1 Introduction

1.1 FEATURES

- 14-Bit 85-MSPS High-Performance Single ADC
- At f_{IN} = 140 MHz, SNR ≥ 71 dBFS, SFDR ≥ 79 dBc
- At f_{IN} = 70 MHz, SNR ≥ 73 dBFS, SFDR ≥ 85 dBc
- Independent Clocks for ADC and DDC With Built-In FIFO
- Programmable Closed-Loop VGA Control With 6-Bit Outputs for ADC
- Received Total Wideband Power (RTWP) Measurement for the Composite Power Across Carriers With Programmable Time Window for Measurement
- 8 UMTS Digital Downconverter (DDC) Channels or 16 CDMA/TD-SCDMA DDC Channels With Programmable 18-Bit Filter Coefficients
- Each DDC Channel Provides:
  - Real or Complex DDC Inputs
  - UMTS Mode Rx Filtering: 6-Stage CIC (m = 1 or 2), up to 40-Tap CFIR, up to 64-Tap PFIR
  - CDMA Mode Rx Filtering: 6-Stage CIC (m = 1 or 2), up to 64-Tap CFIR, up to 64-Tap PFIR
  - Individual Channel-Specific Power Measurements
  - A Dedicated Final AGC
- Test Bus to Monitor Data at Different Stages of the DDC Signal Path
- 3.3-V Analog Supplies, 1.5-V Digital Core Supply, 3.3-V Digital I/O Supply
- 484-Ball Plastic BGA (23 mm × 23 mm) With 1,0-mm Pitch
- Power Dissipation (Eight Active DDC Channels): 2.3 W

1.2 APPLICATIONS

- Wireless Base Station Receiver
- Multi-Carrier Digital Receiver
- UMTS (8 Carriers-1 Sector)
- CDMA (16 Carriers-1 Sector)
- TD-SCDMA (16 Carriers-1 Sector)
- Digital Radio Receivers
- Wideband Receivers
- Software Radios
- Wireless Local Loop
- Intelligent Antenna Systems

Contents

2 General Description

The AFE8405 is a multichannel communications signal processor that provides analog-to-digital conversion and digital downconversion optimized for cellular base transceiver systems. The device supports UMTS, CDMA-1X, and TD-SCDMA air-interface cellular standards.

The AFE8405 provides up to 8 UMTS digital downconverter channels (DDC), 16 CDMA DDCs or 16 TD-SCDMA DDCs. The DDC channels are independent and operate simultaneously.

The AFE8405 DDCs have three input ports; one is hardwired to the internal 14-bit analog-to-digital converter (rxin_a) and two are 16-bit digital inputs (rxin_c, rxin_d). Each DDC channel can be programmed to accept data from any one of the three input ports; rxin_b is not used.

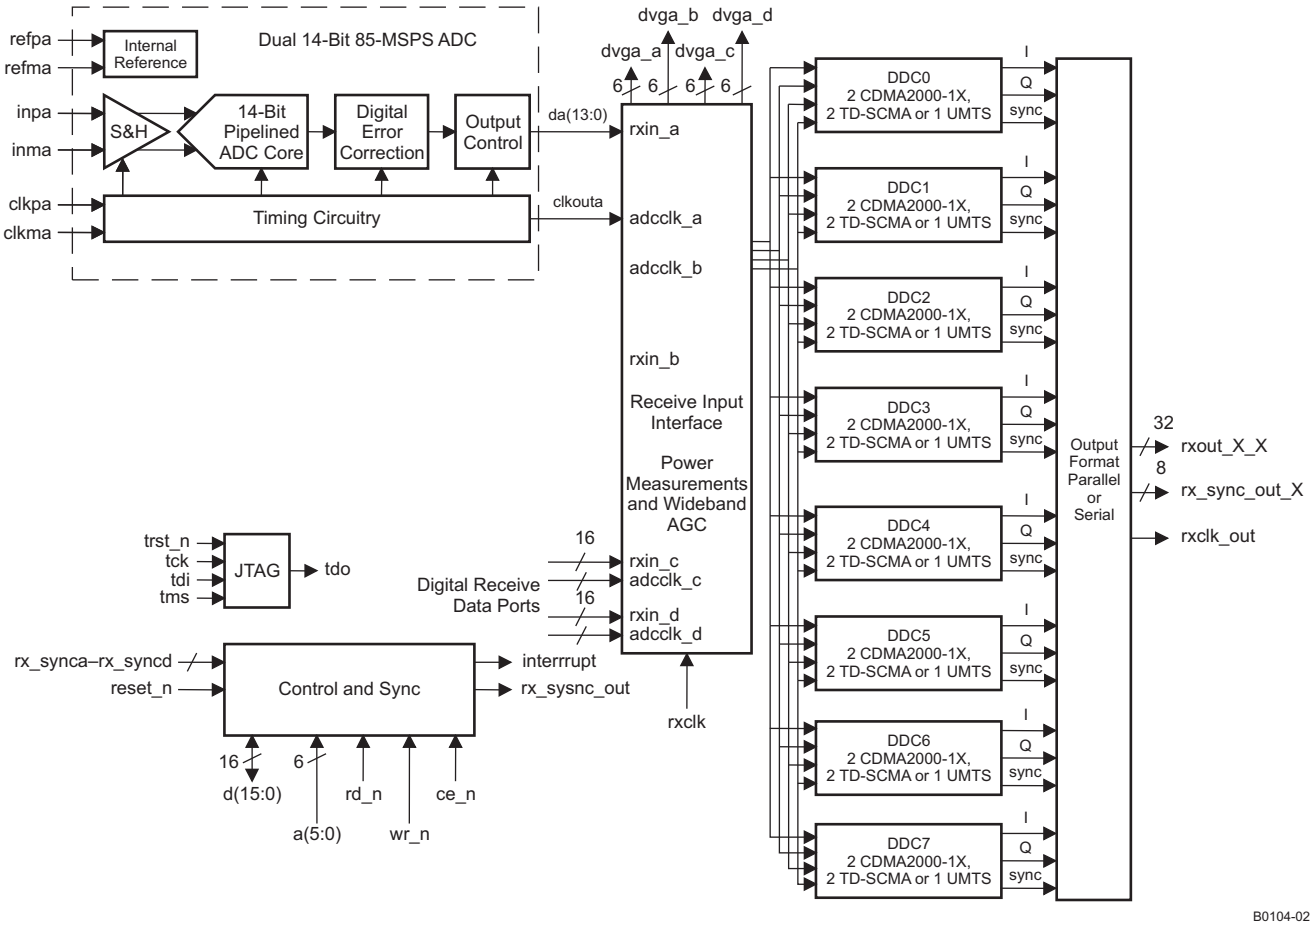

Figure 2-1. Functional Block Diagram

3 SPECIFICATIONS

3.1 PACKAGE ORDERING INFORMATION

PRODUCT	PACKAGE–LEADS	PACKAGE DESIGNATOR	SPECIFIED TEMPERATURE RANGE	PACKAGE MARKING	ORDERING NUMBER	TRANSPORT MEDIA, QUANTITY
AFE8405	Plastic BGA–484	ZDQ	–40°C to 85°C	AFE8405I	AFE8405IZDQ	Tray, 60

3.2 ABSOLUTE MAXIMUM RATINGS(1)

		UNIT
Analog Chip		
AVDD	Analog supply voltage	–0.3 V to 3.7 V
DRVDD	I/O ring supply voltage	–0.3 V to 3.7 V
	Ground difference DRVSS to AVSS	–0.1 V to 0.1 V
	Analog input voltage	–0.15 V to 3.6 V
	Digital input voltage	–0.3 V to DRVDD + 0.3 V
Digital Chip		
VDDS	Pad ring supply voltage	–0.3 V to 3.7 V
DVDD	Core supply voltage	–0.3 V to 1.8 V
	Digital input voltage	–0.3 V to VDDS + 0.3 V
Entire Chip		
	Clamp current for an input or output	–20 mA to 20 mA
T_{STG}	Storage temperature	–65°Cto 140°C
T_J	Junction temperature	105°C
	Lead soldering temperature (10 seconds)	300°C
	ESD classification (tested to EIA/JESD22-A114-B)	Class 2

(1) Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

3.3 RECOMMENDED OPERATING CONDITIONS

		MIN	NOM	MAX	UNIT
Analog Chip					
AVDD	Analog supply voltage	3	3.3	3.6	V
DRVDD	I/O ring supply voltage	3	3.3	3.6	V
V_{ID}	Differential input voltage range		2.3		V
VCM	Common-mode input voltage	1.5		1.6	V
	Differential clock inputs		3		V_{PP}
	Clock input duty cycle		50%		
Digital Chip					
VDDS	I/O ring supply voltage	3		3.6	V
DVDD	Core supply voltage	1.425		1.575	V
	Supply voltage difference, VDDS – DVDD			2	V
Entire Chip					
T_A	Temperature ambient, no air flow	–40		85	°C
T_J(1)	Junction temperature			105	°C

(1) Thermal management is required for full-rate operation. The circuit is designed for junction temperatures up to 125°C. Sustained operation at elevated temperatures reduces long-term reliability. Lifetime calculations based on maximum junction temperature of 105°C.

3.4 THERMAL CHARACTERISTICS

THERMAL CONDUCTIVITY (1)		MIN	TYP	MAX	UNIT
$R_{\theta JA}$	Theta junction-to-ambient (0 LFPM)		14		°C/W
	Theta junction-to-ambient (100 LFPM)		13		°C/W
	Theta junction-to-ambient (250 LFPM)		12.2		°C/W
	Theta junction-to-ambient (500 LFPM)		11.6		°C/W
$R_{\theta JC}$	Theta junction-to-case		2.8		°C/W

(1) Air flow reduces $R_{\theta JA}$ and is highly recommended.

3.5 POWER DISSIPATION

Typical values at T_A = 25°C, UMTS mode, sampling rate = 61.44 MSPS, and rxclk = 122.88 MHz (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_{AVDD}	Analog supply current	Six active DDC channels		123		mA
I_{DRVDD}	Analog I/O supply current			21.5		mA
I_{DVDD}	Digital core supply current			959		mA
I_{VDDS}	Digital I/O supply current (1)			100		mA
	Analog power dissipation			477		mW
	Digital power dissipation (2)			1.439		W
	Total power dissipation (2)			1.9		W
I_{AVDD}	Analog supply current	Eight active DDC channels		123		mA
I_{DRVDD}	Analog I/O supply current			21.5		mA
I_{DVDD}	Digital core supply current			1.198		A
I_{VDDS}	Digital I/O supply current (1)			115		mA
	Analog power dissipation			477		mW
	Digital power dissipation (2)			1.797		W
	Total power dissipation (2)			2.3		W

(1) Current consumption on the digital I/O supply is primarily due to the external loads and follows $C \times V \times F$. Internal loads are estimated at 2 pF per terminal. Data outputs transition once every four clocks, whereas clock outputs transition every cycle. In general, $I_{VDDS} = \Sigma\ (DataPad/4) \times C \times V \times F + \Sigma\ ClockPad \times C \times V \times F$.

(2) Excluding current consumption from the digital I/O supply, which is dependent on external loads

3.6 ANALOG ELECTRICAL CHARACTERISTICS

Typical values at T_A = 25°C, minimum and maximum values over temperature range of T_A = –40°C to 85°C, sampling rate = 80 MSPS, 50% clock duty cycle, AVDD = DRVDD = 3.3 V, –1-dBFS differential input, internal reference, and 3-VPP differential clock (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
	Resolution			14		Bits
Analog Inputs						
V_{ID}	Differential input voltage range			2.3		V_{PP}
C_{ID}	Differential input capacitance			3.2		pF
I_{IC}	Common-mode input current	2 mA per input, 4 mA total		4		mA
	Analog input bandwidth	Source impedance = 50 Ω		750		MHz
Conversion Characteristics						
f_{ADC}	ADC clock rate (f_{clkpa} = f_{clkma} = f_{ADC})	f_{rxclk} = 1 × f_{ADC} ch_rate_sel = rate_sel = 00			85	MSPS
		f_{rxclk} = 2 × f_{ADC} ch_rate_sel = rate_sel = 01			80	
		f_{rxclk} = 4 × f_{ADC} ch_rate_sel = rate_sel = 10			40	
		f_{rxclk} = 8 × f_{ADC} ch_rate_sel = rate_sel = 11			20	
	Data latency – ADC input to FIFO input			16.5		Clock Cycles
Internal Reference Voltages						
refma	Lower reference voltages			1		V
refpa	Upper reference voltages			2.15		V
	Reference error			±3.5		% of FS
cma	Common-mode output voltages			1.55 ±0.05		V
Dynamic DC Characteristics and Accuracy						
	No missing codes			tested		
DNL	Differential linearity error	f_{IN} = 1 MHz		±0.65		LSBs
INL	Integral linearity error	f_{IN} = 1 MHz		±4		LSBs
	Offset error			±4		mV
	Offset temperature coefficient			7		µV/°C
	Gain error			±0.5		% of FS
	Gain temperature coefficient			0.0015		Δ%/°C
Dynamic AC Characteristics						
SNR	Signal-to-noise ratio	f_{IN} = 10 MHz, T_A = 25°C		74.5		dBFS
		f_{IN} = 30 MHz		74		
		f_{IN} = 50 MHz		73.5		
		f_{IN} = 70 MHz, T_A = 25°C		73.5		
		f_{IN} = 70 MHz, T_A =25°C to 85°C	70	73		
		f_{IN} = 70 MHz, T_A –40°C	69	73		
		f_{IN} = 130 MHz		71.5		
		f_{IN} = 170 MHz		70.5		
		f_{IN} = 230 MHz		69		
	RMS output noise	INPA and INMA tied to CMA		1.1		LSBs

ANALOG ELECTRICAL CHARACTERISTICS *(continued)*

Typical values at T_A = 25°C, minimum and maximum values over temperature range of T_A = –40°C to 85°C, sampling rate = 80 MSPS, 50% clock duty cycle, AVDD = DRVDD = 3.3 V, –1-dBFS differential input, internal reference, and 3-VPP differential clock (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
Dynamic AC Characteristics (Continued)						
SFDR	Spurious free dynamic range	f_{IN} = 10 MHz, T_A = 25°C		84		dBc
		f_{IN} = 30 MHz		83.5		
		f_{IN} = 50 MHz		84		
		f_{IN} = 70 MHz, T_A = 25°C		85		
		f_{IN} = 70 MHz, T_A = –40°C to 85°C	77	82		
		f_{IN} = 130 MHz		81		
		f_{IN} = 170 MHz		76		
		f_{IN} = 230 MHz		68.5		
HD2	Second harmonic	f_{IN} = 10 MHz, T_A = 25°C		95.8		dBc
		f_{IN} = 30 MHz		95		
		f_{IN} = 50 MHz		97.5		
		f_{IN} = 70 MHz, T_A = 25°C		95		
		f_{IN} = 130 MHz		81.5		
		f_{IN} = 170 MHz		76		
		f_{IN} = 230 MHz		68.5		
HD3	Third harmonic	f_{IN} = 10 MHz, T_A = 25°C		84		dBc
		f_{IN} = 30 MHz		83.5		
		f_{IN} = 50 MHz		82.5		
		f_{IN} = 70 MHz, T_A = 25°C		85		
		f_{IN} = 130 MHz		92		
		f_{IN} = 170 MHz		79		
		f_{IN} = 230 MHz		83		
	Worst harmonic/spur other than HD2 or HD3	f_{IN} = 10 MHz, T_A = 25°C		95.5		dBc
		f_{IN} = 70 MHz, T_A = 25°C		95		
SINAD	Signal-to-noise plus distortion	f_{IN} = 10 MHz, T_A = 25°C		74		dBFS
		f_{IN} = 30 MHz		73.5		
		f_{IN} = 50 MHz		73.5		
		f_{IN} = 70 MHz, T_A = 25°C		73		
		f_{IN} = 70 MHz, T_A = 25°C to 85°C	70	72		
		f_{IN} = 70 MHz, T_A = –40°C	69	72		
		f_{IN} = 130 MHz		71		
		f_{IN} = 170 MHz		69		
		f_{IN} = 230 MHz		66		
THD	Total harmonic distortion	f_{IN} = 10 MHz, T_A = 25°C		82.5		dBc
		f_{IN} = 30 MHz		82		
		f_{IN} = 50 MHz		82		
		f_{IN} = 70 MHz, T_A = 25°C		83.5		
		f_{IN} = 130 MHz		80		
		f_{IN} = 170 MHz		74		
		f_{IN} = 230 MHz		68		
	Channel-to-channel crosstalk	f_{IN} = 225 MHz		95		dBc

3.7 DIGITAL CHIP DC CHARACTERISTICS

T_A = –40°C to 85°C (unless otherwise noted)

PARAMETER(1) (2)(3)		TEST CONDITIONS	VDDS = 3 V to 3.6 V			UNIT
			MIN	TYP	MAX	
V_{IL}	Voltage input, low				0.8	V
V_{IH}	Voltage input, high		2			V
V_{OL}	Voltage output, low(4)	I_{OL} = 2 mA			0.5	V
V_{OH}	Voltage output high(4)	I_{OH} = –2 mA	2.4		VDDS	V
$\|I_{PU}\|$	Pullup current (**tdi, tms, trst_n, ce_n, wr_n, rd_n, reset_n**)(4)	V_{IN} = 0 V, nominal 20 A	5		35	µA
$\|I_{PD}\|$	Pulldown current (all other inputs and bidirectionals)(4)	V_{IN} = VDDS, nominal 20 µA	5		35	µA
$\|I_{IN}\|$	Leakage current(4)	V_{IN} = 0V or VDDS, outputs in high-impedance state			20	µA
I_{DDQ}	Quiescent supply current, IDVDD or IVDDS(4)	V_{IN} = 0 for pads with pulldowns, V_{IN} = VDDS for inputs with pullups		8		mA
C_{IN}	Capacitance for inputs(5)			5		pF
C_{BI}	Capacitance for bidirectionals(5)			5		pF

(1) Voltages are measured at low speed. Output voltages are measured with the indicated current load.
(2) Currents are measured at nominal voltages, high temperature.
(3) reset_n and interrupt have no timing specifications because they are asynchronous signals.
die_id pins fa002_out, fa002_clk, and fa002_scan are not specified and are for factory use only.
fuse pin fuse_out is not specified and is for factory use only.
test pins zero, scanen, testmode0 and testmode1 are not specified and are for factory use only.
(4) Each part is tested at high temperature for the given specification. Lots are sample tested at –40°C.
(5) Controlled by design and process and not directly tested.

