

High Performance *ActivePSR*TM Primary Switching Regulator

FEATURES

- Patented Primary Side Regulation Technology
- No Opto-Coupler
- Suitable Operation Frequency up to 85kHz
- Best-in-Class Constant Voltage Accuracy
- Proprietary Fast Startup with Big Capacitive Load
- Built-in Soft-Start Circuit
- Integrated Line and Primary Inductance Compensation
- Integrated Programmable Output Cord Resistance Compensation
- Line Under-Voltage, Output Over-Voltage, Output Short-Circuit and Over-Temperature Protection
- Complies with all Global Energy Efficiency and CEC Average Efficiency Standards
- Dedicate Adapter Application from 6W to 12W

APPLICATIONS

- RCC Adapter Replacements
- Linear Adapter Replacements
- Standby and Auxiliary Supplies

GENERAL DESCRIPTION

The ACT365 belongs to the high performance patented *ActivePSR*TM Family of Universal-input AC/DC off-line controllers for adapter applications. It is designed for flyback topology working in discontinuous conduction mode (DCM). The ACT365 meets all of the global energy efficiency regulations (CEC, European Blue Angel, and US Energy Star standards) while using very few external components.

The ACT365 ensures safe operation with complete protection against all fault conditions. Built-in protection circuitry is provided for output short-circuit, output over-voltage, line under-voltage, and over temperature conditions.

The ACT365 *ActivePSR*TM is optimized for high performance, cost-sensitive applications, and utilizes Active-Semi's proprietary primary-side feedback architecture to provide accurate constant voltage, constant current (CV/CC) regulation without the need of an opto-coupler or reference device. Integrated line and primary inductance compensation circuitry provides accurate constant current operation despite wide variations in line voltage and primary inductance. Integrated output cord resistance compensation further enhances output accuracy. The ACT365 achieves excellent regulation and transient response, yet requires less than 150mW of standby power.

The ACT365 is optimized for compact size 6W to 12W adapter applications. It is available in SOP-8 package.

PIN DESCRIPTIONS

PIN	NAME	DESCRIPTION
1	SW	Switch Drive. Switch node for the external NPN transistor. Connect this pin to the external power NPN's emitter. This pin also supplies current to VDD during startup.
2,4,7	G	Ground.
8	BD	Base Drive. Base driver for the external NPN transistor.
6	VDD	Power Supply. This pin provides bias power for the IC during startup and steady state operation.
5	FB	Feedback Pin. Connect this pin to a resistor divider network from the auxiliary winding.
3	CS	Current Sense Pin. Connect an external resistor (R_{CS}) between this pin and ground to set peak current limit for the primary switch. The peak current limit is set by $(0.396V \times 0.9) / R_{CS}$. For more detailed information, see Application Information.

ABSOLUTE MAXIMUM RATINGS^①

PARAMETER	VALUE	UNIT
VDD, BD, SW to G	-0.3 to +28	V
Maximum Continuous VDD Current	100	mA
FB, CS to G	-0.3 to +6	V
Continuous SW Current	Internally limited	A
Maximum Power Dissipation (derate 6.7mW/°C above T _A = 50°C)	0.95	W
Junction to Ambient Thermal Resistance (θ _{JA})	105	°C/W
Operating Junction Temperature	-40 to 150	°C
Storage Junction	-55 to 150	°C
Lead Temperature (Soldering, 10 sec)	300	°C

①: Do not exceed these limits to prevent damage to the device. Exposure to absolute maximum rating conditions for long periods may affect device reliability.

FUNCTIONAL BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

As shown in the *Functional Block Diagram*, to regulate the output voltage in CV (constant voltage) mode, the ACT365 compares the feedback voltage at FB pin to the internal reference and generates an error signal to the pre-amplifier. The error signal, after filtering out the switching transients and compensated with the internal compensation network, modulates the external NPN transistor peak current at CS pin with current mode PFWM (Pulse Frequency and Width Modulation) control. To regulate the output current in CC (constant current) mode, the oscillator frequency is modulated by the output voltage.

SW is a driver output that drives the emitter of an external high voltage NPN transistor. This base-emitter-drive method makes the drive circuit the most efficient.

