5	V	
V_{OH-VOL}	Differential output voltage					
	• TX dominant state ($45\text{ }\Omega < R_{BUS} < 65\text{ }\Omega$)	1.5	2.0	3.0	V	
	• TX recessive state	-50	0.0	50	mV	
$I_{CANL-SK}$	CANL sink current under short-circuit condition ($V_{CANL} \leq 12\text{ V}$, CANL driver ON, TXD low)	40	—	100	mA	
$I_{CANH-SC}$	CANH source current under short-circuit condition ($V_{CANH} = -2.0\text{ V}$, CANH driver ON, TXD low)	-100	—	-40	mA	
V_{CANLP}	CANL, CANH output voltage in sleep modes. No termination load.	-0.1	0.0	0.1	V

t_{REC}	Receiver timing symmetry at 2.0 Mbit/s	-65	—	40	ns	

[1] This timing is not guaranteed in case of fault during startup phase (after power on reset or from LPOFF)

[2] Guaranteed by characterization

[3] For proper CAN operation, TXD must be set to high level before CAN enable by the SPI, and must remain high for at least T_{CAN_READY} .

11 Functional pin description

11.1 Introduction

The 35FS4500/35FS6500 is the fourth generation of the system basis chip, combining:

- High efficiency switching voltage regulator for MCU, and linear voltage regulators for integrated CAN FD interface
- External ICs such as sensors, accurate reference voltage for A to D converters, and keep alive memory supply in low-power mode for MCU static RAM
- Built-in CAN flexible data interface at 2.0 Mbit/s (ISO11898-2 and -5), with local and bus failure diagnostic, protection, and fail-safe operation mode

- Low-power mode, with ultra low-current consumption
- Various wake-up capabilities
- Long duration timer available in normal and low-power mode
- Enhanced safety features with multiple fail-safe outputs and a scheme to support ASIL D applications

11.2 Power supplies (VSUP1, VSUP2, VSUP3)

VSUP1 and VSUP2 are the input pins for the internal supply dedicated to the SMPS regulators. VSUP3 is the input pin for internal voltage reference. VSUP1, 2, and 3 are robust against ISO7637 pulses. VSUP1, 2, and 3 must be connected to the same supply ([Figure 65](#)).

11.3 V_{SENSE} input (VSENSE)

This pin must be connected to the battery line (before the reverse battery protection diode), via a serial resistor. It incorporates a threshold detector to sense the battery voltage, and provide a battery early warning. It also includes a resistor divider to measure VSENSE voltage via the MUX-OUT pin. the VSENSE pin is robust against ISO 7637 pulses.

11.4 Pre-regulator (VPRE)

A highly flexible SMPS pre-regulator is implemented in the 35FS4500/35FS6500. It can be configured as a *non-inverting buck-boost converter* ([Figure 32](#)) or *standard buck converter* ([Figure 31](#)), depending on the external configuration (connection of pin GATE_LS). The configuration is detected automatically during start-up sequence.

The SMPS pre-regulator is working in current mode control and the compensation network is fully integrated in the device. The high-side switching MOSFET is also integrated to make the current control easier. The pre-regulator delivers a typical output voltage of 6.5 V, which is used internally. Current limitation, overcurrent, overvoltage, and undervoltage detectors are provided. VPRE is enabled by default.

11.5 V_{CORE} output (from 1.0 V to 5.0 V range)

The V_{CORE} block of the FS6500 series is an SMPS regulator. The voltage regulator is a step down DC–DC converter operating in voltage control mode. The stability of the converter is done externally, by using the COMP_CORE pin. The V_{CORE} block of the FS4500 series is a linear regulator. In this case, BOOT_CORE and COMP_CORE pins must be left open.

The output voltage of 35FS4500/35FS6500 is configurable to any voltage from a 1.0 V to 5.0 V range using an external resistor divider connected between V_{CORE} and the feedback pin (FB_CORE) (as example in [Figure 1](#), or [Figure 65](#)). Current limitation, overvoltage, and undervoltage detectors are provided. V_{CORE} can be turned on or off via a SPI command, however it is not recommended to turn off V_{CORE} with the SPI when V_{CORE} is configured safety critical (both overvoltage and undervoltage have an impact on fail-safe outputs). V_{CORE} overvoltage information disables V_{CORE}. Diagnostics are reported in the dedicated register and generate an Interrupt. V_{CORE} is enabled by default. For safety purpose, a second resistor bridge (R3/R4 duplicated) connected to FCRBM should be used to detect an external resistor drift.

11.6 V_{CCA} output, 5.0 V or 3.3 V selectable

The V_{CCA} voltage regulator is used to provide an accurate voltage output (5.0 V, 3.3 V) selectable through an external resistor connected to the SELECT pin.

The V_{CCA} output voltage regulator can be configured using an internal transistor delivering very good accuracy ($\pm 1.0\%$ for 5.0 V and 3.3 V configurations), with a limited current capability (100 mA) for an analog to digital

converter, or with an external PNP transistor, giving higher current capability (up to 300 mA) with lower output voltage accuracy ($\pm 3.0\%$ for 300 mA) when using a local ECU supply.

Current limitation, overvoltage, and undervoltage detectors are provided. VCCA can be turned on or off via a SPI command, however it is not recommended to turn off VCCA with the SPI when VCCA is configured safety critical (both overvoltage and undervoltage have an impact on fail-safe outputs). VCCA overcurrent (with the use of external PNP only) and overvoltage information disables VCCA. Diagnostics are reported in the dedicated register and generate an Interrupt. VCCA is enabled by default.

11.7 VAUX output, 5.0 V or 3.3 V selectable

The VAUX pin provides an auxiliary output voltage (5.0 V, 3.3 V) selectable through an external resistor connected to SELECT pin. It uses an external PNP ballast transistor for flexibility and power dissipation constraints. The VAUX output voltage regulator can be used as *auxiliary supply* (local ECU supply) or *sensor supply* (external ECU supply) with the possibility to be configured as a tracking regulator following VCCA.

Current limitation, overvoltage, and undervoltage detectors are provided. VAUX can be turned on or off via a SPI command, however it is not recommended to turn off VAUX with the SPI when VAUX is configured safety critical (both overvoltage and undervoltage have an impact on fail-safe outputs). VAUX overcurrent and overvoltage information disables VAUX, reported in the dedicated register, and generates an Interrupt. VAUX is enabled by default.

11.8 SELECT input pin

11.8.1 VCCA, VAUX voltage configuration

VCCA and VAUX output voltage configurations are set by connecting an external resistor between the SELECT pin and Ground or the SELECT pin and VPRE. According to the value of this resistor, the voltage of VCCA and VAUX are configured after each power on reset, and after a wake-up event when the device is in LPOFF. Information latches until the next hardware configuration read. Regulator voltage values can be read on the dedicated register via the SPI.

Table 7. V_{CCA}/V_{AUX} voltage selection

See [Figure 67](#).

Note: If the SELECT pin is detected open, the VCCA and VAUX regulators start at their minimum output voltage 3.3 V.

V _{CCA} (V)	V _{AUX} (V)	R select	Recommended value
3.3	3.3	< 6.0 kΩ	5.1 kΩ ± 5.0 %
5.0	5.0	10.8 << 13.2 kΩ	12 kΩ ± 5.0 %
3.3	5.0	21.6 << 26.2 kΩ	24 kΩ ± 5.0 %
5.0	3.3	45.9 << 56.1 kΩ	51 kΩ ± 5.0 %

11.8.2 Deep fail-safe configuration

Deep fail-safe function is enabled when the SELECT pin is connected to ground and disabled when the SELECT pin is connected to VPRE. The configuration is done after each power on reset, and after a wake-up event when device is in LPOFF by both the main and the fail-safe logics. The Information is latched until the next hardware configuration read ([Figure 9](#)).

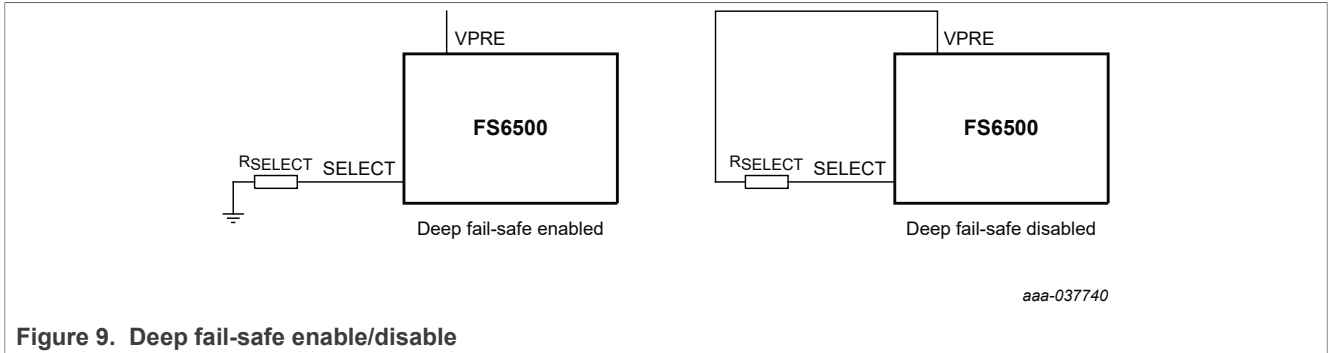

Figure 9. Deep fail-safe enable/disable

11.9 CAN_5V voltage regulator

The CAN_5V voltage regulator is a linear regulator dedicated to the internal CAN FD interface. An external capacitor is required. Current limitation, overvoltage, and undervoltage detectors are provided. If the internal CAN transceiver is not used, the CAN_5V regulator can supply an external load ([Section 12.7.6 "CAN_5V voltage regulator"](#)). CAN_5V is enabled by default.

11.10 Interrupt (INTB)

The INTB output pin generates a low pulse when an Interrupt condition occurs. The INTB behavior as well as the pulse duration are set through the SPI during INIT phase. INTB has an internal pull-up resistor connected to VDDIO.

11.11 CANH, CANL, TXD, RXD

These are the pins of the CAN FD physical interface. The CAN FD transceiver provides the physical interface between the CAN FD protocol controller of an MCU and the physical dual wires CAN bus. The CAN FD interface is connected to the MCU via the RXD and TXD pins.

11.11.1 TXD

TXD is the device input pin to control the CAN bus level. TXD is a digital input with an internal pull-up resistor connected to VDDIO. In the application, this pin is connected to the microcontroller transmit pin. In normal mode, when TXD is high or floating, the CANH and CANL drivers are off, setting the bus in a recessive state. When TXD is low, the CANH and CANL drivers are activated and the bus is set to a dominant state. TXD has a built-in timing protection disabling the bus when TXD is dominant for more than t_{DOUT} . In LPOFF mode, VDDIO is off, pulling this pin to GND.

11.11.2 RXD

RXD is the bus output level report pin. In the application, this pin is connected to the microcontroller receive pin. In normal mode, RXD is a push-pull structure. When the bus is in a recessive state, RXD is high. When the bus is dominant, RXD is low. In LPOFF mode, this pin is in the high-impedance state.

11.11.3 CANH and CANL

These are the CAN bus pins. CANL is a low-side driver to GND, and CANH is a high-side driver to CAN_5V. In normal mode and TXD high, the CANH and CANL drivers are off, and the voltage at CANH and CANL is approximately 2.5 V, provided by the internal bus biasing circuitry. When TXD is low, CANL is pulled to GND and CANH to CAN_5V, creating a differential voltage on the CAN bus.

In LPOFF mode, the CANH and CANL drivers are off, and these pins are pulled to GND via the device R_{IN_CHCL} resistors. CANH and CANL have integrated ESD protection and extremely high robustness versus external disturbance, such as EMC and electrical transients. These pins have current limitation and thermal protection.

11.12 Multiplexer output MUX_OUT

The MUX_OUT pin (Figure 10) delivers analog voltage to the MCU ADC input. The voltage to be delivered to MUX_OUT is selected via the SPI, from one of the following parameters:

- VSENSE
- VIO_0
- VKAM
- Internal 2.5 V reference
- Internal die temperature sensor $T(^{\circ}C) = (V_{AMUX} - V_{AMUX_TP})/V_{AMUX_TP_CO} + 165$

Voltage range at MUX_OUT is from GND to VDDIO (3.3 V or 5.0 V)

Figure 10. Simplified analog multiplexer block diagram

11.13 I/O pins (I/O_0:I/O_5)

The 35FS4500/35FS6500 includes five multi-purpose I/Os (I/O_0 to I/O_5). I/O_0 and I/O_4 are load dump proof and robust against ISO7637 pulses. An external serial resistor must be connected to those pins to limit the current during ISO pulses. I/O_2 and I/O_3 are not load dump proof. I/O_5 requires an external protection (resistor and zener diode) to be load dump proof and robust against ISO 7637 pulses.

Table 8. I/Os configuration

I/O number	Digital input wake-up capability	Analog input	Output gate driver	VKAM	FCCU monitoring	Ext. IC monitoring
IO_0	X	X				
IO_2	X				X	
IO_3	X					
IO_4	X		X			X
IO_5	X	X		X		

- IO_0 is selectable as follows:
Analog input (load dump proof) sent to the MCU through the MUX_OUT pin. Wake-up input on the rising or falling edge or based on the previous state. Digital input (logic level) sent to the MCU through the SPI.
Safety purpose: IO_0 is the only wake-up input to resume from deep fail-safe mode.
- IO_2:3 are selectable as follows:
Digital input (logic level) sent to the MCU through the SPI. Wake-up input on the rising or falling edge or based on the previous state.
Safety purpose: Digital input (logic level) to monitor MCU error signals (both IO_2 AND IO_3 are used if configured as safety inputs). Only bi-stable protocol is available.
When IO_2:3 are used as safety inputs to monitor FCCU error outputs from the NXP MCU, the monitoring is active only when the fail-safe state machine is in 'normal WD' state (Figure 15) and all the phases except the 'normal phase' are considered as an error.

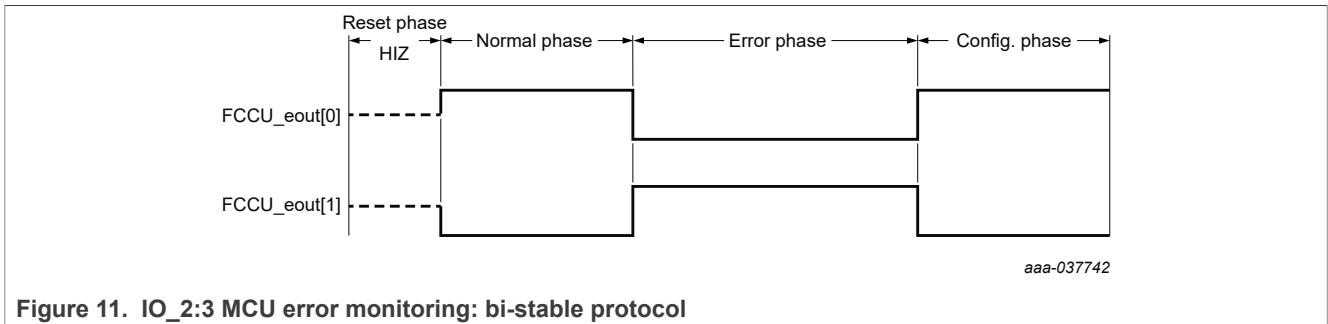

Figure 11. IO_2:3 MCU error monitoring: bi-stable protocol

- IO_4 is selectable as follows:
Digital input (logic level) sent to the MCU through the SPI. Wake-up input (load dump proof) on rising or falling edge or based on previous state. Output gate driver (from V_{PRE}) for low-side logic level MOSFET.
- IO_5 is selectable as follows:
Analog input (20 V max.) sent to the MCU through the MUX_OUT pin. Digital input (logic level) sent to the MCU through the SPI. Wake-up input on rising or falling edge or based on previous state. VKAM output supply.
- IO_4:5 are selectable as follows:
Safety purpose: Digital input (logic level) to perform an IC error monitoring (both IO_4 AND IO_5 are used if configured as safety inputs, see Figure 12).

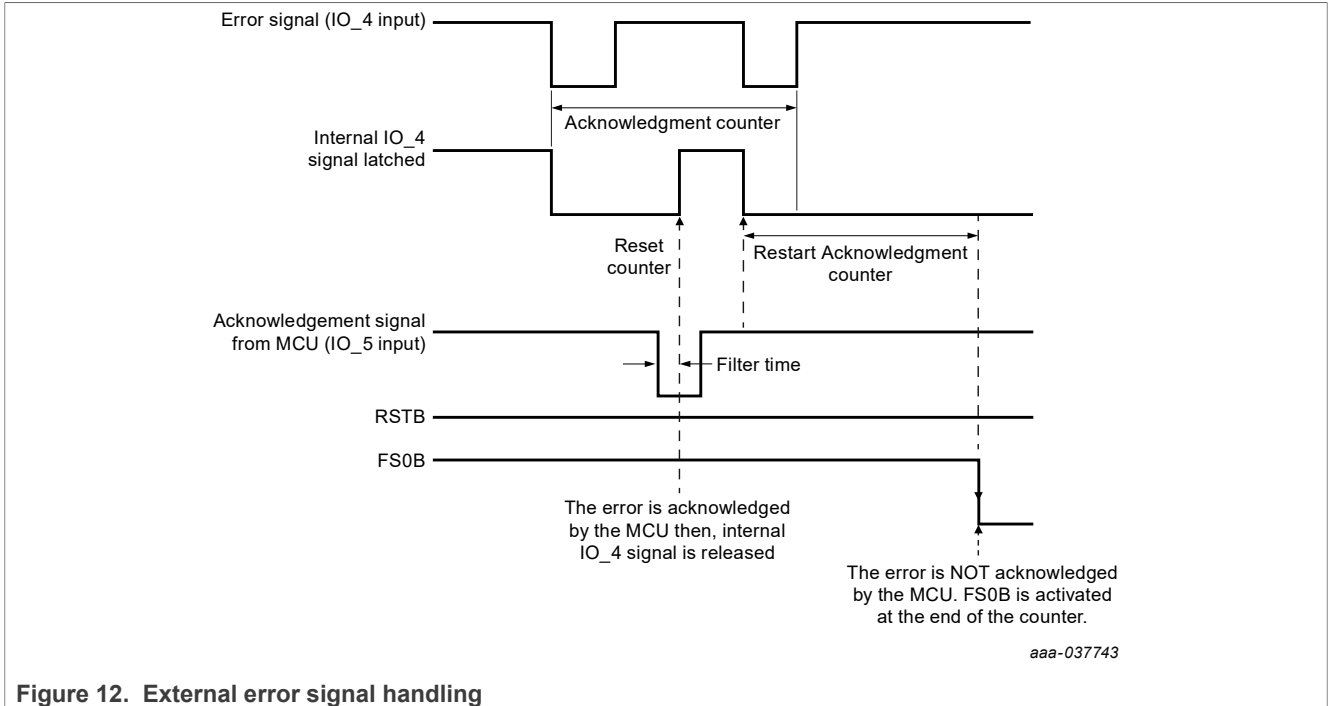

Figure 12. External error signal handling

11.14 SAFE output pins (FS0B, FS1B, RSTB)

11.14.1 FS0B pin

FS0B pin is the primary safe output pin. FS0B is asserted low when a fault event occurs ([Section 12.5.5 "Fail-safe output \(FS0B\) activation"](#)). The objective of this pin is to drive an electrical safe circuitry independent from MCU to deactivate the whole system and set the ECU in a protected and known state.

After each power on reset or after each wake-up event (LPOFF) the FS0B pin is asserted low. The MCU can decide to release the FS0B pin, when the application is ready to start. An external pull-up circuitry is mandatory connected to VDDIO or VSUP3.

- If the pull-up is connected to VDDIO, the value recommended is 5.0 kΩ, there is no current in LPOFF since VDDIO is off in LPOFF mode.
- If the pull-up is connected to VSUP3, the value must be above 10 kΩ, there is a current in the pull-up resistor to consider at application level in LPOFF mode.

11.14.2 FS1B pin

FS1B pin is the secondary safe output pin. FS1B is asserted low with a configurable delay (t_{DELAY}) or duration (t_{DUR}) when FS0B is asserted low ([Section 12.5.6 "Fail-safe output \(FS1B\) activation"](#)). This pin can be used to:

- Open the phases of a motor after a configurable delay starting when FS0B is asserted, to demagnetize the motor coils and reduce the inductive effect when the switch is open.
- Disable an external physical layer during a configurable duration starting when FS0B is asserted, to avoid miscommunication when the module is in fail mode.
- Be a redundant safe output pin to FS0B when $t_{DELAY} = 0$. In this case, FS1B is asserted at the same time than FS0B.
- Any other use case where a second safety pin is needed.

After each power on reset or after each wake-up event (LPOFF) the FS1B pin is asserted low. Then the MCU can decide to release the FS1B pin, when the application is ready to start. An external pull-up circuitry is mandatory, connected to VPU_FS or VDDIO.

11.14.3 RSTB pin

The RSTB pin must be connected to MCU and is active low. An external pull-up resistor must be connected to VDDIO. In default configuration, the RST delay time has three possible values depending on the mode and product configuration:

- The longest one is used automatically following a power on reset or when resulting from LPOFF mode (low-power off).
- The two reset durations are then available in the INIT_FSSM register, which are 1.0 ms and 10 ms. The configured duration is finally used in the normal operation when a fault occurs leading to a reset activation. The INIT_FSSM register is available (writing) in the INIT_FS phase.

11.15 VPU_FS (fail-safe pull-up)

This pin is intended to be the pull-up terminal of FS1B, internally attached to V_{PRE} through a reverse diode protection. When FS1B is used in t_{DELAY} configuration, a configurable external RC network provides an minimum backup delay, in case of a loss of the internal fail-safe oscillator or loss of supply. This independent pull-up (compared to FS0B pull-up) avoid common cause failure between the two safe outputs and guarantee FS1B activation with a delay compared to FS0B in all conditions. When FS1B is used with $t_{DELAY} = 0$ or in t_{DUR} configuration, a pull-up to VDDIO is also possible, taking into account the common cause failure with the same pull-up as FS0B in the safety analysis.

11.16 DEBUG input (entering in debug mode)

The DEBUG pin allows the product to enter debug mode. To activate the debug mode, voltage applied to the DEBUG pin must be within the V_{DEBUG_IL} and V_{DEBUG_IH} range at start-up. If the voltage applied to DEBUG pin is out of these limits, during the SELECT pin configuration, the device settles into normal mode.

In debug mode, the watchdog window is fully open and no watchdog refresh is required. This allows an easy debug of the hardware and software routines (SPI commands). However, the whole watchdog functionality is kept on (seed, LFSR, WD refresh counter, WD error counter,...). WD errors are detected and counted with reaction according to WD_IMPACT bit configuration.

In debug mode, the CAN transceiver is set to normal operation mode by default allowing CAN communication without SPI configuration (FS1B_CAN_IMP bit = 0). To exit debug mode, the pin must be tied to ground through an external pull-down resistor and a power on reset or wake-up from LPOFF occurs.

In debug mode, the fail-safe outputs (FS0B, FS1B) are asserted low at start-up. The release procedure and the assertion conditions are the same than in normal mode.

In debug mode, the Deep fail-safe entry is disabled.

12 Functional device operation

12.1 Mode and state description of the main state machine

The device has several operation modes. The transition and conditions to enter or leave each mode are illustrated in the functional state diagram ([Figure 14](#)). Two state machines work in parallel. The main state machine controls the power management (VPRE, VCORE, VCCA, VAUX, ...) and the fail-safe state machine controls all the safety aspects (WD, RSTB, FS0B, FS1B, ...).