3.8 DIGITAL CHIP AC TIMING CHARACTERISTICS(1)

T_A = –40°C to 85°C (unless otherwise noted)

PARAMETER		MIN	TYP	MAX	UNIT
f_{CK}	Clock frequency (**adcclk_a/b/c/d, rxclk**)(2)			160	MHz
t_{CKL}	Clock low period (below V_{IL}) (**adcclk_a/b/c/d, rxclk**)(2)	2			ns
t_{CKH}	Clock high period (above V_{IH}) (**adcclk_a/b/c/d, rxclk**)(2)	2			ns
t_{RF}	Clock rise and fall times (V_{IL} to V_{IH}) (**adcclk_a/b/c/d, rxclk**)(3)			2	ns
t_{SU}	Input setup (**rx_sync[a–d]**) before **rxclk** rises(2)	2			ns
	Input setup (**rxin_a/b/c/d_[0-15]**) before **rxclk** rises (ADC FIFO blocks bypassed)(2)	2			
	Input setup (**rxin_a/b/c/d_[0-15]**) before **adcclk_a/b/c/d** rises (ADC FIFO blocks enabled)(2)	2			
t_{HD}	Input hold (**rx_sync[a–d**]) after **rxclk** rises(2)	1			ns
	Input hold (**rxin_a/b/c/d_[0-15]**) after **rxclk** rises (adc fifo blocks bypassed)(2)	2.5			
	Input hold (**rxin_ a/b/c/d_[0-15]**) after **adcclk_a/b/c/d** rises (adc fifo blocks enabled)(2)	1			
t_{DLY}	Data output delay (**rx_sync_out_[0-7], rxout_[0-7]_a/b/c/d, rxclk_out, rx_sync_out, dvga_[a-d]_[5-0]**) after **rxclk** rises.(2)			7	ns
t_{OHD}	Data output hold **(rx_sync_out_[0-7], rxout_[0-7]_a/b/c/d, rxclk_out, rx_sync_out, dvga_[a-d]_[5-0]**) after **rxclk** rises.(2)	0.5			ns
f_{JCK}	JTAG clock frequency (**tck**)(2)			40	MHz
t_{JCKL}	JTAG clock low period (below V_{IL}) (**tck**)(2)	10			ns
t_{JCKH}	JTAG clock high period (above V_{IH}) (**tck**)(2)	10			ns
t_{JSU}	JTAG input (**tdi** or **tms**) setup before **tck** goes high(2)	2			ns
t_{JHD}	JTAG input (**tdi** or **tms**) hold time after **tck** goes high(2)	10			ns
t_{JDLY}	JTAG output (**tdo**) delay from falling edge of **tck**.(2)			10	ns
t_{CSU}	Control setup during reads or writes 3 pin mode: **a[5:0]** valid before **rd_n, wr_n or ce_n** falling edge 2 pin mode: **a[5:0]** and **wr_n** valid before **ce_n** falling edge(2)	6			ns
t_{EWCSU}	Control setup during writes 3 pin mode: **d[15:0]** valid before **wr_n** and **ce_n** rising edge 2 pin mode: **d[15:0]** valid before **ce_n** rising edge(2)	10			ns
t_{CHD}	Control hold during writes. 3 pin mode: **a[5:0]** and **d[15:0]** valid after **wr_n** and **ce_n** rise 2 pin mode: **a[5:0], d[15:0]** and **wr_n** valid after **ce_n** rise(2)	6			ns
t_{CSPW}	Control strobe (**ce_n** and **wr_n** low) pulse duration during write.(2)	25			ns
t_{CDLY}	Control output delay **ce_n** and **rd_n** low and **a[5:0]** stable to **d[15:0]** during read.(2)			25	ns
t_{REC}	Control recovery time between reads or writes. (2)			6	ns
t_{HIZ}	Control end of read to Hi-Z. **rd_n** and **ce_n** rise to **d[15:0]** 3-state(4)			10	ns
t_{COH}	Control read **d[15:0]** output hold time	1			ns

(1) Timing is measured from the respective clock at VDDS/2 to input or output at VDDS/2. Output loading is a 50-Ω transmission line whose delay is calibrated out.
(2) Each part is tested at 90°C case temperature for the given specification. Lots are sample tested at –40°C.
(3) Recommended practice
(4) Controlled by design and process and not directly tested.

4.1 Analog Section Signals

Signal Name	Ball	Type	Description
inpa	F3	Input	ADCA analog positive input
inma	F4	Input	ADCA analog negative input
NC	V4	—	
NC	V3	—	
clkpa	H1	Input	ADCA clock positive input
clkma	J1	Input	ADCA clock negative input
NC	R1	—	
NC	T1	—	
refpa	L3	Input	ADCA positive reference input. connect 0.1 μF to AVSS.
refma	K3	Input	ADCA negative reference input; connect 0.1 μF to AVSS.
NC	P3	—	
NC	N3	—	
cma	H3	Output	ADCA common-mode output reference
NC	T3	—	
iref	M3	Input	Current set; connect 56 kΩ to AVSS
clkouta	n/a	Output	ADCA output clock; internally connected to adcclka
da(13:0)	n/a	Output	ADCA output data; internally connected to rxin_a_15:2
fuse_sel	H5	Input	Connect to AVSS; factory use only
pwdn	L9	Input	Connect to AVDD, ADCA output enable; AVDD = enabled, AVSS = disabled
GND	N9	Input	
ovra	G6	Output	ADCA over range indicator bit
NC	N8	—	
pin_configure	T5	Input	Connect to AVDD, factory use only
dll_disable	N10	Input	Connect to AVDD, factory use only
AVDD	M9	Input	
ext_ref	M10	Input	Connect to AVSS, AVDD = external reference, AVSS = internal reference

4.2 Digital Receive Section Signals

Signal Name	Ball	Type	Description
rxclk	R22	Input	Receive digital section clock input
adcclk_a	n/a	Input	rxin_a_x input clock; connected to ADCA output clock
adcclk_b	n/a	Input	Not used, not connected internally
adcclk_c	AA11	Input	rxin_c_x input clock
adcclk_d	AB11	Input	rxin_d_x input clock
rxin_c_ovr	AB6	Input	ADC overflow/overrange bit for rxin_c
rxin_d_ovr	V12	Input	ADC overflow/overrange bit for rxin_d
dvga_a_5	D7	Output	Digital VGA control output for ADC0 MSB
dvga_a_4	D8	Output	Digital VGA control output for ADC0
dvga_a_3	C7	Output	Digital VGA control output for ADC0
dvga_a_2	B7	Output	Digital VGA control output for ADC0
dvga_a_1	A7	Output	Digital VGA control output for ADC0
dvga_a_0	C8	Output	Digital VGA control output for ADC0 LSB
dvga_b_5	B8	Output	Not used
dvga_b_4	A8	Output	Not used
dvga_b_3	D9	Output	Not used
dvga_b_2	D10	Output	Not used
dvga_b_1	C9	Output	Not used
dvga_b_0	B9	Output	Not used
dvga_c_5	AA15	Output	Digital VGA control output for rxin_c MSB, test bus bit 1
dvga_c_4	AB15	Output	Digital VGA control output for rxin_c, test bus bit 0
dvga_c_3	V16	Output	Digital VGA control output for rxin_c, test bus bit 19
dvga_c_2	W16	Output	Digital VGA control output for rxin_c, test bus bit 18
dvga_c_1	Y16	Output	Digital VGA control output for rxin_c, test bus CLK
dvga_c_0	AA16	Output	Digital VGA control output for rxin_c LSB, test bus SYNC
dvga_d_5	AB16	Output	Digital VGA control output for rxin_d MSB, test bus AFLAG
dvga_d_4	V17	Output	Digital VGA control output for rxin_d
dvga_d_3	W17	Output	Digital VGA control output for rxin_d
dvga_d_2	AA17	Output	Digital VGA control output for rxin_d
dvga_d_1	AB17	Output	Digital VGA control output for rxin_d
dvga_d_0	V18	Output	Digital VGA control Output for rxin_d LSB
rxin_c_15	Y7	Input/output	Receive input data bus c bit 15 (MSB), test bus bit 17
rxin_c_14	AA7	Input/output	Receive input data bus c bit 14, test bus bit 16
rxin_c_13	AB7	Input/output	Receive input data bus c bit 13, test bus bit 15
rxin_c_12	Y8	Input/output	Receive input data bus c bit 12, test bus bit 14
rxin_c_11	V10	Input/output	Receive input data bus c bit 11, test bus bit 13
rxin_c_10	AA8	Input/output	Receive input data bus c bit 10, test bus bit 12
rxin_c_9	AB8	Input/output	Receive input data bus c bit 9, test bus bit 11
rxin_c_8	W9	Input/output	Receive input data bus c bit 8, test bus bit 10
rxin_c_7	Y9	Input/output	Receive input data bus c bit 7, test bus bit 9
rxin_c_6	AA9	Input/output	Receive input data bus c bit 6, test bus bit 8
rxin_c_5	AB9	Input/output	Receive input data bus c bit 5, test bus bit 7
rxin_c_4	W10	Input/output	Receive input data bus c bit 4, test bus bit 6
rxin_c_3	Y10	Input/output	Receive input data bus c bit 3, test bus bit 5

Signal Name	Ball	Type	Description
rxin_c_2	AA10	Input/output	Receive input data bus c bit 2, test bus bit 4
rxin_c_1	AB10	Input/output	Receive input data bus c bit 1, test bus bit 3
rxin_c_0	W11	Input/output	Receive input data bus c bit 0 (LSB), test bus bit 2
rxin_d_15	W12	Input/output	Receive input data bus d bit 15 (MSB), test bus bit 35
rxin_d_14	Y12	Input/output	Receive input data bus d bit 14, test bus bit 34
rxin_d_13	AA12	Input/output	Receive input data bus d bit 13, test bus bit 33
rxin_d_12	AB12	Input/output	Receive input data bus d bit 12, test bus bit 32
rxin_d_11	V13	Input/output	Receive input data bus d bit 11, test bus bit 31
rxin_d_10	W13	Input/output	Receive input data bus d bit 10, test bus bit 30
rxin_d_9	Y13	Input/output	Receive input data bus d bit 9, test bus bit 29
rxin_d_8	AA13	Input/output	Receive input data bus d bit 8, test bus bit 28
rxin_d_7	AB13	Input/output	Receive input data bus d bit 7, test bus bit 27
rxin_d_6	V14	Input/output	Receive input data bus d bit 6, test bus bit 26
rxin_d_5	W14	Input/output	Receive input data bus d bit 5, test bus bit 25
rxin_d_4	AA14	Input/output	Receive input data bus d bit 4, test bus bit 24

interrupt	M21	Output	Chip interrupt

4.4 JTAG Signals

Signal Name	Ball	Type	Description
tdi	K22	Input	JTAG test data in
tms	K21	Input	JTAG test mode select
trst_n	J22	Input	JTAG test reset *Note: the trst_n pin should be asserted low after power up to insure the JTAG logic is properly initialized.*
tck	L20	Input	JTAG test clock
tdo	L21	Output	JTAG test data out

4.5 Factory Test and No-Connect Signals

Signal Name	Ball	Type	Description
testmode0	G21	Input	Do not connect; internal pulldown
testmode1	G22	Input	Do not connect; internal pulldown
scanen	H21	Input	Do not connect; internal pulldown
fa002_scan	J20	Input	Do not connect; internal pulldown
fa002_clk	H22	Input	Do not connect; internal pulldown
fa002_out	J21	Output	Do not connect
zero	H20	Input	Do not connect; internal pulldown
fuse_out	F20	Output	Do not connect
fuse_ena	D21	Input	Do not connect; internal pulldown
fuse_bias	F21	Input	Do not connect; internal pulldown

4.6 Power and Ground Signals

Signal Name	Ball	Description
AVDD	H4, J3, L1, L2, M1, M2, M9, N1, N2, R3, T4	Analog power (3.3 V)
DRVDD	H6, H7, J8, K8, L8, P8, R8, T6, T7	Analog I/O power (3.3 V)
AVSS	A1, A2, A3, A4, A5, B1, B2, B3, B4, B5, C1, C2, C3, C4, C5, D1, D2, D3, D4, D5, E1, E2, E3, E4, E5, F1, F2, F5, F6, F7, F8, F9, G1, G2, G3, G4, G5, G7, G8, G9, H2, J2, J4, J5, J6, K1, K2, K4, K5, K6, L4, L5, L6, L7, M4, M5, M6, M7, N4, N5, N6, N7, N9, P1, P2, P4, P5, P6, R2, R4, R5, R6, T2, U1, U2, U3, U4, U5, U6, U7, U8, U9, V1, V2, V5, V6, V7, V8, W1, W2, W3, W4, W5, Y1, Y2, Y3, Y4, AA1, AA2, AA3, AA4, AB1, AB2, AB3, AB4	Analog ground
DRVSS	H8, H9, J7, J9, K7, K9, M8, P7, P9, R7, R9, T8, T9	Analog I/O ground
VDDS	B6, B21, D6, D11, D19, D22, E10, E11, E12, E13, E14, E15, E16, E17, E18, E19, K20, M20, P20, U11, U12, U13, U14, U15, U16, U17, U18, U19, V11, W7, AA6, AA21	Digital I/O power (3.3 V), also called Vpad
DVDD	F22, G10, G19, H10, H19, J10, J19, K10, K19, L10, L19, M19, N19, P10, P19, R10, R19, V22	Digital core power (1.5 V), also called Vcore
DVSS	A6, A21, A22, B22, C6, C10, C14, C18, C22, E6, E7, E8, E9, E20, F10, F11, F12, F13, F14, F15, F16, F17, F18, F19, G11, G12, G13, G14, G15, G16, G17, G18, G20, H11, H12, H13, H14, H15, H16, H17, H18, J11, J12, J13, J14, J15, J16, J17, J18, K11, K12, K13, K14, K15, K16, K17, K18, L11, L12, L13, L14, L15, L16, L17, L18, M11, M12, M13, M14, M15, M16, M17, M18, N11, N12, N13, N14, N15, N16, N17, N18, N22, P11, P12, P13, P14, P15, P16, P17, P18, R11, R12, R13, R14, R15, R16, R17, R18, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, U10, U20, V9, W6, W8, Y5, Y6, Y11, Y14, Y17, AA5, AA22, AB5, AB21, AB22	Digital ground

4.7 Digital Supply Monitoring

Signal Name	Ball	Description
dvddmon	L22	It is recommended that this pin be brought to a probe point for monitoring and debugging purposes.
dvssmon	M22	It is recommended that this pin be brought to a probe point for monitoring and debugging purposes.

4.8 JTAG

The JTAG standard for boundary scan testing is implemented for board testing purposes. Internal scan test is not supported. Five device pins are dedicated for JTAG support: tdi, tdo, tms, tck, and trst_n. The JTAG bsdl configuration file is available at www.ti.com.

NOTE

The trst_n pin should be asserted after power up to insure the JTAG logic is properly initialized.

4.9 AFE8405 and AFE8406 PCB Design Compatibility

The AFE8406 is 14-bit, 85-MSPS, dual-ADC, 8-channel wideband receiver. AFE8405 has a pin- and software-compatible upgrade to AFE8406 for diversity applications. Attention must be paid to the configuration of pins L9, M9, and N9 for PCB design to support AFE8405 and AFE8406 compatibility.

The ADC power-management system is configured by pins L9, M9, and N9. AFE8405/8406 signal names of pin L9, M9 and N9 are shown in the following table.

BALL NO.	AFE8405 SIGNAL NAME	AFE8406 SIGNAL NAME	COMMENT
L9	pwdn	oea	AFE8405 ADCA output enable: AVDD = enable; AVSS = disable
M9	AVDD	pwdn	
N9	GND	oeb	

The AFE8406 has two ADCs (ADCA and ADCB). Their ADC output and power on/off states are configured by pins L9, M9, and N9 as shown in following table.

AFE8406						
M9	L9	N9	Out A	Out B	ADC A	ADC B
0	0	0	Off	Off	On	On
0	0	1	Off	On	On	On
0	1	0	On	Off	On	On
0	1	1	On	On	On	On
1	0	0	Off	Off	Off	Off
1	0	1	Off	On	Off	On
1	1	0	On	Off	On	Off
1	1	1	On	On	On	On

The AFE8405 has one ADC (ADCA). Its output and power on/off states are configured by pin L9. When the ADC is enabled, the configuration corresponds to the AFE8406 configuration with (M9, L9, N9) = (1, 1, 0), which is ADCA on and ADCB off.

The AFE8405 L9, M9, and N9 configuration is recommended for new designs using AFE8405. For current AFE8406 users who would like to use AFE8405 on an AFE8406 PCB for single-ADC applications, if L9, M9, and N9 are in a state where ADCB is is not powered down, device functionality and performance is not affected, but this state results in higher power dissipation.

6 ANALOG-TO-DIGITAL CONVERTERS

The AFE8405 includes a high-performance, single-channel, 14-bit, 85-MSPS analog-to-digital converter (ADC). To provide a complete solution, the ADC channel includes a high-bandwidth linear sample-and-hold stage (S&H) and internal reference. An internal reference is provided, simplifying system design requirements, yet an external reference can be used optionally to suit the accuracy and low-drift requirements of the application.

