ANALOG DEVICES

400 MHz to 1250 MHz Quadrature Modulator with 750 MHz to 1150 MHz Frac-N PLL and Integrated VCO

Data Sheet

ADRF6701

FEATURES

IQ modulator with integrated fractional-N PLL Output frequency range: 400 MHz to 1250 MHz Internal LO frequency range: 750 MHz to 1150 MHz Output P1dB: 10.3 dBm @ 1100 MHz Output IP3: 30.1 dBm @ 1100 MHz Noise floor: -159.4 dBm/Hz @ 1100 MHz Baseband bandwidth: 750 MHz (3 dB) SPI serial interface for PLL programming **Integrated LDOs and LO buffer** Power supply: 5 V/240 mA 40-lead 6 mm × 6 mm LFCSP

APPLICATIONS

Cellular communications systems GSM/EDGE, CDMA2000, W-CDMA, TD-SCDMA, LTE **Broadband wireless access systems** Satellite modems

GENERAL DESCRIPTION

The ADRF6701 provides a quadrature modulator and synthesizer solution within a small 6 mm \times 6 mm footprint while requiring minimal external components.

The ADRF6701 is designed for RF outputs from 400 MHz to 1250 MHz. The low phase noise VCO and high performance quadrature modulator make the ADRF6701 suitable for next generation communication systems requiring high signal dynamic range and linearity. The integration of the IQ

modulator, PLL, and VCO provides for significant board savings and reduces the BOM and design complexity.

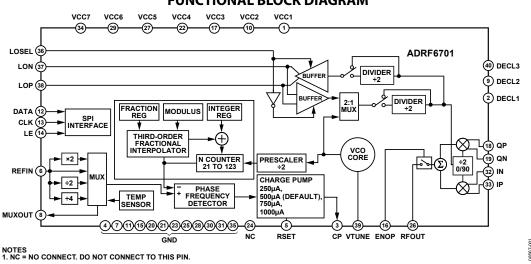

The integrated fractional-N PLL/synthesizer generates a $2 \times f_{LO}$ input to the IQ modulator. The phase detector together with an external loop filter is used to control the VCO output. The VCO output is applied to a quadrature divider. To reduce spurious components, a sigma-delta (Σ - Δ) modulator controls the programmable PLL divider.

The IQ modulator has wideband differential I and Q inputs, which support baseband as well as complex IF architectures. The single-ended modulator output is designed to drive a 50 Ω load impedance and can be disabled.

The ADRF6701 is fabricated using an advanced silicongermanium BiCMOS process. It is available in a 40-lead, exposed-paddle, Pb-free, 6 mm × 6 mm LFCSP package. Performance is specified from -40°C to +85°C. A lead-free evaluation board is available.

Table 1.

Part No.	Internal LO Range	IQ Modulator ±3 dB RF Output Range
ADRF6701	750 MHz	400 MHz
	1150 MHz	1250 MHz
ADRF6702	1550 MHz	1200 MHz
	2150 MHz	2400 MHz
ADRF6703	2100 MHz	1550 MHz
	2600 MHz	2650 MHz

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES 1. NC = NO CONNECT. DO NOT CONNECT TO THIS PIN. 2. THE EXPOSED PADDLE SHOULD BE SOLDERED TO A LOW IMPEDANCE GROUND PLANE.

Figure 3. Pin Configuration

Pin No.	Mnemonic	Description
1, 10, 17, 22, 27, 29, 34	VCC1, VCC2, VCC3, VCC4, VCC5, VCC6, VCC7	Power Supply Pins. The power supply voltage range is 4.75 V to 5.25 V. Drive all of these pins from the same power supply voltage. Decouple each pin with 100 pF and 0.1 µF capacitors located close to the pin.
2	DECL1	Decoupling Node for Internal 3.3 V LDO. Decouple this pin with 100 pF and 0.1 μF capacitors located close to the pin.
3	СР	Charge Pump Output Pin. Connect VTUNE to this pin through the loop filter. If an external VCO is being used, connect the output of the loop filter to the VCO's voltage control pin. The PLL control loop should then be closed by routing the VCO's frequency output back into the ADRF6701 through the LON and LOP pins.
4, 7, 11, 15, 20, 21, 23, 25, 28, 30, 31, 35	GND	Ground. Connect these pins to a low impedance ground plane.
24	NC	Do not connect to this pin.
5	RSET	Charge Pump Current. The nominal charge pump current can be set to 250 μ A, 500 μ /750 μ A, or 1000 μ A using DB10 and DB11 of Register 4 and by setting DB18 to 0 (CP reference source).
		In this mode, no external RSET is required. If DB18 is set to 1, the four nominal charge pump currents ($I_{NOMINAL}$) can be externally tweaked according to the following equation:
		$R_{SET} = \left(\frac{217.4 \times I_{CP}}{I_{NOMINAL}}\right) - 37.8\Omega$
		where I _{CP} is the base charge pump current in microamps. For further details on the charge pump current, see the Register 4—PLL Charge Pump, PFD, and Reference Path Control section.
6	REFIN	Reference Input. The nominal input level is 1 V p-p. Input range is 12 MHz to 160 MHz. This pin has high input impedance and should be ac-coupled. If REFIN is being driven by laboratory test equipment, the pin should be externally terminated with a 50 Ω resistor (place the ac-coupling capacitor between the pin and the resistor). When driven from an 50 Ω RF signal generator, the recommended input level is 4 dBm.
8	MUXOUT	Multiplexer Output. This output allows a digital lock detect signal, a voltage proportional to absolute temperature (VPTAT), or a buffered, frequency-scaled reference signal to be accessed externally. The output is selected by programming DB21 to DB23 in Register 4.
9	DECL2	Decoupling Node for 2.5 V LDO. Connect 100 pF, 0.1 μF and 10 μF capacitors between this pin and ground.
12	DATA	Serial Data Input. The serial data input is loaded MSB first with the three LSBs being the control bits.