12.1.1 Buck or buck boost configuration

An external low-side logic level MOSFET (N-type) is required to operate in non-inverting buck-boost converter. The connection of the external MOSFET is detected automatically during the start-up phase (after a power on reset or from LPOFF).

- If the external low-side MOSFET is **not** connected (GATE_LS pin connected to PGND), the product is configured as a standard buck converter.
- If the external low-side MOSFET is connected (GATE_LS pin connected to external MOSFET gate), the product is configured as a non-inverting buck-boost converter.

The automatic detection is done by pushing 300 μ A current on Gate_LS pin and monitoring the corresponding voltage generated. If a voltage > 120 mV is detected before the 120 μ s timeout, the non-inverting buck-boost configuration is locked. Otherwise, the standard buck configuration is locked. The boost driver has a current capability of \pm 300 mA.

12.1.2 V_{PRE} on

Pre-regulator is an SMPS regulator. In this phase, the pre-regulator is switched on and a softstart with a specified duration t_{PRE_SOFT} controls the VPRE output capacitor charge.

12.1.3 SELECT pin configuration

This phase detects the required voltage level on VAUX and VCCA, according to the resistor value connected between the SELECT pin and Ground or VPRE, and configures the deep fail-safe function.

12.1.4 V_{CORE}/V_{AUX}/V_{CCA} on

In this stage, the three regulators V_{CORE}, V_{AUX}, V_{CCA} are switched on at the same time with a specified soft start duration. The CAN_5V is also started at this time.

12.1.5 INIT main

This mode is automatically entered after the device is *powered on*. When RSTB is released, initialization phase starts where the device can be configured via the SPI. During INIT phase, some registers can only be configured in this mode (see [Table 18](#) and [Table 19](#)). Other registers can be written in this mode, and also in normal mode.

Once the INIT registers configurations are complete, a last register called 'INIT_INT' must be configured to switch to normal mode. Writing data in this register (even same default values), automatically locks the INIT registers, and the product switches automatically to normal mode in the main state machine.

12.1.6 Normal

In this mode, all device functions are available. This mode is entered by a SPI command from the INIT phase by writing in the INIT_INT register. While in normal mode, the device can be set to low-power mode (LPOFF) using secured SPI command.

12.1.7 Low-power mode off

The main state machine has three LPOFF modes with different conditions to enter and exit each LPOFF mode, as described hereafter. After wake-up from LPOFF, all the regulators are enabled by default. In LPOFF, all the regulators are switched off, except VKAM. The register configuration and the ISO pulse requirement are valid for the three LPOFF modes.

12.1.7.1 LPOFF - sleep

Entering in low-power mode LPOFF - sleep is only available if the product is in normal mode by sending a secured SPI command. In this mode, all the regulators are turned off and the MCU connected to the V_{CORE} regulator is unpowered. Only VKAM is available if VKAM is used (specific part number for VKAM on by default).

Once the 35FS4500/35FS6500 is in LPOFF - sleep, the device monitors external events to wake-up and leave the low-power mode. The wake-up events can occur and depending of the device configuration from:

- CAN physical layer
- I/O inputs
- Timer

When a wake-up event is detected, the device starts the main state machine again by detecting the V_{PRE} configuration (buck or buck-boost), the wake-up source is reported to the dedicated SPI register, and the fail-safe state machine is also restarted.

12.1.7.2 LPOFF - auto WU

LPOFF - auto WU is entered when the device is in the INIT or normal mode and if the V_{PRE} voltage level is passing the $V_{PRE_UV_4P3}$ threshold (typ 4.3 V). It can be also entered by sending a secured SPI command if the product is in normal mode. It allows a POR and complete restart of the fail-safe state machine. After 1.0 ms the device attempts to recover by switching on V_{PRE} again.

12.1.7.3 LPOFF - deep FS

LPOFF - deep FS is entered when the device is in deep fail-safe and if the key is off (IO_0 is low). To exit this mode, a transition to high level on IO_0 is required. IO_0 is usually connected to the key on key off signal (see [Section 12.3 "Deep fail-safe state"](#)).

12.1.7.4 Register configuration in LPOFF

In LPOFF, the register settings of the main state machine are kept because the internal 2.5 V main digital regulator is available for wake-up operation. However, the register settings of the fail-safe state machine are erased because the 2.5 V fail-safe digital regulator is not available in LPOFF. As a consequence, after a wake-up event, the configuration of the fail-safe registers must be done again during initialization phase (256 ms open window).

12.1.7.5 ISO pulse in LPOFF

If the application has to sustain ISO pulses on V_{BAT} in LPOFF mode, the connection of an external zener diode and a serial resistor to the ground is mandatory (see [Figure 13](#)). During repetitive ISO pulses on V_{BAT} , the capacitors connected on V_{SUP} line are more and more charged and cannot be discharged due to the extremely low-current needed to maintain wake-up capabilities on IOs and CAN. As a consequence, if a leakage path is not created artificially with those discrete components, the voltage on V_{SUP} line can exceed the absolute maximum rating supported by this pin.

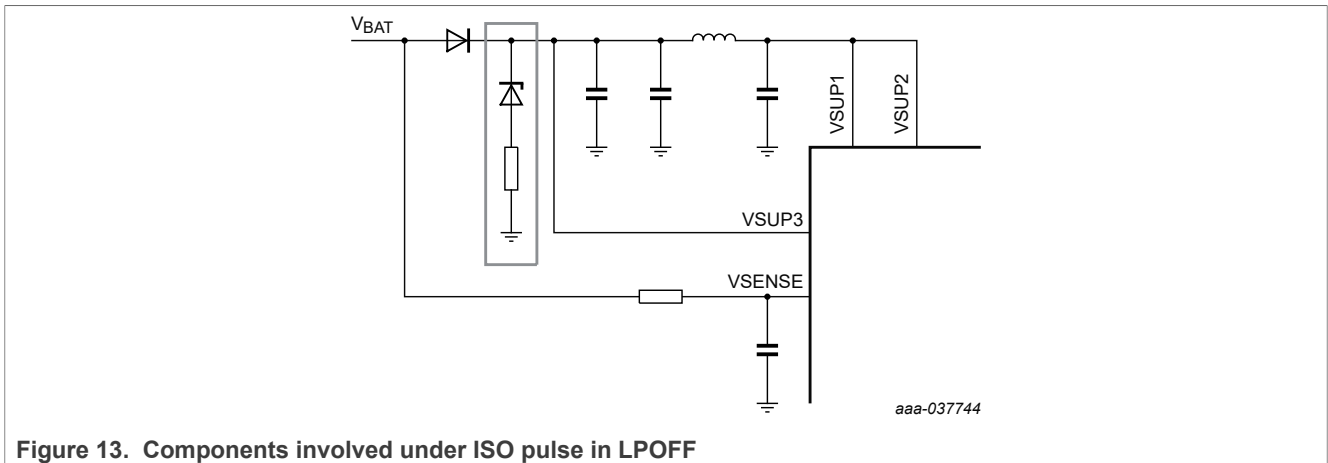

Figure 13. Components involved under ISO pulse in LPOFF

12.2 Mode and state description of fail-safe state machine

12.2.1 LBIST

Included in the fail-safe machine, the logic built-in self test (LBIST) verifies the correct functionality of the FSSM at start-up. The fail-safe state machine is fully checked. If an issue is reported, the SAFE output pins FS0B and FS1B stays low and a flag is reported, the RSTB pin is released to allow diagnostic by the MCU. LBIST is run at start-up and after each wake-up event when the device is in LPOFF mode.

LBIST fail does not gate the RSTB pin release, but prevents the FS0B and FS1B pins release. It allows the MCU diagnostic keeping the application in a safe state.

12.2.2 Select pin configuration

This phase detects the required voltage level to apply on VAUX and VCCA according to the resistor value connected between the SELECT pin and Ground or VPRE, and the deep fail-safe configuration. This mode is the equivalent mode seen in the main state machine. In the fail-safe machine this detection is used to internally set the UV/OV threshold on VCCA and VAUX for the voltage supervision, and to enable/disable the deep fail-safe feature.

12.2.3 ABIST

Included in the fail-safe machine, the analog built-in self test (ABIST) verifies the correct functionality of the analog part of the device like the overvoltage and undervoltage detections of the voltage supervisor and the fail-safe outputs feedback. ABIST fail does not gate the RSTB pin release, but prevents the FS0B and FS1B pins release. It allows the MCU diagnostic, keeping the application in safe state.

12.2.3.1 ABIST1

The first ABIST1 ([Table 9](#)) is always run at start-up and after each wake-up event when device is in LPOFF mode.

Table 9. Regulators and fail-safe pins checked during ABIST1

Parameters	Overvoltage	Undervoltage	OK/NOK
VPRE	X		
VCORE (including FCRBM)	X	X	
VCCA	X	X	
RSTB			X
FS0B			X

12.2.3.2 ABIST2

The second ABIST2 ([Table 10](#)) is run on demand by a SPI command from the MCU. ABIST2 must be executed and pass for FS1B and VAUX, when VAUX is declared safety critical (overvoltage and/or undervoltage have an impact on fail-safe outputs) to release the FS0B pin. Consequently, ABIST2 must be executed at start-up and after each wake-up event when device is in LPOFF mode, to release the fail-safe pin FS0B.

Table 10. Regulators and fail-safe pins checked during ABIST2

Parameters	Overvoltage	Undervoltage	OK/NOK
VAUX	X	X	
FS1B			X

12.2.4 Release RSTB

In this state, the device releases the RSTB pin.

12.2.5 INIT_FS

This mode is automatically entered after the device is *powered on* and the built-in self tests (logic LBIST and analog ABIST1) have been executed. This INIT_FS mode starts as soon as RSTB is released.

In this mode, the device can be configured via the SPI within a maximum time of 256 ms, including first watchdog refresh. Some registers can only be configured in this mode and is locked when leaving INIT_FS mode (see [Table 18](#) and [Table 19](#)). It is recommended, to configure first the device before sending the first WD refresh. As soon as the first good watchdog refresh is sent by the MCU, the device leaves this mode and goes into normal WD mode.

12.2.6 Normal WD

In this mode, the device waits for a periodic watchdog refresh coming from the MCU, within a specific configured window timing. Configuration of the watchdog window period can be set during INIT_FS phase or in this mode. This mode is exited if a fault occurs leading to an RSTB activation (external reset request included).

12.2.7 Assert RSTB

When the reset pin is asserted low by the device, a delay runs, to release RSTB, if there are no faults present. The reset low duration time is configurable via the SPI in the INIT_FSSM register, which is accessible for writing only in the INIT_FS phase.

12.2.8 Assert FSxB and ABIST2

These functions are executed in parallel to INIT_FS or normal WD states of the fail-safe state machine.

12.3 Deep fail-safe state

When the deep fail-safe function is enabled, the fail-safe state machine monitors and count the number of faults happening, in case of fault detection (see Section 12.5.3 "Fault error counter"). As soon as either the fault error counter reaches its final value or the RESET pin remains asserted low for more than 8.0 s, the device moves to deep fail-safe state in the functional state diagram (Figure 14).

When the device is in deep fail-safe state, all the regulators are off (except VKAM if VKAM was on), RSTB, FS0B, and FS1B are activated. To exit this state, a key off/key on action is needed. IO_0 is usually connected to key signal. Key off (IO_0 low) moves the device to LPOFF-deep FS, and key on (IO_0 high) wakes up the device.

During power up phase, the 8.0 s timer starts when the fail-safe state machine enters in the 'Wait_VPRE' state and stops when the RSTB pin is released. During 'INIT_FS' state, the 8.0 s timer can be disabled in the register INIT_FS_IMPACT. During 'normal WD' state, the 8.0 s timer is activated at each RSTB pin assertion.

12.4 Functional state diagram

Figure 14. Simplified state diagram

12.5 Fail-safe machine

To fulfill safety critical applications, the 35FS4500/35FS6500 integrates a dedicated fail-safe machine (FSM). The FSM is composed of three main sub-blocks: the voltage supervisor (VS), the fail-safe state machine (FSSM), and the fail-safe output driver (FSO). The FSM is electrically independent from the rest of the circuitry, to avoid common cause failure.

For this reason, the FSM has its own voltage regulators (analog and digital), dedicated band gap, and its own oscillator. Three power supply pins (VSUP 1, 2, 3) are used to overcome a pin lift issue. The internal voltage regulators are directly connected on VSUP (one bonding wire per pin is used). Additionally, the ground connection is redundant as well to avoid any loss of ground.

All the voltages generated in the device are monitored by the voltage supervisor (under and overvoltage) owing to a dedicated internal voltage reference (different from the one used for the voltage regulators). The result is reported to the MCU through the SPI and delivered to the fail-safe state machine (FSSM) for action, in case of a fault. All the safety relevant signals feed the FSSM, which handles the error handling and controls the fail-safe outputs.

There are three fail-safe outputs: RSTB (asserted low to reset the MCU), FS0B, and FS1B (asserted low to control any fail-safe circuitry). The fail-safe machine is in charge of bringing and maintaining the application in a fail-safe state.

12.5.1 Fail-safe machine state diagram

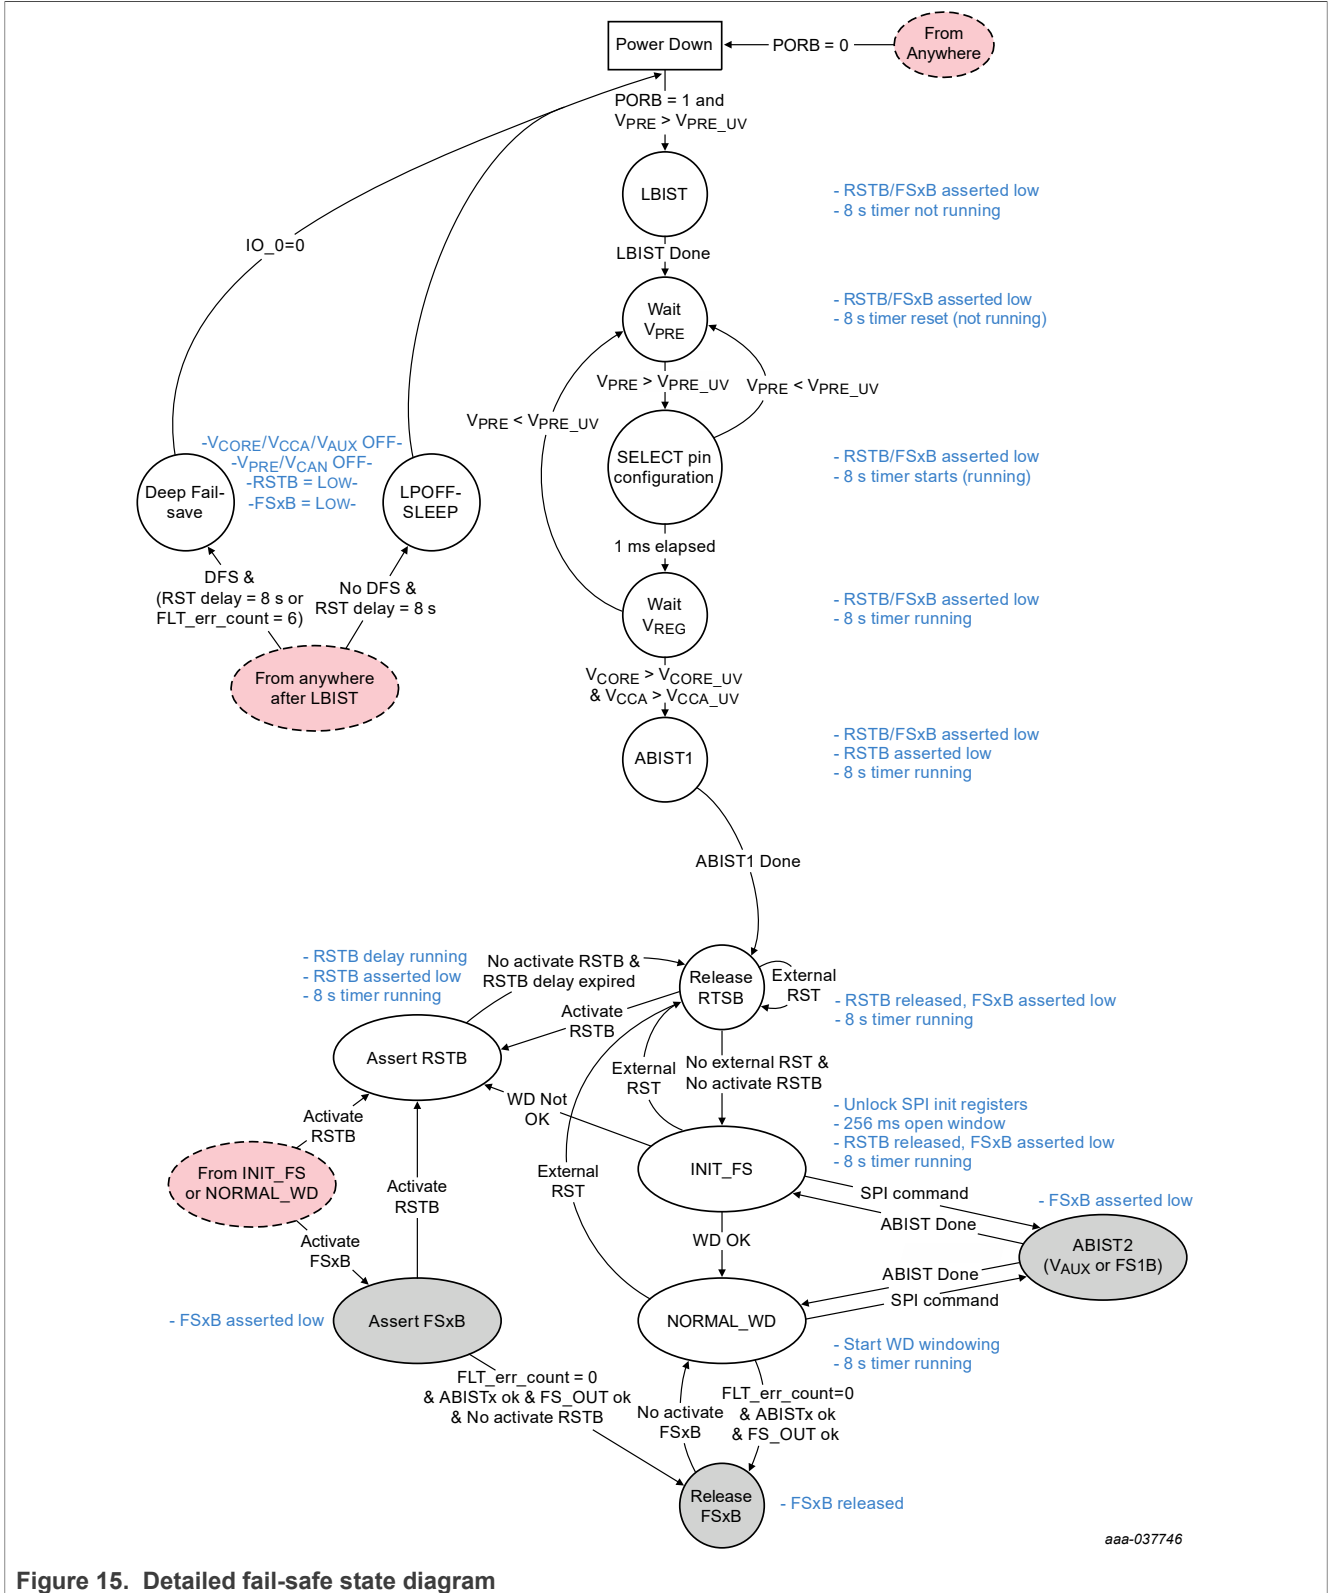

Figure 15. Detailed fail-safe state diagram

12.5.2 Watchdog operation

A windowed watchdog is implemented in the 35FS4500/35FS6500 and is based on question/answer principle (challenger). The watchdog must be continuously triggered by the MCU in the open watchdog window, otherwise an error is generated. The error handling and watchdog operations are managed by the fail-safe state machine. For debugging purpose, this functionality can be inhibited by setting the right voltage on the DEBUG pin at start-up.

The watchdog window duration is selectable through the SPI during the INIT_FS phase or in normal mode. The following values are available: 1.0 ms, 2.0 ms, 3.0 ms, 4.0 ms, 6.0 ms, 8.0 ms, 12 ms, 16.0 ms, 24 ms, 32 ms, 64 ms, 128 ms, 256 ms, 512 ms, and 1024 ms. The watchdog can also be inhibited through the SPI register in INIT_FS phase to allow *reprogramming* (ie.at vehicle level thru CAN).

An 8-bit pseudo-random word is generated by implementing a linear feedback shift register in the 35FS4500/35FS6500. The MCU can send the seed of the LFSR or use the LFSR generated by the 35FS4500/35FS6500 during the INIT phase and performs a pre-defined calculation. The result is sent through the SPI during the *open* watchdog window and verified by the 35FS4500/35FS6500. When the result is right, a new LFSR is generated and the watchdog window is restarted. When the result is wrong, the WD error counter is incremented, the watchdog window is restarted, an INTB is generated, and the LFSR value is not changed. Any access to the WD register during the *closed* watchdog window is considered a wrong WD refresh.

12.5.2.1 Normal operation (first watchdog refresh)

At power up, when the RSTB is released as high (after around 16.5 ms), the INIT phase starts for a maximum duration of 256 ms and this is considered as a fully open watchdog window. During this initialization phase the MCU sends the seed for the LFSR, or uses the default LFSR value generated by the 35FS4500/35FS6500 (B2h), available in the WD_LFSR register ([Section 13.4.8 "WD_LFSR"](#)). Using this LFSR, the MCU performs a simple calculation based on this formula. As an example, the result of this calculation based on LFSR default value (B2h) is 4Dh.

Figure 16. Watchdog answer calculation

The MCU sends the results in the WD_ANSWER register ([Section 13.4.9 "WD_ANSWER"](#)). When the watchdog is properly refreshed during the open window, the 256 ms open window is stopped and the initialization phase is finished. A new LFSR is generated and available in the WD_LFSR register ([Section 13.4.8 "WD_LFSR"](#)). If the watchdog refresh is wrong or if the watchdog is not refreshed during this 256 ms open window (INIT_FS phase), the device asserts the RSTB, FS0B, and the fault error counter is incremented by '1'.

After a good watchdog refresh, the device enters the Normal WD refresh mode, where open and closed windows are defined either by the configuration made during initialization phase in the WD_WINDOW register ([Section 13.4.7 "WD_WINDOW"](#)), or by the default value already present in this register (3.0 ms).

12.5.2.2 Normal watchdog refresh

The watchdog must be refreshed during every open window of the window period configured in the register WD_ANSWER. Any WD refresh restarts the window. This ensures the synchronization between MCU and 35FS4500/35FS6500.

The duration of the *window* is selectable through the SPI with no access restriction, meaning the window duration can be changed in the INIT phase or normal mode. Doing the change in normal operation allows the system integrator to configure the watchdog window duration on the fly:

- The new WD window duration (except after disable) is taken into account when a write in the WD_ANSWER register occurs (good or bad WD answer) or when the previous WD window is finished without any writing (WD timeout)
- The new WD window duration after disable is taken into account when the SPI command is validated

The duty cycle of the window is set to 50 % ± 10 % and is not modifiable.