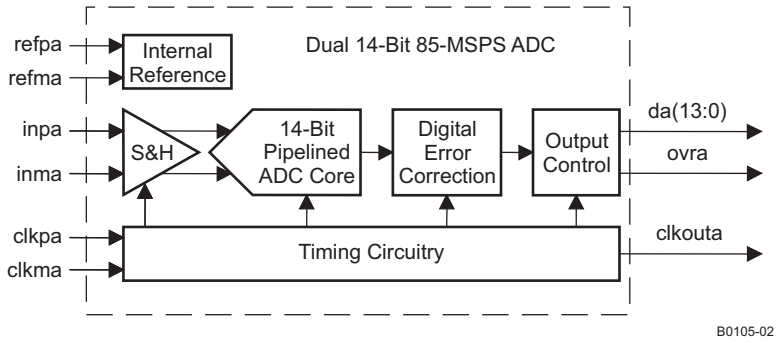

Figure 6-1. ADC Block Diagram

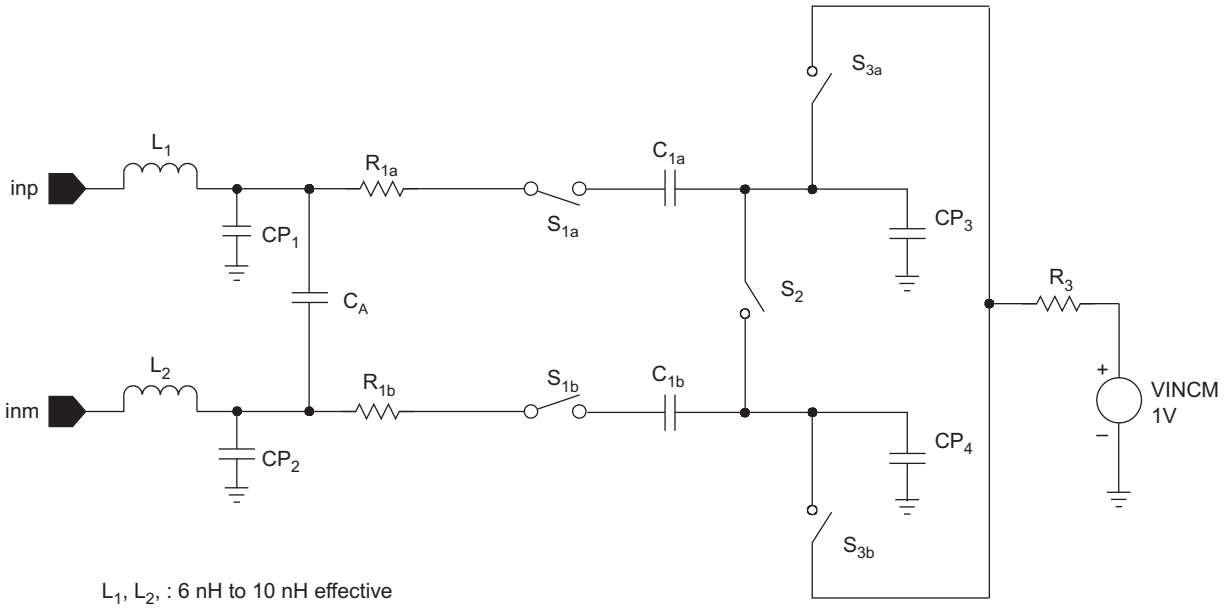
The ADC digital output data and output clocks are connected directly to the rxin_a port of the AFE8405 digital section. The ovra output connects directly to the AFE8405 digital section and also to a package ball. The ADC outputs can be accessed through the test bus in decimate-by-32× mode only.

6.1 ADC Operation

The conversion process is initiated by a falling edge of the external input clocks. Once the signal is captured by the input S&H, the input sample is sequentially converted by a series of small resolution stages, with the outputs combined in a digital correction logic block. Both the rising and the falling clock edges are used to propagate the sample through the pipeline every half clock cycle. This process results in data latency of 16.5 clock cycles, after which the output data is available as a 14-bit parallel word, coded in binary 2s-complement format to the AFE8405 receive section.

6.2 ADC Input Configuration

The analog input for the ADC consists of a differential sample-and-hold architecture implemented using a switched-capacitor technique shown in Figure 6-2.



L_1, L_2, : 6 nH to 10 nH effective
R_{1a}, R_{1b} : 5 Ω to 8 Ω
C_{1a}, C_{1b} : 2.2 pF to 2.6 pF
CP_1, CP_2 : 1.8 pF to 2.2 pF
CP_3, CP_4 : 1.2 pF to 1.8 pF
C_A : 0.8 pF to 1.2 pF
R_3 : 80 Ω to 120 Ω
Switches : S_{1a}, S_{1b} : On Resistance : 35 Ω to 50 Ω
S_2 : On Resistance : 7.5 Ω to 15 Ω
S_{3a}, S_{3b} : On Resistance : 40 Ω to 60 Ω
All switches Off Resistance : 10 GΩ

All switches are on in sampling phase which is approximately one half of a clock period.

S0175-01

Figure 6-2. Analog Input Stage

This differential input topology produces a high level of ac performance for high sampling rates. It also results in a high usable input bandwidth, especially important for high intermediate-frequency (IF) or undersampling applications. The ADC requires each of the analog inputs (inp, inm) to be externally biased around the common-mode level of the internal circuitry (cmx). For a full-scale differential input, each of the differential lines of the input signal swings symmetrically between cm + 0.575 V and cm – 0.575 V. This means that each input is driven with a signal of up to cm ± 0.575 V, so that each input has a maximum differential signal of 1.15 V_{PP} for a total differential input signal swing of 2.3 V_{PP}. The maximum swing is determined by the two reference voltages, the top reference (refpa) and the bottom reference (refma).

The ADC obtains optimum performance when the analog inputs are driven differentially. The circuit shown in Figure 6-3 shows one possible configuration using an RF transformer.

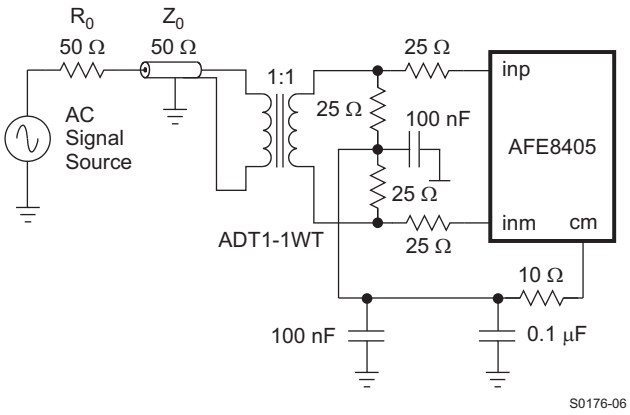


Figure 6-3. Transformer Input to Convert Single-Ended Signal to Differential Signal

The single-ended signal is fed to the primary winding of an RF transformer. Because the input signal must be biased around the common-mode voltage of the internal circuitry, the common-mode voltage (V_{CM}) from the ADC is connected to the center-tap of the secondary winding. To ensure a steady low-noise V_{CM} reference, best performance is obtained when the common-mode output is filtered to ground with a 10-Ω series resistor and parallel 0.1-µF and 0.001-µF low-inductance capacitors.

Output V_{CM} is designed to drive the ADC input directly. When providing a custom common-mode level, be aware that the input structure of the ADC sinks a common-mode current in the order of 200 µA (100 µA per input). Equation 6-1 describes the dependency of the common-mode current and the sampling frequency:

$$20 + \frac{400\mu A \times f_s(\text{in MSPS})}{125\ \text{MSPS}} \quad (6\text{-}1)$$

This equation helps to design the output capability and impedance of the driving circuit accordingly.

When it is necessary to buffer or apply a gain to the incoming analog signal, it is possible to combine single-ended operational amplifiers with an RF transformer, or to use a differential input/output amplifier without a transformer, to drive the input of the AFE8405 ADC. Texas Instruments offers a wide selection of single-ended operational amplifiers (including the THS3201, THS3202, OPA847, and OPA695) that can be selected depending on the application. An RF gain block amplifier, such as Texas Instruments THS9001, can also be used with an RF transformer for high-input-frequency applications. The THS4503/6/9 are recommended differential input/output amplifiers. Table 6-1 lists the recommended amplifiers.

Table 6-1. Recommended Amplifiers to Drive the Input of the AFE8405

INPUT SIGNAL FREQUENCY	RECOMMENDED AMPLIFIER	TYPE OF AMPLIFIER	USE WITH TRANSFORMER?
DC to 20 MHz	THS4503/6/9	Differential in/out amplifier	No
DC to 50 MHz	OPA847	Operational amplifier	Yes
10 MHz to 120 MHz	OPA695	Operational amplifier	Yes
	THS3201	Operational amplifier	Yes
	THS3202	Operational amplifier	Yes
Over 100 MHz	THS9001	RF gain block	Yes

When using single-ended operational amplifiers (such as the THS3201, THS3202, OPA847, or OPA695) to provide gain, a three-amplifier circuit is recommended with one amplifier driving the primary of an RF transformer and one amplifier in each of the legs of the secondary driving the two differential inputs of the ADC. These three amplifier circuits minimize even-order harmonics. For high-frequency inputs, an RF gain block amplifier can be used to drive a transformer primary; in this case, the transformer secondary connections can drive the input of the ADC directly, as shown in Figure 6-3, or with the addition of the filter circuit shown in Figure 6-4.

Figure 6-4 illustrates how R_{IN} and C_{IN} can be placed to isolate the signal source from the switching inputs of the ADC and to implement a low-pass RC filter to limit the input noise in the ADC. It is recommended that these components be included in the AFE8405 circuit layout when any of the amplifier circuits discussed previously are used. The components allow fine-tuning of the circuit performance. Any mismatch between the differential lines of the ADC input produces a degradation in performance at high input frequencies, mainly characterized by an increase in the even-order harmonics. In this case, special care should be taken to keep as much electrical symmetry as possible between both inputs.

Another possible configuration for lower-frequency signals is the use of differential input/output amplifiers that can simplify the driver circuit for applications requiring dc coupling of the input. Flexible in their configurations (see Figure 6-5), such amplifiers can be used for single-ended-to-differential conversion and signal amplification.

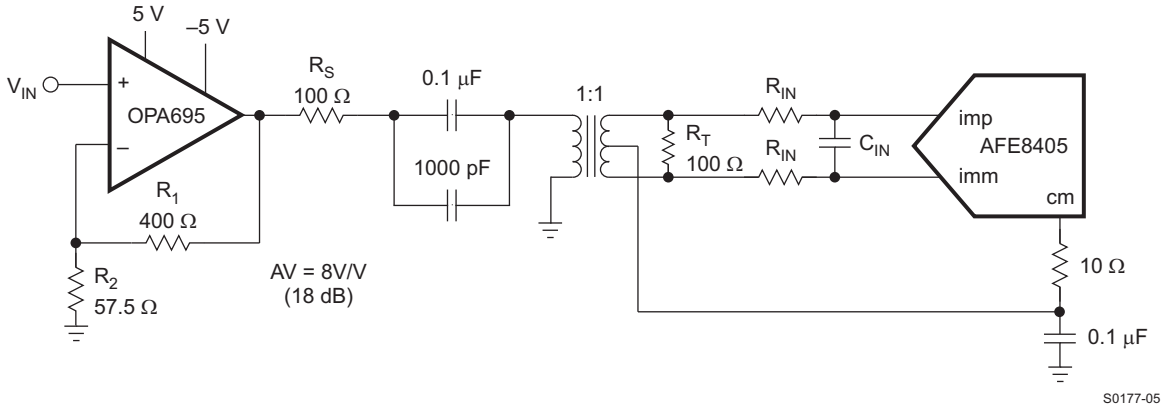

Figure 6-4. Converting a Single-Ended Input Signal to a Differential Signal Using an RF Transformer

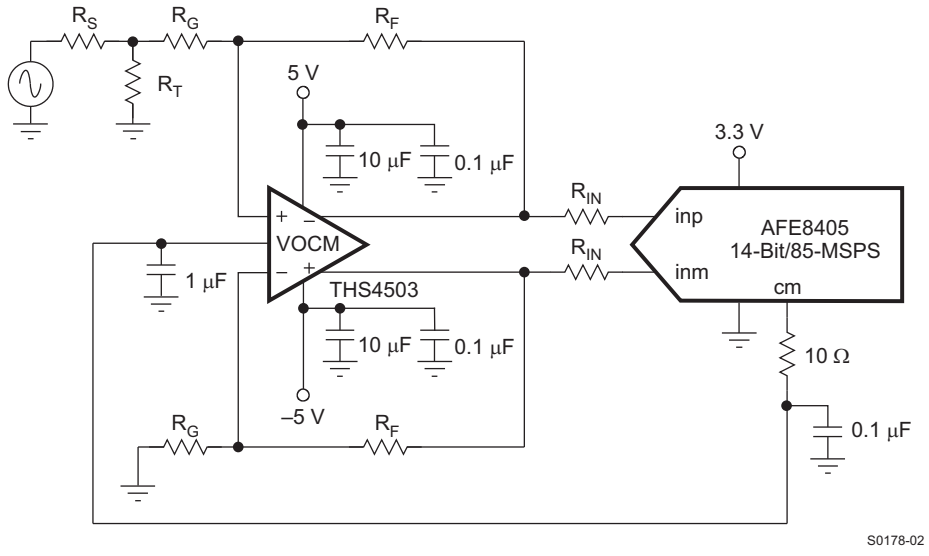

Figure 6-5. Using the THS4503 With the AFE8405

6.3 ADC Input Voltage Overstress

The AFE8405 ADC can handle absolute maximum voltages of 3.6 V dc on the input pins inp and inm. For dc inputs between 3.6 V and 3.8 V, a 25-Ω resistor is required in series with the input pins. For inputs above 3.8 V, the device can handle only transients, which must have less than 5% duty cycle of overstress. The input pins connect internally to an ESD diode to AVDD, as well as a switched capacitor circuit. The sampling capacitor of the switched capacitor circuit connects to the input pins through a switch in the sample phase. In this phase, an input larger than 2.65 V would cause the switched capacitor circuit to present an equivalent load of a forward biased diode to 2.65 V in series with a 60-Ω impedance. Also, beyond the voltage on AVDD, the ESD diode to AVDD starts to become forward biased.

In the phase where the sampling switch is off, the diode loading from the input switched capacitor circuit is disconnected from the pin, while the ESD loading to AVDD is still present.

CAUTION

A violation of any of the previously stated conditions could damage the device (or reduce its lifetime) either due to electromigration or gate oxide integrity. Care should be taken not to expose the device to input overvoltage for extended periods of time, as it may degrade device reliability.

6.4 ADC Reference Circuit

The AFE8405 ADC has built-in internal reference generation, requiring no external circuitry on the printed circuit board (PCB). For optimum performance, it is best to connect both refp and refm to ground with a 1-µF decoupling capacitor in series with a 20-Ω resistor, as shown in the Figure 6-6. In addition, an external 56.2-kΩ resistor should be connected from iref to AVSS to set the proper current for the operation of the ADC, as shown in Figure 6-6. No capacitor should be connected between these pins; only the 56.2-kΩ resistor should be used.

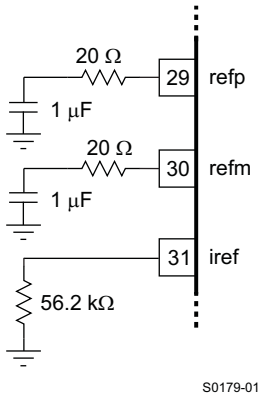

Figure 6-6. REFP, REFM, and IREF Connections for Optimum Performance

6.5 ADC Clock Input

The AFE8405 ADC clock input can be driven with either a differential clock signal or a single-ended clock input, with little or no difference in performance between the configurations. The common-mode voltage of the clock inputs is set internally to cm using internal 5-kΩ resistors that connect clkp and clkm to cm, as shown in Figure 6-7.

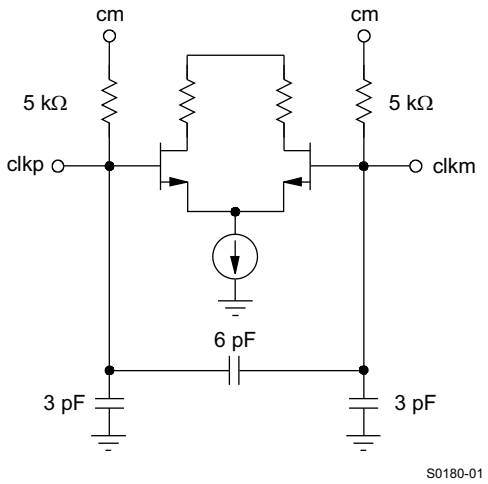

Figure 6-7. Clock Inputs

When driven with a single-ended CMOS clock input, it is best to connect clkm to ground with a 0.01-µF capacitor, while clkp is ac-coupled with a 0.01-µF capacitor to the clock source, as shown in Figure 6-8.

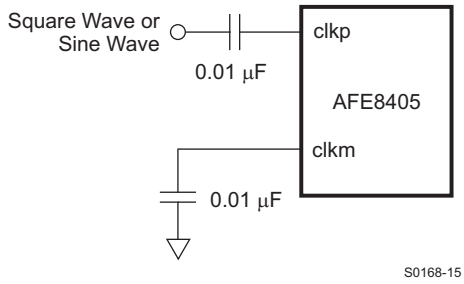

Figure 6-8. AC-Coupled, Single-Ended Clock Input

The ADC clock input can also be driven differentially, reducing susceptibility to common-mode noise. In this case, it is best to connect both clock inputs to the differential input clock signal with 0.01-µF capacitors, as shown in Figure 6-9.