Rev. 0 | Page 8 of 36

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
13	CLK	Serial Clock Input. This serial clock input is used to clock in the serial data to the registers. The data is latched into the 24-bit shift register on the CLK rising edge. Maximum clock frequency is 20 MHz.
14	LE	Latch Enable. When the LE input pin goes high, the data stored in the shift registers is loaded into one of the six registers, the relevant latch being selected by the first three control bits of the 24-bit word.
16	ENOP	Modulator Output Enable/Disable. See Table 6.
18, 19, 32, 33	QP, QN, IN, IP	Modulator Baseband Inputs. Differential in-phase and quadrature baseband inputs. These inputs should be dc-biased to 0.5 V.
26	RFOUT	RF Output. Single-ended, 50 Ω internally biased RF output. RFOUT must be ac-coupled to its load.
36	LOSEL	LO Select. This digital input pin determines whether the LOP and LON pins operate as inputs or outputs. This pin should not be left floating. LOP and LON become inputs if the LOSEL pin is set low and the LDRV bit of Register 5 is set low. In addition to setting LOSEL and LDRV low and providing an external 2× LO, the LXL bit of Register 5 (DB4) must be set to 1 to direct the external LO to the IQ modulator. LON and LOP become outputs when LOSEL is high or if the LDRV bit of Register 5 (DB3) is set to 1. A 1× LO or 2× LO output can be selected by setting the LDIV bit of Register 5 (DB5) to 1 or 0 respectively (see Table 7).
37, 38	LON, LOP	Local Oscillator Input/Output. The internally generated $1 \times LO$ or $2 \times LO$ is available on these pins. When internal LO generation is disabled, an external $1 \times LO$ or $2 \times LO$ can be applied to these pins.
39	VTUNE	VCO Control Voltage Input. This pin is driven by the output of the loop filter. Nominal input voltage range on this pin is 1.3 V to 2.5 V. If the external VCO mode is activated, this pin can be left open.
40	DECL3	Decoupling Node for VCO LDO. Connect a 100 pF capacitor and a 10 μF capacitor between this pin and ground.
	EP	Exposed Paddle. The exposed paddle should be soldered to a low impedance ground plane.

THEORY OF OPERATION

The ADRF6701 integrates a high performance IQ modulator with a state of the art fractional-N PLL. The ADRF6701 also integrates a low noise VCO. The programmable SPI port allows the user to control the fractional-N PLL functions and the modulator optimization functions. This includes the capability to operate with an externally applied LO or VCO.

The quadrature modulator core within the ADRF6701 is a part of the next generation of industry-leading modulators from Analog Devices, Inc. The baseband inputs are converted to currents and then mixed to RF using high performance NPN transistors. The mixer output currents are transformed to a single-ended RF output using an integrated RF transformer balun. The high performance active mixer core, coupled with the low-loss RF transformer balun results in an exceptional OIP3 and OP1dB, with a very low output noise floor for excellent dynamic range. The use of a passive transformer balun rather than an active output stage leads to an improvement in OIP3 with no sacrifice in noise floor. At 950 MHz, the ADRF6701 typically provides an output P1dB of 10 dBm, OIP3 of 32 dBm, and an output noise floor of -157.8 dBm/Hz. Typical image rejection under these conditions is -44 dBc with no additional I and Q gain compensation.

PLL + VCO

The fractional divide function of the PLL allows the frequency multiplication value from REFIN to the LOP/LON outputs to be a fractional value rather than restricted to an integer as in traditional PLLs. In operation, this multiplication value is INT + (FRAC/MOD) where INT is the integer value, FRAC is the fractional value, and MOD is the modulus value, all of which are programmable via the SPI port. In previous fractional-N PLL designs, the fractional multiplication was achieved by periodically changing the fractional value in a deterministic way. The downside of this was often spurious components close to the fundamental signal. In the ADRF6701, a sigma delta modulator is used to distribute the fractional value randomly, thus significantly reducing the spurious content due to the fractional function.