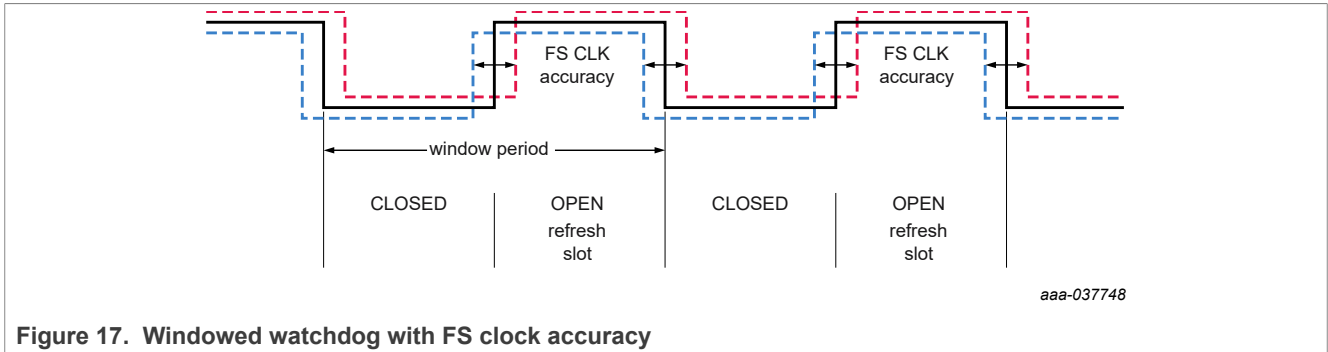

Figure 17. Windowed watchdog with FS clock accuracy

12.5.2.3 Watchdog in debug mode

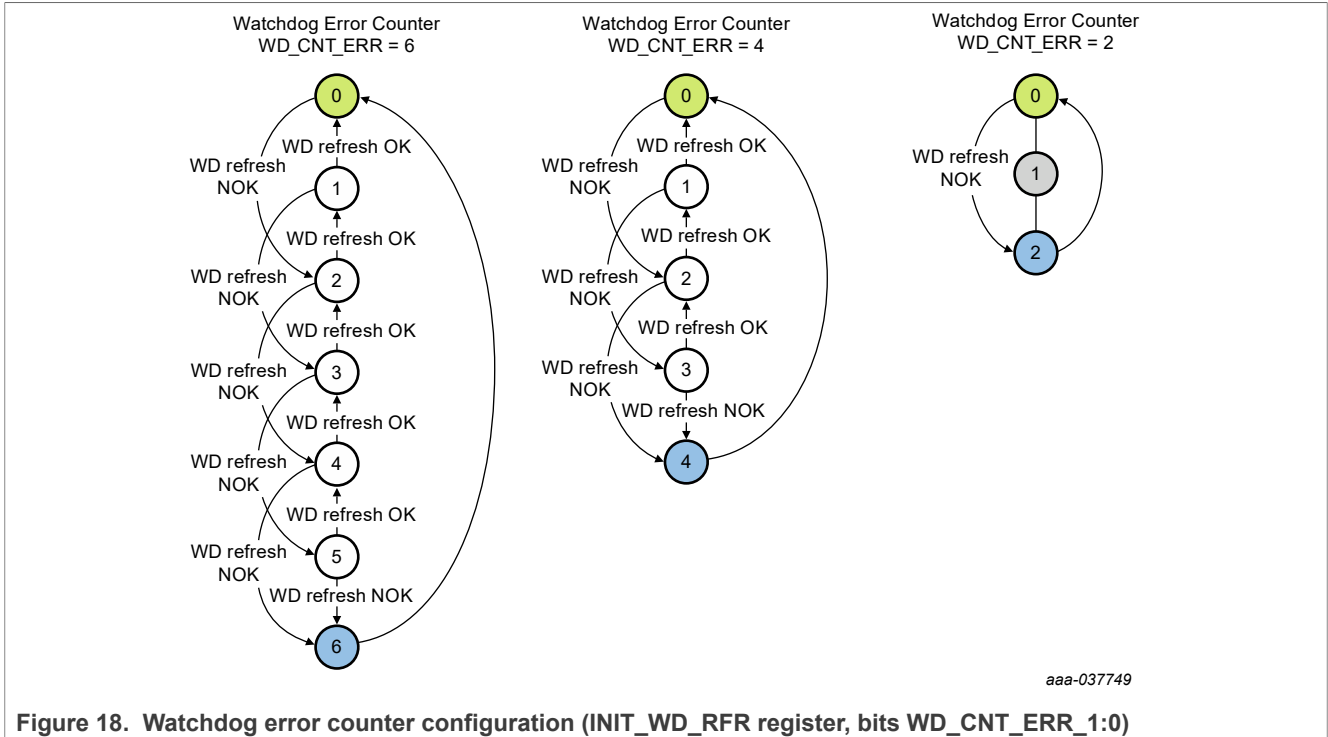

When the device is in debug mode (entered via the DEBUG pin), the watchdog continues to operate, but does not affect the device operation by asserting a reset of the fail-safe pins. For the user, operation appears without the watchdog. If needed and to debug the watchdog itself, the user can operate as in normal mode and check LFSR values, the watchdog refresh counter, the watchdog error counter, and the reset counter. This allows the user to debug their software and ensure a good watchdog strategy in the application.

12.5.2.4 Wrong watchdog refresh handling

Error counters and strategy are implemented in the device to manage wrong watchdog refreshes from the MCU. According to consecutive numbers of wrong watchdog refreshes, the device can decide to assert the RSTB and/or FS0B pin, depending on the safety configuration set during the INIT_FS phase (WD_IMPACT bit in INIT_SF_IMPACT register, [Table 85](#)).

12.5.2.5 Watchdog error counter

The watchdog error counter is implemented in the device to filter the incorrect watchdog refresh. Each time a watchdog failure occurs, the device increments this counter by 2. The WD error counter is decremented by 1 each time the watchdog is properly refreshed. This principle ensures a cyclic 'OK/NOK' behavior converges to a failure detection. To allow flexibility in the application, the maximum value of this counter is configurable in the INIT_WD_CNT register, but only when device is in INIT_FS mode.

12.5.2.6 Watchdog refresh counter

The watchdog refresh counter is used to decrement the fault error counter. Each time the watchdog is properly refreshed, the watchdog refresh counter is incremented by '1'. Each time the watchdog refresh counter reaches '6' and if next WD refresh is also good, the fault error counter is decremented by '1' (case with WD_CNT_RFR_1:0 configured at 6).

Whatever the position the watchdog refresh counter is in, each time there is a wrong refresh watchdog, the watchdog refresh counter is reset to '0'. To allow flexibility in the application, the maximum value of this watchdog refresh counter is configurable in the INIT_WD_CNT register, but only when the device is in the INIT_FS mode.

Table 11. Watchdog error table

		Window	
		CLOSED	OPEN
SPI	BAD key	WD_NOK	WD_NOK
	GOOD key	WD_NOK	WD_OK
	None (timeout)	No_issue	WD_NOK

Any access to the watchdog register during the *closed* watchdog window is considered as a wrong watchdog refresh. Watchdog timeout, meaning no WD refresh during closed or open windows, is considered as a wrong WD refresh.

12.5.3 Fault error counter

The fault error counter manages and counts the number of faults occurring in the application. This counter is incremented not only for the fault linked to consecutive wrong refresh watchdogs, but also for other sources of fault (undervoltage, overvoltage, external reset,...).

The fault error counter is incremented by 1, each time RSTB and/or FS0B pin is asserted. When FS0B is asserted, the fault error counter is incremented by 1, every time the watchdog error counter maximum value is reached. The fault error counter has two output values (intermediate and final).

- The intermediate value can be used to force the FS0B activation or to generate a RSTB pulse depending on the FLT_ERR_IMP_1:0 bit configuration in INIT_FAULT register.
- The final value is used to handle the transition to deep fail-safe when the SELECT pin is connected to Ground. If the SELECT pin is connected to VPRE, the main state machine remains in normal mode and the regulators remain on.

The intermediate value of the fault error counter is configurable to '1' or '3' using the FLT_ERR_FS bit in the INIT_FAULT register (Table 82). The final value of the fault error counter is based on the intermediate configuration. This configuration must be done during the INIT_FS phase.

- FLT_ERR_FS = 0 / Intermediate = 3; Final = 6 (Figure 20).
- FLT_ERR_FS = 1 / Intermediate = 1; Final = 2 (Figure 21).

In any condition, if the RSTB pin is asserted low for a duration longer than eight seconds, the device goes to:

- Deep fail-safe if the DFS function is enabled (SELECT pin connected to ground)
- LPOFF-sleep if the DFS function is disabled (SELECT pin connected to VPRES)
- The following faults lead to an increment of the fault error counter and can be configured:
 - Watchdog error counter = max value (6 by default)
 - VCore, VCCA, VAUX undervoltage
 - VCore, VCCA, VAUX overvoltage
 - FCRBM follows VCore configuration
 - IO_23 error detection (FCCU)
 - IO_45 error detection (external IC error)
- The following faults lead to an increment of the fault error counter and cannot be configured:
 - VPRES Overvoltage
 - Watchdog refresh not OK or watchdog timeout during INIT phase
 - SPI DED
 - ABIST1, ABIST2 fail
 - RSTB short to high (by cascaded effect of FS0B assertion)
 - External reset (except reset extension by MCU after reset assertion by the device)

Figure 20. Fault error counter (FLT_ERR_FS = 0, WD_CNT_RFR = 6)

12.5.3.1 Fault error counter intermediate value

The [Figure 22](#) illustrates the fault error counter increment when the watchdog error counter maximum value is reached.

The [Figure 23](#) illustrates the RSTB and FS0B possible behavior at the fault error counter intermediate value depending on WD_IMPACT_1:0 and FLT_ERR_IMP_1:0 bits configurations:

- #1, WD_IMPACT_1:0 = '01' & FLT_ERR_IMP_1:0 = '01': WD impact on RSTB only and FS0B is asserted low if FLT_ERR_CNT ≥ intermediate value
- #2, WD_IMPACT_1:0 = '10' & FLT_ERR_IMP_1:0 = '10': WD impact on FS0B only and RSTB is asserted low if FLT_ERR_CNT ≥ intermediate value and WD error counter = WD_CNT_ERR[1:0]

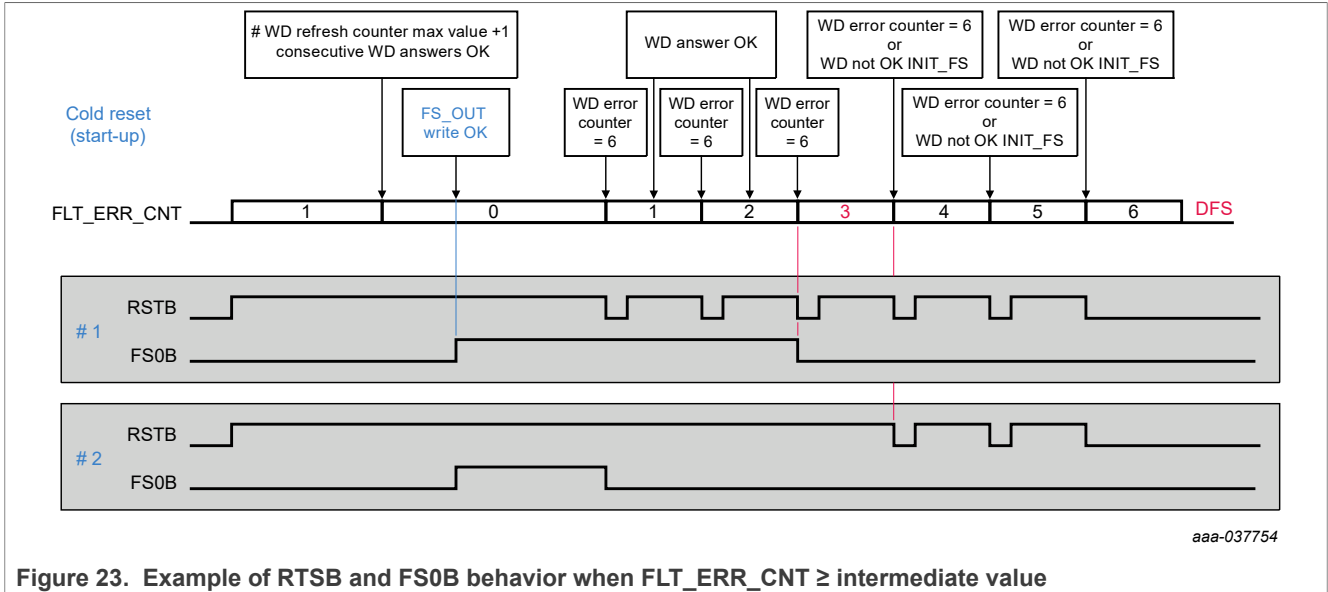

Figure 23. Example of RTSB and FS0B behavior when FLT_ERR_CNT ≥ intermediate value

12.5.3.2 Fault error counter at start-up or resuming from LPOFF mode

At start-up or when resuming from LPOFF mode the fault error counter starts at level 1 and FS0B is asserted low. To release FS0B, the fault error counter must go back to a '0' value due to several consecutive good watchdog refreshes. The right command is sent to the RELEASE_FSxB register (Figure 25). With the default watchdog refresh counter configuration (WD_RFR_CNT = 6), seven consecutive good watchdog refreshes decrease the fault error counter to 0 (Figure 24).

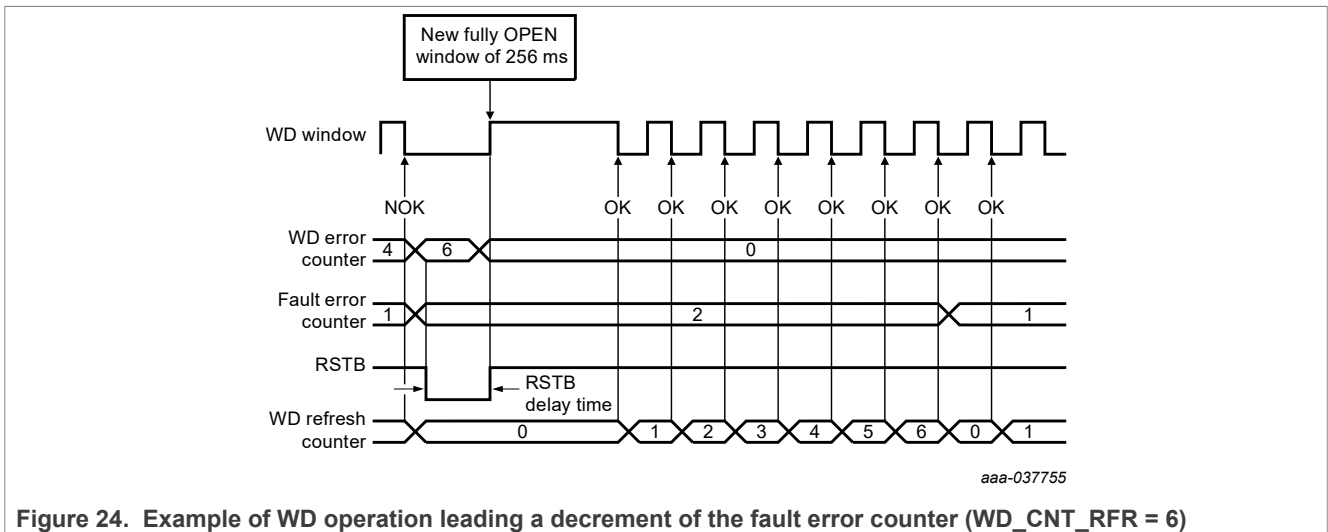

Figure 24. Example of WD operation leading a decrement of the fault error counter (WD_CNT_RFR = 6)

Figure 25. Fault error counter and FS0B deactivation sequence (FLT_ERR_FS = 0 & WD_CNT_ERR = 6)

12.5.4 RESET (RSTB) activation

The activation of RSTB depends on the fail-safe state machine configuration performed during the INIT_FS phase.

The following faults impact on RSTB activation can be configured:

- Watchdog error counter = max value (6 by default)
- VCORE, VCCA, VAUX undervoltage
- VCORE, VCCA, VAUX overvoltage
- FCRBM follows VCORE configuration
- IO_23 error detection (FCCU)
- Fault error counter level

The following faults impact on RSTB activation cannot be configured:

- VPRE overvoltage
- Watchdog refresh not OK or watchdog timeout during INIT phase
- FS0B short to high
- RSTB pulse requested by SPI

12.5.5 Fail-safe output (FS0B) activation

The activation of FS0B depends on the fail-safe state machine configuration performed during the INIT_FS phase.

The following faults impact on FS0B activation can be configured:

- Watchdog error counter = max value (6 by default)
- VCORE, VCCA, VAUX undervoltage
- VCORE, VCCA, VAUX overvoltage
- FCRBM follows VCORE configuration
- IO_23 error detection (FCCU)
- IO_45 error detection (external IC error)
- Fault error counter level

The following faults impact on FS0B activation cannot be configured:

- VPRE overvoltage
- Watchdog refresh not OK or watchdog timeout during INIT phase
- LBIST, ABIST1/2 fail
- RSTB, FS1B short to high
- FS0B low requested by SPI

- SPI DED

12.5.6 Fail-safe output (FS1B) activation

The activation of FS1B follows the activation of FS0B with a configurable delay (t_{DELAY}) or for a configurable duration (t_{DUR}).

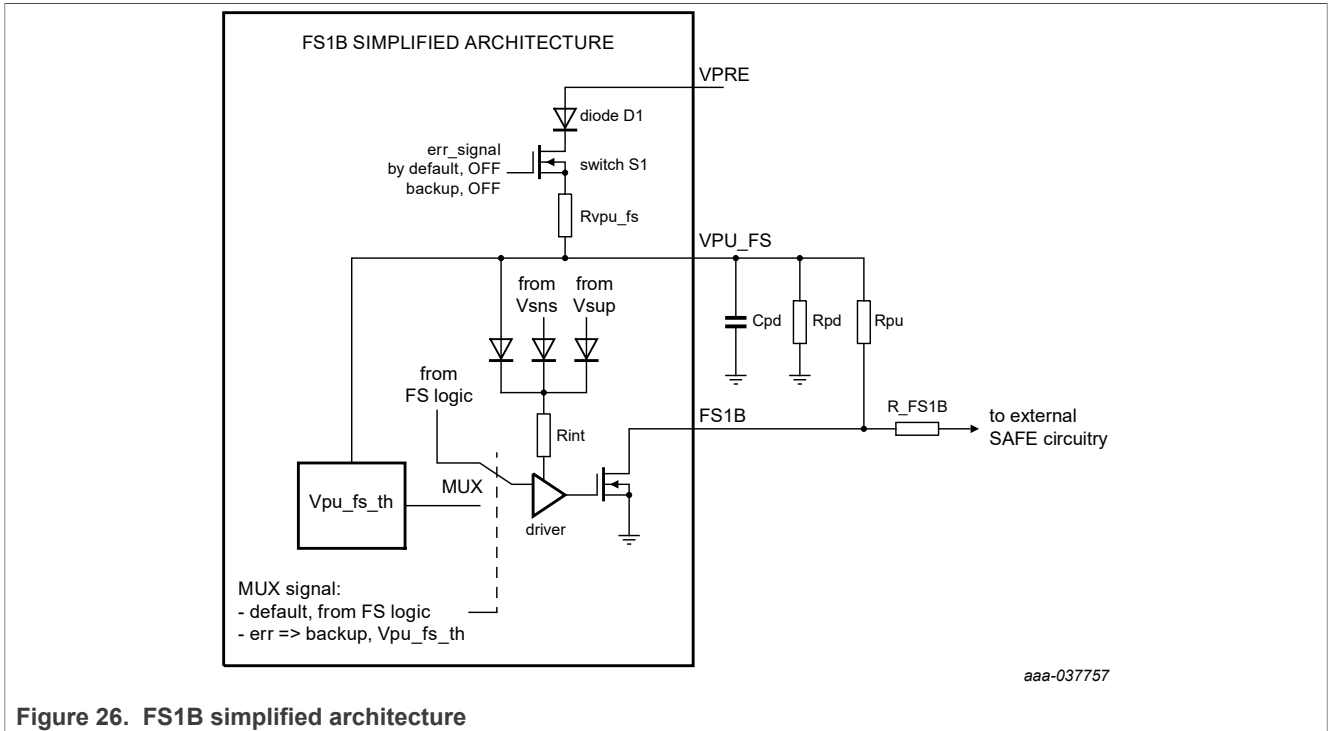

Figure 26. FS1B simplified architecture

VPU_FS is internally connected to VPRE with a reverse diode protection and protected against short-circuit by R_{VPU_FS} . The R_{FS1B} resistor is needed to be robust against ISO7637 pulses.

12.5.6.1 t_{DELAY} operation

In t_{DELAY} configuration, FS1B is asserted low with a delay after FS0B is activated, and remains asserted until it is released by the SPI.

The delay between FS0B and FS1B activation is configurable via the SPI from 0 ms to 3150 ms with the combination of FS1B_TIME_3:0 and FS1B_TIME_RANGE bits. This digital delay is generated by the fail-safe logic with an accuracy of $\pm 10\%$. FS1B can be activated at the same time as FS0B if $t_{DELAY} = 0$ or after a programmable delay if $t_{DELAY} > 0$ (Figure 27).

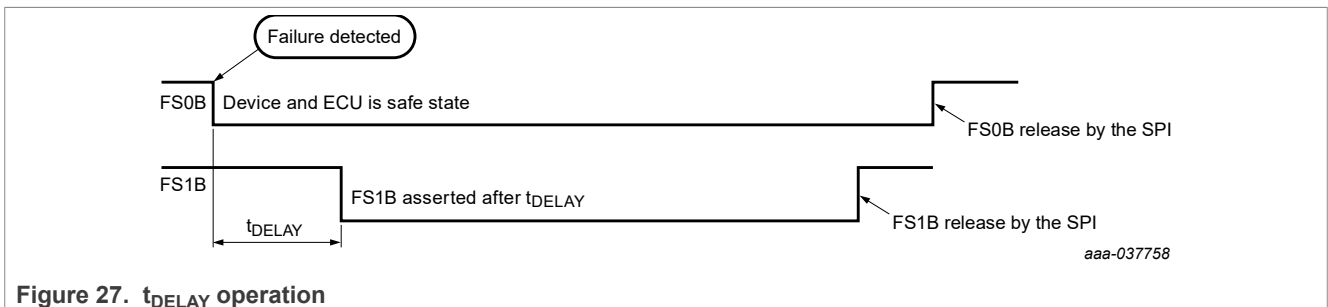

Figure 27. t_{DELAY} operation

To ensure the FS1B delay is guaranteed in all system failure cases, VPU_FS pin must be used as a FS1B pull-up (Figure 26).

The R_{PD}/C_{PD} components at VPU_FS provide a configurable backup delay under system failure (loss of internal fail-safe oscillator or loss of power supply). VPU_FS circuit consumption is negligible (~1.0 µA). Consequently, the external components R_{PD}/C_{PD} can be easily calculated for the desired backup delay (Figure 28).

Figure 28. Backup delay operation

R_{PD}/C_{PD} calculation:

- $R_{TOT} = R_{INT} // R_{PD}$ with $R_{INT} = 1.0\text{ M} \pm 50\%$
- $V_{PU_FS} = [(V_{PRE} - V_{DIODE}) \times R_{TOT} / (R_{TOT} + R_{VPU_FS})]$
- $V_{PU_FS_TH} = V_{PU_FS} \times e^{(-t_{DELAY} / R_{TOT} C_{PD})}$
- $t_{DELAY} = -R_{TOT} C_{PD} \times \ln(V_{PU_FS_TH} / V_{PU_FS})$

R_{PD}/C_{PD} typical use case:

- $t_{DELAY} = 33\text{ ms}$, $V_{PU_FS_TH} = 3.2\text{ V}$, $V_{PU_FS} = 5.5\text{ V}$
- $R_{PD} = 16\text{ K}\Omega$, $C_{PD} = 3.3\text{ }\mu\text{F}$

The switch S1 is opened by default and must be closed by a SPI command, due to the FS1B_DLY_REQ bit in the SF_OUTPUT_REQUEST register, before releasing the FS1B pin. V_{PU_FS} rise time is limited by the time constant of R_{VPU_FS} × C_{PD}. 95 % of V_{PU_FS} is reached after 3 × R_{VPU_FS} × C_{PD} = 15 ms. It is recommended to select high R_{PD} resistor value to be negligible versus R_{VPU_FS} and low C_{PD} capacitor value to reduce V_{PU_FS} rising time.