Fast Startup

VDD is the power supply terminal for the ACT365. During startup, the ACT365 typically draws only 20µA supply current. The startup resistor from the rectified high voltage DC rail supplies current to the base of the NPN transistor. This results in an amplified emitter current to VDD through the SW pin via Active-Semi's proprietary fast-startup circuitry until it exceeds the V_{DDON} threshold 19V. At this point, the ACT365 enters internal startup mode with the peak current limit ramping up in 10ms. After switching starts, the output voltage begins to rise. The VDD bypass capacitor must supply the ACT365 internal circuitry and the NPN base drive until the output voltage is high enough to sustain VDD through the auxiliary winding. The V_{DDOFF} threshold is 5.5V; therefore, the voltage on the VDD capacitor must remain above 5.5V while the output is charging up.

Constant Voltage (CV) Mode Operation

In constant voltage operation, the ACT365 captures the auxiliary flyback signal at FB pin through a resistor divider network R5 and R6 in Figure 6. The signal at FB pin is pre-amplified against the internal reference voltage, and the secondary side output voltage is extracted based on Active-Semi's proprietary filter architecture.

This error signal is then amplified by the internal error amplifier. When the secondary output voltage is above regulation, the error amplifier output voltage decreases to reduce the switch current. When the secondary output voltage is below regulation, the error amplifier output voltage

increases to ramp up the switch current to bring the secondary output back to regulation. The output regulation voltage is determined by the following relationship:

$$V_{OUTCV} = 2.20V \times \left(1 + \frac{R_{FB1}}{R_{FB2}}\right) \times \frac{N_S}{N_A} - V_D \quad (1)$$

where R_{FB1} (R5) and R_{FB2} (R6) are top and bottom feedback resistor, N_S and N_A are numbers of transformer secondary and auxiliary turns, and V_D is the rectifier diode forward drop voltage at approximately 0.1A bias.

Standby (No Load) Mode

In no load standby mode, the ACT365 oscillator frequency is further reduced to a minimum frequency while the current pulse is reduced to a minimum level to minimize standby power. The actual minimum switching frequency is programmable with an output preload resistor.

Loop Compensation

The ACT365 integrates loop compensation circuitry for simplified application design, optimized transient response, and minimal external components.

Output Cable Resistance Compensation

The ACT365 provides programmable output cable resistance compensation during constant voltage regulation, monotonically adding an output voltage correction up to predetermined percentage at full power. There are four levels to program the output cable compensation by connecting a resistor (R10 in Figure 3) from the SW pin to VDD pin. The percentage at full power is programmable to be 3%, 6%, 9% or 12%, and by using a resistor value of 300k, 150k, 75k or 33k respectively. If there is no resistor connection, there is no cord compensation.

This feature allows for better output voltage accuracy by compensating for the output voltage droop due to the output cable resistance.

Constant Current (CC) Mode Operation

When the secondary output current reaches a level set by the internal current limiting circuit, the ACT365 enters current limit condition and causes the secondary output voltage to drop. As the output voltage decreases, so does the flyback voltage in a proportional manner. An internal current shaping circuitry adjusts the switching frequency based on the flyback voltage so that the transferred power remains proportional to the output voltage, resulting

FUNCTIONAL DESCRIPTION CONT'D

in a constant secondary side output current profile. The energy transferred to the output during each switching cycle is $\frac{1}{2}(L_P \times I_{LIM}^2) \times \eta$, where L_P is the transformer primary inductance, I_{LIM} is the primary peak current, and η is the conversion efficiency. From this formula, the constant output current can be derived:

$$I_{OUTCC} = \frac{1}{2} \times L_P \times \left(\frac{0.396 V \times 0.9}{R_{CS}} \right)^2 \times \left(\frac{\eta \times f_{SW}}{V_{OUTCV}} \right) \quad (2)$$

where f_{SW} is the switching frequency and V_{OUTCV} is the nominal secondary output voltage.

The constant current operation typically extends down to lower than 40% of nominal output voltage regulation.

Primary Inductance Compensation

The ACT365 integrates a built-in proprietary (patent-pending) primary inductance compensation circuit to maintain constant current regulation despite variations in transformer manufacturing. The compensated range is $\pm 7\%$.

Primary Inductor Current Limit Compensation

The ACT365 integrates a primary inductor peak current limit compensation circuit to achieve constant input power over line and load ranges.

Protection

The ACT365 incorporates multiple protection functions including over-voltage, over-current and over-temperature.

Output Short Circuit Protection

When the secondary side output is short circuited, the ACT365 enters hiccup mode operation. In this condition, the VDD voltage drops below the V_{DDOFF} threshold and the auxiliary supply voltage collapses. This turns off the ACT365 and causes it to restart. This hiccup behavior continues until the short circuit is removed.