BASIC CONNECTIONS FOR OPERATION

Figure 35 shows the basic connections for operating the ADRF6701 as they are implemented on the device's evaluation board. The seven power supply pins should be individually decoupled using 100 pF and 0.1 μ F capacitors located as close as possible to the pins. A single 10 μ F capacitor is also recommended. The three internal decoupling nodes (labeled DECL3, DECL2, and DECL1) should be individually decoupled with capacitors as shown in Figure 35.

The four I and Q inputs should be driven with a bias level of 500 mV. These inputs are generally dc-coupled to the outputs of a dual DAC (see the DAC-to-IQ Modulator Interfacing and IQ Filtering sections for more information).

A 1 V p-p (0.353 V rms) differential sine wave on the I and Q inputs results in a single sideband output power of +4.1 dBm (at 950 MHz) at the RFOUT pin (this pin should be ac-coupled as shown in Figure 35). This corresponds to an IQ modulator voltage gain of -0.2 dB.

The reference frequency for the PLL (typically 1 V p-p between 12 MHz and 160 MHz) should be applied to the REFIN pin, which should be ac-coupled. If the REFIN pin is being driven from a 50 Ω source (for example, a lab signal generator), the pin should be terminated with 50 Ω as shown in Figure 35 (an RF drive level of +4 dBm should be applied). Multiples or fractions of the REFIN signal can be brought back off-chip at the multiplexer output pin (MUXOUT). A lock-detect signal and an analog voltage proportional to the ambient temperature can also be brought out on this pin by setting the appropriate bits on (DB21-DB23) in Register 4 (see the Register Description section).

EXTERNAL LO

The internally generated local oscillator (LO) signal can be brought off-chip as either a $1 \times LO$ or a $2 \times LO$ or a $4 \times LO$ (via the LOP and LON pins) by asserting the LOSEL pin and making the appropriate internal register settings. The LO output must be disabled whenever the RF output of the IQ modulator is disabled.

The LOP and LON pins can also be used to apply an external LO. This can be used to bypass the internal PLL/VCO or if operation using an external VCO is desired. To turn off the PLL Register 6, Bits[20:17] must be zero.

08567-034

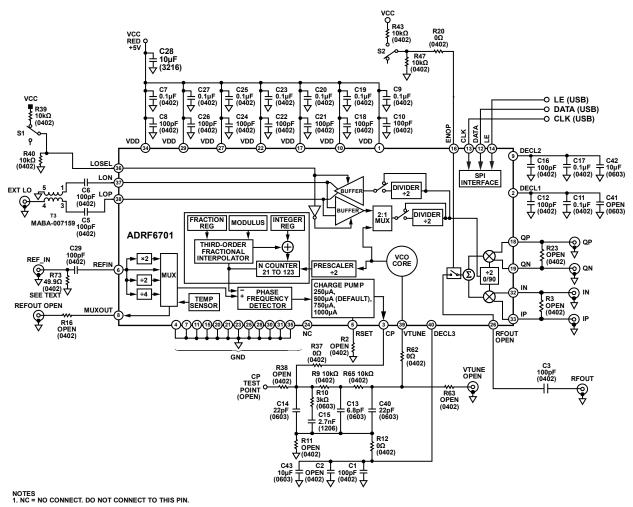

Figure 35. Basic Connections for Operation (Loop Filter Set to 130 kHz)

LOOP FILTER

The loop filter is connected between the CP and VTUNE pins. The return for the loop filter components should be to Pin 40 (DECL3). The loop filter design in Figure 35 results in a 3 dB loop bandwidth of 130 kHz. The ADRF6701 closed loop phase noise was also characterized using a 3.5 kHz loop filter design. The recommended components for both filter designs are shown in Table 8. For assistance in designing loop filters with other characteristics, download the most recent revision of ADIsimPLL[™] from www.analog.com/adisimpll. Operation with an external VCO is possible. In this case, the return for the loop filter components is ground (assuming a ground reference on the external VCO tuning input). The output of the loop filter is connected to the external VCO's tuning pin. The output of the VCO is brought back into the device on the LOP and LON pins (using a balun if necessary).

DAC-TO-IQ MODULATOR INTERFACING

The ADRF6701 is designed to interface with minimal components to members of the Analog Devices, Inc., family of TxDACs^{*}. These dual-channel differential current output DACs provide an output current swing from 0 mA to 20 mA. The interface described in this section can be used with any DAC that has a similar output.

An example of an interface using the AD9122 TxDAC is shown in Figure 36. The baseband inputs of the ADRF6701 require a dc bias of 500 mV. The average output current on each of the outputs of the AD9122 is 10 mA. Therefore, a single 50 Ω resistor to ground from each of the DAC outputs results in an average current of 10 mA flowing through each of the resistors, thus producing the desired 500 mV dc bias for the inputs to the ADRF6701.