The external R_{PD}/C_{PD} components connected to VPU_FS are used to generate an FS1B backup delay. This backup delay can be verified at the application level to cover latent faults on these components, by opening the internal switch connecting VPRE to VPU_FS with the FS1B_DLY_REQ bit in the SF_OUPUT_REQ register (FS0B must be asserted first). The backup delay accuracy depends only on external component accuracy.

12.5.6.2 t_{DURATION} operation

In t_{DURATION} configuration, FS1B is asserted low at the same time as FS0B for a configurable duration, and is automatically released after t_{DURATION} timing (Figure 29). The FS1B activation duration is configurable via the SPI from 0 ms to 3150 ms with the combination of the FS1B_TIME_3:0 and FS1B_TIME_RANGE bits. This digital duration is generated by the fail-safe logic with an accuracy of ±10 %.

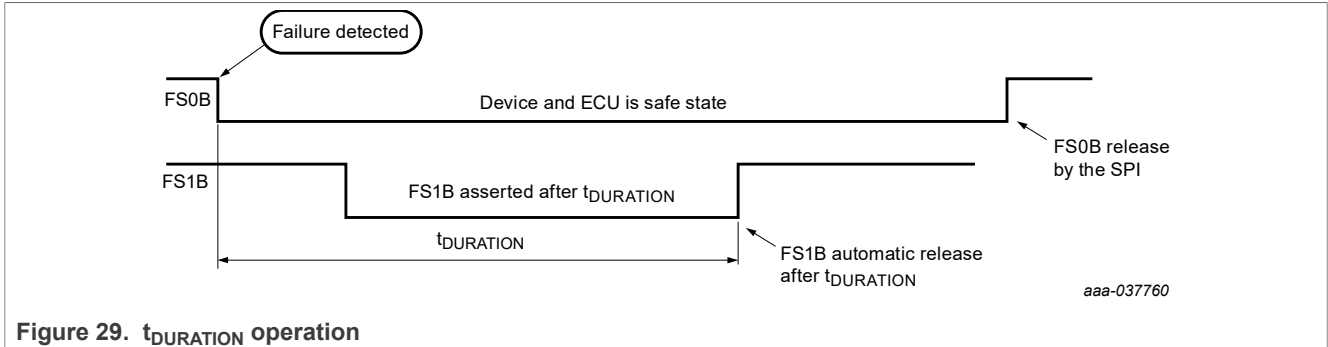

Figure 29. $t_{DURATION}$ operation

12.5.7 Fail-safe outputs (FS0B and FS1B) release

When the fail-safe outputs FS0B and consequently FS1B are asserted low by the device due to a fault, some conditions must be validated before allowing these pins to be released by the device. These conditions are:

- ABIST2_FS1B_OK = 1 if part number with FS1B
- ABIST2_VAUX_OK = 1 except if VAUX_FS_OV_1:0 = VAUX_FS_UV_1:0 = "00"
- Fault is removed
- Fault error counter must be at '0'
- Close the S1 switch if FS1B backup delay was engaged (FS1B_DLY_DRV bit = 1)
- RELEASE_FSxB register must be filled with the right value

12.5.7.1 RELEASE_FSxB register

When a fault is removed and the fault error counter changes back to level '0', a right word must be filled in the RELEASE_FSxB register. The value depends on the current WD_LFSR. LSB, MSB must be swapped, and a negative operation per bit must be applied.

FS0B and FS1B can be released independently or at the same time, depending on the configuration of the first three bits of the RELEASE_FSxB register (Table 12). The RELEASE_FSxB write command must be done after the WD_LFSR read command within the same WD period. The RELEASE_FSxB write command can be done one time only after the WD_LFSR read command. If FS0B and FS1B are released sequentially, the procedure must be done a first time for FS0B, and a second time for FS1B.

Table 12. RELEASE_FSxB register based on LFSR value

	WD_LFSR_7:0	b7	b6	b5	b4	b3	b2	b1	b0
Release FS0B	RELEASE_FSxB_7:0	0	1	1	\bar{b}_0	\bar{b}_1	\bar{b}_2	\bar{b}_3	\bar{b}_4
Release FS1B	RELEASE_FSxB_7:0	1	1	0	\bar{b}_3	\bar{b}_4	\bar{b}_5	\bar{b}_6	\bar{b}_7
Release FS0B and FS1B	RELEASE_FSxB_7:0	1	0	1	\bar{b}_0	\bar{b}_1	\bar{b}_2	\bar{b}_6	\bar{b}_7

12.5.8 SPI DED

Some SPI registers affect some safety critical aspects of the fail-safe functions, and thus are required to be protected against SEU (single event upset). Only fail-safe registers are concerned. During INIT_FS mode, access to fail-safe registers for product configuration is open. Once the INIT_FS phase is over, the Hamming circuitry is activated to protect registers content.

At this stage, if there is one single bit flip, the detection is made due to Hamming code, the error is corrected automatically (fully transparent for the user), and a flag is sent. If there are two errors (DED - dual error detection), the detection is made due to Hamming code but detected errors cannot be corrected. The flag is sent, and FS0B is activated.

12.6 Input voltage range

Due to the flexibility of the pre-regulator, the device can cover a wide battery input voltage range. However, a more standard voltage range can still be covered using only the buck configuration.

Figure 30. Input voltage range

- $V_{SUP} > 28\text{ V}$: Potential V_{PRE} thermal limitation

$R_{DS(on)}$, Current limitation and overcurrent detection are specified for $V_{SUP} < 28\text{ V}$.

- $V_{SUP} > 19\text{ V}$: Mux_out limitation

V_{SENSE} and IO_0 maximum analog input voltage range is 19 V. Internal 2.5 V reference voltage accuracy degraded.

- Buck only, $V_{SUP} < V_{SUP_UV_7}$:

CAN communication is guaranteed for $V_{SUP} > 6.0\text{ V}$. For V_{CCA} and V_{AUX} 5.0 V configuration, undervoltage triggers at low V_{SUP} (refer to $V_{CCA_UV_5}$ and $V_{AUX_UV_5}$).

12.7 Power management operation

A thermal sensor is implemented as close as possible to the pass transistor of each regulator (V_{PRE} , V_{CORE} , V_{CCA} , V_{CAN}) and an associated individual thermal shutdown (T_{SD}) protects these regulators independently. When the T_{SD} threshold of a specific regulator is reached, this regulator only is switched off and the information

is reported in the main state machine. The regulator restarts automatically when the junction temperature of the pass transistor decrease below the T_{SD} threshold.

12.7.1 VPRE voltage pre-regulator

A highly flexible SMPS pre-regulator is implemented in the 35FS4500/35FS6500. Depending on the input voltage requirement, the device can be configured as *non-inverting buck-boost converter* (Figure 32) or *standard buck converter* (Figure 31). An external logic level MOSFET (N-type) is required to operate in *non-inverting buck-boost converter*. The connection of the external MOSFET is detected automatically during the start-up phase.

The converter operates in current control mode in any configuration. The high-side switching MOSFET is integrated to make the current control easier. The PWM frequency is fixed at a typical 440 kHz. The compensation network is fully integrated. the V_{PRE} output voltage is regulated between 6.0 V and 7.0 V.

If the full current capability is not used for V_{CORE}, V_{CCA}, V_{AUX}, and CAN_5V, an additional external LDO can be connected to VP_{RE} to fulfill application needs, while the current load remains below the maximum current capability in all conditions.

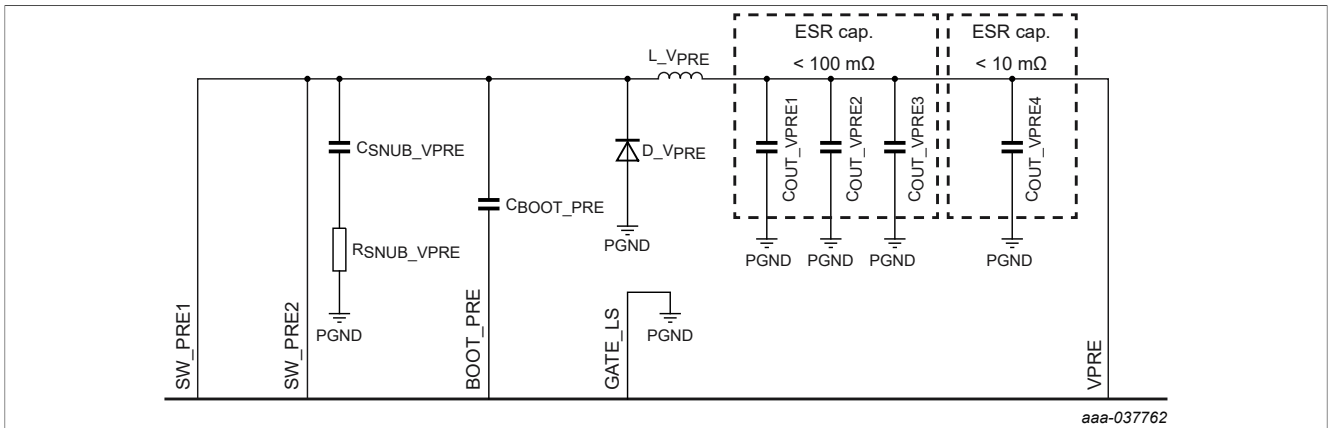

Figure 31. Pre-regulator: buck configuration

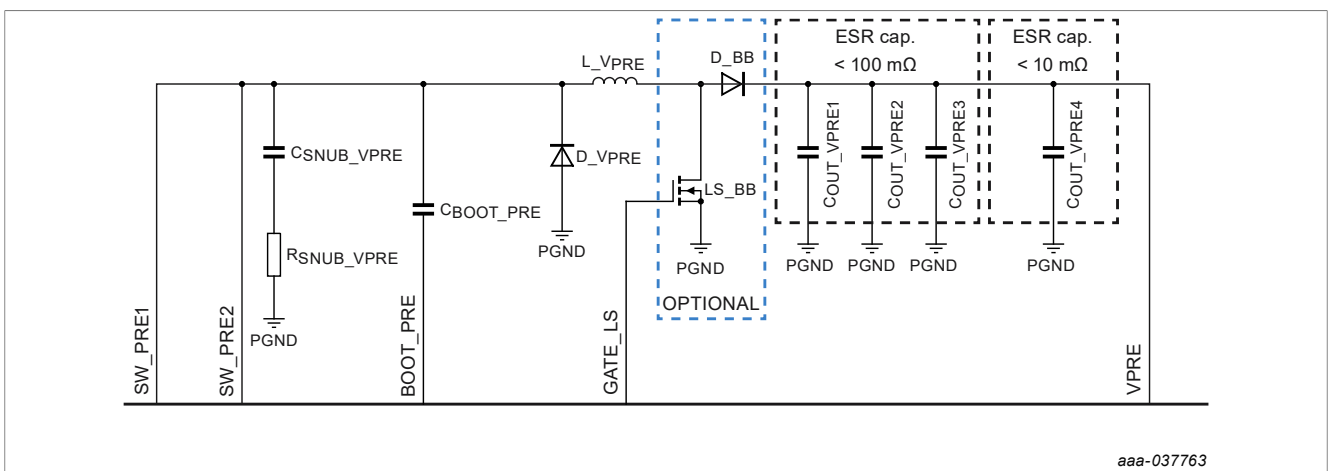

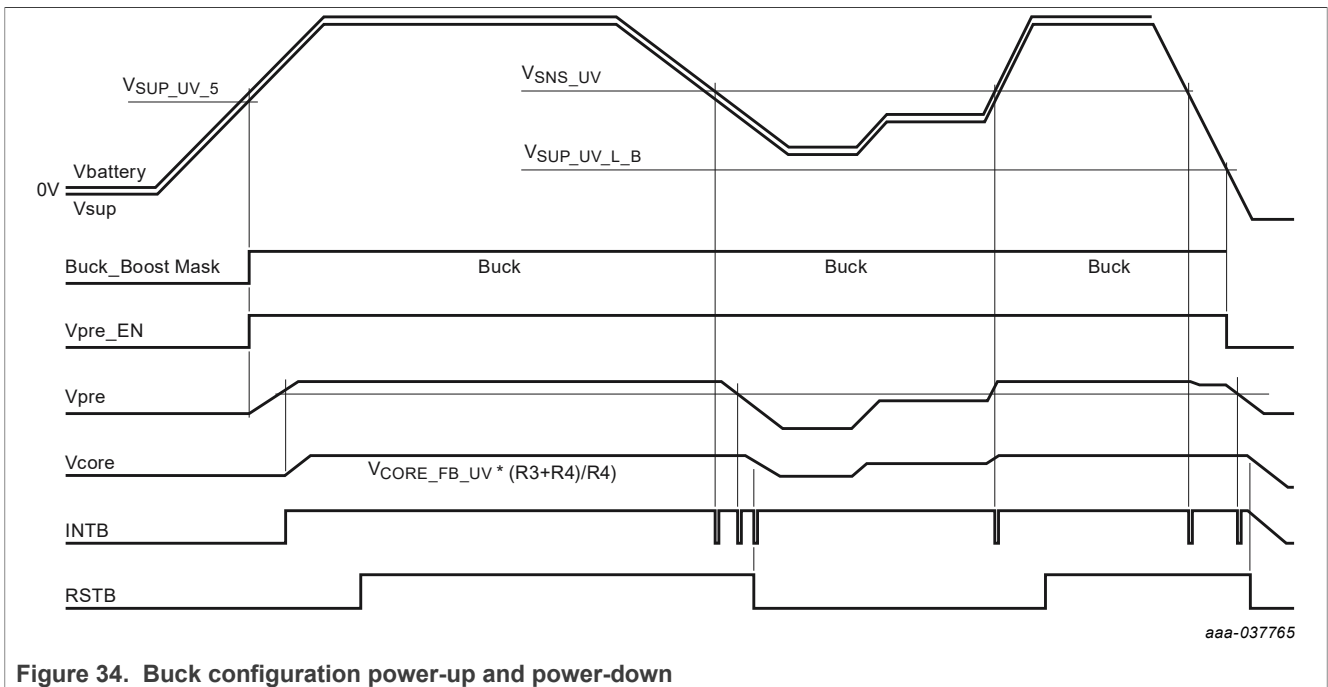

Figure 32. Pre-regulator: buck boost configuration

When the converter is set up to work in boost mode at low V_{SUP} , the transition between buck and boost mode is automatically handled by the device at the $V_{SUP_UV_7}$ threshold. Transition between buck mode and boost mode is based on hysteresis (Figure 33).

- When $V_{SUP} > V_{SUP_UV_7}$, the converter works in buck mode and the V_{PRE} output is regulated at 6.5 V typ.
- When $V_{SUP} < V_{SUP_UV_7}$, the converter works in boost mode and the V_{PRE} output is regulated at 6.3 V typ.

12.7.1.1 Power up and power down sequence

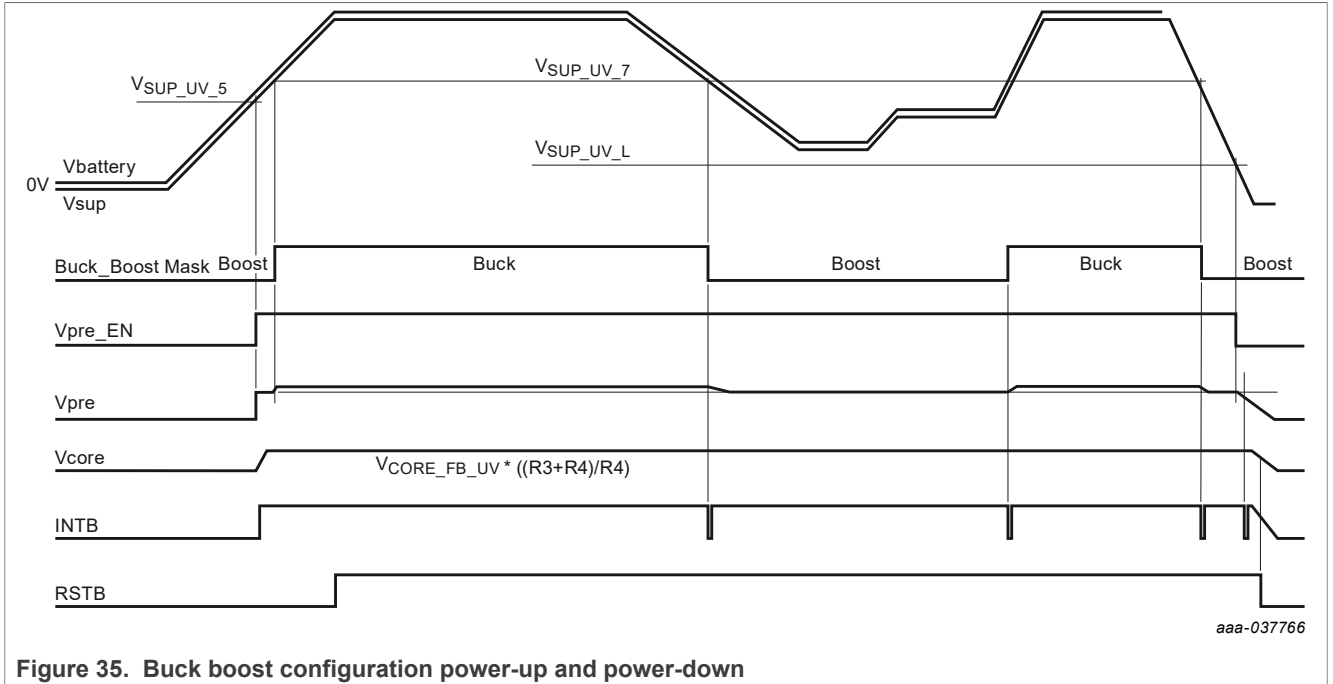

Figure 35. Buck boost configuration power-up and power-down

12.7.1.2 Cranking management

When VPRE is set up to work in buck only mode, the application can work down to VSUP = VSUP_UV_L_B = 4.5 V with a minimum of 500 mA current guaranteed on VPRE.

Figure 36. Behavior during cranking (buck configuration)

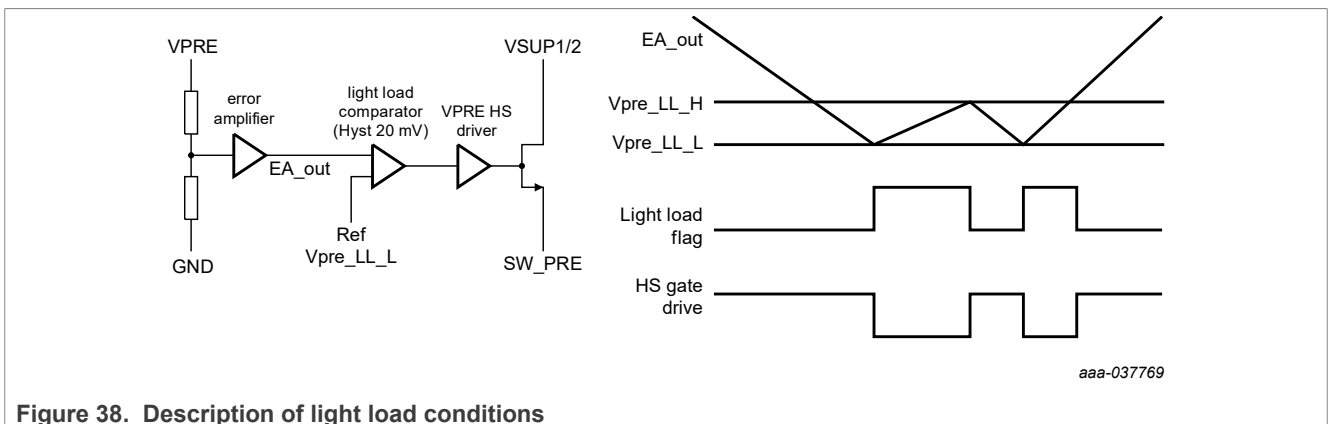

When VPRE is set up to work in buck-boost mode, the application can work down to VSUP = VSUP_UV_L = 2.7 V with a minimum of 300 mA current guaranteed on VPRE. The buck-boost configuration helps to pass the LV124 specification requiring a minimum of 3.2 V on VBAT supply during cold cranking conditions.

12.7.1.3 Light load condition

To improve the converter efficiency and avoid any unwanted output voltage increase, the VPRE voltage regulator operates in pulse skipping mode during light load conditions.

The transition between normal mode and pulse skipping mode is based on the comparison between the error amplifier output (EA_out) and pre-defined thresholds VPRE_LL_H and VPRE_LL_L. When the error amplifier output reaches VPRE_LL_L, the VPRE high-side transistor is switched off. When the error amplifier output reaches VPRE_LL_H, the VPRE high-side transistor is switched on again for the next switching period (Figure 38).

12.7.1.4 Input power feed forward condition

To improve the converter efficiency during high input power conditions, the VPRE switching frequency is reduced from 440 kHz to 220 kHz, when $V_{SUP} > V_{SUP_IPFF}$, to decrease the switching losses. The transition between the two frequencies is transparent for the application.

Figure 39. Input power feed forward principle

12.7.1.5 Overcurrent detection and current limitation

12.7.1.5.1 Overcurrent protection

To ensure the integrity of the high-side MOSFET, an overcurrent detection is implemented. The regulator is switched off by the main state machine when the I_{PRE_OC} overcurrent detection threshold is reached three consecutive times. The overcurrent detection is blanked when the pass transistor is switched on during t_{PRE_OC} to avoid parasitic switch off of the high-side gate driver.

The VPRE output voltage decrease causes an undervoltage condition on one of the cascaded regulators (VCORE, VCCA, VAUX) and brings the device into fail-safe state. The overcurrent protects the regulator in case the SW_PRE pin is shorted to GND. The overcurrent works in buck mode only.

12.7.1.5.2 Current limitation

A current limitation is also implemented to avoid uncontrolled power dissipation inside the device (duty cycle control) and limits the current. VPRE current limitation is automatically set based on the buck or buck-boost configuration. In buck only mode, the lowest current limitation I_{PRE_LIM2} is applied while in buck-boost mode, the highest current limitation I_{PRE_LIM1} is applied. The current limitation is blanked when the pass transistor is switched on during $t_{PRE_BLK_LIM}$ to allow short-circuit detection on the SW_PRE pin.

When I_{PRE_LIM} threshold is reached during buck mode, the high-side integrated MOSFET is switched off. When the I_{PRE_LIM} threshold is reached during boost mode, the external low-side MOSFET is switched off. In both cases, the MOSFET is not switched on again before the next rising edge of the switching clock.

The current limitation induces a duty cycle reduction and leads to the VPRE output voltage gradually dropping, which may cause an undervoltage condition on one of the cascaded regulators (VCORE, VCCA, VAUX) and bring the device to the fail-safe state. The current limitation does not switch off the regulator. The current limitation protects the regulator when the VPRE pin is shorted to GND.