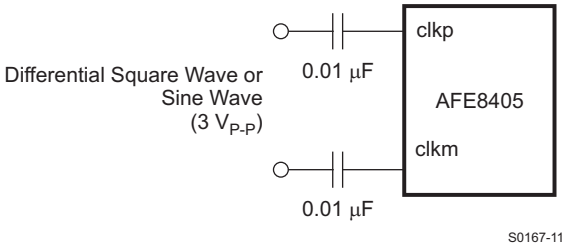

Figure 6-9. AC-Coupled, Differential Clock Input

For high-input-frequency sampling, it is recommended to use a clock source with low jitter. Additionally, the internal ADC core uses both edges of the clock for the conversion process. This means that, ideally, a 50% duty cycle should be provided.

Bandpass filtering of the source can help produce a 50% duty-cycle clock and reduce the effect of jitter. When using a sinusoidal clock, the clock jitter further improves as the amplitude is increased. In that sense, using a differential clock allows for the use of larger amplitudes without exceeding the supply rails and absolute maximum ratings of the ADC clock input.

7 RECEIVE DIGITAL SIGNAL PROCESSING

The downconversion section of the AFE8405 consists of the receive input interface, the rx_distribution bus, and eight digital downconverter blocks.

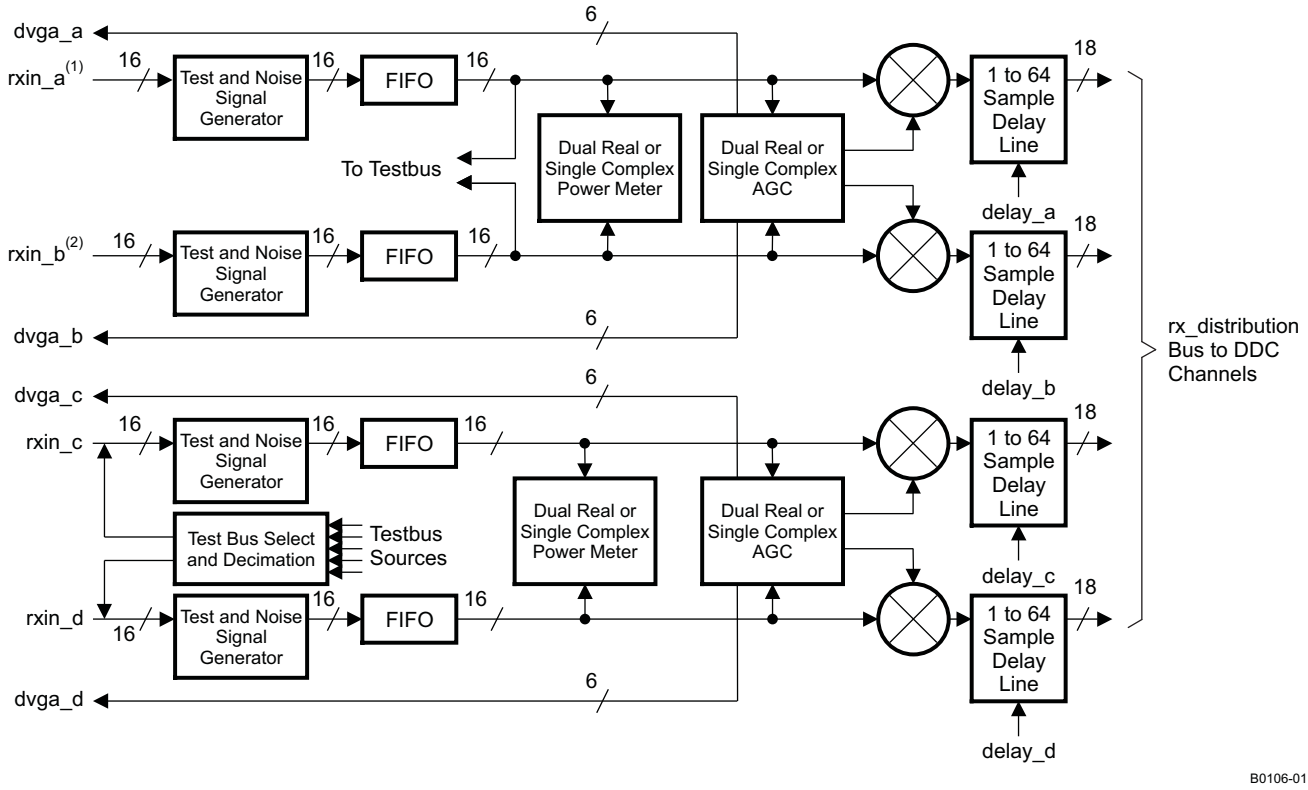
The purpose of the receive input interface is to accept signal data from three 16-bit input ports, measure the input signal power, control the digital VGA, and distribute the data to the DDC blocks. The input interface also has a user-controlled test generator and noise source.

The rx_distribution bus distributes the three channels of signal data to each of the eight DDC blocks.

Each DDC block selects one of the three channels (or two for complex input data) from the rx_distribution bus and then performs downconversion tuning, programmable delay, channel filtering with decimation, power measurement, fixed gain adjust, and/or automatic gain control. Each DDC block can support one UMTS channel, two CDMA channels, or two TD-SCDMA channels. An optional mode permits stacking two DDC blocks in UMTS mode to provide double-length final pulse-shape filtering.

Tuned, filtered, and decimated signal data is output in bit-serial or parallel format.

7.1 Receive Input Interface



(1) Hard-wired to internal ADCA

(2) The rxin_b port is not used and not connected internally.

Figure 7-1. Receive Data Input Interface

The AFE8405 receive input data interface accepts data from several sources:

- Signal data from the integrated 14-bit ADC (rxin_a)
- Signal data presented at the two 16-bit digital data input ports (rxin_c and rxin_d)
- An LFSR test signal generator allows the AFE8405 to be tested using a known repetitive data sequence.

For the rxin_c and rxin_d input ports, signal data can be provided in binary or 2s-complement form. The location of the ADC's MSB can be programmed to allow additional AGC headroom if desired. For example, a 14-bit ADC may be connected with the MSBs aligned or shifited down to allow the AGC additional gain range before clipping the signal.

Signal data can be accepted at rates up to rxclk in UMTS mode for either eight normal channels or four double-length final pulse-shaping filter channels. In CDMA mode, the maximum input rate is rxclk for real inputs, or rxclk/2 for complex inputs. For maximum filter performance, higher clock rates generally allow longer filters.

Complex signal data is input with I data driving one input port and Q data driving another. This means that there is only one signal data port available when using complex input mode (rxin_c and rxin_d).

Signal input data is clocked into eight-stage FIFOs using a matching external clock signal, adcclk_a/b/c/d. Signal data is clocked out of the FIFO from a gated rxclk (the AFE8405 receive section clock). The FIFO allows an arbitrary phase relationship between adcclk_a/c/d and rxclk. The frequency relationship is mandated by the programmed configuration.

The test and noise generator can supply test sequences or add noise to the input signal data. The test sequences, when combined with the checksum generators, are useful for initial board debug or power-on self-test.

For applications that require receiver desensitization, the noise generator can add noise to input data streams.

The ADC input port, rxin_a, can be passed to the test-bus control block, decimated by 32×, and routed directly to the AFE8405 test-bus output pins. The key requirement of this function is to be able to verifiy the performance of the ADC by reconstructing the samples, while limiting the output sample rate to less than 5 MHz using an 85-MHz ADC sample rate.

Many other internal chip signals can be routed to the test bus for evaluation and debug purposes. When the test bus is enabled, the rxin_c and rxin_d ports are driven as digital outputs.

Each of the four outputs to the DDC channels includes a 1- to 64-sample delay line.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ssel_ddc(2:0)	Selects the sync source for the DDC data input multiplexer and mixer. This sets the sync source for DDC input clock generation and synchronization for all DDC channels.
offset_bin_X	Selects offset binary input when set, 2s complement input when cleared. X = {a, b, c, d}. Note that the internal ADCs use 2s complement format, so offset_bin_a must be set.
msb_pos_X(2:0)	Identifies the connection location of the ADC's MSB. Programmed values of {0..7} correspond to msb at {rxin_x_15.. rxin_x_8}. X = {a, b, c, d}

7.1.1 Receive FIFO

The receive FIFO consists of an eight-stage memory and two counters generating the input write pointer and output read pointer. When the FIFO receives a sync signal, the input and output pointers are initialized with a write-to-read pointer offset of four samples. Input samples from rxin_X (writes) are clocked with the adcclk_X input clock rising edges, and the input pointer advances on each clock rising edge. Output samples (reads) and the output pointer are clocked with the rxclk input signal rising edges, divided by the programmed sample rate loaded into the rate_sel(1:0) control register.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
adc_fifo_bypass	When set, bypasses the input FIFOs and input data is latched directly using the rxclk. When cleared, input data is latched using the adcclk_a/b/c/d inputs.
ssel_adc_fifo(2:0)	Selects the sync source for the FIFO state machines. This sync signal initializes the FIFO input and output pointers.
rate_sel(1:0)	This selects the FIFO input and output rate; {rxclk, rxclk/2, rxclk/4 or rxclk/8}. For example, with rxclk at 153.6 MHz, set rate_sel to 0, 1, 2, or 3, respectively, for adcclk_a/b/c/d 153.6, 76.8, 38.4, or 19.2 MHz. Must be set the same as DDCCONFIG1 register ch_rate_sel(1:0).
adc_fifo_strap_ab	When set, the rxin_a and rxin_b FIFO input and output pointers are synchronized to support complex input signals. (Note: rxin_b is not used.)
adc_fifo_strap_cd	When set, the rxin_c and rxin_d FIFO input and output pointers are synchronized to support complex input signals.

7.1.2 Receive Input Power Meters

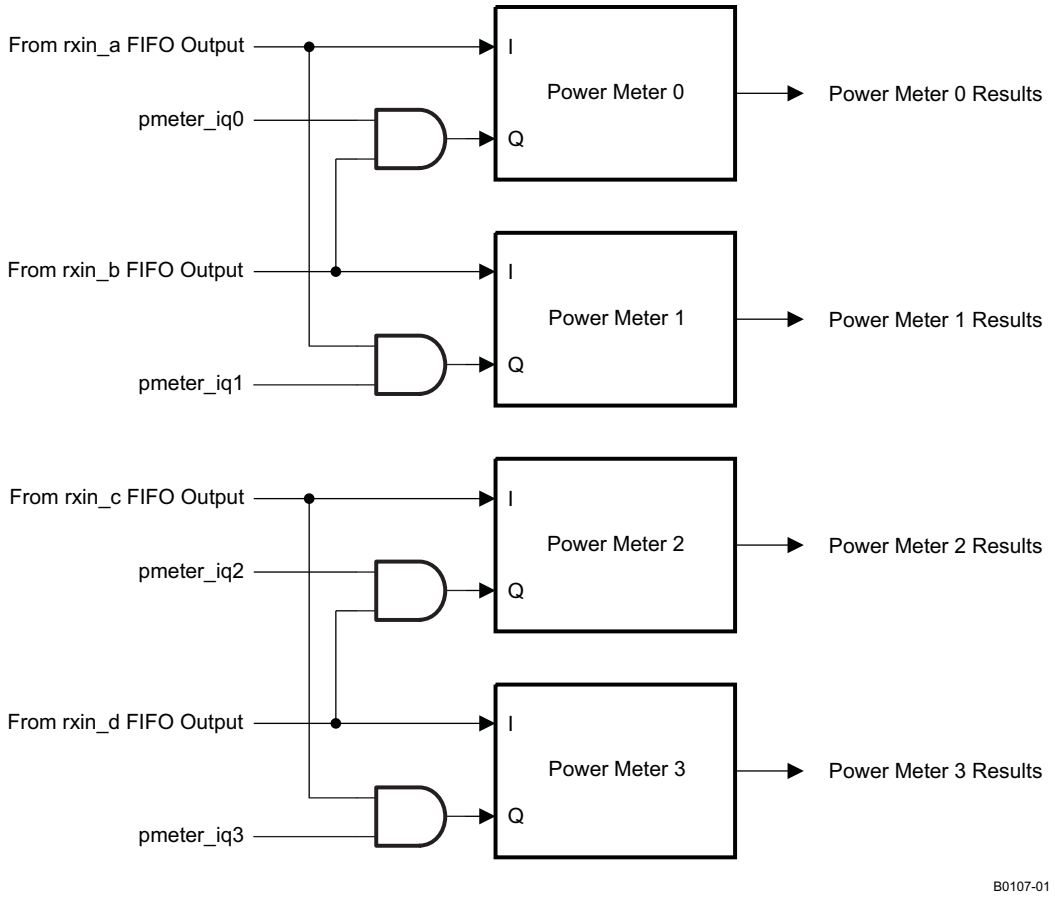


Figure 7-2. Receive Input Power Meters

Four receive input RMS power meters are provided by design. For real inputs, three power meters (power meter 0/2/3) can be used to measure the RMS power of the combined carriers in each of the three input signals from rxin_a/c/d (the Q input is held at zero). For complex inputs from rxin_c and rxin_d, one power meter can be use to measure the combined complex power and the other can be disabled (rxin_b is not used in the AFE8405).

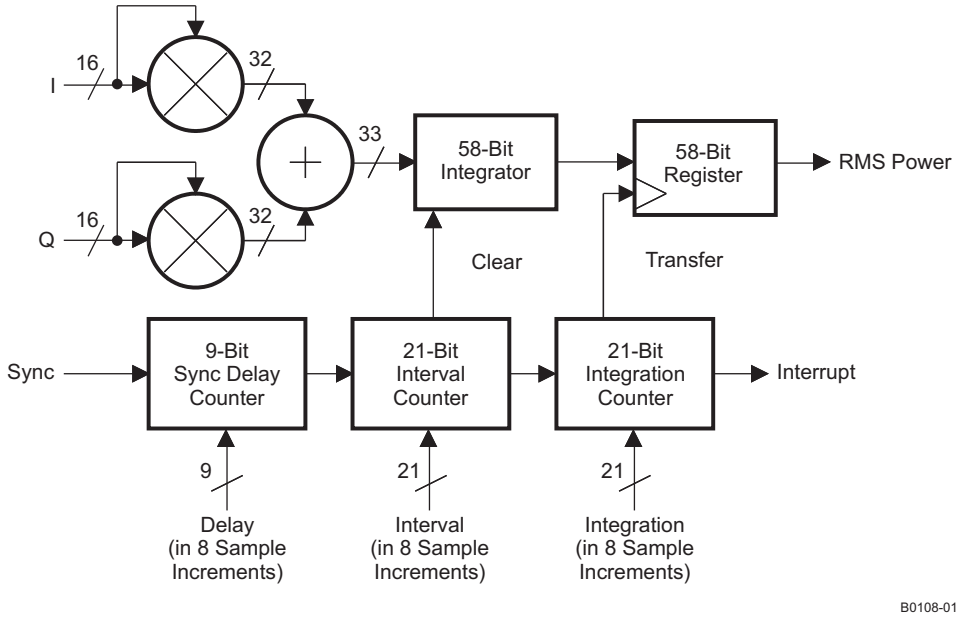

Figure 7-3. Detailed Functionality of Receive Input Power Meter

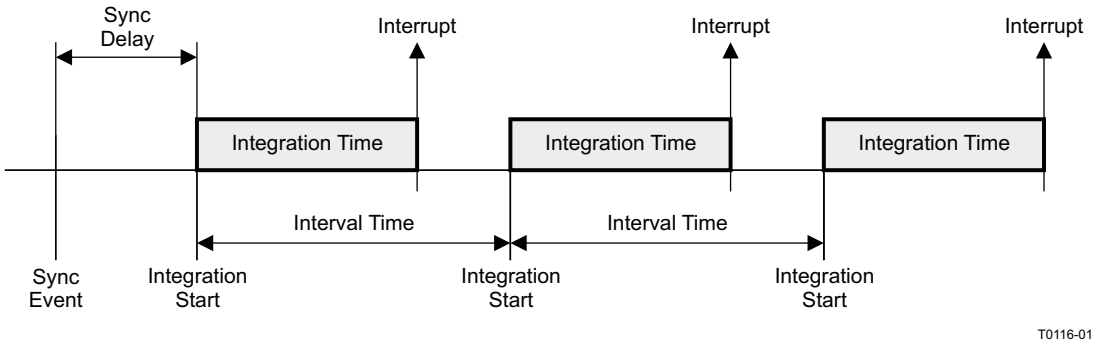

Figure 7-4. Receive Input Power Meter Timing

Power is calculated by squaring each 16-bit I (I and Q for complex inputs) sample, summing, and then integrating the summed-squared results into a 58-bit accumulator over a programmable integration period. The integration period is programmed into the 21-bit counter, in eight-sample increments. The power read is:

Power = $[(I^2) \times (N \times 8 + 1)]$ for real inputs, where N is the integration count.

Power = $[(I^2 + Q^2) \times (N \times 8 + 1)]$ for complex inputs, where N is the integration count.

A programmable 21-bit interval counter sets the power measurement interval (how often power is measured) in eight-sample increments. A measurement integration period is started at the beginning of each interval period.

The process begins with a sync event starting the 9-bit delay counter. After ($8 \times$ sync_delay + 2) samples, the integration interval is started. Integration continues until the integration count is met, at which point the 58-bit integrator results are transferred to the read-only register and an interrupt is generated. A new measurement period starts at the end of the interval period.

The 21-bit counters in eight-sample increments allow up to 104.8-mS interval times at 160-MHz clock.