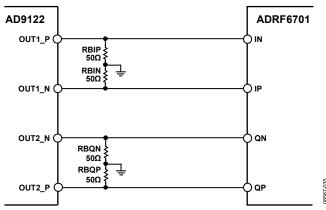

Figure 36. Interface Between the AD9122 and ADRF6701 with 50 Ω Resistors to Ground to Establish the 500 mV DC Bias for the ADRF6701 Baseband Inputs

The AD9122 output currents have a swing that ranges from 0 mA to 20 mA. With the 50 Ω resistors in place, the ac voltage swing going into the ADRF6701 baseband inputs ranges from 0 V to 1 V (with the DAC running at 0 dBFS). So the resulting drive signal from each differential pair is 2 V p-p differential with a 500 mV dc bias.

ADDING A SWING-LIMITING RESISTOR

The voltage swing for a given DAC output current can be reduced by adding a third resistor to the interface. This resistor is placed in the shunt across each differential pair, as shown in Figure 37. It has the effect of reducing the ac swing without changing the dc bias already established by the 50 Ω resistors.

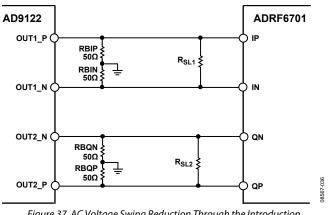

Figure 37. AC Voltage Swing Reduction Through the Introduction of a Shunt Resistor Between the Differential Pair

The value of this ac voltage swing limiting resistor(R_{SL} as shown in Figure 37) is chosen based on the desired ac voltage swing and IQ modulator output power. Figure 38 shows the relationship between the swing-limiting resistor and the peak-to-peak ac swing that it produces when 50 Ω bias-setting resistors are used. A higher value of swing-limiting resistor will increase the output power of the ADRF6701 and signal-to-noise ratio (SNR) at the cost if higher intermodulation distortion. For most applications, the optimum value for this resistor will be between 100 Ω and 300 Ω .

When setting the size of the swing-limiting resistor, the input impedance of the I and Q inputs should be taken into account. The I and Q inputs have a differential input resistance of 920 Ω . As a result, the effective value of the swing-limiting resistance is 920 Ω in parallel with the chosen swing-limiting resistor. For example, if a swing-limiting resistance of 200 Ω is desired (based on Figure 37), the value of R_{SL} should be set such that

 $200 \ \Omega = (920 \times R_{SL})/(920 + R_{SL})$

resulting in a value for R_{SL} of 255 Ω .

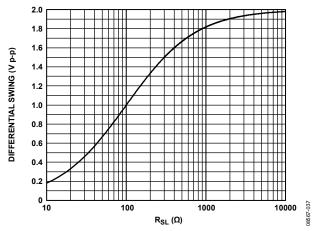

Figure 38. Relationship Between the AC Swing-Limiting Resistor and the Peak-to-Peak Voltage Swing with 50 Ω Bias-Setting Resistors

Data Sheet

ADRF6701

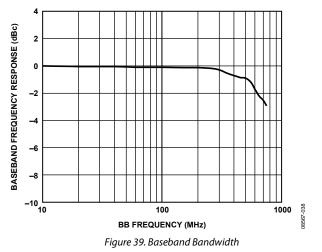

IQ FILTERING

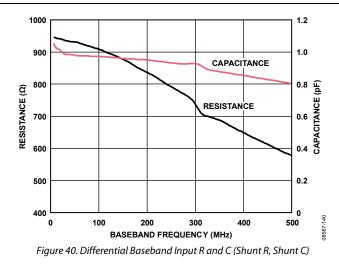

An antialiasing filter must be placed between the DAC and modulator to filter out Nyquist images and broadband DAC noise. The interface for setting up the biasing and ac swing discussed in the Adding a Swing-Limiting Resistor section, lends itself well to the introduction of such a filter. The filter can be inserted between the dc bias setting resistors and the ac swing-limiting resistor. Doing so establishes the input and output impedances for the filter.

Unless a swing-limiting resistor of 100 Ω is chosen, the filter must be designed to support different source and load impedances. In addition, the differential input capacitance of the I and Q inputs (1 pF) should be factored into the filter design. Modern filter design tools allow for the simulation and design of filters with differing source and load impedances as well as inclusion of reactive load components.

BASEBAND BANDWIDTH

Figure 39 shows the frequency response of the ADRF6701's baseband inputs. This plot shows 0.5 dB and 3 dB bandwidths of 350 MHz and 750 MHz respectively. Any flatness variations across frequency at the ADRF6701 RF output have been calibrated out of this measurement.

DEVICE PROGRAMMING AND REGISTER SEQUENCING

The device is programmed via a 3-pin SPI port. The timing requirements for the SPI port are shown in Table 3 and Figure 2.