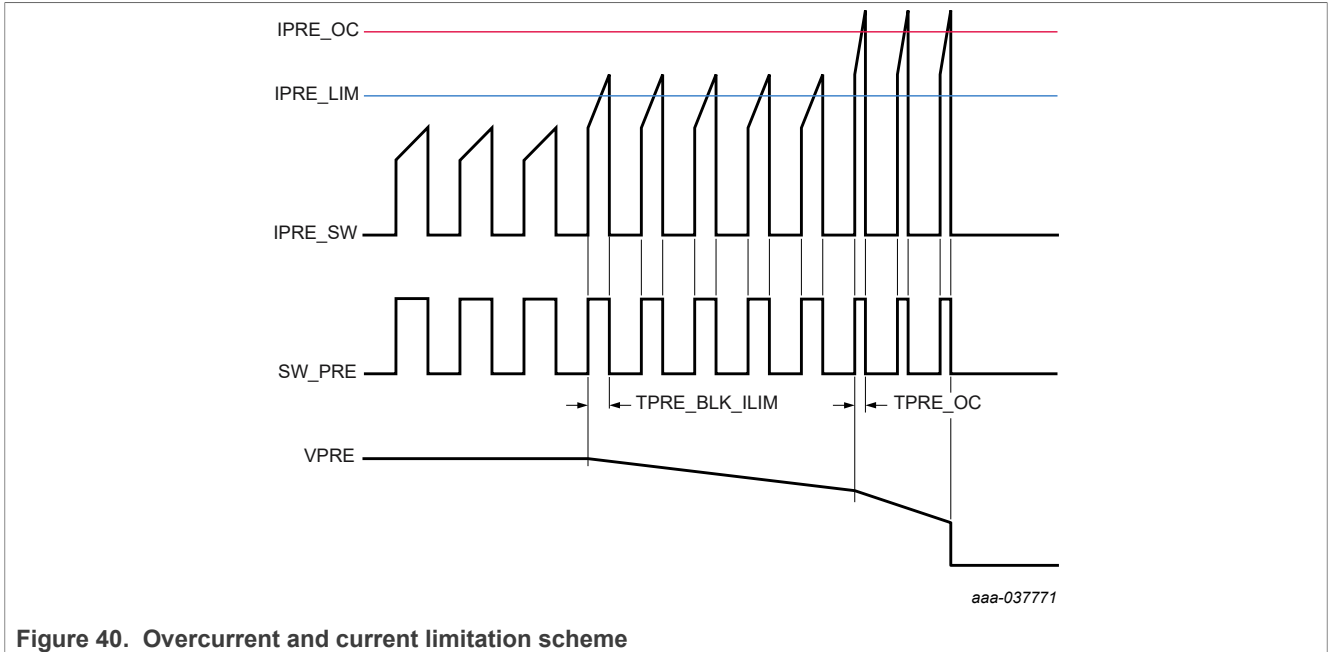

Figure 40. Overcurrent and current limitation scheme

12.7.1.6 VPRE voltage monitoring

The overvoltage detection switches off the regulator. The undervoltage detector is disabled when the regulator is switched off, reporting an undervoltage. Diagnostic is reported in the dedicated register and generates an Interrupt. The undervoltage detection does not switch off the regulator. However, VPRE decrease may induce an undervoltage on a regulator attached to VPRE (VCORE, VCCA, VAUX, or CAN_5V), and bring the application in fail-safe state depending on the supervisor configuration (registers INIT_VCORE_OVUV_IMPACT, INIT_VCCA_OVUV_IMPACT, INIT_VAUX_OVUV_IMPACT).

12.7.1.7 VPRE efficiency

VPRE efficiency versus current load is given for information based on typical external component criteria described in [Figure 41](#), close to the graph and at typical automotive Vsup voltage (14 V). The efficiency is valid in buck mode only and above a 200 mA load on VPRE, to be in continuous mode on the 22 μH inductor. The efficiency is calculated and has to be verified by measurement at the application level.

Figure 41. V_{PRE} efficiency

12.7.2 V_{CORE} voltage regulator

This voltage regulator is a step-down DC–DC converter in the FS6500 series and a linear regulator in the FS4500 series.

12.7.2.1 V_{CORE} DC–DC converter

The 35FS6500 voltage regulator is a step-down DC–DC converter operating in voltage control mode. The high-side switching MOSFET, connected to V_{PRE}, is integrated in the device, and the PWM frequency is fixed at 2.4 MHz typical. The output voltage is configurable from a 1.0 V to 5.0 V range, and adjustable around these voltages with an external resistor divider (R3/R4) connected between V_{CORE} and the feedback pin (FB_{CORE}) (Figure 42). $V_{CORE} = V_{CORE_FB} \times ((R3 + R4)/R4)$.

The voltage accuracy is ±2.0 % (without the external resistor bridge R3/R4 accuracy) and the maximum output current is 1.5 A. The stability of the overall converter is done by an external compensation network (R1/C1/R2/C2) connected to the pin COMP_{CORE}. It is recommended to use 1.0 % accuracy resistors and set R4 = 8.06 kΩ and adjust R3 to obtain the final V_{CORE} voltage needed for the MCU core supply.

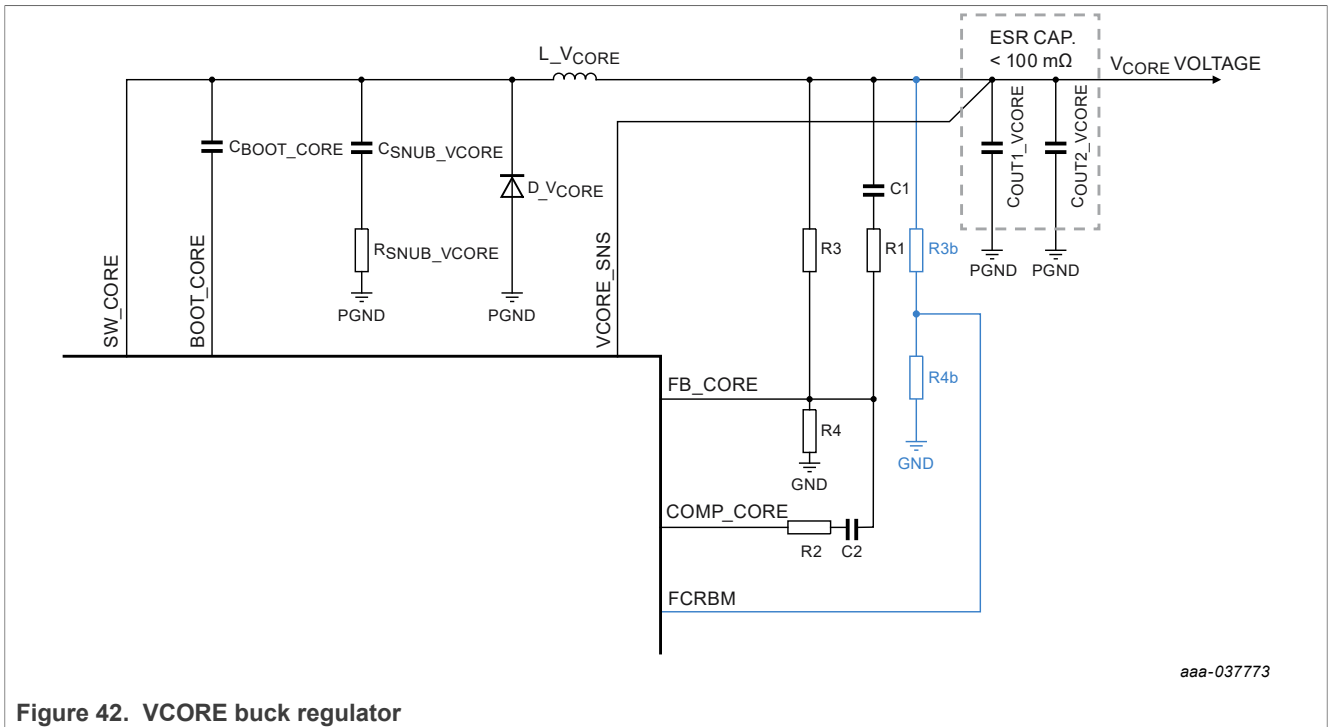

Figure 42. V_CORE buck regulator

12.7.2.2 Light load condition

To improve the converter efficiency and avoid any unwanted output voltage increase, the V_CORE voltage regulator operates in pulse skipping mode during light load conditions. The principle is the same as the VPRE implementation described in detail in [Section 12.7.1.3 "Light load condition"](#).

12.7.2.3 Current limitation

A current limitation is implemented to avoid uncontrolled power dissipation inside the device (duty cycle control) and limits the current below I_{CORE_LIM} . The current limitation is banked when the pass transistor is switched on during $t_{CORE_BLK_LIM}$ to avoid parasite detection. When the I_{CORE_LIM} threshold is reached, the high-side integrated MOSFET is switched off. The MOSFET is not switched on again before the next rising edge of the switching clock.

The current limitation induces a duty cycle reduction and leads to the V_CORE output voltage to fall gradually and may cause an undervoltage condition, bringing the device into a fail-safe state. The current limitation does not switch off the regulator.

12.7.2.4 Voltage monitoring

The overvoltage detection switches off the regulator. The regulator remains on during an undervoltage detection. Diagnostic is reported in the dedicated register, generates an interrupt, and may bring the application into the fail-safe state, depending on the supervisor configuration (register INIT_VCORE_OVUV_IMPACT).

For safety purposes, the FCRBM pin monitors the external resistor bridge (R3/R4) used to setup the final V_CORE voltage through a second resistor bridge (R3b/R4b) to detect an external resistor drift or disconnection. The monitoring compares the FB_Core and FCRBM pins ([Figure 43](#)) and triggers when $FB_Core - FCRBM > \pm 150$ mV max.

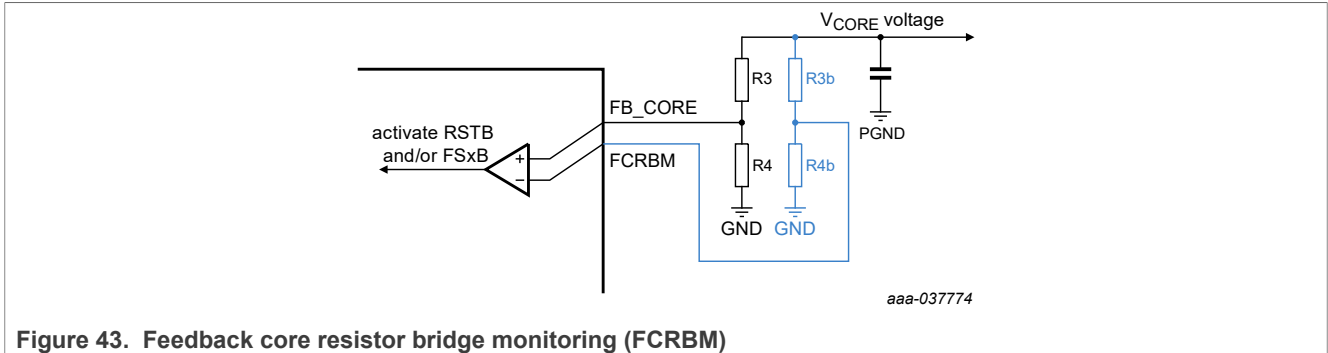

Figure 43. Feedback core resistor bridge monitoring (FCRBM)

If the second resistor bridge (R3b/R4b) is not mounted, FCRBM must be connected directly to FB_Core to satisfy $V_{FB_core} = FCRBM$ in all conditions.

12.7.2.5 V_{CORE} efficiency

V_{CORE} efficiency versus current load is given for information based on typical external component criteria described in Table 48, close to the graph and at three typical V_{CORE} voltages (5.0 V, 3.3 V, and 1.2 V), covering most of the MCU supply ranges. The efficiency is valid above a 200 mA load on V_{CORE} to be in continuous mode in the 2.2 μH inductor. The efficiency is calculated and has to be verified by measurement at the application level. One of the major contributor degrading the efficiency at V_{CORE} = 1.2 V is the external diode during the recirculation phase. The lower the diode forward voltage (V_F) is, the better the efficiency.

Figure 44. V_{CORE} efficiency

12.7.2.6 V_{CORE} linear regulator

The 35FS4500 voltage regulator is a linear regulator. The pass device, connected to V_{PRE}, is integrated. The output voltage range is configurable from 1.0 V to 5.0 V, and adjustable around these voltages with an external resistor divider (R3/R4) connected between V_{CORE} and the feedback pin (FB_CORE) (see Figure 45). $V_{CORE} = V_{CORE_FB} \times ((R3 + R4)/R4)$.

The voltage accuracy is ±2.0 % (without the external resistor bridge R3/R4 accuracy) and the max. output current is 0.5 A. In this case, the BOOT_CORE and COMP_CORE pins (used in buck converter mode only)

must be left open. It is recommended to use 1.0 % accuracy resistors and set $R4 = 8.06 \text{ k}\Omega$ and adjust $R3$ to obtain the final V_{CORE} voltage needed for the MCU core supply. When V_{CORE} is used in linear mode, the power dissipation must be taken into account at low-voltage.

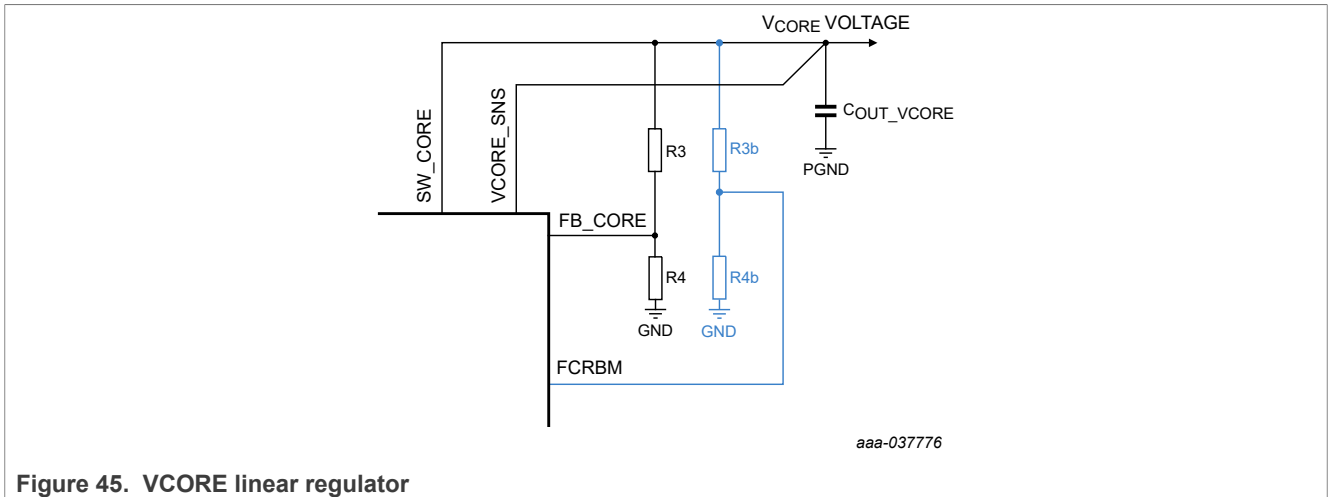

Figure 45. V_{CORE} linear regulator

12.7.2.7 Current limitation

Similar to the buck converter mode, a current limitation is implemented to avoid uncontrolled power dissipation inside the device ([Section 12.7.2.3 "Current limitation"](#)).

12.7.2.8 Voltage monitoring

The linear regulator has the same voltage monitoring than the DC–DC buck converter ([Section 12.7.2.4 "Voltage monitoring"](#)).

12.7.3 Charge pump and bootstrap

Both switching MOSFETs of VPRE and V_{CORE} SMPS are driven by external bootstrap capacitors. Additionally, a charge pump is implemented to ensure 100 % duty cycle for both converters. Each converter uses a 100 nF external capacitor minimum to operate properly.

12.7.4 VCCA voltage regulator

VCCA is a linear voltage regulator mainly dedicated to supply the MCU I/Os, especially the ADC. The output voltage is selectable at 5.0 V or 3.3 V. Since this output voltage can be used to supply MCU I/Os, the output voltage selection is done using an external resistor connected to the SELECT pin and ground or VPRE. When VCCA is used with the internal MOS transistor, the VCCA_E pin must be connected to VPRE. The voltage accuracy is $\pm 1.0 \%$ for 5.0 V and 3.3 V configuration with an output current capability at 100 mA.

When VCCA is used with an external PNP transistor to boost the current capability up to 300 mA, the connection is detected automatically during the start-up sequence of the 35FS4500/35FS6500. In such condition, the internal pass transistor is switched off and all the current is driven through the external PNP to reduce the internal power dissipation. The output voltage accuracy with an external PNP is reduced to $\pm 3.0 \%$ at 300 mA current load. The VCCA output voltage is used as a reference for the auxiliary voltage supply (V_{AUX}) when V_{AUX} is configured as a tracking regulator.

12.7.4.1 Current limitation

A current limitation is implemented to avoid uncontrolled power dissipation of the internal MOSFET or external PNP transistor. By default, the current limitation threshold is selected based on the auto detection of the external PNP during start-up phase.

- When the internal MOSFET transistor is used, the current is limited to $I_{CCA_LIM_INT}$ and the regulator is kept on
- When the external PNP transistor is used, the current is limited to $I_{CCA_LIM_OUT}$ and the regulator is switched off after a dedicated duration $t_{CCA_LIM_OFF}$ under current limitation. A SPI command is needed to restart the regulator.

In case of an external PNP configuration only, the lowest current limitation threshold can be selected by the SPI in the register `INIT_VREG` instead of the highest one. A current limitation foldback scheme is implemented to reduce the current limitation to $I_{CCA_LIM_FB}$ when V_{CCA} is below $V_{CCA_LIM_FB}$, limiting the power dissipation in the external PNP transistor during a short-circuit to GND of the V_{CCA} pin.

12.7.4.2 Voltage monitoring

The overvoltage detection switches the regulator off. The regulator remains on if an undervoltage is detected. A diagnostic is reported in the dedicated register, generating an Interrupt and may bring the application into fail-safe state, depending on the supervisor configuration (register `INIT_VCCA_OVUV_IMPACT`).

12.7.5 VAUX voltage regulator

VAUX is a highly flexible linear voltage regulator, which can be used either as an auxiliary supply dedicated to additional device in the ECU or as a sensor supply (i.e. outside the ECU). An external PNP transistor must be used (no internal current capability).

If VAUX is not used in the application, the VAUX, VAUX_E, and VAUX_B pins must be left open. It is recommended to turn the V_{AUX} driver off and disable the V_{AUX} safety impact by the SPI (`VAUX_EN=0` in `REG_MODE` register and all bits of `INIT_VAUX_OVUV_IMPACT` register at 0).

If VAUX is used as an auxiliary supply, the output voltage is selectable between 5.0 V and 3.3 V. Since this voltage rail can be used to supply MCU IOs, the selection is done with an external resistor connected between the SELECT pin and ground or VPRE. In such case, the voltage accuracy is $\pm 3.0\%$, with a maximum output current capability of 400 mA.

If VAUX is used as a sensor supply rail, the output voltage is selectable between 5.0 V and 3.3 V. V_{CCA} can be used as reference for the sensor supply used as tracker. In this case, the V_{AUX} voltage must match V_{CCA} , limiting the resistor configuration at the SELECT pin to 5.1 k Ω ($V_{AUX} = V_{CCA} = 3.3$ V) and 12 k Ω ($V_{AUX} = V_{CCA} = 5.0$ V). The tracker mode selection is done during the INIT phase and secured (bit `VAUX_TRK_EN` in the `INIT_VREG` register). The tracking accuracy is ± 15 mV.

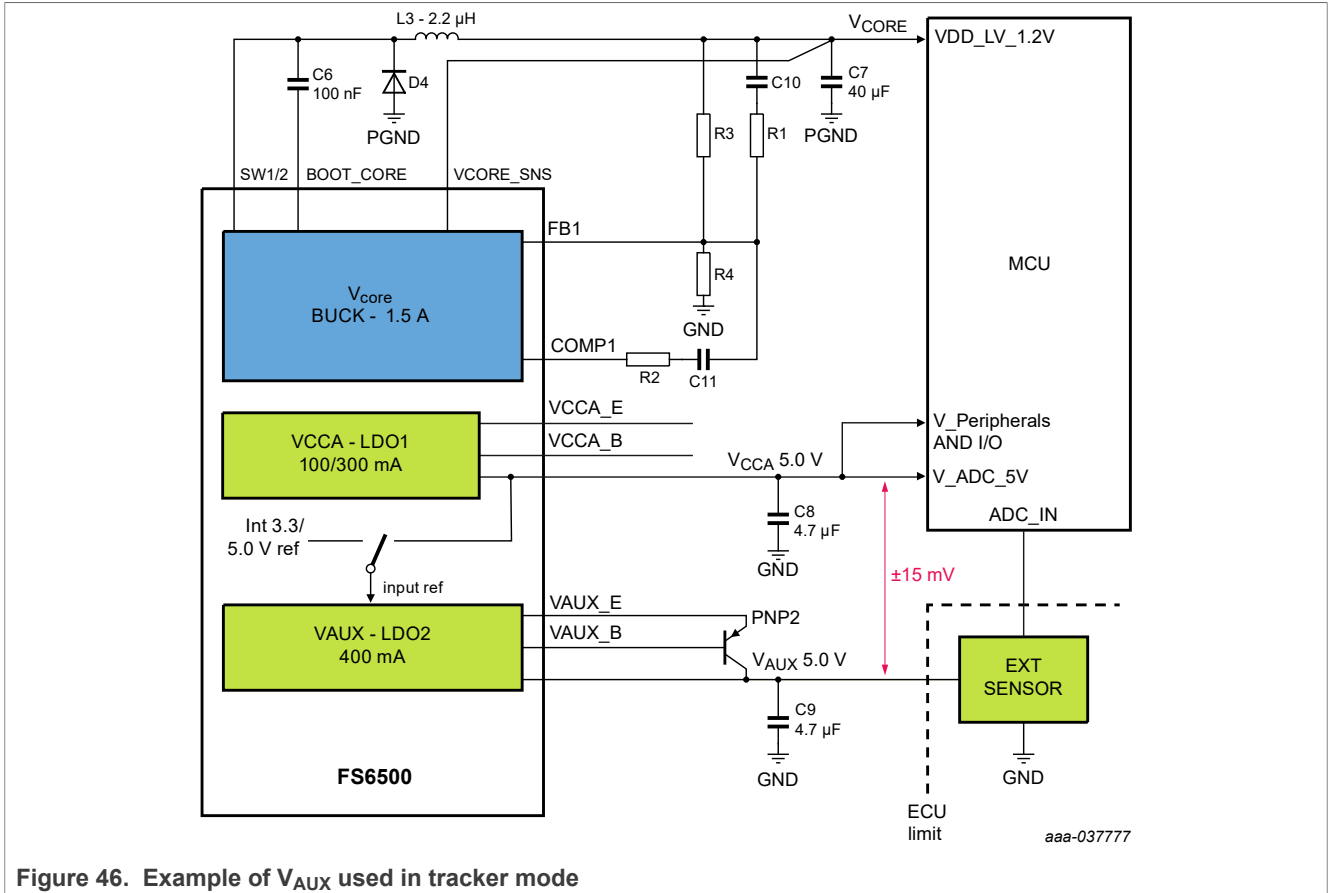

Figure 46. Example of V_{AUX} used in tracker mode

12.7.5.1 Current limitation

A current limitation is implemented to avoid uncontrolled power dissipation of the external PNP transistor. The current is limited to I_{AUX_LIM} and the regulator is switch off after a dedicated duration $t_{AUX_LIM_OFF}$ under current limitation. A SPI command is needed to restart the regulator. A current limitation foldback scheme is implemented to reduce the current limitation to $I_{AUX_LIM_FB}$ when V_{AUX} is below $V_{AUX_LIM_FB}$, limiting the power dissipation in the external PNP transistor during a short-circuit to GND of the VAUX pin.