NOTE

Each of the four composite RMS power meter blocks has its own delay sync, interval, and integration period counters, as well as separate sync source registers.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
recv_pmeterX(57:0)	58-bit power measurement result. X = {0, 1, 2, 3}.
recv_pmeterX_sqr_sum(20:0)	21-bit integration (square and sum) period. X = {0, 1, 2, 3}.
recv_pmeterX_sync_delay(8:0)	Power meter delay sync period. X = {0, 1, 2, 3}.
recv_pmeterX_strt_intrvl(20:0)	21-bit measurement interval. X = {0, 1, 2, 3}. *The strt_intrvl value must be greater than the sqr_sum value.*
ssel_recv_pmeter_X(2:0)	Sync source. X = {0, 1, 2, 3}.
pmeterX_iq	Selects complex power measurement input mode when set. X = {0, 1, 2, 3}.
recv_pmeterX_ena	Enables power meter when set. X = {0, 1, 2, 3}.

7.1.3 Receive Input AGC (RAGC)

Input signals from the ADCs can be used to create a front-end composite AGC loop when combined with a digitally controlled variable-gain amplifier (DVGA) connected before the ADCs. The AGC system operates by integrating the square of the ADC samples over a programmable interval and applying a table-driven error signal to a loop integrator based on the squared integration output. The error table maps the signal power to a user-programmed error value. The loop integrator output is used to drive map tables to control the DVGA output pins and a gain adjustment multiplier. Fast updates can be enabled if desired, to cause the loop integrator to adjust quickly to interfering signals. The ADC input signals can also be passed through a high-pass filter to remove dc offset before squaring the input.

The programmable error table, integrator mapping tables, and clip thresholds, when combined with the user-programmable interval timers, provide a highly flexible AGC function.

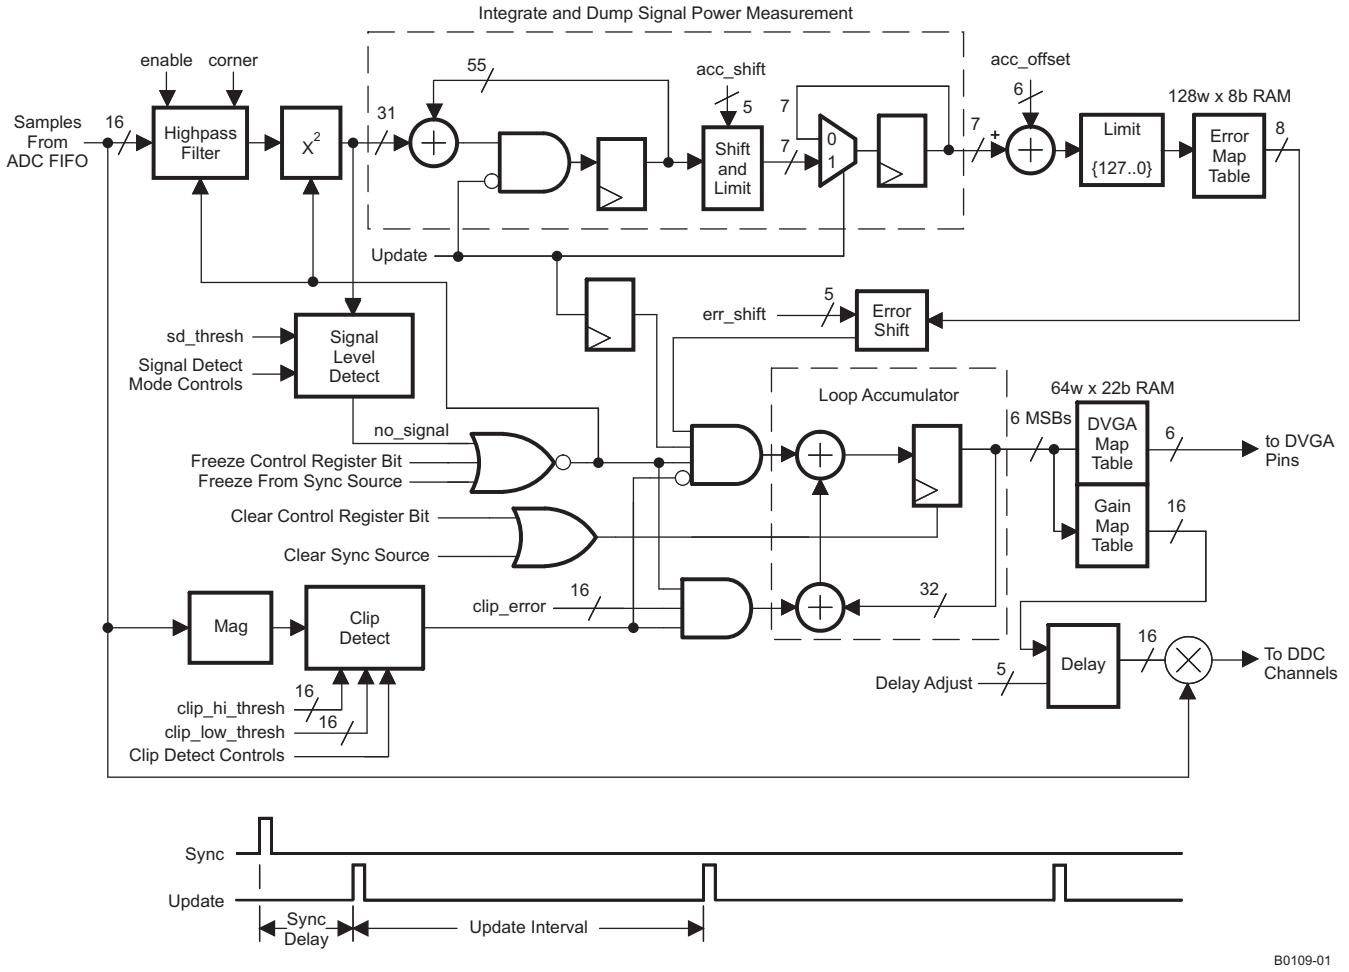

Figure 7-5. Receive Input AGC

The AGC measurement interval timer is a 24-bit timer initialized by a sync after a programmable 8-bit delay. During the integration interval, the squared input signal is shifted by the programmed value and accumulated. At the end of the interval time, an update pulse is generated, and the selected 7 bits of the 55-bit accumulated power is upper-limit checked and transferred to the power holding register. A programmable offset is applied, and the following limit check produces a 7-bit address value for the RAM error map table. The user-programmable error map table and following gain-shift setting are used to determine the loop error signal to be added to the 32-bit AGC loop accumulator. The error value is only added to the loop accumulator once per update. The loop accumulator upper 6 MSBs are used as the address for the programmable DVGA map table and gain map table. The gain map table address can be delayed from 0 to 31 clock cycles to align DVGA changes to signal level changes at the output of the AGC.

The AGC includes four sources for freezing the loop and holding the loop accumulator constant. A general sync source can be used to control the freeze directly; when the selected sync source is high, the AGC is held, and when low, the AGC operates. A control register bit freezes the AGC in the same fashion; when the bit is set, the AGC is held, and when cleared, the AGC operates. A signal level detector is provided that can be used to freeze the AGC loop automatically in the event of input signal loss. A programmable signal detection threshold value, number of samples below the signal detection threshold, and window timer are used to determine when no signal is present. Finally, a programmable number of AGC updates after sync can be programmed, and the AGC is held until the next sync event. Freeze holds the loop accumulator constant, the integrate-and-dump accumulator constant, and the interval timer constant. When freeze is released, the interval timer resumes counting.

A sync event always reinitializes the integrate-and-dump interval timer and terminates the pending update to the loop accumulator from the current integrate-and-dump measurement interval. For example, if a sync event occurs during an integrate-and-dump interval, that interval is terminated without updating the loop, and the integrate-and-dump accumulator is cleared. After the programmed sync delay, a new interval starts.

The AGC includes a dual-threshold clip-detect function, using two programmable 16-bit thresholds and programmable counters. The clip detector causes immediate loop accumulator updates while the clip event is active. The 16-bit clip error value is aligned at the MSBs of the loop accumulator. Clip events are qualified when a programmed number of samples are above the clip-high threshold during the programmable clip window time. For example, a clip event can be defined as eight samples above the clip-high threshold in a 256-sample window; the clip-high threshold, the number of samples above the clip-high threshold, and the sample window time are programmable. Once the clip event has occurred, the clip duration is controlled by the clip-low threshold value, clip-low samples value, and clip-low timer. The clip event is cleared when the number of samples below the clip-low threshold exceeds the programmed value within the clip-low timer window. The clip-low threshold, number of clip-low samples, and the clip-low window timer are programmable.

The AGC blocks can be paired together, rxin_a with rxin_b, and rxin_c with rxin_d, to produce a complex input AGC mode. The clip detector output from the rxin_b/d AGCs is logically ORed with the rxin_a/c clip detect outputs. The squared input function before the integrate-and-dump and signal-level detector is replaced with an $I^2 + Q^2$ power calculation. The accumulator MSBs from the rxin_a/c AGCs are connected to the rxin_c/d DVGA map table and gain map table inputs. This arrangement allows the AGCs to operate in a direct-conversion receiver system by controlling the $I^2 + Q^2$ complex signal level.

The high-pass filter is a 32-bit accumulator followed by an adjustable shift to control the corner frequency, a subtractor to remove the accumulated offset, and a final limiter to produce a 16-bit result. The high-pass filter function is enabled by setting hp_ena; clearing hp_ena holds the accumulator reset.

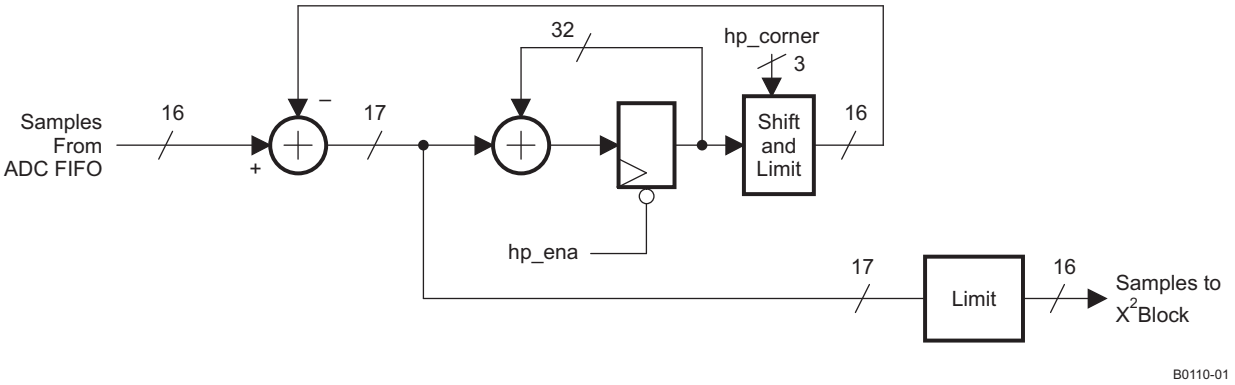

Figure 7-6. High-Pass Filter in Receive Input AGC

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ragc_bypass_X	Bypasses the entire receive AGC circuit when set. X = {0, 1, 2, 3}
hp_ena_X	Enables high pass filter when set
hp_corner_X(2:0)	Adjusts the corner frequency of the high-pass filter
integ_interval_X(23:0)	Integrate-and-dump signal-power measurement interval in samples.
acc_shift_X(4:0)	Shift-down amount following the integrate-and-dump accumulator.
acc_offset_X(5:0)	Offset value applied to the shifted integrate-and-dump output.
ragc_sync_delay_X(7:0)	AGC sync delay interval, from 1 to 256 samples
ssel_ragc_interval_X(2:0)	Sync source selection for the interval timer
ssel_ragc_freeze_X(2:0)	Sync source selection for AGC freeze

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ssel_ragc_clear_X(2:0)	Sync source selection for the AGC loop accumulator clear
ragc_freeze_X	Register bit to freeze the AGC when set
ragc_clear_X	Register bit to clear the AGC accumulator when set
ragc_update_X(7:0)	Sets the number of updates per sync event, after which no further updates occur until the next sync event. Program to 0x00 to update continually.
sd_ena_X	Enables freezing the AGC with the signal detector when set
sd_thresh_X(15:0)	Signal-detection threshold for AGC channel X. This 16-bit word is lined up with bits 23 down to 8 of the square output. The smallest signal level that can be programmed is therefore 16 LSBs on the ADC input, and the largest is 4095 LSBs at the ADC input.
sd_samples_X(15:0)	The number of samples below the signal detect threshold within the signal detect sample timer window required to freeze on the AGC.
sd _timer_X(15:0)	Window timer to qualify signal detection.
clip_hi_thresh_X(15:0)	Clip detector high threshold
clip_lo_thresh_X(15:0)	Clip detector low threshold
clip_hi_samples_X(7:0)	A clip event is detected when the number of samples above the clip-high threshold within the clip-high sample timer window exceeds this value.
clip_lo_samples_X(7:0)	A clip event ends when the number of samples below the clip-low threshold within the clip-low sample timer window exceeds this value.
clip_hi_timer_X(15:0)	Window timer to qualify clip events
clip_lo_timer_X(15:0)	Window timer to determine when the clip event ends.
clip_error_X(15:0)	Error signal applied to the AGC accumulator when a clip event is active. This data is MSB aligned, and therefore can cause immediate changes to the accumulator.
ragc_error_map_X	128-word × 8-bit memory holding the log to error look up table
dvga_map_X	64-word × 6-bit memory holding the accumulator to DVGA look-up table
gain_map_X	64-word × 16-bit memory holding the accumulator to GAIN look-up table (256 decibels is unity gain).
delay_adj_X(4:0)	Delay between DVGA output updates and gain map updates to compensate for ADC pipeline delays, etc.
err_shift_X(4:0)	Error map table shift-up output before adding to loop accumulator
complex_01	Enables complex AGC mode on inputs rxin_a and rxin_b when set
complex_23	Enables complex AGC mode on inputs rxin_c and rxin_d when set
ragc_accum_X(31:0)	32-bit read-only register holding the current contents of the loop accumulator.
3-state(10:7)	3-state controls for the dvga_d/c/b/a output pins; pins are in the high-impedance state when the 3-state bits are set.
ragc_mpu_ram_read	When set, the receive AGC map RAMs are readable via the MPU control interface. *The AFE8405 signal path is not operational when this bit is set, it is intended for debug purposes only.*

7.1.4 Test and Noise Signal Generator

The test and noise generator can generate test signals to replace the rxin_a/b/c/d inputs as a tool for debug, evaluation, and self-test. Checksum generators included in the individual DDC channels at the outputs can be used in conjunction with the noise generator and the internal sync timer block to create the built-in self-test function.

The test and noise signal source included in this block is a 23-bit linear feedback shift register (LFSR) with a fixed polynomial and fixed initialization state. A sync input is required to initialize the LFSR, and the sync source is connected to the ddc_counter output signal.

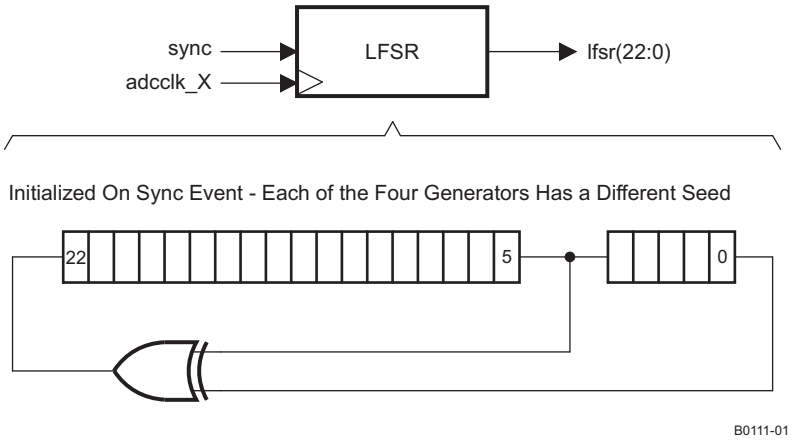

Figure 7-7. Noise Signal Generator

Receive Input Port	LFSR Seed Value, MSB to LSB
rxin_a	100 0000 0000 0000 0001 0000 (0x40 0010)
rxin_b	010 0110 1110 0110 1100 1110 (0x26 E6CE)
rxin_c	110 1110 1010 0010 1001 1000 (0x6E A298)
rxin_d	000 1011 0001 1110 1011 0111 (0x0B 1EB7)

The 23-bit LFSR output signal if used to create a 16-bit dout(15:0) test signal using XOR combinations of the LFSR bits.