Output Over Voltage Protection

The ACT365 includes output over-voltage protection circuitry, which shuts down the IC when the output voltage is 40% above the normal regulation voltage for 4 consecutive switching cycles. The ACT365 enters hiccup mode when an output over voltage fault is detected.

Over Temperature Shutdown

The thermal shutdown circuitry detects the ACT365

die temperature. The typical over temperature threshold is 135°C with 20°C hysteresis. When the die temperature rises above this threshold the ACT365 is disabled until the die temperature falls by 20°C, at which point the ACT365 is re-enabled.

TYPICAL APPLICATION

Design Example

The design example below gives the procedure for a DCM flyback converter using the ACT365. Refer to Application Circuit in Figure 3, the design for an adapter application starts with the following specification:

Input Voltage Range	85VAC - 265VAC, 50/60Hz
Output Power, P_o	10.5W
Output Voltage, V_{OUTCV}	5.0V
Full Load Current, I_{OUTFL}	2.1A
OCP Current, I_{OUTMAX}	2.4A
Transformer Efficiency, η_{xfm}	0.89
System Efficiency CC, η_{system}	0.76
System Efficiency CV, η	0.77

The operation for the circuit shown in Figure 3 is as follows: the rectifier bridge BD1 and the capacitor C1/C2 convert the AC line voltage to DC. This voltage supplies the primary winding of the transformer T1 and the startup resistor R7. The primary power current path is formed by the transformer's primary winding, the NPN transistor, the ACT365 internal MOSFET and the current sense resistor R9. The network consisting of capacitor C4 and diode D6 provides a VDD supply voltage for ACT365 from the auxiliary winding of the transformer. C4 is the decoupling capacitor of the supply voltage and energy storage component for startup. The diode D8 and the capacitor C5/C6 rectifies and filters the output voltage. The resistor divider consisting of R5 and R6 programs the output voltage.

The minimum and maximum DC input voltages can be calculated:

$$V_{INDCMIN} = \sqrt{2V_{ACMIN}^2 - \frac{2P_{OUT} \left(\frac{1}{2f_L} - t_C \right)}{\eta \times C_{IN}}} \\ = \sqrt{2 \times 85^2 - \frac{2 \times 10.5 \left(\frac{1}{2 \times 50} - 4.5ms \right)}{76\% \times 2 \times 10 \mu F}} \approx 90V \quad (3)$$

$$V_{INDCMAX} = \sqrt{2} \times V_{ACMAX} = \sqrt{2} \times 265 = 375V \quad (4)$$

TYPICAL APPLICATION CONT'D

where η is the estimated circuit efficiency, f_L is the line frequency, t_C is the estimated rectifier conduction time, C_{IN} is empirically selected to be $2 \times 10\mu\text{F}$ electrolytic capacitors based on the $2\mu\text{F/W}$ rule of thumb.

When the transistor is turned off, the voltage on the transistor's collector consists of the input voltage and the reflected voltage from the transformer's secondary winding. There is a ringing on the rising top edge of the flyback voltage due to the leakage inductance of the transformer. This ringing is clamped by a RCD network if it is used. Design this clamped voltage as 50V below the breakdown of the NPN transistor. The flyback voltage has to be considered with selection of the maximum reverse voltage rating of secondary rectifier diode. If a 40V Schottky diode is used, then the flyback voltage can be calculated:

$$V_{RO} = \frac{V_{INDC\text{MAX}} \times (V_{OUTCV} + V_{DS})}{V_{DREV} - V_{OUTCV}} = \frac{375 \times (5 + 0.5)}{40 \times 0.8 - 5} = 76\text{V} \quad (5)$$

where V_{DS} is the Schottky diode forward voltage, V_{DREV} is the maximum reverse voltage rating of the diode and V_{OUTCV} is the output voltage.

The maximum duty cycle is set to be 46% at low line voltage $85V_{AC}$ and the circuit efficiency is estimated to be 76%. Then the full load input current is:

$$I_{IN} = \frac{V_{OUTCV} \times I_{OUTPL}}{V_{INDC\text{MIN}} \times \eta} = \frac{5 \times 2.1}{90 \times 76\%} = 153.5\text{mA} \quad (6)$$

The maximum input primary peak current at full load base on duty of 46%:

$$I_{PK} = \frac{2 \times I_{IN}}{D} = \frac{2 \times 153.5}{46\%} = 667\text{mA} \quad (7)$$

The primary inductance of the transformer:

$$L_P = \frac{V_{INDC\text{MIN}} \times D}{I_{PK} \times f_{SW}} = \frac{90 \times 46\%}{667\text{mA} \times 60\text{kHz}} \approx 1.0\text{mH} \quad (8)$$

