## 7. Register Bank

There is a total of 6 registers each containing several parameters. For a detailed description of the parameters refer to register table. The serial register has read/write function. D[15:12] are the register address, D[11] defines the read or write mode and D[10:0] are the data.

Serial Interface Write sequence

Serial Interface Read sequence

1. At power-on, the default values specified for each parameter are taken.
2. If less than 16-bit data are read during the CS low time period, the data is cancelled.
  - a. The write operation is cancelled.
  - b. The read operation is interrupt.
3. If more than 16-bit data are read during the CS low time period, the last 16 bits are kept.
  - a. Address & R/W are always defined form CSB falling edge.
  - b. The write operation load last 11 bit data before CSB rising edge.
  - c. The read operation is "D0" is output to SDA until CSB rising edge.
4. All items are set at the falling edge of the vertical sync, except R0[1:0].
5. When GRB is activated through the serial interface, all registers are cleared, except the GRB value.
6. Register R/W setting: D11 = "L" → write mode; D11 = "H" → read mode.
7. The register setting values are valid when VCC already goes to high and after VSYNC starts.
8. It is suggested that VSYNC, HSYNC, DCLK always exists in the same time. But if HSYNC, DCLK stops, only VSYNC operating, the register setting is still valid.

9. If the chip goes to standby mode, the register value will still keep. MCU can wake up the chip only by changing standby mode value from low to high.
10. The register setting values are rewritten by the influence of static electricity, a noise, etc. to unsuitable value, incorrect operating may occur. It is suggested that the SPI interface will setup as frequently as possible.

White chromaticity		X	$\theta = 0^\circ$	0.26	0.31	0.36		Note 7
		Y	$\theta = 0^\circ$	0.28	0.33	0.38		

Note 1 : To be measured in the dark room. Ambient temperature =25°C, and LED lightbar voltage  $V_L = 12V$ .

Note 2 :To be measured on the center area of panel with a viewing cone of 1°by Topcon luminance meter BM-5A, after 15 minutes operation.

Note 3. Definition of response time:

The output signals of photo detector are measured when the input signals are changed from "black" to "white"(falling time) and from "white" to "black"(rising time), respectively.

The response time is defined as the time interval between the 10% and 90% of amplitudes. Refer to figure as below.

Note 4. Definition of contrast ratio:

Contrast ratio is calculated with the following formula.

$$\text{Contrast ratio (CR)} = \frac{\text{Photo detector output when LCD is at "White" state}}{\text{Photo detector output when LCD is at "Black" state}}$$

Note 5. White  $V_i = V_{i50} + 1.5V$

Black  $V_i = V_{i50} \pm 2.0V$

“±” means that the analog input signal swings in phase with  $V_{COM}$  signal.

“ $\bar{\pm}$ ” means that the analog input signal swings out of phase with  $V_{COM}$  signal.

$V_{i50}$  : The analog input voltage when transmission is 50%

The 100% transmission is defined as the transmission of LCD panel when all the input terminals of module are electrically opened.

Note 6. Definition of viewing angle, Refer to figure as below.

Note 7. Measured at the center area of the panel when all the input terminals of LCD panel are electrically opened.

**G. Suggestion- System block**

According to there are some risks of EMI issue.  
Please refer to this function block before design.  
If add SSC (Spread Spectrum Clocking) IC on the clock of system may cause  
USB abnormal work. Please add USB controller to control USB data.