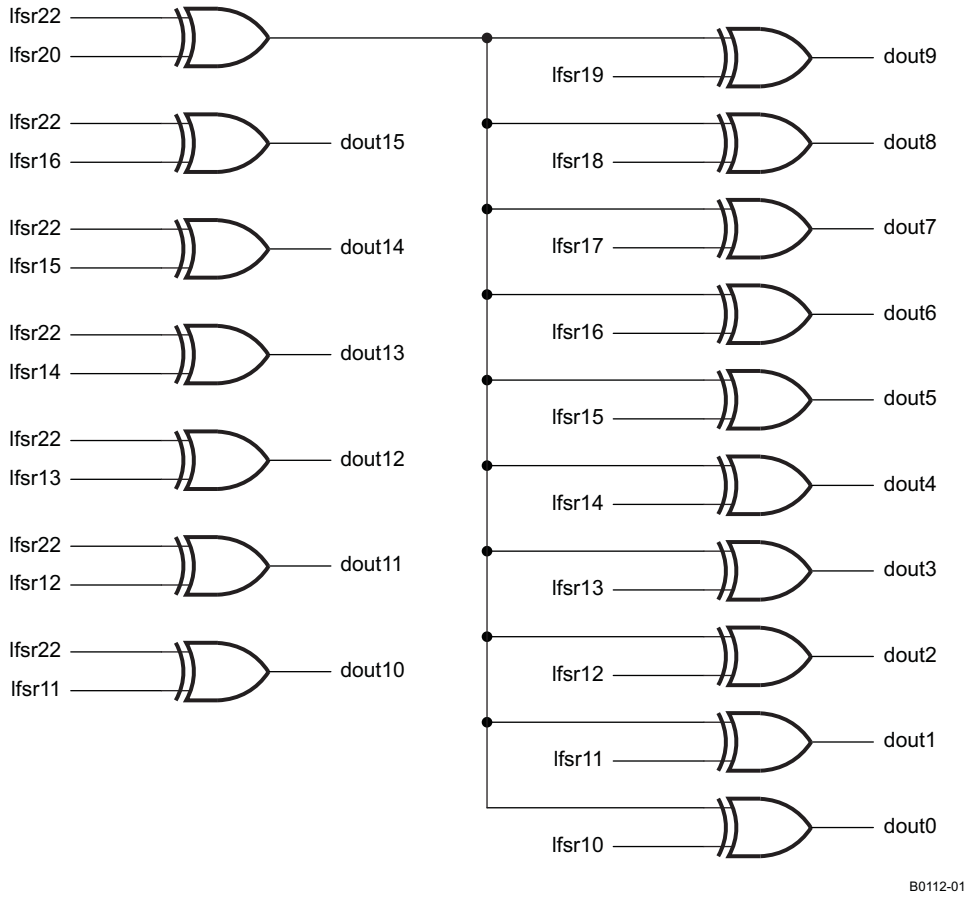

Figure 7-8. Mapping of LFSR Values to Output Bits

To enable the test signal generator, the slf_tst_ena control bit is set. The rxin_a/b/c/d signals are then replaced by the four generator output streams. To use this test signal generator as a signal source for self-test, the user must also set the adc_fifo_bypass control bit. Setting the adc_fifo_bypass control bit causes the adcclk_a/b/c/d input clocks to be internally replaced with rxclk/N, where N is programmed with the rate_sel(1:0) control bits to {1, 2, 4, or 8}.

The test signal generators can also output a programmable constant value. All four test signal generators output the same programmable constant value.

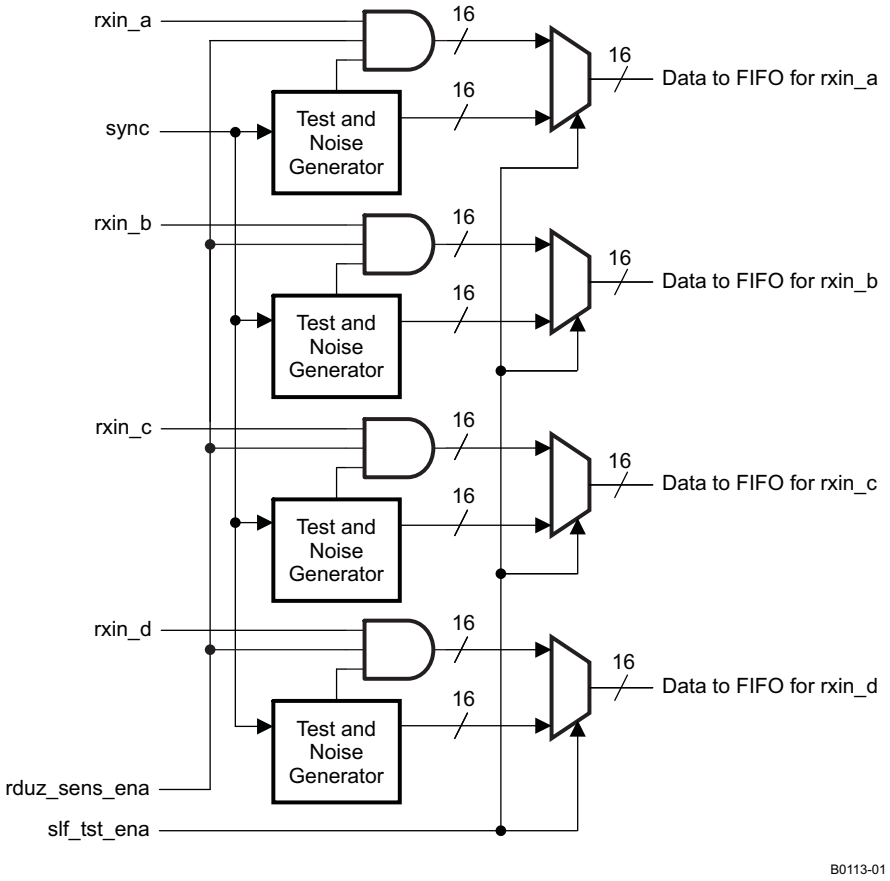

Figure 7-9. Block Diagram of Noise Generator Input Options

The LFSR circuits can also be used to add noise to the rxin_a/b/c/d input signals by setting the rduz_sens_ena control register bit. The magnitude of the noise added can be adjusted by programming the nz_pwr_mask(15:0) control register. In Figure 7-10, X = {a ,b, c, or d}.

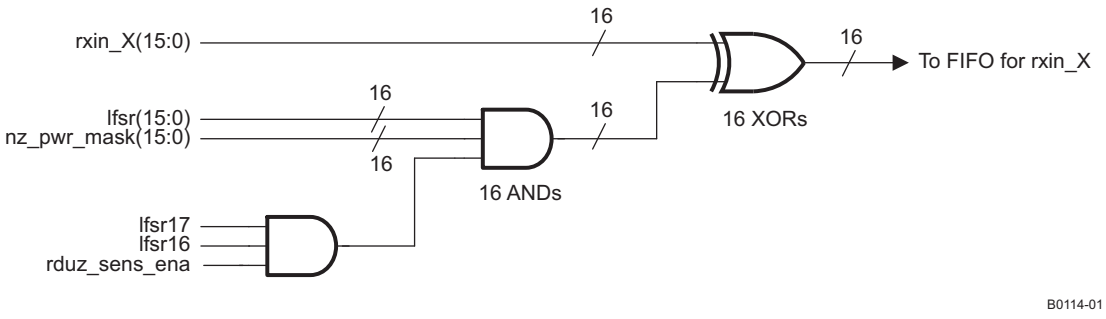

Figure 7-10. Detail Circuit for Adding Noise Generator Signal to rxin Signal

PROGRAMMING	
VARIABLE	**DESCRIPTION**
slf_tst_ena	When set, the test signal generators replace the rxin_a/b/c/d input signals with internally generated pseudorandom sequences. The fifo_bypass bit must be set when this bit is set.
rduz_sens_ena	Enables the LFSR, adding noise to the ADC input data when set.
nz_pwr_mask(15:0)	Selects the power of the noise added to the ADC input data.
adc_fifo_bypass	When set, the FIFO is essentially bypassed, and the adcclk_a/b/c/d clock input ports are ignored.
ddc_counter(31:0)	32-bit general-purpose counter interval
ddc_counter_width(7:0)	8-bit general-purpose counter timeout pulse counter
ssel_ddc_counter(2:0)	Sync source selection for the general purpose counter
self_test_constant(17:0)	18-bit self-test constant value applied to all four rxin_a/b/c/d inputs when self_test_const_ena is set.
self_test_const_ena	Enables the self-test constant value for rxin_a/b/c/d

7.1.5 Sample Delay Lines

The four sample delay line blocks each consist of a 64-register memory and a state machine. The state machine uses a counter to control the write (input) pointer, and the programmed read offset register data to create the read (output) pointer. Programming larger read offset register values increases the effective delay at a resolution equal to the sample rate.

The read offset registers, delay_line_X, are double-buffered. Writes to these registers may occur anytime, but the actual values used by the circuit are not updated until a delay line sync event occurs.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
delay_line_X(5:0)	Read offset into the 64-element memory for each delay line. X = {0, 1, 2, 3}.
ssel_delay_line_X(2:0)	Selects the sync source used to update the double-buffered delay line register.

7.1.6 Test Bus

When the test bus is enabled, the rxin_c(15:0) and rxin_d(15:0) ports become outputs, and the dvga_c and dvga_d pins are combined with the rxin_c(15:0) and rxin_d(15:0) pins to allow 36-bit wide signals from the DDC channels and the receive input interface to be multiplexed to this test output port. Many of these sources can be decimated to reduce the output sample rates.

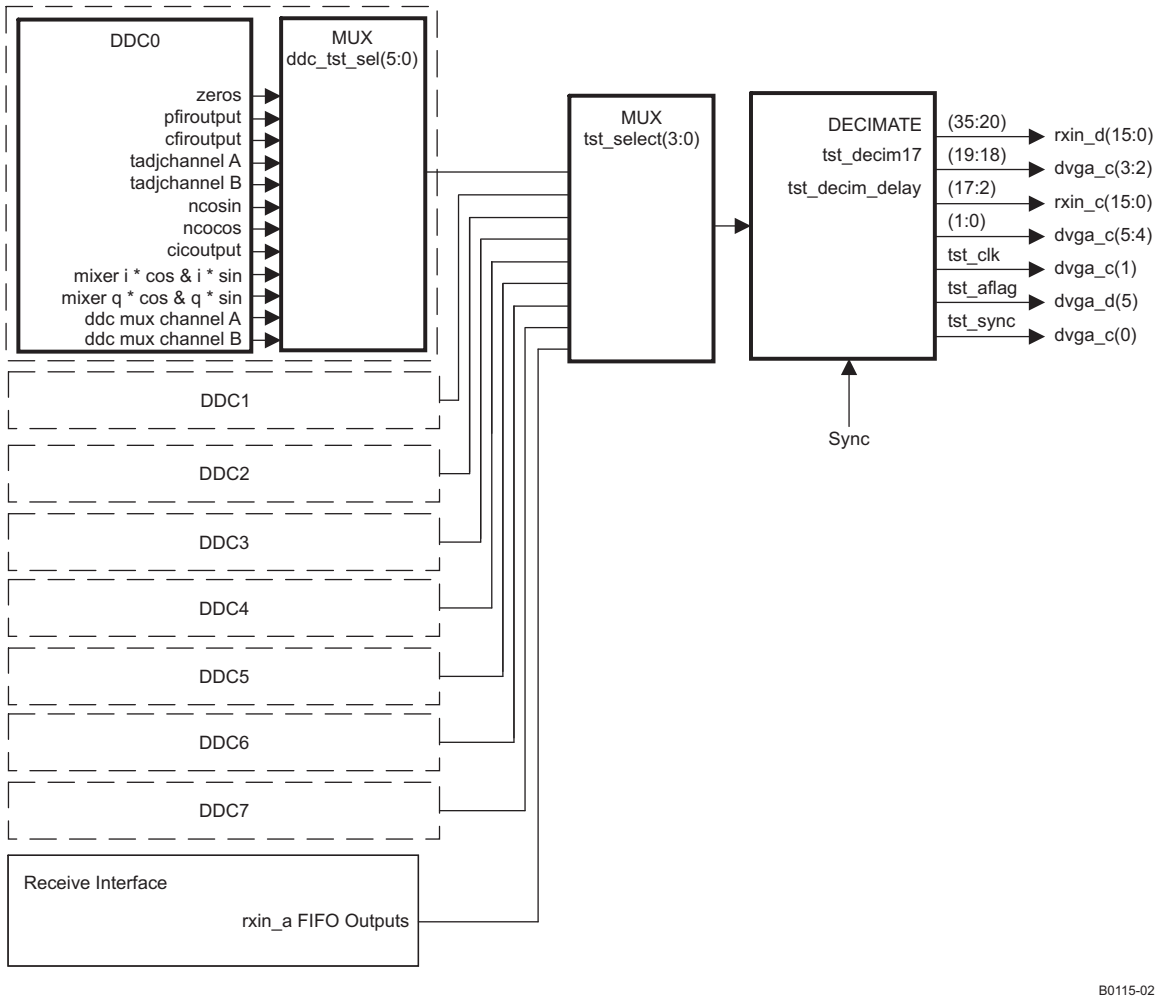

Figure 7-11. Test Bus Output Circuit Showing Options for Selecting Signal

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ssel_tst_decim(2:0)	Selects the sync source for the testbus decimator
tst_decim_delay(3:0)	Sets the test-bus decimator delay from sync
tst_decim17	Must be cleared
tst_on	Enables the test bus; rxin_c(15:0) and rxin_d(15:0) are changed from inputs to outputs, dvga_c(5:0) and dvga_d(5) are used as part of the test bus.
tst_select(3:0)	Selects the source block for the testbus output: DDC0–DDC7 or receive interface.
ddc_tst_sel(5:0)	Selects the signal to be output from the DDC block
tst_rate_sel(4:0)	Sets the test-bus output clock period to (tst_rate_sel + 1) rxclk cycles. When the testbus source is set to the ADC FIFO, tst_rate_sel(4:0) must be set to 0 for an output.
tst_clk_pol	Selects the polarity of the test clock output at dvga_c(1) when the test bus is enabled; 0 for rising edge in the center of valid data, 1 for falling edge in the center of valid data. No effect when tst_rate_sel is 0 0000.

7.2 DDC Organization

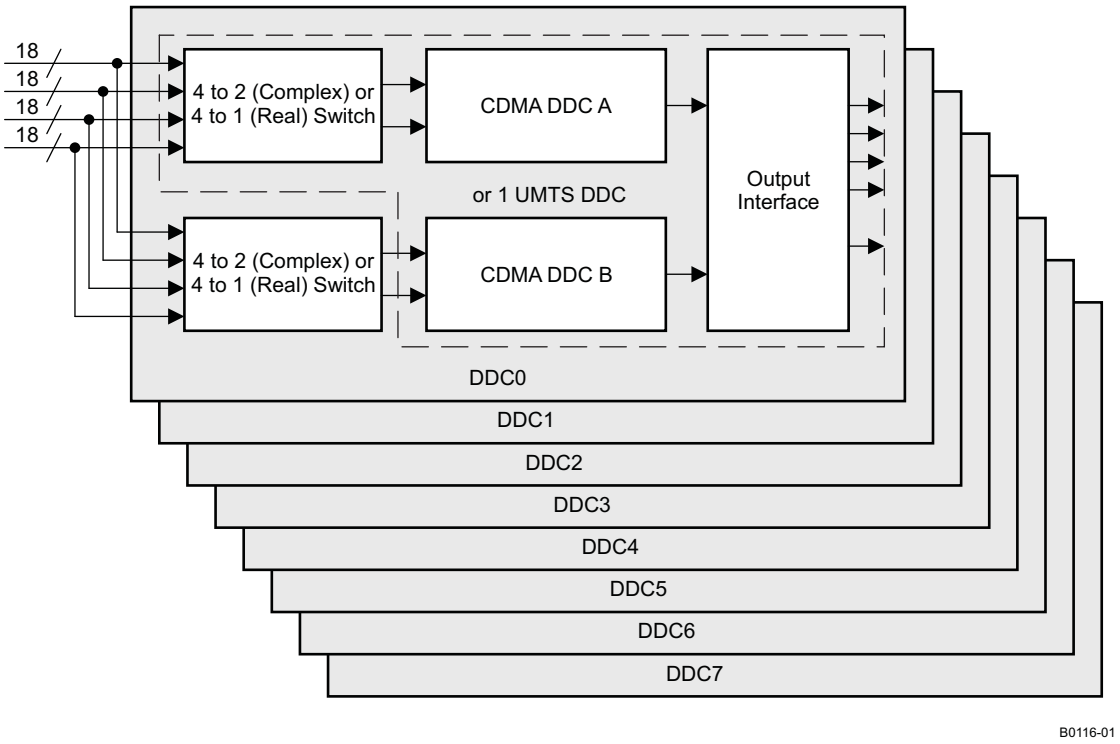

Figure 7-12. DDC Organization for Single-Length Filter Mode

The AFE8405 provides downconversion for up to eight UMTS receive channels, 16 CDMA2000 receive channels or 16 TD-SCDMA receive channels. Downconversion channels are organized into 8 DDC blocks. Each individual DDC block provides two CDMA2000 or two TD-SCDMA DDC channels, A and B, or one UMTS channel.

Both CDMA DDC channels in a DDC block can be independently tuned, though they would likely be used as diversity pairs and tuned to the same frequency. Filter coefficients are shared between the two CDMA DDC channels within a block.

Two adjacent DDC blocks (for example, DDC0 and DDC1) can be strapped together to form a single UMTS DDC channel with double-length final pulse shaping filtering. The AFE8405 can therefore provide four UMTS DDC channels with double-length final PFIR filtering as shown in the following diagram.