ACT365 needs to work in DCM in all conditions, thus N_P/N_S should meet

$$\frac{L_P \times I_{PK}}{V_{INDC\text{MIN}}} + \frac{L_P \times I_{PK}}{(V_{OUTCV} + V_{DS}) \times \frac{N_P}{N_S}} < \frac{0.9}{f_{SW}} \Rightarrow \frac{N_P}{N_S} > 16.16 \quad (9)$$

The auxiliary to secondary turns ratio N_A/N_S :

$$\frac{N_A}{N_S} = \frac{V_{DD} + V_{DA} + V_R}{V_{OUTCV} + V_{DS} + V_{CORD}} = \frac{11 + 0.25 + 1}{5 + 0.3 + 0.35} \approx 2.2 \quad (10)$$

Where V_{DA} is diode forward voltage of the auxiliary side and V_R is the resistor voltage.

An EPC17 transformer gapped core with an effective inductance A_{LE} of 80nH/T^2 is selected. The number of turns of the primary winding is:

$$N_P = \sqrt{\frac{L_P}{A_{LE}}} = \sqrt{\frac{1.0\text{mH}}{80\text{nH/T}^2}} = 110 \quad (11)$$

The number of turns of secondary and auxiliary windings can be derived when $N_P/N_S=14$:

$$N_S = \frac{N_S}{N_P} \times N_P = \frac{1}{14} \times 110 \approx 8 \quad (12)$$

$$N_A = \frac{N_A}{N_S} \times N_S = 2.2 \times 9 = 20 \quad (13)$$

The current sense resistance (R_{CS}) determines the current limit value based on the following equation:

$$R_{CS} = \frac{0.9 \times V_{CSLIM}}{\sqrt{\frac{(I_{OUTFL} + I_{OUTMAX}) \times (V_{OUT} + V_{DS})}{L_P \times f_{SW} \times \left(\frac{\eta_{system}}{\eta_{xfm}}\right)}}} = \frac{0.9 \times 0.396}{\sqrt{\frac{(2.1 + 2.5) \times 5.3}{1.0 \times 60 \times \left(\frac{0.76}{0.89}\right)}}} = 0.52\text{R} \quad (14)$$

The voltage feedback resistors are selected according to below equation:

$$R_{FB1} = \frac{N_A}{N_P} \times \frac{L_P}{R_{CS}} \times K = \frac{20}{110} \times \frac{1.0}{0.52} \times 200000 \approx 68\text{k} \quad (15)$$

In actual application 66.5K is selected.

Where K is IC constant and $K = 200000$.

$$R_{FB2} = \frac{V_{FB}}{(V_{OUTCV} + V_{DS}) \frac{N_A}{N_S} - V_{FB}} R_{FB1} \quad (16)$$

$$= \frac{2.20}{(5 + 0.45) \times 2.2 - 2.20} \times 66.5\text{K} \approx 15\text{k}$$

When selecting the output capacitor, a low ESR electrolytic capacitor is recommended to minimize ripple from the current ripple. The approximate equation for the output capacitance value is given by:

$$C_{OUT} = \frac{I_{OUTCC} \times D}{f_{SW} \times \Delta V_{RIPPLE}} = \frac{2.1 \times 0.46}{60\text{kHz} \times 50\text{mV}} = 320\mu\text{F} \quad (17)$$

A 1000 μF electrolytic capacitor is used to keep the ripple small.

PCB Layout Guideline

Good PCB layout is critical to have optimal performance. Decoupling capacitor (C_4), current sense resistor (R_9) and feedback resistor (R_5/R_6) should be placed close to V_{DD} , CS and FB pins respectively. There are two main power path loops. One is formed by C_1/C_2 , primary winding, NPN transistor and the ACT365. The other is the secondary winding, rectifier D8 and output capacitors (C_5, C_6). Keep these loop areas as small as possible. Connect high current ground returns,

TYPICAL APPLICATION CONT'D

the input capacitor ground lead, and the ACT365 G pin to a single point (star ground configuration).

V_{FB} Sampling Waveforms

ACT365 senses the output voltage information through the V_{FB} waveforms. Proper V_{FB} waveforms are required for IC to operate in a stable status. To avoid mis-sampling, 1.0 μ s blanking time is added to blank the ringing period due to the leakage inductance and the circuit parasitic capacitance.

Figure 2 is the recommended V_{FB} waveform to guarantee the correct sampling point so that the output information can be sent back into the IC to do the appropriate control.