Figure 47. V_{AUX} current limitation scheme with foldback mechanism

12.7.5.2 Voltage monitoring

The overvoltage detection switches the regulator off. The regulator remains on if an undervoltage is detected. A diagnostic is reported in the dedicated register, generating an interrupt and may bring the application into the fail-safe state, depending on the supervisor configuration (register INIT_VAUX_OVUV_Impact).

12.7.6 CAN_5V voltage regulator

The CAN_5V voltage regulator is a linear regulator fully dedicated to the internal CAN interface. By default, the CAN_5V regulator and the undervoltage detector are enabled and the overvoltage detector is disabled. The overvoltage detector can be enabled by the SPI during INIT_MAIN state.

If the overvoltage detector is enabled, the CAN_5V regulator switches off when an overvoltage is detected. The undervoltage detector is disabled when the regulator is switched off reporting an undervoltage. A diagnostic is reported in the dedicated register, generating an Interrupt. The CAN_5V regulator is not a safety regulator. Consequently, the CAN_5V voltage monitoring (overvoltage, undervoltage) never asserts the RSTB or FS0B fail-safe pins.

If the 35FS4500/35FS6500 internal CAN FD transceiver is not used in the application, the CAN_5V regulator can be used to supply an external stand-alone CAN or FLEX-RAY transceiver, provided the current load remains below the maximum current capability in all conditions. In this case, the internal CAN FD transceiver must be put into sleep mode without wake-up capability.

12.7.7 VKAM

The keep alive memory supply is shared with IO_5 pin. When VKAM is used, IO_5 is not available and vice versa. Depending on the part number selection (Table 2), VKAM can be on or off by default.

- If VKAM is on by default, VKAM starts as soon as VSUP3 is > 4.5 V. VKAM can still be turned off/on by the SPI.
- If VKAM is off by default, VKAM is turned on/off by the SPI.

Figure 48. VKAM start-up strategy

VKAM is the only supply available in low-power mode (LPOFF). VKAM can be used to supply the MCU static RAM or any other external IC which does not exceed the current capability. A current limitation is implemented. Neither voltage monitoring, nor thermal shutdown are implemented. VKAM can be selected at the MUX_OUT pin to be monitored by the MCU ADC. The VKAM supply is available down to $V_{SUP} = V_{SUP_UV_L} = 2.7\text{ V}$ when the device is in normal mode, and down to $V_{SUP} = 4.5\text{ V}$ when the device is in low-power mode off.

12.7.8 Power dissipation

The 35FS4500/35FS6500 provides high performance SMPS and linear regulators to supply high end MCUs in automotive applications. Each regulator can deliver:

- V_{PRE} (6.5 V) up to 2.0 A
- V_{CORE} (from 1.0 V to 5.0 V range) up to 1.5 A
- V_{CCA} (3.3 V or 5.0 V) up to 100 mA (with internal MOS) or up to 300 mA (with external PNP)
- V_{AUX} (3.3 V or 5.0 V) up to 400 mA (with external PNP)
- V_{CAN} (5.0 V) up to 100 mA

A thermal dissipation analysis has to be performed based on the application use case to ensure the maximum silicon junction temperature does not exceed 150 °C.

Two use cases covering the two main V_{CORE} voltage configurations are provided in [Figure 49](#).

- use case 1: $V_{CORE} = 3.3\text{ V}$, $I_{CORE} = 0.7\text{ A}$, V_{CCA} with int. MOS
- use case 2: $V_{CORE} = 1.2\text{ V}$, $I_{CORE} = 1.4\text{ A}$, V_{CCA} with ext. PNP

Both use cases have a total internal power dissipation below 0.9 W. A junction to ambient thermal resistivity of 30 °C/W allows the application to work up to an ambient temperature of 150 °C. A good soldering of the package expose pad is highly recommended to achieve such thermal performance.

Figure 49. Power dissipation use case

The main contributors to the device power dissipation are the V_{PRE} , V_{CORE} , and V_{CCA} (when used with an internal PMOS) regulators. In comparison, the power dissipation from the Internal IC, VAUX, and CAN transceiver are negligible. V_{PRE} power dissipation is mainly induced by the loading of the regulators it is supplying, mainly V_{CORE} , V_{CCA} , and V_{AUX} which are application dependant. The total device power dissipation, depending on the variation of these three regulators, is detailed in [Figure 50](#) with the environmental conditions in the associated table.

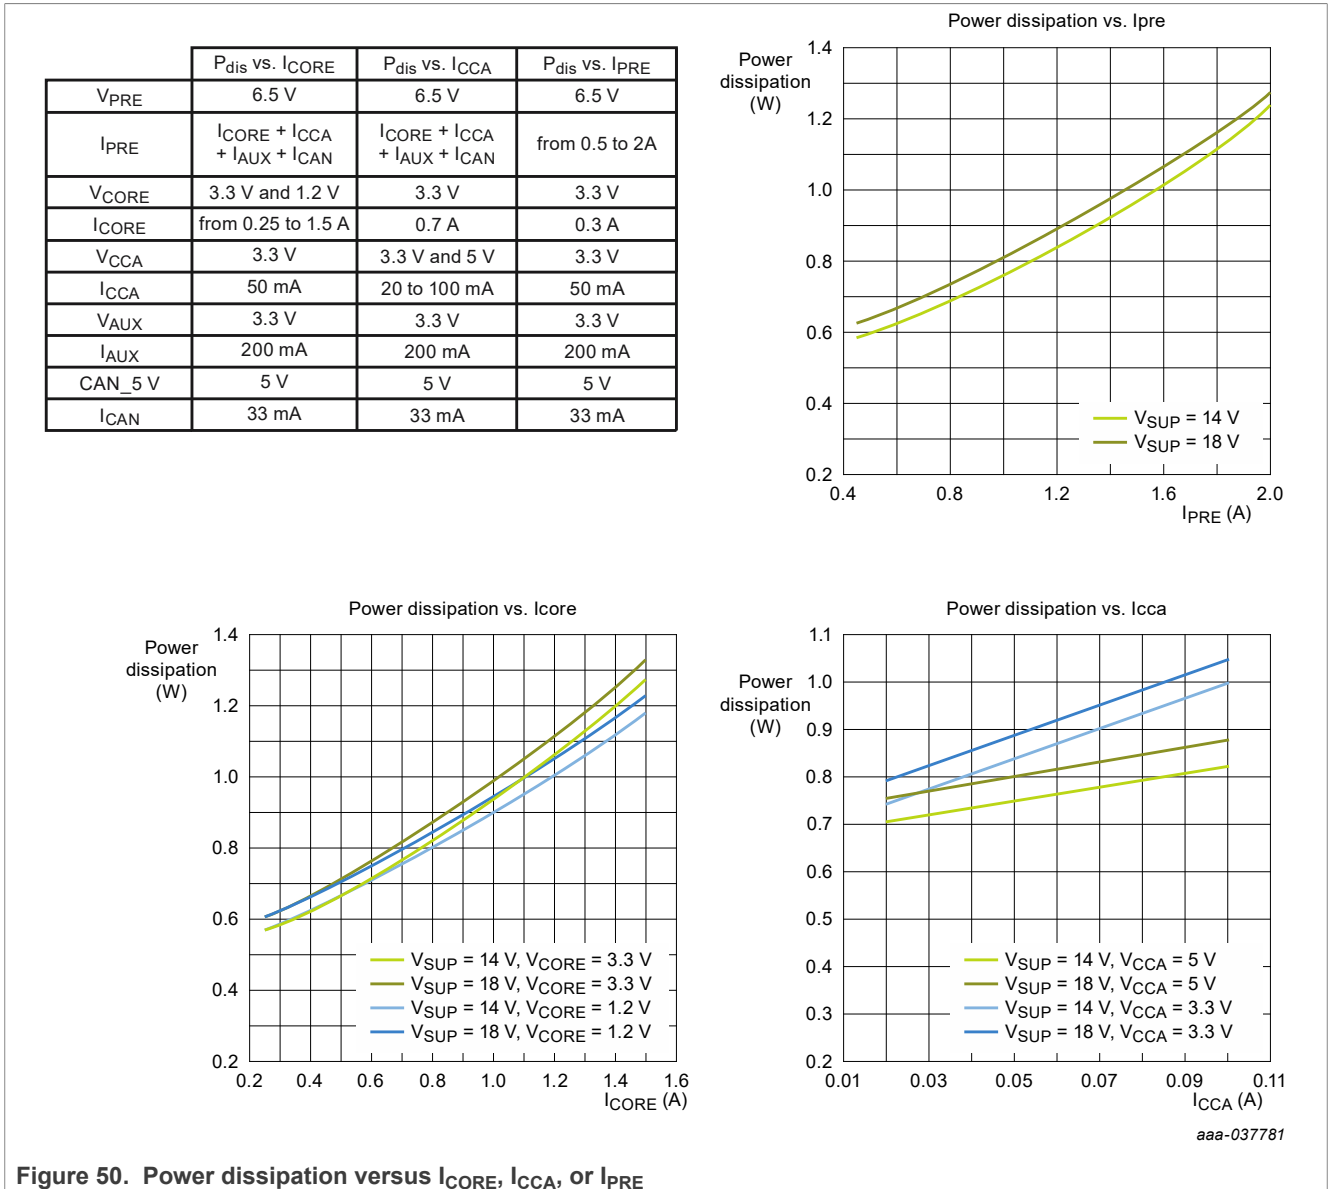

Figure 50. Power dissipation versus I_{CORE} , I_{CCA} , or I_{PRE}

12.7.9 Start-up sequence

To provide a safe and well known start-up sequence, the 35FS4500/35FS6500 includes an undervoltage lockout. This $V_{SUP_UV_5}$ undervoltage lockout applies when the device is under a power on reset condition or released from LPOFF. All the different voltage rails start automatically as described in [Figure 51](#).

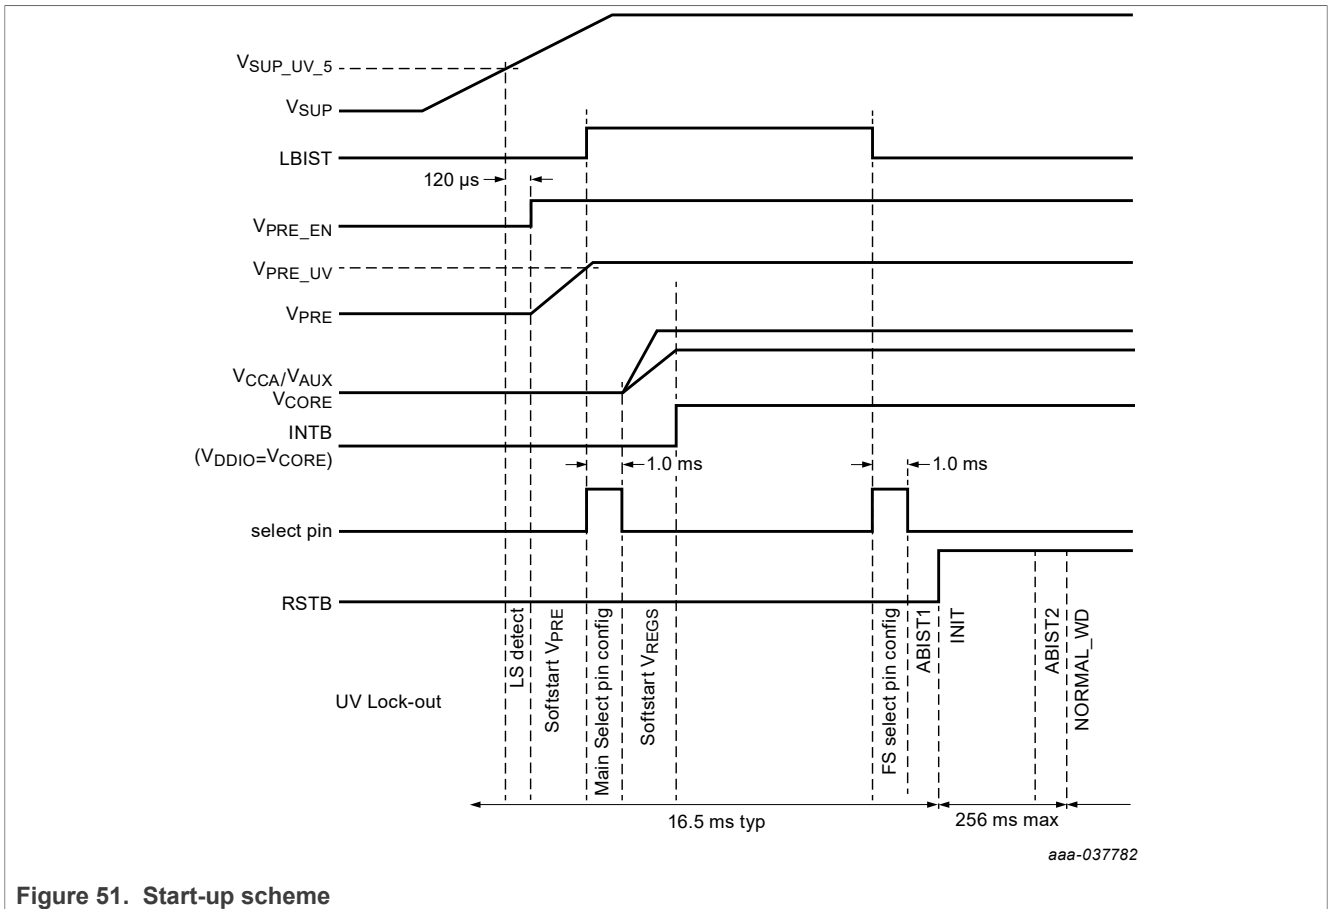

Figure 51. Start-up scheme

The final value of V_{AUX} and V_{CCA} depends on the hardware configuration (resistor values at the SELECT pin). The typical start-up sequence takes around 16.5 ms to release RSTB. RSTB can be pulled low after those 16.5 ms by the MCU, if it is not ready to run after power up. Refer to [Section 12.7.7 "VKAM"](#) for the VKAM start-up sequence.

12.8 Long duration timer

The device includes a long duration timer, with an integrated oscillator. The timer is configurable by the SPI and can operate in normal mode and low-power mode. It provides several functions and offers a large range of counting periods, as well as a calibration mechanism, for internal oscillator compensation.

The timer is not part of the safety circuitry, and is not covered by LBIST (logic built in self test). However it can be activated in normal mode, and all prescaler options can be selected, to allow timer circuitry verification. The timer is based on a 24-bit counter, with a 32768 Hz oscillator, allowing a 1.0 s time base.

Figure 52. Long duration timer block diagram

12.8.1 Timer characteristics

In normal operation, the timer can count up to 194 days, with 1 second resolution. In calibration mode, the prescaler 2 is bypassed and the timer can count up to 2.28 hours, with 488 micro second resolution. The calibration principle consists in activation of the counter for a dedicated and accurate duration, due to the MCU accurate clock and timing. The MCU then reads back the timer count, compares the count versus the accurate time of activation, then calculates a time offset. It is recommended to perform the calibration between $-20\text{ }^{\circ}\text{C}$ and $+85\text{ }^{\circ}\text{C}$.

	Osc freq	Osc period	Prescaler	Counter resolution	Max count	
Operation	32768 Hz	30.52 μs	16 \times 2048	1 s	4660 Hrs	194 days
Calibration	32768 Hz	30.52 μs	16	488 μs	8192 s	2.28 Hrs

12.8.2 Calibration procedure

The calibration procedure consists of activating the counter for a specific duration and comparing the result with the MCU's accurate clock and timing. Once the timer expires, the MCU reads back its final value to compare with its own accurate time of activation and to calculate a time offset. NXP recommends performing the calibration between $-20\text{ }^{\circ}\text{C}$ and $85\text{ }^{\circ}\text{C}$. Calibration example:

- Select the timer function 1 and set the after run value to 65535 (~32 s).
- Start the counter.
- Read the counter when the MCU RTC reaches 20 s (must be less than 30 s with $\pm 5.0\%$ oscillator accuracy).
- If the oscillator period is at exact typical value (absolutely no deviation error), expected reading is 40960.
- The exact reading calculates the error correction factor $ECF = \text{exact_reading} / \text{expected_reading}$.
- $ECF < 1$ if the oscillator is faster than the exact typical value.
- $ECF > 1$ if the oscillator is slower than the exact typical value.
- After calibration, the new after run or wake-up values to set the counter are *after run* \times *ECF* and *wake-up* \times *ECF*.

12.8.3 Timer functions

- **Function 1**
In normal mode, count and generate a flag or an Interrupt when the counter reaches the after run value.
- **Function 2**
In normal mode, count until the counter reaches the after run value and enters into low-power mode.
- **Function 3**
In normal mode, count until the counter reaches the after run value and enters into low-power mode. Once in low-power mode, count until the counter reaches the wake-up value and wakes up.
- **Function 4**
In low-power mode, count until the counter reaches the wake-up value and wakes up.
- **Function 5**
In low-power mode, count and do not wake-up unless the counter overflow occurs, or if the device wakes up by another source (CAN, IO).

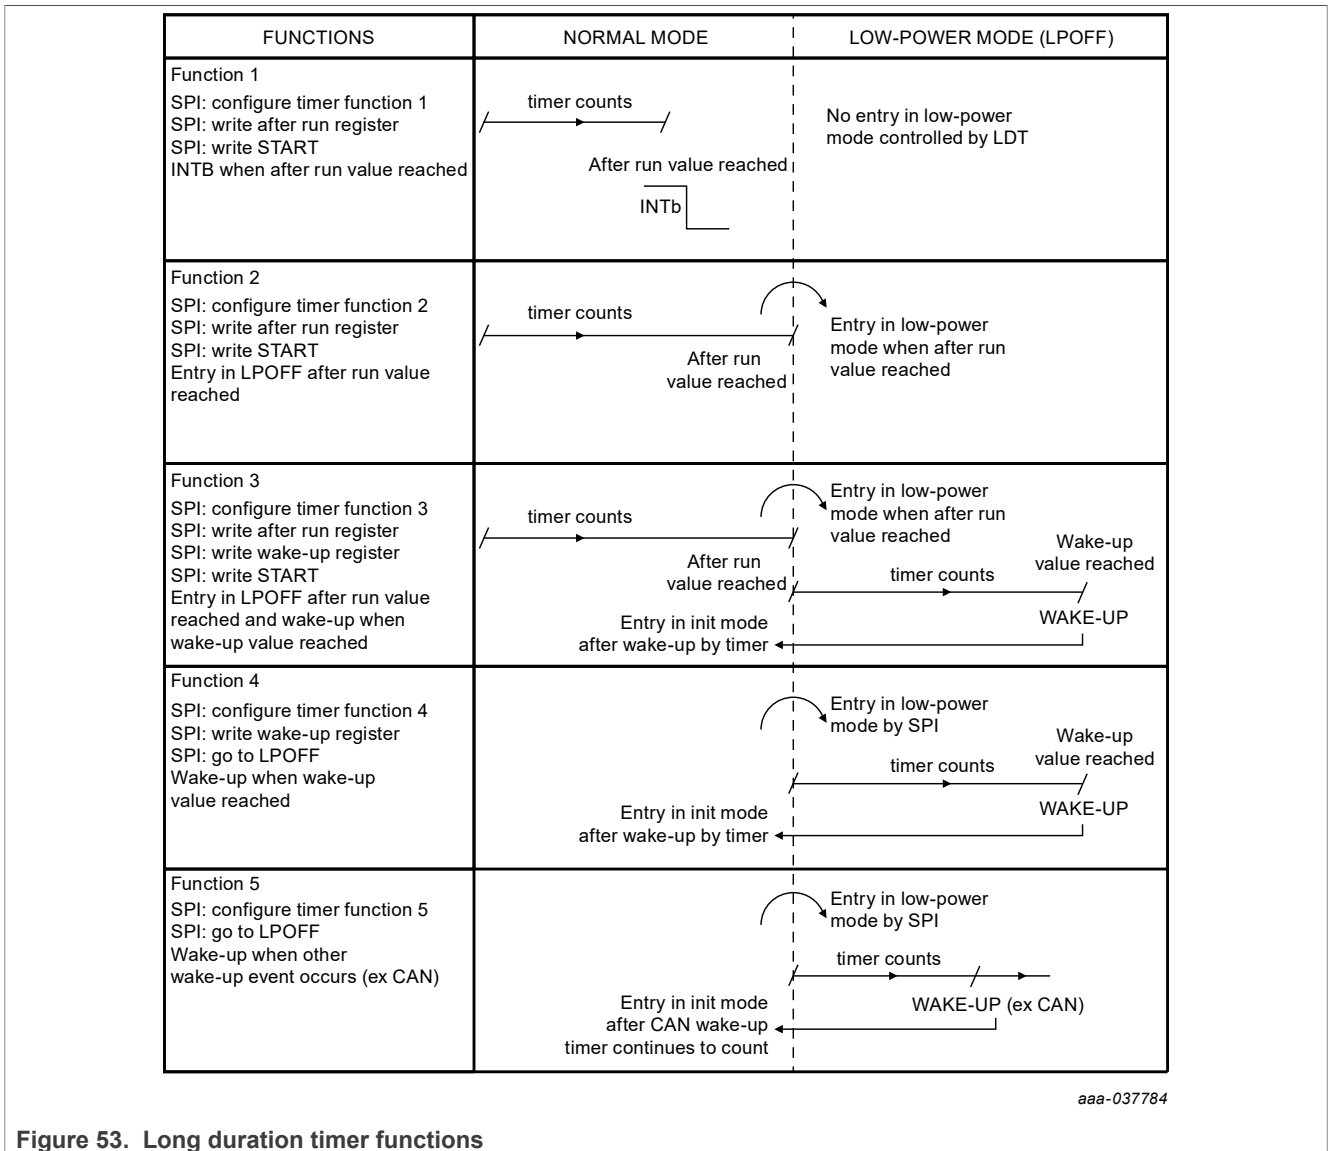

Figure 53. Long duration timer functions

12.8.4 Timer operation

The timer is configured and operates with the LONG_DURATION_TIMER register. The 16-bit after-run value and the 24-bit wake-up value are configured and read in the corresponding registers.

The Figure 54 describes the independent state machine of long duration timer (LDT). After a POR of the device, the LDT is in idle mode waiting for configuration. The after-run timer function starts when the LDT_ENABLE bit is set by SPI. The wake-up timer function starts when the device enters in LPOFF mode.

- When function 1 is selected and the counter reaches the after run value (EOT), an interrupt is generated and the counter is stopped. The counter must be disabled (~ENABLE) before reading its value and enabled again.
- When function 2 is selected and the counter reaches the after run value (EOT), the device goes to LPOFF mode and the counter is stopped. The counter must be disabled (~ENABLE) before reading its value and enabled again.
- When function 3 is selected and the counter reaches the after run value (EOT), the device goes to LPOFF mode. The counter is reset and restart to count. When the counter reaches the wake-up value (EOT), the device wakes up and the counter is stopped. The counter must be disabled (~ENABLE) before reading its value and enabled again.
- When function 4 is selected and the counter reaches the wake-up value (EOT), the device wakes up and the counter is stopped. The counter must be disabled (~ENABLE) before reading its value and enabled again.
- When function 5 is selected and the counter overflows (OVRFLW), the device wakes up and the counter is stopped. The counter must be disabled (~ENABLE) before reading its value and enabled again. Overflow means counter max value is reached (all 24 bits at "1").
- When function 5 is selected and the devices wakes up by CAN, or IO, the counter is running. The counter must be disabled (~ENABLE) before reading its value and enabled again.