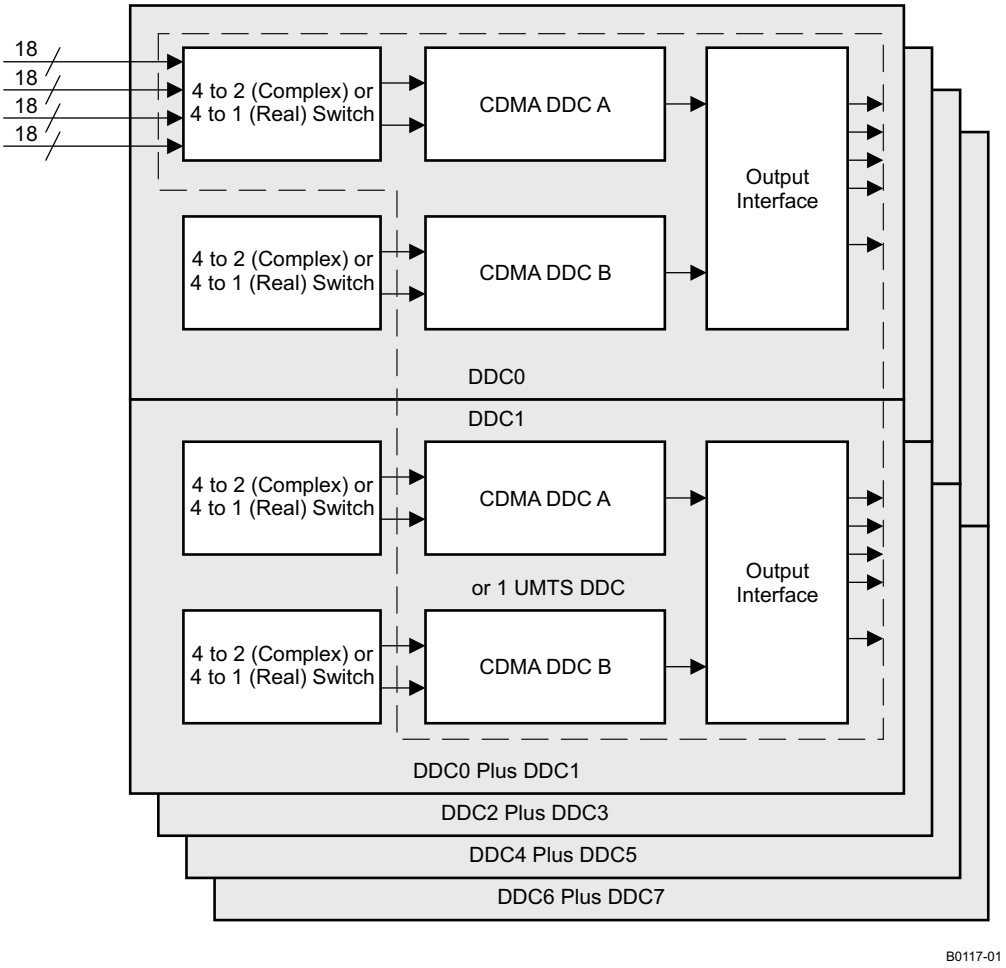

Figure 7-13. DDC Organization for Double-Length Filter Mode

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ddc_ena	When set, turns on the DDC.
cdma_mode	When set, puts the DDC block in dual-channel CDMA mode.
gbl_ddc_write	When set, all subsequent programming (writes only) for DDC0 and DDC1 is also written to DDC2/4/6 and DDC3/5/7.

7.2.1 Downconverter Function Blocks

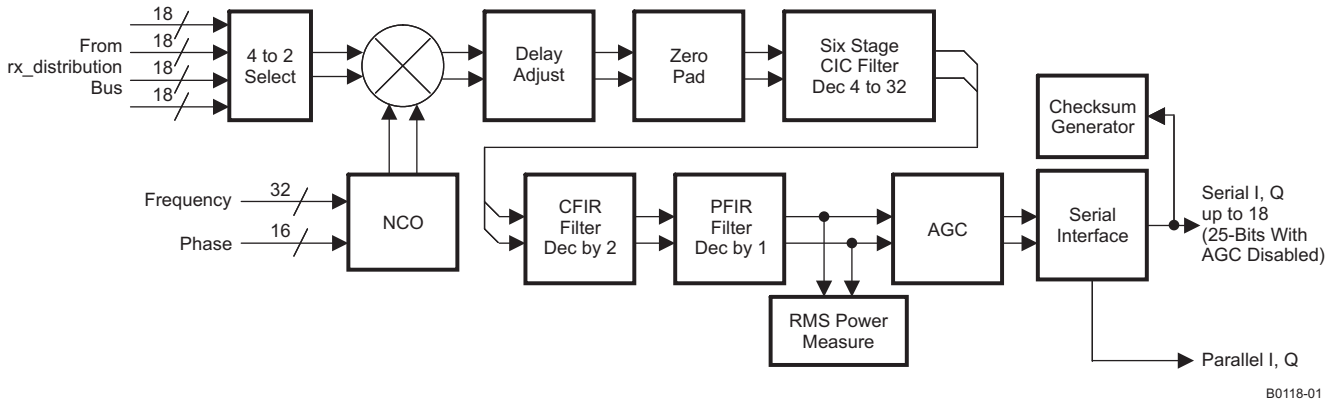

Figure 7-14. DDC Functional Block Diagram

Each AFE8405 downconversion block can process two CDMA carriers or a single UMTS carrier. Signal data is selected from one of four ports for real inputs, or two of four ports for complex inputs. Data from the selected port(s) is multiplied with a complex, programmable, numerically controlled oscillator (NCO) which tunes the signal of interest to baseband. The delay adjust and zero pad blocks permit adjustment of the delay in the end-to-end channel. Zero padding interpolates the signal to the rxclk rate. Filtering consists of a six-stage CIC filter which decimates the tuned data by a factor from 4 to 32, a compensating FIR filter (CFIR) which decimates by a factor of two, followed by a programmable FIR filter (PFIR) which does not decimate. The output interface block can be programmed to decimate by 2 if desired.

The RMS power meter measures the power within the channel bandwidth. The AGC automatically drives the gain and keeps the magnitude of the signal at a user-specified level. This allows fewer bits to represent the signal. The serial output interface formats and rounds the output data. Each of the previously mentioned blocks is described in greater detail in the following sections.

7.2.2 DDC Mixer

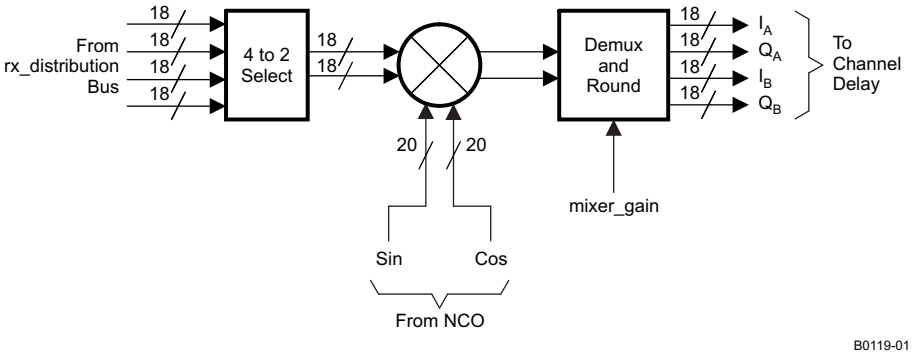

Figure 7-15. Mixer Functional Block Diagram

The receive mixer translates the input (from one of the input signal sources) to baseband where subsequent filtering is performed to isolate the signal of interest. The mixer is a complex multiplier that accepts 18-bit I and 18-bit Q signal data from the receive input interface and 20-bit sine and cosine sequences from the NCO. The NCO generates a mixing frequency (sometimes referred to as a local oscillator, or LO) specified by the user so that the desired signal is tuned to 0 Hz.

A DDC channel can support one UMTS signal directly, or two CDMA channels at half the input rate. When in CDMA mode, the path selection and the mixer tuning and phase of each channel can be set independently. The mixer output produces two complex streams; one representing the signal path for the A-side DDC, the other for the B-side. Each of these streams drives a channel delay and zero pad block.

The maximum input rate for UMTS is rxclk for either real or complex input data.

The maximum input rate in CDMA mode with real inputs is rxclk (remix_only is set, see the following).

The maximum input rate in CDMA mode with complex inputs is rxclk/2 due to sharing of multiplier resources.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ddcmux_sel_a(3:0)	Programs the I and Q complex input data routing onto two of the four input ports for stream A of CDMA DDC
ddcmux_sel_b(3:0)	Programs the I and Q complex input data routing onto two of the four input ports for stream B of CDMA DDC
remix_only	For CDMA mode only, set this bit for real input data at the rxclk rate. For complex inputs in CDMA mode, the maximum input data rate is rxclk/2, and this bit must be cleared. For CDMA mode with real inputs at the rxclk/2 rate or lower, this bit must be cleared.
zero_qsample	When set, the Q samples used by the mixer are always zero. This bit should be set for real only inputs in UMTS mode, or real-only inputs in CDMA mode when the input sample rate is rxclk/2 or lower.
ch_rate_sel(1:0)	Specifies the input channel data rate (rxclk, rxclk/2, rxclk/4, or rxclk/8 MSPS). **MUST BE SET THE SAME AS REGISTER rate_sel(1:0).**
mixer_gain	When asserted, adds 6 dB of gain in the mixer. This gain is highly recommended.

7.2.3 DDC Numerically Controlled Oscillator (NCO)

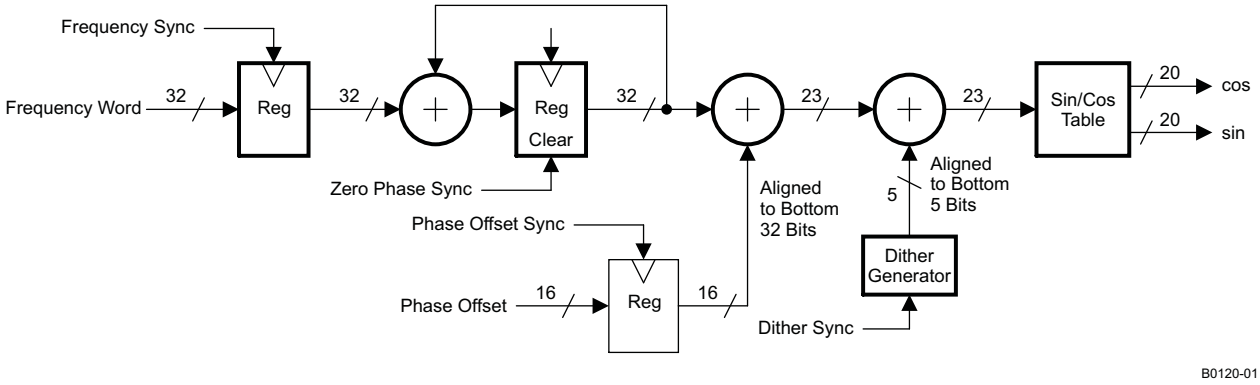

Figure 7-16. Detailed NCO Circuit

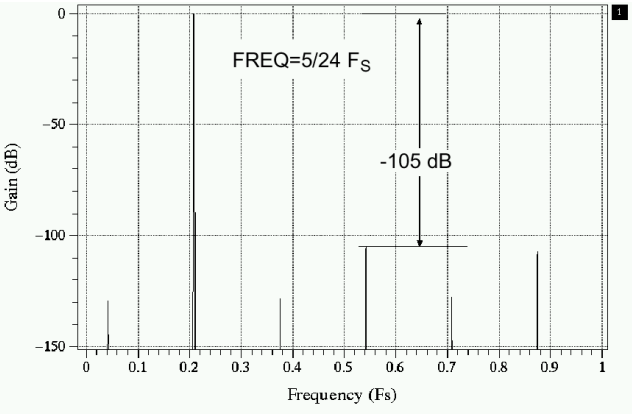
The NCO is a digital complex oscillator that is used to translate (or downconvert) an input signal of interest to baseband. The block produces programmable complex digital sinusoids by accumulating a frequency word which is programmed by the user. The output of the accumulator is a phase argument that indexes into a sin/cos ROM table which produces the complex sinusoid. A phase offset can be added prior to indexing if desired for channel calibration purposes. This changes the sin/cos phase with respect to the NCOs of other channels.

A 5-bit dither generator is provided and generates a small level of digital pseudonoise that is added to the phase argument below the bottom bits and is useful for reducing NCO spurious outputs. This dither generation is enabled by setting the dither_ena bit; the magnitude of the dither can be reduced by setting one or both of the dither_mask bits.

DITHER PROGRAMMING	
VARIABLE	**DESCRIPTION**
dither_ena	When set, turns dither on. Clearing turns dither off.
dither_mask(1:0)	Masks the MSB and MSB – 1 dither bits, respectively, when set.

The NCO spurious levels are better than –115 dBc. Added phase dither randomizes the periodic nature of the phase accumulation process and reduces low-level spurious energy. For some frequencies (N × Fs/24, where N = {1, 2, ..., 23}), dither is ineffective. In these cases, an initial phase of 4 reduces NCO spurs. Figure 7-17 shows the spur level performance of the NCO without dither, with dither, and with a phase offset value.



a) Worst Case Spectrum Without Dither

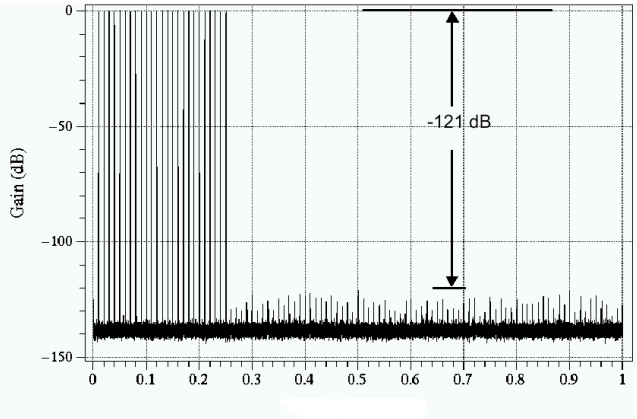
Figure 7-19. NCO Spectra (0 and Fs/4) - Without Dither or Phase Initialization



b) Plot With Dither or Phase Initialization

Figure 7-20. NCO Spectra (0 and Fs/4) - With Dither or Phase Initialization

The tuning frequency is specified as a 32-bit frequency word and is programmed as two sequential 16-bit words over the control port. The NCO frequency resolution is $f_{clk}/ 2^{32}$, where f_{clk} is the ADCCLK frequency. As an example, at an input clock rate of 61.44 MHz, the frequency step size would be approximately 14 mHz. The frequency word is determined by the formula:

Frequency word (in decimal) = $2^{32} \times$ tuning frequency / f_{clk}

Note that frequency tuning words can be positive or negative valued. Specifying a positive frequency value translates complex negative frequencies upwards towards 0 Hertz. Specifying a negative tuning frequency translates complex positive frequencies downwards towards 0 Hz.

FREQUENCY PROGRAMMING	
VARIABLE	**DESCRIPTION**
phase_add_a(31:0)	32-bit tuning frequency word for the A-side DDC when in CDMA mode. Also for UMTS mode.
phase_add_b(31:0)	32-bit tuning frequency word for the B-side DDC when in CDMA mode. Not used in UMTS mode.

Each of the 16 CDMA DDC channels can be loaded with unique frequency values.

The phase of the NCO sin/cos output can be adjusted relative to the phase of other channel NCOs by specifying a phase offset. The phase offset is programmed as a 16-bit word, yielding a step size of about 5.5 m°. The phase offset word is determined by the formula:

Phase offset word = $2^{16} \times$ offset_in_degrees / 360, or

Phase offset word = $2^{16} \times$ offset_in_radians / 2π

PHASE PROGRAMMING	
VARIABLE	**DESCRIPTION**
phase_offset_a(15:0)	16-bit phase offset word for the A-side DDC when in CDMA mode. Also for UMTS mode.
phase_offset_b(15:0)	16-bit phase offset word for the B-side DDC when in CDMA mode. Not used in UMTS mode.

Each of the 16 CDMA DDC channels can be loaded with unique phase-offset values.

Various synchronization signals are available which are used to synchronize the NCOs of all channels with respect to each other. Frequency sync and phase-offset sync determine when frequency and phase offset changes occur. For example, generating a frequency sync after programming the two frequency words causes the NCO (or multiple NCOs) to change frequency at that time, rather than after each of the three frequency words is programmed over the control bus. The zero-phase sync signal is used to force the sine and cosine oscillators to their zero-phase state. Dither sync can be used to synchronize the dither generators of multiple NCOs. The NCOs used in the transmit section are identical to what is described for the receive section. Note that there is one set of syncs provided for each DDC. When one DDC is used to process two CDMA signals, the syncs are shared between them.

SYNC PROGRAMMING	
VARIABLE	**DESCRIPTION**
ssel_nco(2:0)	Sync source for NCO accumulator reset
ssel_dither(2:0)	Sync source for NCO dither reset
ssel_freq(2:0)	Sync source for NCO frequency register loading
ssel_phase(2:0)	Sync source for NCO phase register loading

7.2.4 DDC Filtering and Decimation

The purpose of the receive filter chain is to isolate the signal of interest (and reject all others) that has been previously translated to baseband via the mixer and NCO. The overall decimation through the chain must be considered. The goal, generally, is to output the isolated signal at a rate that is twice (2×) the signal's chip rate. For UMTS this would be 7.68 MSPS and for CDMA the output rate should be 2.4576 MSPS. TD-SCDMA systems require the output rate be the chip rate of 1.28 MSPS. The output interface is programmed to decimate by 2 for the TD-SCDMA case.

Receive filtering and decimation is performed in several stages:

1. Zero-padding to interpolate the input sample rate (if needed) up to the rxclk rate
2. High-rate decimation (4 to 32) using a six-stage cascade-integrate-comb filter (CIC)
3. Decimate-by-two compensation filtering using the programmable compensating FIR filter (CFIR)
4. Pulse-shape filtering via the programmable FIR filter (PFIR) with no decimation
5. Output interface, serial or parallel format, with no decimation or decimate-by-2

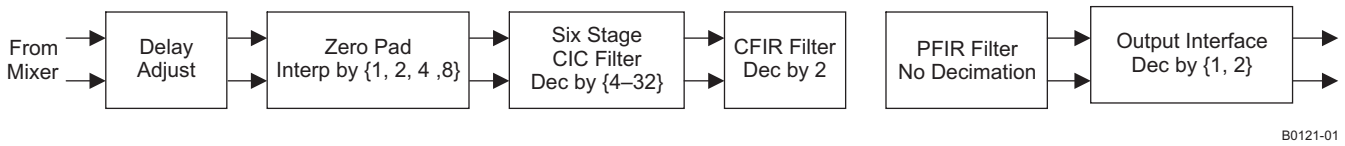


Figure 7-21. DDC Filtering Functional Block Diagram

Table 7-1 contains some examples of decimation and sample rates at the output of each block for UMTS, CDMA and TD-SCDMA standards at various supported input samples. For each example, the differential ADC clocks are provided to the AFE8405 at the input sample rate and rxclk is provided at the zero-pad output rate.