Eight programmable registers, each with 24 bits, control the operation of the device. The register functions are listed in Table 9. The eight registers should initially be programmed in reverse order, starting with Register 7 and finishing with Register 0. Once all eight registers have been initially programmed, any of the registers can be updated without any attention to sequencing.

Software is available on the ADRF6701 product page at www.analog.com that allows programming of the evaluation board from a PC running Windows[®] XP or Windows Vista.

To operate correctly under Windows XP, Version 3.5 of Microsoft .NET must be installed. To run the software on a Windows 7 PC, XP emulation mode must be used (using Virtual PC).

REGISTER SUMMARY

Table 9. Register Functions

Register	Function
Register 0	Integer divide control (for the PLL)
Register 1	Modulus divide control (for the PLL)
Register 2	Fractional divide control (for the PLL)
Register 3	Σ - Δ modulator dither control
Register 4	PLL charge pump, PFD, and reference path control
Register 5	LO path and modulator control
Register 6	VCO control and VCO enable
Register 7	External VCO enable

08567-039

REGISTER DESCRIPTION REGISTER 0—INTEGER DIVIDE CONTROL (DEFAULT: 0x0001C0)

With Register 0, Bits[2:0] set to 000, the on-chip integer divide control register is programmed as shown in Figure 41.

Divide Mode

Divide mode determines whether fractional mode or integer mode is used. In integer mode, the RF VCO output frequency (f_{VCO}) is calculated by

$$f_{VCO} = 2 \times f_{PFD} \times (INT) \tag{1}$$

where:

 f_{VCO} is the output frequency of the internal VCO.

 f_{PFD} is the frequency of operation of the phase-frequency detector. *INT* is the integer divide ratio value (21 to 123 in integer mode).

Integer Divide Ratio

The integer divide ratio bits are used to set the integer value in Equation 2. The INT, FRAC, and MOD values make it possible to generate output frequencies that are spaced by fractions of the PFD frequency. The VCO frequency (f_{VCO}) equation is

$$f_{VCO} = 2 \times f_{PFD} \times (INT + (FRAC/MOD))$$
(2)

where:

INT is the preset integer divide ratio value (24 to 119 in fractional mode).

MOD is the preset fractional modulus (1 to 2047).

FRAC is the preset fractional divider ratio value (0 to MOD – 1).

REGISTER 1—MODULUS DIVIDE CONTROL (DEFAULT: 0x003001)

With Register 1, Bits[2:0] set to 001, the on-chip modulus divide control register is programmed as shown in Figure 42.

Modulus Value

The modulus value is the preset fractional modulus ranging from 1 to 2047.

REGISTER 2—FRACTIONAL DIVIDE CONTROL (DEFAULT: 0x001802)

With Register 2, Bits[2:0] set to 010, the on-chip fractional divide control register is programmed as shown in Figure 43.

Fractional Value

The FRAC value is the preset fractional modulus ranging from 0 to <MDR.

REGISTER 3— Σ - Δ MODULATOR DITHER CONTROL (DEFAULT: 0x10000B)

With Register 3, Bits[2:0] set to 011, the on-chip Σ - Δ modulator dither control register is programmed as shown in Figure 44. The recommended and default setting for dither enable is enabled (1).

The default value of the dither magnitude (15) should be set to a recommended value of 1.

The dither restart value can be programmed from 0 to $2^{17} - 1$, though a value of 1 is typically recommended.

Figure 44. Register 3— Σ - Δ Modulator Dither Control Register Map

REGISTER 4—PLL CHARGE PUMP, PFD, AND REFERENCE PATH CONTROL (DEFAULT: 0x12A7E4)

With Register 4, Bits[2:0] set to 100, the on-chip charge pump, PFD, and reference path control register is programmed as shown in Figure 45.

CP Current

The nominal charge pump current can be set to 250 μ A, 500 μ A, 750 μ A, or 1000 μ A using DB10 and DB11 of Register 4 and by setting DB18 to 0 (CP reference source).

In this mode, no external RSET is required. If DB18 is set to 1, the four nominal charge pump currents ($I_{NOMINAL}$) can be externally tweaked according to the following equation:

$$R_{SET} = \left(\frac{217.4 \times I_{CP}}{I_{NOMINAL}}\right) - 37.8\,\Omega\tag{3}$$

where I_{CP} is the base charge pump current in microamps.