Figure 54. Long duration timer state machine

12.9 CAN transceiver

The CAN (controller area network) transceiver provides the physical interface between the CAN protocol controller of an MCU and the physical dual wires CAN bus. The 35FS4500/35FS6500 integrated CAN interface is compliant with flexible data standard at 2.0 Mbit/s. It offers excellent EMC and ESD performance, and meets the ISO 11898-2 and ISO11898-5 standards.

Figure 55. CAN simplified block diagram

12.9.1 Operating modes

12.9.1.1 Normal mode

When the CAN mode bit configuration is '11' (CAN in normal operation), the device is able to transmit information from TXD to the bus and report the bus level to the RXD pin. When TXD is high, CANH and CANL drivers are off and the bus is in the recessive state (unless it is in an application where another device drives the bus to the dominant state). When TXD is low, the CANH and CANL drivers are on and the bus is in the dominant state. When the CAN mode bit configuration is '01' (CAN in listen only), the device is only able to report the bus level to the RXD pin. The TXD driver is off and the device is not able to transmit information from TXD to the bus. TXD is maintained high by an internal pull-up resistor TXD_{PULL-UP} connected to VDDIO.

Figure 56. CAN timing diagram

12.9.1.2 Sleep mode

When the device is in LPOFF mode, the CAN transceiver is automatically set in sleep mode with or without wake-up capability, depending on the CAN mode bit configuration. In this case, the CANH and CANL pins are pulled down to GND via the internal R_{IN} resistor, the TXD and RXD pins are pulled to GND, and both driver and receiver are off. The CAN mode is automatically changed to sleep with wake-up capability if not configured to sleep without wake-up capability when the device enters LPOFF. After LPOFF, the initial CAN mode prior to enter LPOFF is restored (Table 13).

Table 13. CAN transition when device goes to LPOFF

CAN state before entering LPOFF		CAN state in LPOFF		CAN state after LPOFF	
CAN_mode [1:0]	CAN state	CAN_mode [1:0]	CAN state	CAN_mode [1:0]	CAN state
00	Sleep, no wake-up capability	00	Sleep, no wake-up capability	00	Sleep, no wake-up capability
01	Listen Only	10	Sleep, wake-up capability	01	Listen Only
10	Sleep, wake-up capability			10	Sleep, wake-up capability
11	Normal			11	Normal

12.9.2 Fault detection

12.9.2.1 TXD permanent dominant (timeout)

If TXD is set low for a time longer than t_{DOUT} , the CAN drivers are disabled and the CAN bus returns to the recessive state. The CAN receiver continues to operate. This prevents the bus to be set in the dominant state permanently in case a failure sets the TXD input to a permanent low level.

The CAN_mode MSB bit is set to 0 and the flag TXD_dominant is reported in the DIAG_CAN_FD register. The device recovers from this error detection after setting the CAN_mode to normal operation and when a high level

is detected on TXD. The TXD failure detection is operating when the CAN transceiver is in normal mode and listen only mode.

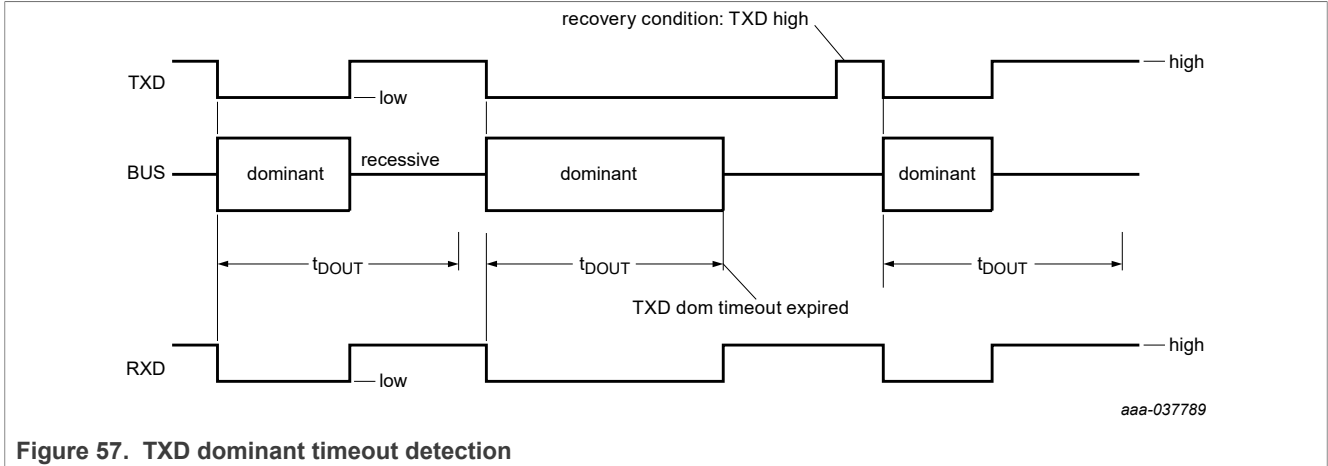

Figure 57. TXD dominant timeout detection

12.9.2.2 RXD permanent recessive

If RXD is detected high for seven consecutive receive/dominant cycles, the CAN drivers and receiver are disabled and the CAN bus returns to the recessive state. This prevent a CAN protocol controller from starting a CAN message on the TXD pin, while RXD is shorted to a recessive level and seen from a CAN controller as a bus idle state.

The CAN_mode MSB bit is set to 0 and the flag RXD_REC is reported in the DIAG_CAN_FD register. The device recovers from this error detection after setting the CAN_mode to normal operation. The RXD failure detection is operating when the CAN transceiver is in normal mode and listen only mode.

12.9.2.3 CAN bus short-circuits

CANL/CANH short to GND and CANL/CANH short to the battery are detected and reported to the device main logic. The CAN driver and receiver are not disabled. They are detected and reported to the device main logic.

CANL short to GND is detected when CANL is < 0.5 V, 500 ns after TXD is activated low, and five consecutive times, as illustrated for CANL short to GND in Figure 58. CANH short to the battery is detected when CANH is > 5.2 V, 500 ns after TXD is activated low, and five consecutive times. CANL short to the battery and CANH short to GND are detected when I_{CANL} or I_{CANH} > 75 mA (typ), 500 ns after TXD is activated low, and five consecutive times.

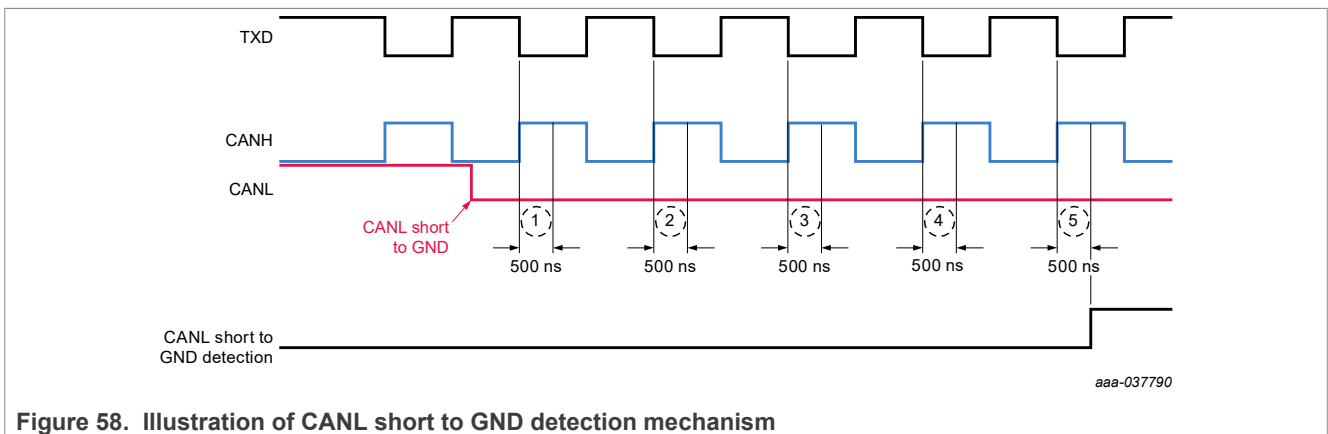

Figure 58. Illustration of CANL short to GND detection mechanism

If the CAN bus is dominant for a time longer than t_{DOM} , due for instance to an external short-circuit from another CAN node, the flag CAN_DOM is reported in the DIAG_CAN_FD register. This failure disables the bus driver. The CAN bus dominant failure detection is operating when the CAN transceiver is in normal mode and listen only mode.

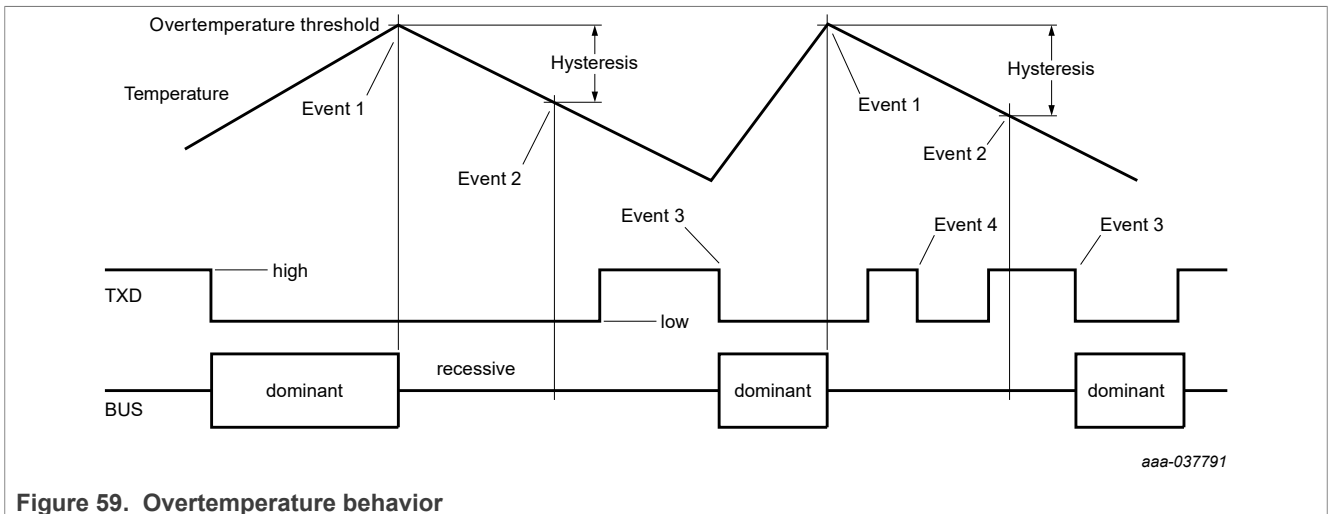

12.9.2.4 CAN current limitation

The current flowing in and out of the CANH and CANL driver is limited to 100 mA, in case of a short-circuit (parameters I_{CANL-SK} and I_{CANH-SC}).

12.9.2.5 CAN overtemperature

If the driver temperature exceeds the TSD (T_{OT}), the CAN drivers are disabled and the CAN bus returns to the recessive state. The CAN receiver continues to operate. The CAN_mode MSB bit is set to 0 and the flag CAN_OT is reported in the DIAG_CAN_2 register.

A hysteresis is implemented in this protection feature. The device overtemperature and recovery conditions are shown in Figure 59. The CAN drivers remain disabled until the temperature has fallen below the OT threshold minus hysteresis. The device recovers from this error detection after setting the CAN_mode to normal operation and when a high level is detected on TXD.

12.9.2.6 Distinguish CAN diagnostics and CAN errors

The CAN errors can generate an interruption while the CAN diagnostics are reported in the digital for information only. The interruption generated by the CAN errors can be inhibited setting the INT_INH_CAN bit in the INIT_INH_INT register. The list of CAN diagnostic and CAN error bits is provided in Table 14.

Table 14. CAN diagnostic and CAN error bits

Register	Bit	Flag type	Effect
DIAG_CAN_1	CANH_BATT	Diagnostic	No impact on CAN transceiver
	CANH_GND	Diagnostic	No impact on CAN transceiver
	CANL_BATT	Diagnostic	No impact on CAN transceiver
	CANL_GND	Diagnostic	No impact on CAN transceiver
	CAN_DOM	Error	Turn off CAN transceiver
	RXD_REC	Error	Turn off CAN transceiver
	TXD_DOM	Error	Turn off CAN transceiver
DIAG_CAN_2	CAN_OT	Error	Turn off CAN transceiver
	CAN_OC	Diagnostic	No impact on CAN transceiver

12.9.3 Wake-up mechanism

The device include bus monitoring circuitry to detect and report bus wake-ups when the device is in LPOFF and when CAN mode configuration is different from sleep/no wake-up capability. Multiple dominant pulse wake-up detection is implemented. The event must occur within the t_{3PTOX} timeout. $t_{3PTOX} = t_{3PTO1}$ OR t_{3PTO2} , depending on the SPI selection. The wake-up events are reported in the WU_SOURCE register.

12.9.3.1 Multiple pulse detection

To activate wake-up report, three events must occur on the CAN bus:

- event 1: a dominant level longer than t_{1PWU} followed by
- event 2: a dominant level longer than t_{3PWU} followed by
- event 3: a dominant level longer than t_{3PWU}

The three events and the timeout function avoiding a permanent dominant state on the bus generates permanent wake-up situation which would prevent system to enter in low-power mode.

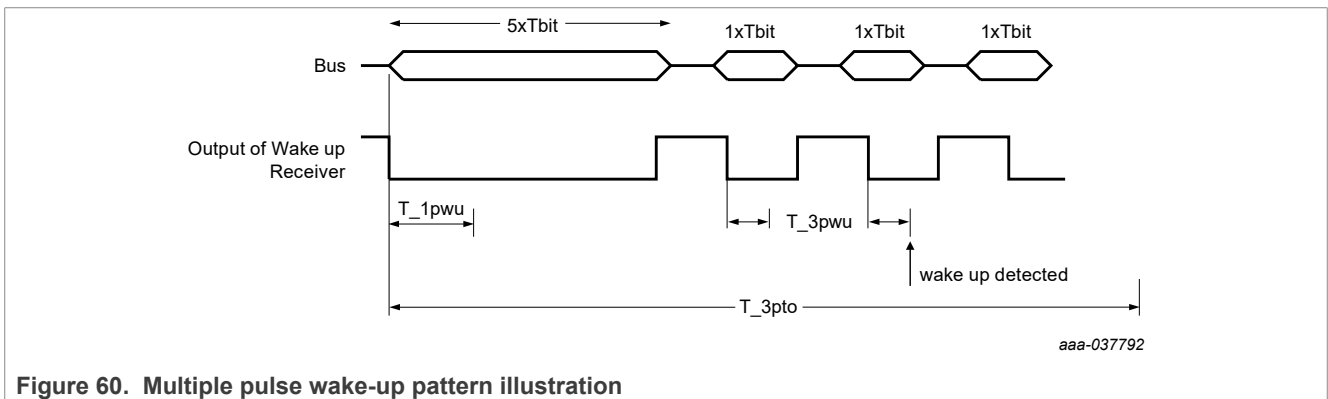

Figure 60. Multiple pulse wake-up pattern illustration

13 Serial peripheral interface

13.1 High level overview

13.1.1 SPI

The device uses a 16-bit SPI, with the following arrangement:

MOSI, primary out secondary in bits:

- Bit 15 read/write
- Bit 14 main or fail-safe register target
- bit 13 to 9 (A4 to A0) to select the register address. Bit 8 is a parity bit in write mode, next bit (=0) in read mode.
- bit7 to 0 (D7 to D0): control bits

MISO, primary in secondary out bits:

- bits 15 to 8 (S15 to S8) are device status bits
- bits 7 to 0 (Do7 to Do0) are either extended device status bits, device internal control register content or device flags.

[Figure 61](#) is an overview of the SPI implementation.

13.1.2 Parity bit 8 calculation

The parity bit 8 is used in write mode only (bit 15 = 1). It is calculated based on the number of logic ones contained in the bit 15–9, 7–0 sequence (this is the whole 16 bits of the write command except bit 8). In read mode, the parity bit should be set to 0.

Bit 8 must be set to 0 if the number of ones is odd.

Bit 8 must be set to 1 if the number of ones is even.

13.1.3 Device status on MISO

When a write operation is performed to store data or a control bit in the device, the MISO pin reports a 16-bit fixed device status composed of two bytes: device fixed status (bits 15 to 8) + extended device status (bits 7 to 0). In a read operation, MISO reports the fixed device status (bits 15 to 8), and the next eight bits are content of the selected register. A standard serial peripheral interface (SPI) is integrated to allow bi-directional communication between the 35FS4500/35FS6500 and the MCU. The SPI is used for configuration and diagnostic purposes.

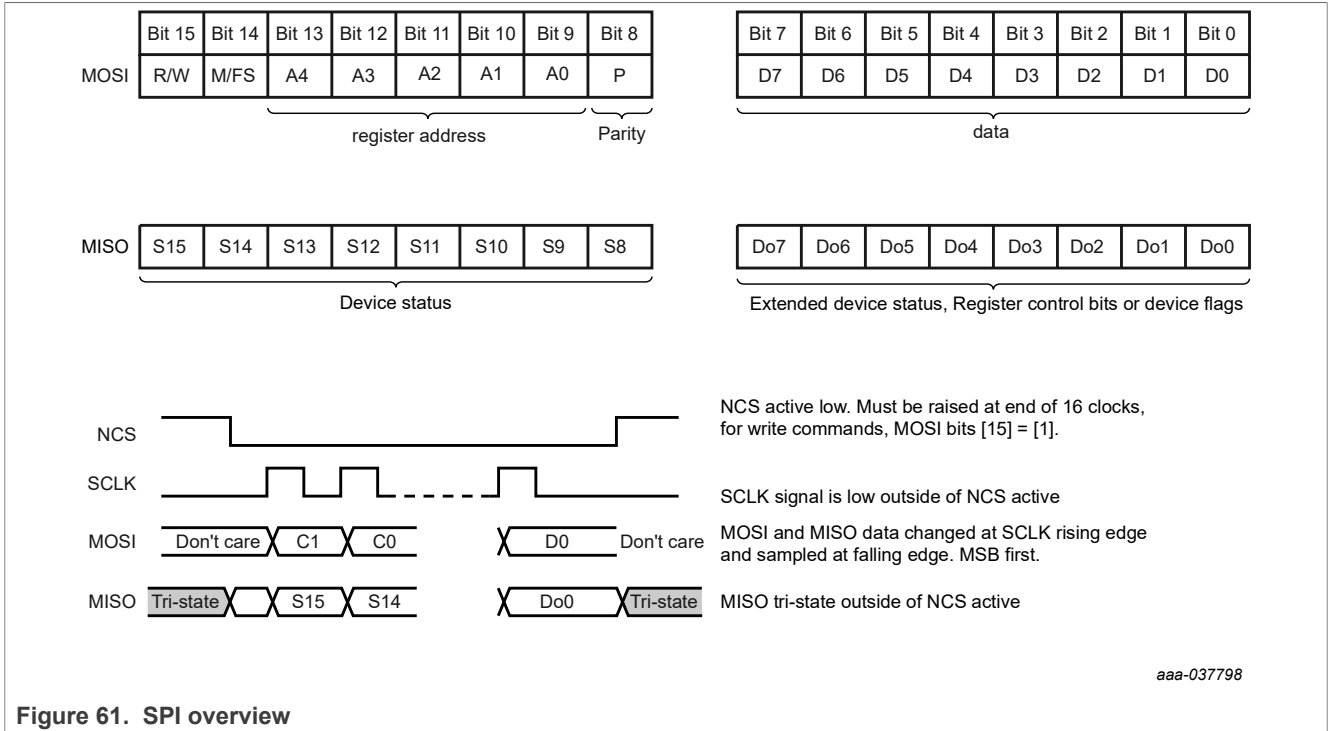

Figure 61. SPI overview

The device contains several registers. Their address is coded on 7 bits (bits 15 to 9). Each register controls or reports part of the device function. Data can be written to the register, to control the device operation or set default value or behavior. Every register can also be read back to ensure its content (default setting or value previously written) is correct.

13.1.4 Register description

Although the minimum time between two NCS low sequences is defined by t_{ONNCS} (Figure 7), two consecutive accesses to the fail-safe registers must be done with a 3.5 μ s minimum NCS high time in between. Although the minimum time between two fail-safe registers accesses is 3.5 μ s, some SPI accesses to the main registers can be done in between (Figure 8).

