GENERAL DESCRIPTION

The AD7110 LOGDAC™ is a monolithic CMOS digitally controlled audio attenuator (U.S. Patent No. 4521764). With the addition of an external operational amplifier it provides 0 to 88.5dB of attenuation in 1.5dB steps, plus full muting of the audio input signal for digital input code 1111XX, where X can be 1 or 0. The audio input is applied to the V_{IN} pin and the device delivers a logarithmically related output current which is determined by a 6-bit binary input code. Loudness compensation switches are provided on the device to enable additional bass boost at low volume settings.

The device is manufactured using an advanced thin-film on CMOS monolithic wafer fabrication process and is packaged in a 16-pin DIP.

CAUTION:
ESD (Electro-Static-Discharge) sensitive device. The digital control inputs are diode protected, however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RESOLUTION: Nominal change in attenuation when moving between two adjacent binary codes. The AD7110 resolution is 1.5dB.

MONOTONICITY: The AD7110 digitally controlled audio attenuator is monotonic if the analog output decreases (or remains constant) as the digital input code (attenuation setting) increases.

FEEDTHROUGH ERROR: That portion of the input signal which reaches the output when the digital input code is set to mute the input signal.

ANALOG CIRCUIT PERFORMANCE:

Table I gives the nominal attenuation in dB for the AD7110 for all digital input codes. It also shows the Loudness Switch states and the nominal output voltage when using an external operational amplifier (as shown in Figure 1) and a fixed -10 volt reference applied to V_{IN} (pin 15). It may be seen that the transfer function for the circuit of Figure 1 is given by

$$V_{OUT} = -V_{IN}\ 10\ \exp -\left\{\frac{1.5N}{20}\right\}$$

where N is the binary input for values 0 to 59. For N = 60 through 63 the input is fully muted, that is, the attenuation is infinite.

HIGH FREQUENCY AMPLIFIERS

R_{FB} and the output capacitance of the AD7110 create a phase lag in the output amplifier's feedback circuit. This phase lag, in conjunction with the amplifier's phase lag, may cause ringing or oscillation. When using a high speed amplifier, shunting the amplifier input to output with 30–50pF of feedback capacitance (C1) ensures stability.

DC PERFORMANCE OF AD7110

For fixed-reference applications, an output amplifier with low offset voltage (less than 50µV) is required, e.g. the AD517L. This combination will provide the utmost stability at the expense of slow settling times.