The PFD phase offset multiplier ($\theta_{PFD,OFS}$), which is set by Bits[16:12] of Register 4, causes the PLL to lock with a nominally fixed phase offset between the PFD reference signal and the divided-down VCO signal. This phase offset is used to linearize the PFD-to-CP transfer function and can improve fractional spurs. The magnitude of the phase offset is determined by the following equation:

$$|\Delta\Phi|(\deg) = 22.5 \frac{\theta_{PFD,OFS}}{I_{CP,MULT}}$$
(4)

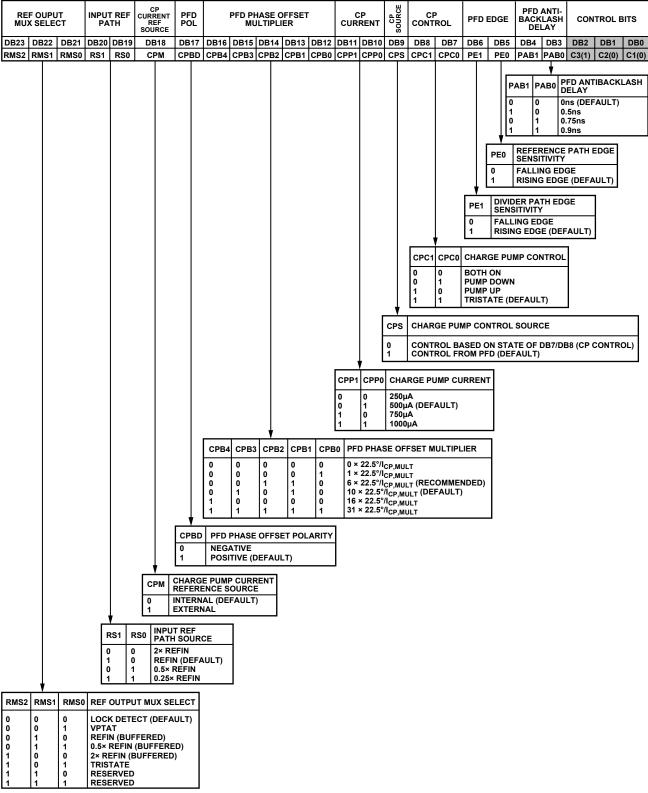

The default value of the phase offset multiplier ($10 \times 22.5^{\circ}$) should be set to a recommended value of $6 \times 22.5^{\circ}$.

This phase offset can be either positive or negative depending on the value of DB17 in Register 4.

The reference frequency applied to the PFD can be manipulated using the internal reference path source. The external reference frequency applied can be internally scaled in frequency by $2\times$, $1\times$, $0.5\times$, or $0.25\times$. This allows a broader range of reference frequency selections while keeping the reference frequency applied to the PFD within an acceptable range.

The device also has a MUXOUT pin that can be programmed to output a selection of several internal signals. The default mode is to provide a lock-detect output to allow the user to verify when the PLL has locked to the target frequency. In addition, several other internal signals can be passed to the MUXOUT pin as described in Figure 35.

Data Sheet

REGISTER 5—LO PATH AND MODULATOR CONTROL (DEFAULT: 0X0000E5)

With Register 5, Bits[2:0] set to 101, the LO path and modulator control register is programmed as shown in Figure 46.

The modulator output or the complete modulator can be disabled using the modulator bias enable and modulator output enable addresses of Register 5.

The LO port (LOP and LON pins) can be used to apply an external $2 \times$ LO or $4 \times$ LO (that is, bypass internal PLL) to the IQ modulator. A differential LO drive of 0 dBm is recommended.

The LO port can also be used as an output where a $2 \times$ LO or $1 \times$ LO can be brought out and used to drive another mixer. The nominal output power provided at the LO port is 3 dBm.

The mode of operation of the LO port is determined by the status of the LOSEL pin (3.3 V logic) along with the settings in a number of internal registers (see Table 10).

The internal VCO of the device can also be bypassed. In this case, the charge pump output drives an external VCO through the loop filter. The loop is completed by routing the VCO into the device through the LO port.

Table 10. LO Port Configuration^{1, 2}

LON/LOP Function	LOSEL	Register 5 Bit DB5 (LDIV)	Register 5 Bit DB4 (LXL)	Register 5 Bit DB3 (LDRV)	Register 7 Bit DB4 (LDIV2)
Input (4× LO)	0	Х	1	0	0

Output (Disabled)	0	Х	0	0	Х
Output (1×LO)	0	0	0	1	0
Output (1×LO)	1	0	0	0	0
Output (1×LO)	1	0	0	1	0
Output (2×LO)	0	1	0	1	0
Output (2×LO)	1	1	0	0	0
Output (2×LO)	1	1	0	1	0

¹ X = don't care.

² LOSEL should not be left floating.

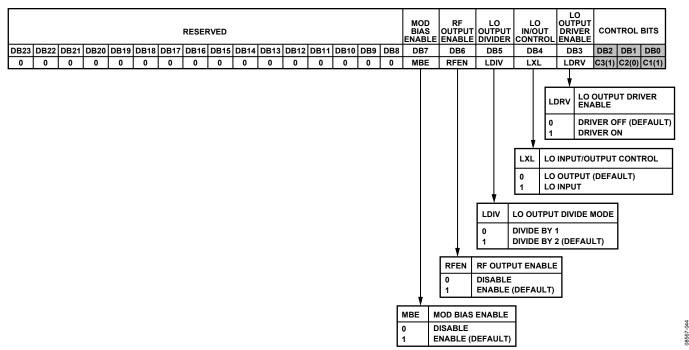

Figure 46. Register 5—LO Path and Modulator Control Register Map

8567-

REGISTER 6—VCO CONTROL AND VCO ENABLE (DEFAULT: 0X1E2106)

With Register 6, Bits[2:0] set to 110, the VCO control and enable register is programmed as shown in Figure 47.