13.2 Detailed operation

13.2.1 SPI command organization

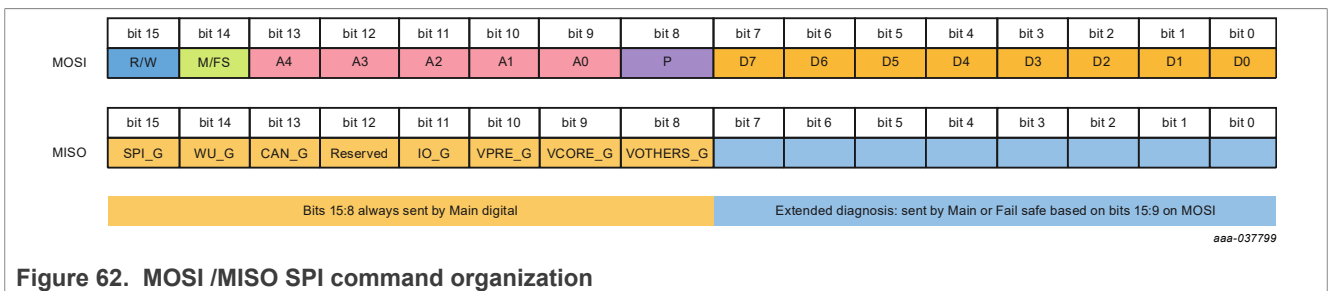

Figure 62. MOSI /MISO SPI command organization

Table 15. MOSI bits description

R/W	Description	Set if it is a read or write command
	0	Read
	1	Write
M/FS	Description	Split the addresses between fail-safe state machine and main logic
	0	Main
	1	Fail-safe
A4:A0	Description	Set the address to read or write
	0	See register mapping
	1	
P	Description	Parity bit (only use in write mode). Set to 0 in read mode
	0	Number of '1' (bit 15:9 and bit 7:0) is odd
	1	Number of '1' (bit 15:9 and bit 7:0) is even
D7:D0	Description	Data in write mode. Must be set to 00h in read mode
	0	See register details
	1	

13.2.2 Main logic general diagnostic

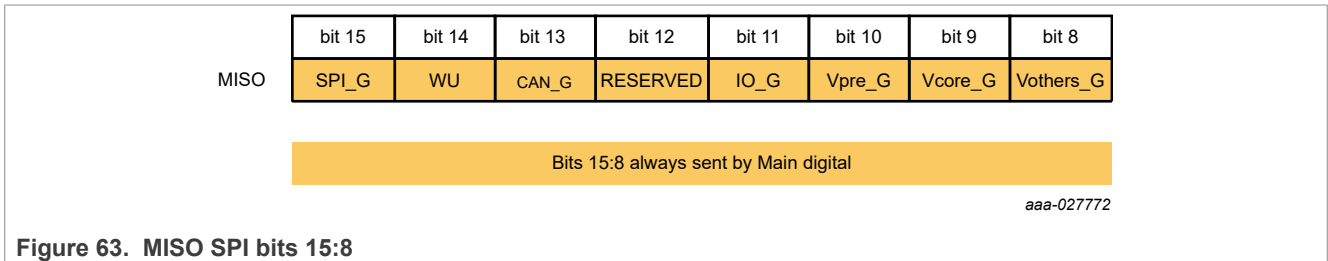

Figure 63. MISO SPI bits 15:8

Table 16. MISO bits description

SPI_G	Description	Report an error in the SPI communication
	0	No failure
	1	Failure
	Reset condition	Power on reset/ read
WU_G	Description	Report a wake-up event. Logical OR of all wake-up sources
	0	No WU_G event
	1	WU_G event
	Reset condition	Power on reset/when initial event cleared on read
CAN_G	Description	Report a CAN event (diagnostic)
	0	No event
	1	CAN event
	Reset Condition	Power on reset/when initial event cleared on read

13.2.6 Secured SPI command

Some SPI commands must be secured to avoid unwanted change of the critical bits. The secured bits in the fail-safe machine and the main state machine are calculated from the data bits sent as follows:

Table 20. Secured SPI

Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
Data 3	Data 2	Data 1	Data 0	Secure 3	Secure2	Secure 1	Secure 0

- Secure 3 = NOT(Bit5)
- Secure 2 = NOT(Bit4)
- Secure 1 = Bit7
- Secure 0 = Bit6

13.3 Detail of main logic register mapping

13.3.1 INIT_VREG

Table 21. INIT_VREG register configuration

Table 22. INIT_VREG description and configuration of the bits

ICCA_LIM	Description	Configure the current limitation threshold for VCCA. Only available for external PNP.
	0	ICCA_LIM_OUT (reset value)
	1	ICCA_LIM_INT
	Reset condition	Power on reset
TCCA_LIM_OFF	Description	Configure the current limitation duration before VCCA is switched off. Only available for external PNP.
	0	10 ms
	1	50 ms (reset value)
	Reset condition	Power on reset
IPFF_DIS	Description	DISABLE the input power feed forward (IPFF) function of VPRE
	0	Enabled (reset value)
	1	Disabled
	Reset condition	Power on reset

Table 22. INIT_VREG description and configuration of the bits...continued

VCAN_OV_MON	Description	CAN_5V overvoltage monitoring
	0	Off. V _{CAN OV} is not monitored. Flag is ignored (reset value)
	1	On. V _{CAN OV} is monitored. If OV the CAN_5V regulator is switched off.
	Reset condition	Power on reset
TAUX_LIM_OFF	Description	Configure the current limitation duration before VAUX is switched off.
	0	10 ms
	1	50 ms (reset value)
	Reset condition	Power on reset
VAUX_TRK_EN	Description	Configure VAUX regulator as a tracker of VCCA
	0	No tracking (reset value)
	1	Tracking mode enabled and latched
	Reset condition	Power on reset
BAT_FAIL	Description	Report a battery disconnection (POR of the main logic)
	0	NO POR
	1	POR occurred (reset value)
	Reset condition	Power on reset
	Clear condition	Read

- **BAT_FAIL** = POR_M or V_{SUP_UV_L} or BG_OK (reset sources of main logic). BAT_FAIL bit is cleared by a SPI read.

13.3.2 INIT_WU1

Table 23. INIT_WU1 register configuration

Write

Table 24. INIT_WU1 description and configuration of the bits

WU_IO0_1:0	Description	IO_0 wake-up configuration
	00	NO wake-up capability
	01	Wake-up on rising edge - or high level (reset value)
	10	Wake-up on falling edge - or low level
	11	Wake-up on any edge
	Reset condition	Power on reset
WU_IO2_1:0	Description	IO_2 wake-up configuration
	00	No wake-up capability (reset value)
	01	Wake-up on rising edge - or high level
	10	Wake-up on falling edge - or low level
	11	Wake-up on any edge
	Reset condition	Power on reset
WU_IO3_1:0	Description	IO_3 wake-up configuration
	00	No wake-up capability (reset value)
	01	Wake-up on rising edge - or high level
	10	Wake-up on falling edge - or low level
	11	Wake-up on any edge
	Reset condition	Power on reset
WU_IO4_1:0	Description	IO_4 wake-up configuration
	00	No wake-up capability (reset value)
	01	Wake-up on rising edge - or high level
	10	Wake-up on falling edge - or low level
	11	Wake-up on any edge
	Reset condition	Power on reset

Table 28. INIT_INT description and configuration of the bits

INT_DURATION	Description	Define the duration of the interrupt pulse
	0	100 µs (reset value)
	1	25 µs
	Reset condition	Power on reset

Table 28. INIT_INH_INT description and configuration of the bits...continued

INT_INH_ALL	Description	Inhibit ALL the interrupt
	0	All INT sources (reset value)
	1	All INT inhibited
	Reset condition	Power on reset
INT_INH_VSNS	Description	Inhibit the interrupt for V _{SNS_UV}
	0	All INT sources (reset value)
	1	V _{SNS_UV} INT inhibited
	Reset condition	Power on reset
INT_INH_VPRE	Description	Inhibit the interrupt for V _{PRE} status event
	0	All INT sources (reset value)
	1	V _{PRE} status change inhibited
	Reset condition	Power on reset
INT_INH_VCORE	Description	Inhibit the interrupt for V _{CORE} status event
	0	All INT sources (reset value)
	1	V _{CORE} status change inhibited
	Reset condition	Power on reset
INT_INH_VOTHER	Description	Inhibit the interrupt for V _{CCA} /V _{AUX} and V _{CAN} status event
	0	All INT sources (reset value)
	1	V _{CCA} /V _{AUX} /V _{CAN} status change inhibited
	Reset condition	Power on reset
INT_INH_CAN	Description	Inhibit the interrupt for CAN error bits
	0	All INT sources (reset value)
	1	CAN error bits change inhibited
	Reset condition	Power on reset

Table 30. INIT IO_WU2 description and configuration of the bits

INT_INH_5	Description	Inhibit the interrupt pulse for IO_5 (masked in IO_G)
	0	INT not masked (reset value)
	1	INT masked
	Reset condition	Power on reset
INT_INH_4	Description	Inhibit the interrupt pulse for IO_4 (masked in IO_G)
	0	INT not masked (reset value)
	1	INT masked
	Reset condition	Power on reset
INT_INH_3	Description	Inhibit the interrupt pulse for IO_3 (masked in IO_G)
	0	INT not masked
	1	INT masked (reset value)
	Reset condition	Power on reset
INT_INH_2	Description	Inhibit the interrupt pulse for IO_2 (masked in IO_G)
	0	INT not masked
	1	INT masked (reset value)
	Reset condition	Power on reset
INT_INH_0	Description	Inhibit the interrupt pulse for IO_0 (masked in IO_G)
	0	INT not masked (reset value)
	1	INT masked
	Reset condition	Power on reset

13.3.6 LONG_DURATION_TIMER

Table 31. LONG_DURATION_TIMER register description

Table 32. LONG_DURATION_TIMER description and configuration of the bits

F2:F0	Description	Select timer operating function
	000	Function 1: in normal mode count and generate flag or INT when counter reaches the after run value (reset value)
	001	Function 2: in normal mode count until after run value is reached, then enters in LPOFF
	010	Function 3: in normal mode count until after run value is reached, then enters in LPOFF. Once in LPOFF, count until wake-up value is reached and wake-up.
	011	Function 4: in LPOFF, count until wake-up value is reached and wake-up
	100	Function 5: in LPOFF, count and do not wake-up. Counter value is stored in wake-up register.
	101... 111	N/A
	Reset condition	Power on reset
REG_SE	Description	Counter register selection
	0	Read programmed wake-up register (reset value)
	1	Read real time counter into wake-up register (after counter is stopped with LDT_ENABLE bit)
	Reset condition	Power on reset
MODE	Description	Operating mode selection
	0	Calibration mode (488 μ s resolution)
	1	Normal mode (1 s resolution) (reset value)
	Reset condition	Power on reset
LDT_ENABLE	Description	LDT counter control
	0	LDT counter stop (reset value)
	1	LDT counter start
	Reset condition	Power on reset
LDT_RUNNING	Description	Counter status
	0	Counter not running (reset value)
	1	Counter running
	Reset condition	Power on reset
LDT_INT	Description	Counter interrupt generation when function 1 is selected
	0	No INT generated (reset value)
	1	INT generated when counter reach after run value
	Reset condition	Power on reset/read

13.3.7 HW_CONFIG

Table 33. HW_CONFIG register description

Table 34. HW_CONFIG description and configuration of the bits

LS_DETECT	Description	Report the hardware configuration of V _{PRE}
	0	Buck-boost
	1	Buck only
	Reset condition	Power on reset/refresh after LPOFF
VCCA_PNP_DET	Description	Report the connection of an external PNP on V _{CCA}
	0	External PNP connected
	1	Internal MOSFET
	Reset condition	Power on reset/refresh after LPOFF
VCCA_HW	Description	Report the hardware configuration for V _{CCA}
	0	3.3 V
	1	5.0 V
	Reset condition	Power on reset/refresh after LPOFF
VAUX_HW	Description	Report the hardware configuration for V _{AUX}
	0	5.0 V
	1	3.3 V
	Reset condition	Power on reset/refresh after LPOFF
DFS_HW1	Description	Report the deep fail-safe hardware configuration (main logic)
	0	Deep fail-safe disable
	1	Deep fail-safe enable
	Reset condition	Power on reset/refresh after LPOFF
DBG_HW	Description	Report the configuration of the DEBUG mode
	0	Normal operation
	1	Debug mode selected
	Reset condition	Power on reset/refresh after LPOFF

13.3.8 WU_SOURCE

Table 35. WU_SOURCE register description

Read

Table 36. WU_SOURCE description and configuration of the bits

IO_5_WU	Description	Report a wake-up event from IO_5
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
IO_4_WU	Description	Report a wake-up event from IO_4
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
IO_3_WU	Description	Report a wake-up event from IO_3
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
IO_2_WU	Description	Report a wake-up event from IO_2
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
IO_0_WU	Description	Report a wake-up event from IO_0
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
AUTO_WU	Description	Report an automatic wake-up event
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read
LDT_WU	Description	Report a wake-up event from long duration timer
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read

Table 36. WU_SOURCE description and configuration of the bits...continued

PHY_WU	Description	Report a wake-up event from CAN physical layer
	0	No wake-up (reset value)
	1	Wake-up event detected
	Reset condition	Power on reset/read CAN_WU

13.3.9 DEVICE_ID

Table 37. DEVICE_ID register description

WD_ANSWER_7:0	Description	WD answer from the MCU
	0...	Answer = (NOT(((LFSR × 4)+6)-4))/4
	1...	
	Reset condition	Power on reset/RSTB low
RSTB	Description	Report a reset event
	0	No reset (reset value)
	1	Reset occurred
	Reset condition	Power on reset/read

Table 92. WD_ANSWER description and configuration of the bits...continued

FSxB	Description	Report a fail-safe event
	0	No fail-safe
	1	Fail-safe event occurred (default state at power-up and after LPOFF as FS0B/FS1B are asserted low) (reset value)
	Reset condition	Power on reset/read
WD_BAD_DATA	Description	Report a watchdog data refresh error
	0	WD data refresh ok (reset value)
	1	Wrong WD data refresh
	Reset condition	Power on reset/read
FSO_G	Description	Report a fail-safe output failure
	0	No failure (reset value)
	1	Failure
	Reset condition	Power on reset/read
IO_FS_G	Description	Report an IO monitoring error
	0	No error (reset value)
	1	Error detected
	Reset condition	Power on reset/read
WD_BAD_TIMING	Description	Report a watchdog timing refresh error
	0	WD timing refresh OK (reset value)
	1	Wrong WD timing refresh
	Reset condition	Power on reset/read
ERR_INT_HW	Description	Report an error from an internal redundant structure of the fail-safe state machine
	0	No error (reset value)
	1	Error detected
	Reset condition	Power on reset/read
ERR_INT_SW	Description	Report an error from the EDC of the fail-safe state machine (error detection correction)
	0	No error (reset value)
	1	Error detected
	Reset condition	Power on reset/read

- **FSO_G** = RSTB_short_high or FS0B_short_high or FS0B_short_low or FS1B_short_high or FS1B_short_low
- **IO_FS_G** = IO_23_fail or IO_45_fail

Values of the two registers WD_COUNTER and DIAG_SF_ERR are updated at the end of any SPI access to one of the three registers WD_ANSWER, WD_COUNTER, and DIAG_SF_ERR. To always get up to date values, it is recommended to make two consecutive SPI accesses to WD_COUNTER and DIAG_SF_ERR registers or access (read or write) WD_ANSWER register first.

Example1: read or write WD_ANSWER to update the registers, read WD_COUNTER and DIAG_SF_ERR to report the latest information

Example2: read WD_COUNTER to update the register, read again WD_COUNTER to report the latest information

FS1	Description	Report the FS1B function availability (depends on part number)
	0	Disabled
	1	Enabled
	Reset condition	Power on reset

14 List of interruptions and description

The INTB output pin generates a low pulse when an Interrupt condition occurs. The INTB behavior as well as the pulse duration are set through the SPI during INIT phase. It is possible to mask some Interruption source (see [Section 13.3 "Detail of main logic register mapping"](#)).

Table 113. Interruptions list

Event	Description
V _{SNS_UV}	Detection of V _{BATTERY} below 8.5 V
V _{SUP_UV_7}	Detection of V _{SUP} below 7.0 V (after reverse current protection diode)
I _{PPF}	Input power feed forward. Based on V _{SUP} and I _{PRE_PEAK}
I _{LIM_PRE}	Pre-regulator current limitation
T _{WARN_PRE}	Temperature warning on the pass transistor
BoB	Return the running state of V _{PRE} converter (buck or boost mode)
V _{PRE_STATE} (V _{PRE_SMPS_EN})	Return the activation state of V _{PRE} DC/DC converter
V _{PRE_OV}	Report a V _{PRE} overvoltage detection
V _{PRE_UV}	Report a V _{PRE} undervoltage detection
T _{WARN_CORE}	Temperature warning on the pass transistor
V _{CORE_STATE} (V _{CORE_SMPS_EN})	Return the activation state of V _{CORE} DC/DC converter
V _{CORE_OV}	Report a V _{CORE} overvoltage detection
V _{CORE_UV}	Report a V _{CORE} undervoltage detection
I _{LIM_CCA}	V _{CCA} current limitation
I _{LIM_CCA_OFF}	Current limitation maximum duration expiration. Only used when external PNP connected.
T _{WARN_CCA}	Temperature warning on the pass transistor (internal pass transistor only)
TSD _{VCCA}	Temperature shutdown of the V _{CCA}
V _{CCA_OV}	Report a V _{CCA} overvoltage detection
V _{CCA_UV}	Report a V _{CCA} undervoltage detection
I _{LIM_AUX}	V _{AUX} current limitation
I _{LIM_AUX_OFF}	Current limitation maximum duration expiration. Only used when external PNP connected.
TSD _{VAUX}	Temperature shutdown of the V _{AUX}
V _{AUX_OV}	Report a V _{AUX} overvoltage detection
V _{AUX_UV}	Report a V _{AUX} undervoltage detection
I _{LIM_CAN}	V _{CAN} current limitation
V _{CAN_OV}	Report a V _{CAN} overvoltage detection
TSD _{CAN}	Temperature shutdown on the pass transistor. Auto restart when T _J < (TSD _{CAN} – TSD _{CAN_HYST}).
V _{CAN_UV}	Report a V _{CAN} undervoltage detection
IO_0	Report IO_0 digital state change
IO_2	Report IO_2 digital state change
IO_3	Report IO_3 digital state change

Table 113. Interruptions list...continued

Event	Description
IO_4	Report IO_4 digital state change
IO_5	Report IO_5 digital state change
IO_0_WU	Report IO_0 wake-up event
IO_2_WU	Report IO_2 wake-up event
IO_3_WU	Report IO_3 wake-up event
IO_4_WU	Report IO_4 wake-up event
IO_5_WU	Report IO_5 wake-up event
CAN_WU	Report a CAN wake-up event
CAN_OT	CAN overtemperature detection
RXD_REC	CAN RXD recessive clamping detection (short-circuit to 5.0 V)
TXD_DOM	CAN TXD dominant clamping detection (short-circuit to GND)
CAN_DOM	CAN bus dominant clamping detection
INT_REQ	MCU request for an interrupt pulse
LDT_F1	Long duration timer configured in function 1 and after run value is reach
SPI_ERR	Secured SPI communication check
SPI_CLK	Report a wrong number of CLK pulse different than 16 during the NCS low pulse in main state machine
SPI_REQ	Invalid SPI access (wrong write or read, write to INIT registers in normal mode, wrong address)
SPI_PARITY	Report a parity error in main state machine

15 Typical applications

35FS4500-35FS6500 v.1.0	28 July 2017	Data sheet: product preview

Legal information

Data sheet status

Document status ^{[1][2]}	Product status ^[3]	Definition
Objective [short] data sheet	Development	This document contains data from the objective specification for product development.
Preliminary [short] data sheet	Qualification	This document contains data from the preliminary specification.
Product [short] data sheet	Production	This document contains the product specification.

[1] Please consult the most recently issued document before initiating or completing a design.

[2] The term 'short data sheet' is explained in section "Definitions".

[3] The product status of device(s) described in this document may have changed since this document was published and may differ in case of multiple devices. The latest product status information is available on the Internet at URL <https://www.nxp.com>.

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Short data sheet — A short data sheet is an extract from a full data sheet with the same product type number(s) and title. A short data sheet is intended for quick reference only and should not be relied upon to contain detailed and full information. For detailed and full information see the relevant full data sheet, which is available on request via the local NXP Semiconductors sales office. In case of any inconsistency or conflict with the short data sheet, the full data sheet shall prevail.

Product specification — The information and data provided in a Product data sheet shall define the specification of the product as agreed between NXP Semiconductors and its customer, unless NXP Semiconductors and customer have explicitly agreed otherwise in writing. In no event however, shall an agreement be valid in which the NXP Semiconductors product is deemed to offer functions and qualities beyond those described in the Product data sheet.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Limiting values — Stress above one or more limiting values (as defined in the Absolute Maximum Ratings System of IEC 60134) will cause permanent damage to the device. Limiting values are stress ratings only and (proper) operation of the device at these or any other conditions above those given in the Recommended operating conditions section (if present) or the Characteristics sections of this document is not warranted. Constant or repeated exposure to limiting values will permanently and irreversibly affect the quality and reliability of the device.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at <https://www.nxp.com/profile/terms>, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

No offer to sell or license — Nothing in this document may be interpreted or construed as an offer to sell products that is open for acceptance or the grant, conveyance or implication of any license under any copyrights, patents or other industrial or intellectual property rights.

Quick reference data — The Quick reference data is an extract of the product data given in the Limiting values and Characteristics sections of this document, and as such is not complete, exhaustive or legally binding.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately. Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

Suitability for use in automotive applications (functional safety) —

This NXP product has been qualified for use in automotive applications. It has been developed in accordance with ISO 26262, and has been ASIL classified accordingly. If this product is used by customer in the development of, or for incorporation into, products or services (a) used in safety critical applications or (b) in which failure could lead to death, personal injury, or severe physical or environmental damage (such products and services hereinafter referred to as "Critical Applications"), then customer makes the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, safety, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. As such, customer assumes all risk related to use of any products in Critical Applications and NXP and its suppliers shall not be liable for any such use by customer. Accordingly, customer will indemnify and hold NXP harmless from any claims, liabilities, damages and associated costs and expenses (including attorneys' fees) that NXP may incur related to customer's incorporation of any product in a Critical Application.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.

11.8	SELECT input pin	28	12.5.3.1	Fault error counter intermediate value	46
11.8.1	VCCA, VAUX voltage configuration	28	12.5.3.2	Fault error counter at start-up or resuming from LPOFF mode	47
11.8.2	Deep fail-safe configuration	28	12.5.4	RESET (RSTB) activation	48
11.9	CAN_5V voltage regulator	29	12.5.5	Fail-safe output (FS0B) activation	48
11.10	Interrupt (INTB)	29	12.5.6	Fail-safe output (FS1B) activation	49
11.11	CANH, CANL, TXD, RXD	29	12.5.6.1	tDELAY operation	49
11.11.1	TXD	29	12.5.6.2	tDURATION operation	50
11.11.2	RXD	29	12.5.7	Fail-safe outputs (FS0B and FS1B) release	51
11.11.3	CANH and CANL	29	12.5.7.1	RELEASE_FSxB register	51
11.12	Multiplexer output MUX_OUT	30	12.5.8	SPI DED	51
11.13	I/O pins (I/O_0:I/O_5)	30	12.6	Input voltage range	52
11.14	SAFE output pins (FS0B, FS1B, RSTB)	32	12.7	Power management operation	52
11.14.1	FS0B pin	32	12.7.1	VPRE voltage pre-regulator	53
11.14.2	FS1B pin	32	12.7.1.1	Power up and power down sequence	54
11.14.3	RSTB pin	33	12.7.1.2	Cranking management	55
11.15	VPU_FS (fail-safe pull-up)	33	12.7.1.3	Light load condition	56
11.16	DEBUG input (entering in debug mode)	33	12.7.1.4	Input power feed forward condition	57
12	Functional device operation	33	12.7.1.5	Overcurrent detection and current limitation	57
12.1	Mode and state description of the main state machine	33	12.7.1.6	VPRE voltage monitoring	58
12.1.1	Buck or buck boost configuration	34	12.7.1.7	VPRE efficiency	58
12.1.2	VPRE on	34	12.7.2	VCORE voltage regulator	59
12.1.3	SELECT pin configuration	34	12.7.2.1	VCORE DC-DC converter	59
12.1.4	VCORE/VAUX/VCCA on	34	12.7.2.2	Light load condition	60
12.1.5	INIT main	34	12.7.2.3	Current limitation	60
12.1.6	Normal	34	12.7.2.4	Voltage monitoring	60
12.1.7	Low-power mode off	34	12.7.2.5	VCORE efficiency	61
12.1.7.1	LPOFF - sleep	35	12.7.2.6	VCORE linear regulator	61
12.1.7.2	LPOFF - auto WU	35	12.7.2.7	Current limitation	62
12.1.7.3	LPOFF - deep FS	35	12.7.2.8	Voltage monitoring	62
12.1.7.4	Register configuration in LPOFF	35	12.7.3	Charge pump and bootstrap	62
12.1.7.5	ISO pulse in LPOFF	35	12.7.4	VCCA voltage regulator	62
12.2	Mode and state description of fail-safe state machine	36	12.7.4.1	Current limitation	63
			12.7.4.2	Voltage monitoring	63

12.7.5	VAUX voltage regulator	63	13.3.17	DIAG_CAN_2	99
12.7.5.1	Current limitation	64	13.3.18	DIAG_SPI	99
12.7.5.2	Voltage monitoring	65	13.3.19	MODE	100
12.7.6	CAN_5V voltage regulator	65	13.3.20	REG_MODE	102
12.7.7	VKAM	65	13.3.21	IO_OUT_AMUX	103
12.7.8	Power dissipation	66	13.3.22	CAN_MODE	104
12.7.9	Start-up sequence	67	13.3.23	LDT_AFTER_RUN_1	105
12.8	Long duration timer	68	13.3.24	LDT_AFTER_RUN_2	105
12.8.1	Timer characteristics	69	13.3.25	LDT_WAKE_UP_1	106
12.8.2	Calibration procedure	69	13.3.26	LDT_WAKE_UP_2	106
12.8.3	Timer functions	70	13.3.27	LDT_WAKE_UP_3	107