The VCO tuning band is normally selected automatically by the band calibration algorithm, although the user can directly select the VCO band using Register 6.

The VCO BSSRC bit (DB9) determines whether the result of the calibration algorithm is used to select the VCO band or if the band selected is based on the value in VCO band select (DB8 to DB3).

The VCO amplitude can be controlled through Register 6. The VCO amplitude setting can be controlled between 0 and 63. The default value of 8 should be set to a recommended value of 63.

The internal VCOs can be disabled using Register 6.

The internal charge pump can be disabled through Register 6. By default, the charge pump is enabled.

To turn off the PLL (for example, if the ADRF6701 is being driven by an external LO), set Register 6, Bits[20:17] to zero.

REGISTER 7—EXTERNAL VCO ENABLE AND SECOND LO DIVIDER

With Register 7, Bits[2:0] set to 111, the external VCO control register is programmed as shown in Figure 48.

The external VCO enable bit allows the use of an external VCO in the PLL instead of the internal VCO. This can be advantageous in cases where the internal VCO is not capable of providing the desired frequency or where the internal VCO's phase noise is higher than desired. By setting this bit (DB22) to 1, and setting Register 6, Bits[15:10] to 0, the internal VCO is disabled, and the output of an external VCO can be fed into the part differentially on Pin 38 and Pin 37 (LOP and LON). Because the loop filter is already external, the output of the loop filter simply needs to be connected to the external VCO's tuning voltage pin.

In addition, Register 7 provides control over a divide-by-2 block in the LO path using Bit DB4. If DB4 is set to 1, then the divideby-2 block is bypassed, and an external $2 \times$ LO can be used to drive the modulator.

CHARACTERIZATION SETUPS

Figure 49 and Figure 50 show characterization bench setups used to characterize the ADRF6701. The setup shown in Figure 49 was used to do most of the testing. An automated VEE program was used to control equipment over the IEEE bus. The setup was used to measure SSB, OIP2, OIP3, OP1dB, LO, and USB NULL. For phase noise and reference spurs measurements, see the phase noise setup on Figure 50. Phase noise was measured on LO and modulator output.

ADRF670x PHASE NOISE STAND SETUP ALL INSTRUMENTS ARE CONNECTED IN DAISY CHAIN FASHION VIA GBIP CABLE UNLESS OTHERWISE NOTED.

EVALUATION BOARD

Figure 52 shows the schematic of the device's RoHS-compliant evaluation board. This board was designed using Rogers 4350 material to minimize losses at high frequencies. FR4 material would also be adequate but with the slightly higher trace loss of this material.

Whereas the on-board USB interface circuitry of the evaluation board is powered directly from the PC, the main section of the evaluation board requires a separate 5 V power supply.

The evaluation board is designed to operate using the internal VCO (default configuration) of the device or with an external VCO. To use an external VCO, R62 and R12 should be removed. 0 Ω resistors should be placed in R63 and R11. A side-launched SMA connector (Johnson 142-0701-851) must be soldered to the pad labeled VTUNE. The input of the external VCO should be connected to the VTUNE SMA connector and a portion of the VCO's output should be connected to the EXT LO SMA connector. In addition to these hardware changes, internal register settings must also be changed (as detailed in the Register Description section) to enable operation with an external VCO.

Additional configuration options for the evaluation board are described in Table 11.

The serial port of the ADRF6701 can be programmed from a PC's USB port (a USB cable is provided with the evaluation board). The on-board USB interface circuitry can if desired be bypassed by removing the 0 Ω resistors, R15, R17, and R18 (see Figure 52) and driving the ADRF6701 serial interface through the P3 4-pin header (P3 must be first installed, Samtec TSW-104-08-G-S).

EVALUATION BOARD CONTROL SOFTWARE

USB-based programming software is available to download from the ADRF6701 product page at www.analog.com (Evaluation Board Software Rev 6.1.0). To install the software, download and extract the zip file. Then run the following installation file: ADRF6X0X_6p1p0_customer_installer.exe. To operate correctly under Windows XP, Version 3.5 of Microsoft .NET must be installed. To run the software on a Windows 7 PC, XP emulation mode must be used (using Virtual PC).

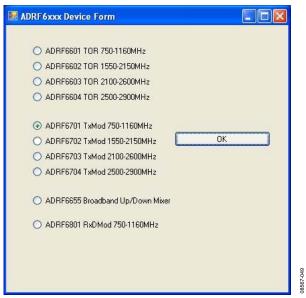

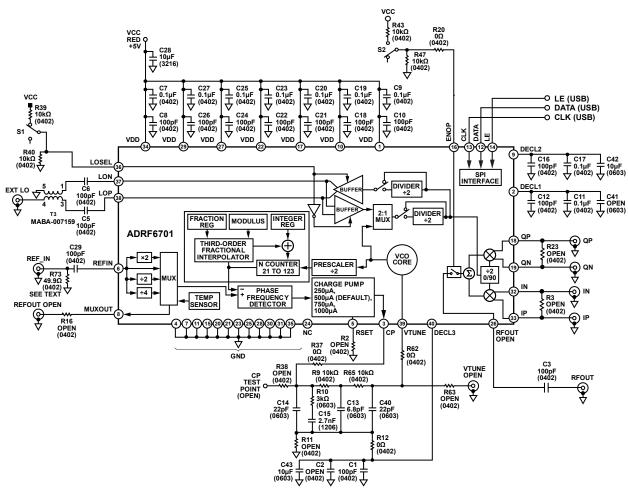

Figure 51. Control Software Opening Menu

Figure 51 shows the opening window of the software where the user selects the device being programmed. Figure 55 shows a screen shot of the control software's main controls with the default settings displayed. The text box in the bottom left corner provides an immediate indication of whether the software is successfully communicating with the evaluation board. If the evaluation board is connected to the PC via the USB cable provided and the software is successfully communicating with the on-board USB circuitry, this text box shows the following message: **ADRF6X0X eval board connected**.

Table 11. Evaluation Board Configuration Options

Component	Description	Default Condition/ Option Settings
S1, R39, R40	LO select. Switch and resistors to ground LOSEL pin. The LOSEL pin setting in combination with internal register settings, determines whether the LOP/LON pins function as inputs or outputs. With the LOSEL pin grounded, register settings can set the LOP/LON pins to be inputs or outputs.	
EXT LO, T3	LO input/output. An external $1 \times LO$ or $2 \times LO$ can be applied to this single-ended input connector. Alternatively, the internal $1 \times$ or $2 \times LO$ can be brought out on this pin. The differential LO signal on LOP and LON is converted to a single-ended signal using a broadband 1:1 balun (Macom MABA-007159, 4.5 MHz to 3000 MHz frequency range). The balun footprint on the evaluation board is also designed to accommodate Johanson baluns: 3600BL14M050 (1:1, 3.3 GHz to 3.9 GHz) and 3700BL15B050E (1:1, 3.4 GHz to 4 GHz).	T3 = Macom MABA-007159 EXT LO SMA connector = installed
REFIN SMA Connector, R73	Reference input. The input reference frequency for the PLL is applied to this connector. Input resistance is set by R73 (49.9 Ω).	F _{REFIN} = 153.6 MHz R73 = 49.9 Ω
REFOUT SMA Connector, R16	Multiplexer output. The REFOUT connector connects directly to the device's MUXOUT pin. The on-board multiplexer can be programmed to bring out the following signals: REFIN, 2× REFIN, REFIN/2, REFIN/4, Temperature sensor output voltage (VPTAT), Lock detect indicator.	REFOUT SMA connector = open R16 = open
CP Test Point, R38	Charge pump test point. The unfiltered charge pump signal can be probed at this test point. Note that this pin should not be probed during critical measurements such as phase noise.	CP = open R38 = open
C13, C14, C15, C40R9, R10, R37, R65 R11, R12, R62, R63, VTUNE SMA Connector	Loop filter. Loop filter components. Internal vs. external VCO. When the internal VCO is enabled, the loop filter components connect directly to the VTUNE pin (Pin 39) by installing a 0 Ω resistor in R62. In addition, the loop filter components should be returned to Pin 40 (DECL3) by installing a 0 Ω resistor in R12. To use an external VCO, R62 should be left open. A 0 Ω resistor should be installed in R63, and the voltage input of the VCO should be connected to the VTUNE SMA connector. The output of the VCO is brought back into the PLL via the LO IN/OUT SMA connector. In addition, the loop filter components should be returned to ground by installing a 0 Ω resistor in R11. Loop filter return.	See Table 8 R12 = 0 Ω (0402) R11 = open (0402) R62 = 0 Ω (0402) R63 = open (0402) VTUNE = open
R2	RSET. This pin is unused and should be left open.	R2 = open (0402)
R23, R3	Baseband input termination. Termination resistors for the baseband filter of the DAC can be placed on R23 and R3. In addition to terminating the baseband filters, these resistors also scale down the baseband voltage from the DAC without changing the bias level. These resistors are generally set in the 100 Ω to 300 Ω range.	R3 = R23 = open (0402)
P3 4-Pin Header, R15, R17, R18	USB circuitry bypass. The USB circuitry can be bypassed, allowing for the serial port of the ADRF6701 to be driven directly. P3 (Samtec TSW-104-08-G-S) must be installed, and 0 Ω resistors (R15, R17 and R18) must be removed.	P3 = open R15, R17, R18 = 0 Ω (0402)