Table 7-1. Examples of Decimation and Sample Rates(1)

	Input Sample Rate (MSPS)	Zeros Added	rxclk(MHz) and Zero-Pad Output Rate (MSPS)	CIC Decimation	CIC Output Rate (MSPS)	CFIR Decimation	CFIR Output Rate (MSPS)	PFIR Decimation	PFIR Output Rate (MSPS)	Output Decimation
UMTS	76.80	1	153.6	10	15.36	2	7.68	1	7.68	1
UMTS	61.44	1	122.88	8	15.36	2	7.68	1	7.68	1
CDMA	78.6432	0	78.6432	16	4.9152	2	2.4576	1	2.4576	1
CDMA	78.6432	1	157.2864	32	4.9152	2	2.4576	1	2.4576	1
CDMA	61.44	1	122.88	25	4.9152	2	2.4576	1	2.4576	1
TD-SCDMA	81.92	0	81.92	16	5.12	2	2.56	1	2.56	2
TD-SCDMA	76.80	0	76.80	15	5.12	2	2.56	1	2.56	2
TD-SCDMA	76.80	1	153.6	30	5.12	2	2.56	1	2.56	2
TD-SCDMA	61.44	1	122.88	24	5.12	2	2.56	1	2.56	2

(1) The DDC output interfaces, both serial and parallel formats, can be programmed to decimate by 2. For the TD-SCDMA examples listed, the DDC output rate is 1.28 Msps (1× chip rate).

7.2.5 DDC Channel Delay Adjust and Zero Insertion

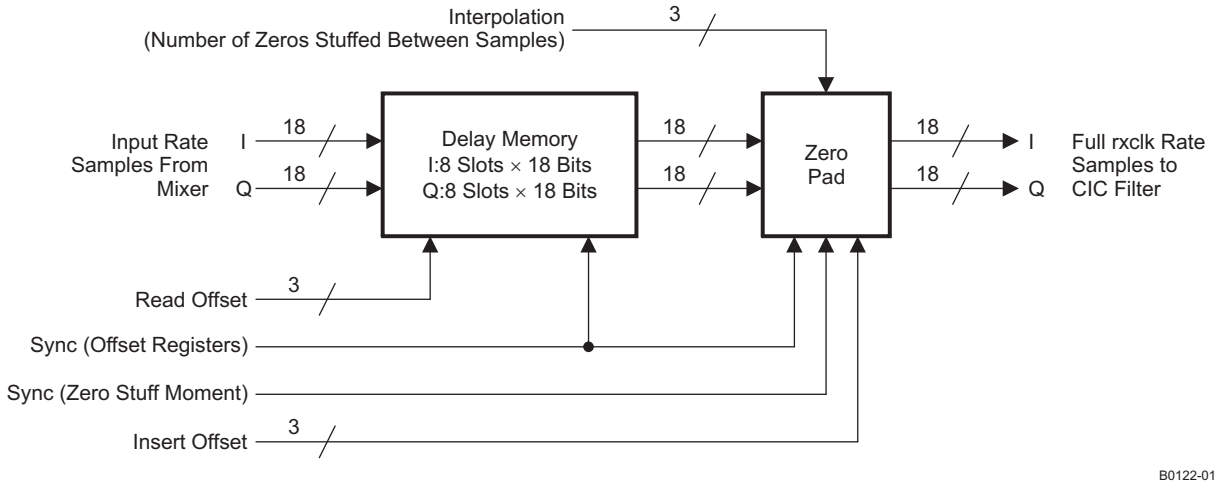

Figure 7-22. DDC Delay and Zero Insertion Block

The receive-channel delay-adjust function is used to add programmable delays in the channel downconvert path. Adjusting channel delay can be used to compensate for analog elements external to the AFE8405 digital downconversion such as cables, splitters, analog downconverters, filters, etc.

The delay memory block consists of an eight-register memory and a state machine. The state machine uses a counter to control the write (input) pointer, and the programmed read offset register data to create a read (output) pointer. Programming larger read offset register values increases the effective delay at a resolution equal to the input sample rate.

The zero-pad block is used in conjunction with the delay memory for delay adjustments. For example, with input rates of rxclk/8, the zero-pad block interpolates the input data to rxclk by inserting seven zeros. The zero-pad's sync and insert-offset controls specify when the zeros are inserted relative to the sync signal. This permits a fine adjustment at the rxclk resolution.

The read offset register, tadf_offset_course_a/b, and the insert offset register, tadj_offset_fine_a/b, are double-buffered. Writes to these registers may occur anytime, but the actual values used by the circuit are not updated until a register sync.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
tadj_offset_coarse_a(2:0)	Read offset into the eight-element memory for the UMTS or CDMA mode-A channel DDC.
tadj_offset_coarse_b(2:0)	Read offset into the eight-element memory for the CDMA mode-B channel DDC when in CDMA mode.
tadj_offset_fine_a(2:0)	Controls the zero-pad (or stuff) insert offset (fine adjust) for the UMTS or CDMA mode-A channel of the DDC.
tadj_offset_fine_b(2:0)	Controls the zero-pad (or stuff) insert offset (fine adjust) for the CDMA mode-B channel of the DDC when in CDMA mode.
tadj_interp(2:0)	The interpolation value (1, 2, 4, or 8). Same used for both the A and B channels when in CDMA mode. Selects the number of zeros to be inserted.
ssel_tadj_fine(2:0)	Selects the sync source for the fine time-adjust, zero-stuff moment. Same for A and B channels when in CDMA mode.
ssel_tadj_reg(2:0)	Selects the sync source used to update the double-buffer caurse- and fine-delay selection registers. Same for A and B channels when in CDMA mode.

7.2.6 DDC CIC Filter

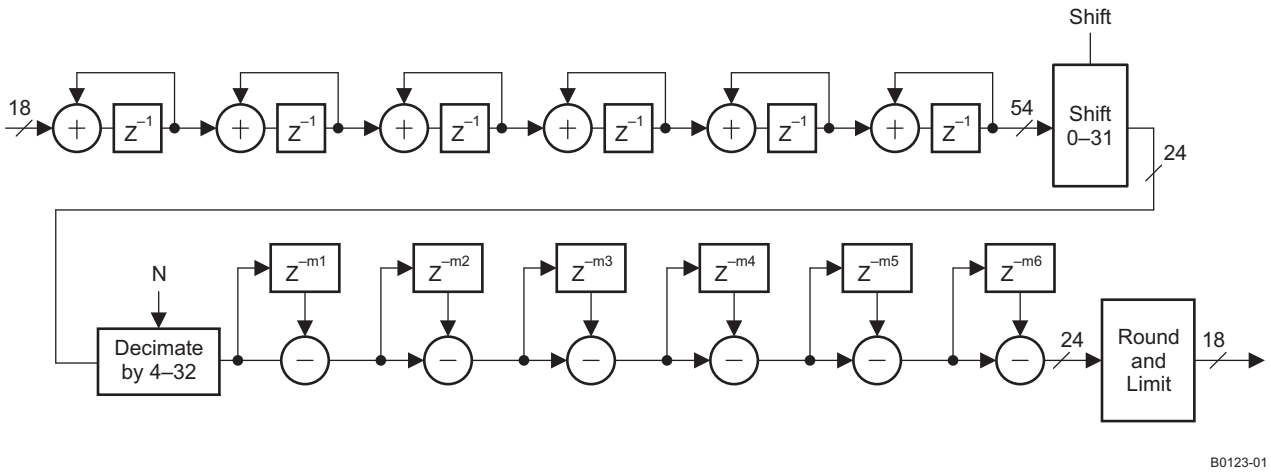

Figure 7-23. DDC CIC Filter Block Diagram

The CIC filter provides the first stage of filtering and large-value decimation. The filter consists of six stages and decimates over a range from 4 to 32.

I data and Q data are handled separately with two CIC filters. In addition, when in CDMA mode (two CDMA channels processed within a single DDC), another pair of CIC filters handles the B-side channel.

The filter response is 6×(sin(x)/x) in character where the key attribute is that the resulting response nulls signal aliases from decimation. A consequence of this desirable behavior is that only a small portion of the passband can be used, generally less than 25%. This means that the CIC decimation value should be chosen so that the signal exiting the CIC filter is oversampled by at least a factor of four.

The filter is equivalent to six stages of an FIR filter with uniform coefficients (six combined boxcar filter stages). Each filter would be of length N if m = 1, or 2N if m = 2.

The filter is made up of six banks of 54-bit accumulator sections followed by six banks of 24-bit subtractor sections. Each of the subtractor sections can be independently programmed with a differential delay of either one or two. A shift block follows the last integration stage and can shift the 54-bit accumulated data down by 36-rcic_shift (a programmable factor from 0 to 31 bits).

The CIC filter exhibits a droop across its frequency response. The following CFIR filter compensates for the CIC droop with a gradually rising frequency response. It is also possible to compensate for CIC droop in the PFIR filter.

The gain of the receive CIC filter is:

$Ncic^6 \times 2^{(\text{number of stages where M=2})} \times 2^{(-36+RCIC\_SHIFT)}$, where RCIC_SHIFT is 0 to 31.

There is no rollover protection internal to the CIC or at the final round, so the user must ensure no sample exceeds full scale prior to rounding. For practical purposes, this means the CIC gain can only compensate for peak gain less than one or must be less than or equal to one. A fixed gain of 12 dB at the output of the CIC can also be programmed.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
cic_decim(4:0)	The CIC decimation ratio (4 to 32). The ratio is cic_decim + 1. This ratio applies to both A and B channels of the DDC block in CDMA mode.
cic_scale_a(4:0)	The shift value for the A channel. A value of 0 is no shift; each increment in value increases the amplitude of the shifter output by a factor of 2.
cic_scale_b(4:0)	The shift value for the B channel. A value of 0 is no shift; each increment in value increases the amplitude of the shifter output by a factor of 2.
cic_gain_ddc	When asserted, adds a gain of 12 dB at the CIC output.
cic_m2_ena_a(5:0)	Sets the differential delay value M for each of the CIC subtractor stages for the UMTS or CDMA mode A channel.
cic_m2_ena_b(5:0)	Sets the differential delay value M for each of the CIC subtractor stages for the CDMA mode B channel.
cic_bypass	Bypasses the CIC filter when set, for factory use only.
ssel_cic(2:0)	Sets syncing (1 of 8 sources) for the CIC decimation moment.

7.2.7 DDC Compensating FIR Filter (CFIR)

The receive compensating FIR filter (CFIR) decimates the output of the CIC filter by a fixed factor of two. Filter coefficient size, input data size, and output data size are 18 bits. The CFIR length can be programmed. This permits turning off taps and saving power if shorter filters are appropriate (the CFIR power dissipation is proportional to its length).

The filter is organized in two partial filter blocks, each containing a data RAM, a coefficient RAM, and a dual multiplier; and a common state machine and output accumulator.

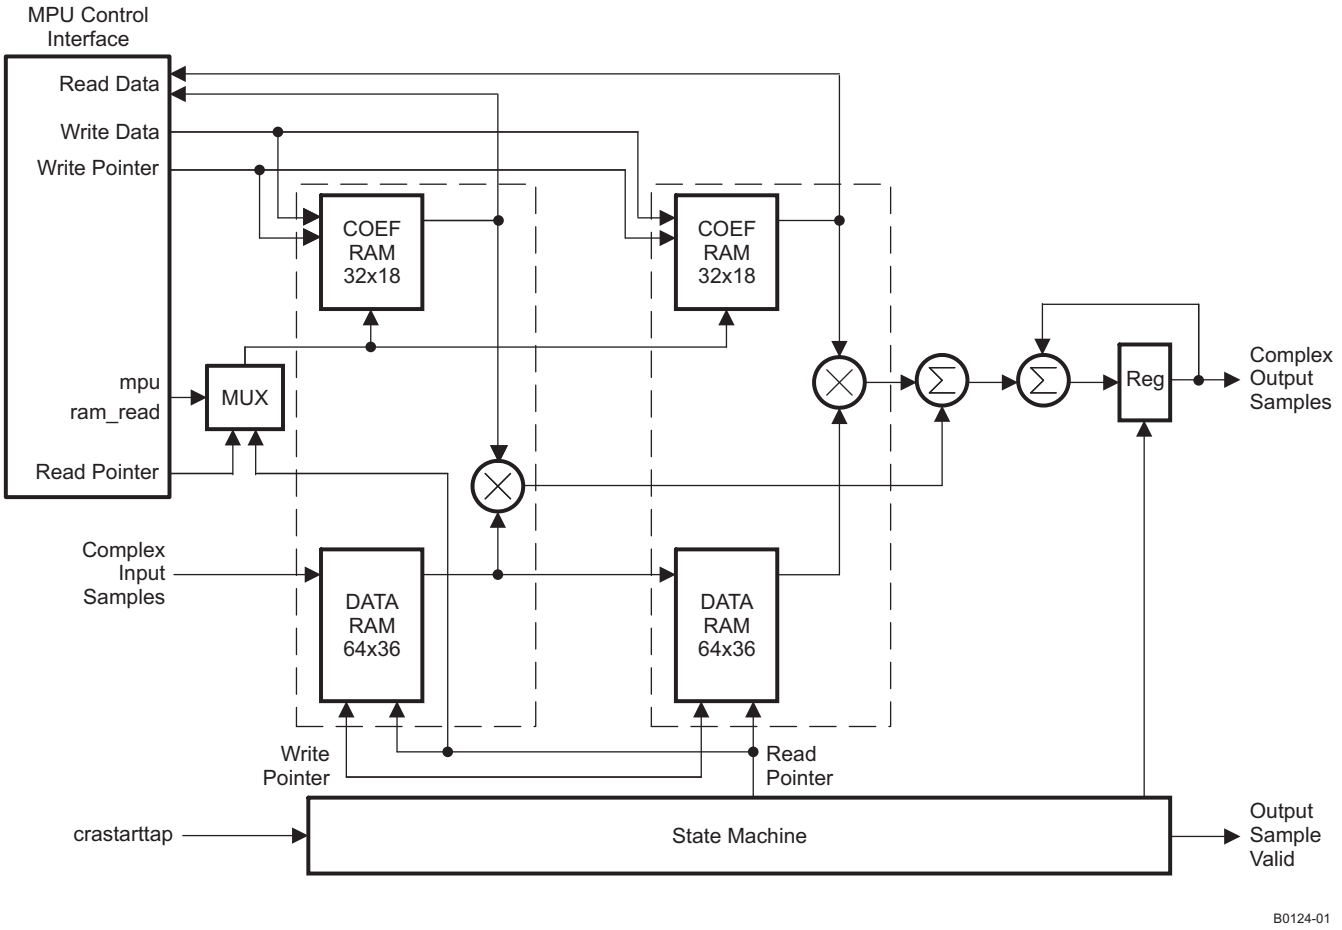

Figure 7-24. DDC CFIR Block Diagram

The maximum CFIR filter length is a function of AFE8405 rxclk clock rate, output sample rate, and the number of coefficient memory registers. The maximum number of taps is 64 and the minimum number is 14. Lengths between these limits can be specified in increments of 2.

Subject to the above minimum and maximum values, in the general case, the number of taps available is:

UMTS mode: 2 × (rxclk ֏tput sample rate)

CDMA mode if cic_decim is even (decimating by an odd number): 2 × (cic_decim)

CDMA mode if cic_decim is odd (decimating by an even number): 2 × (cic_decim + 1)

Example CFIR filter lengths available based on mode and rxclk frequency:

Mode	rxclk (MHz)	CIC DECIMATION	cic_decim	CFIR MAX LENGTH	CFIR MIN LENGTH	COMMENTS
UMTS	153.6	10	9	40	14	UMTS
UMTS	122.88	8	7	32	14	UMTS
CDMA	157.2864	32	31	64	14	CDMA2000
CDMA	122.88	25	24	48	14	CDMA2000
CDMA	78.6432	16	15	32	14	CDMA2000 low-power configuration
CDMA	153.6	30	29	60	14	TD-SCDMA
CDMA	81.92	16	15	32	14	TD-SCDMA
CDMA	76.8	15	14	28	14	TD-SCDMA low-power configuration

A single set of programmed tap values is used for both the A-side and B-side DDC channels (two CDMA channels) within a single DDC block when in CDMA mode.

After the CFIR filter performs the convolution, gain is applied at full precision, the signal is rounded, and then hard limited. A shifter at the output of the filter then scales the data by either 2e-19 or 2e-18. The gain through the filter is therefore:

$$\text{Sum(CFIR coefficients)} \times 2^{-(18 \text{ or } 19)}$$

Coefficients are organized in two groups of 32 words, each 18 bits wide. For fully utilized filters, the 64 coefficients are loaded 0 through 31 into the first RAM, and 32 through 63 into the second RAM. The 16-bit MSBs and 2-bit LSBs are written into the RAMs using different page register values. Shorter filters require the coefficients be loaded into the 2 RAMs equally, starting from address 0.

For example, a CFIR coefficient set for a symmetric 58-tap TD-SCDMA CFIR is:

Taps	Coefficient	Taps	Coefficient
0 = 57	–13	15 = 42	–4,975
1 = 56	–20	16 = 41	–4,649
2 = 55	14	17 = 40	–232
3 = 54	101	18 = 39	6,581
4 = 53	184	19 = 38	11,266
5 = 52	133	20 = 37	8,917
6 = 51	–147	21 = 36	–1,957
7 = 50	–562	22 = 35	–16,736
8 = 49	–768	23 = 34	–25,469
9 = 48	–364	24 = 33	–17,599
10 = 47	719	25 = 32	11,560
11 = 46	1,905	26 = 31	56,455
12 = 45	2,126	27 = 30	102,215
13 = 44	567	28 = 29	131,071
14 = 43	–2,416		

The first 29 coefficients are loaded into addresses 0 through 28 in the first coefficient RAM, and the remaining 29 are loaded into addresses 0 through 28 in the second coefficient RAM. Loading the 18-bit coefficients requires 2 writes per coefficient, one for the upper 16 bits and another for the lower 2 bits.

To program this coefficient set for the DDC2 CFIR, the following control microprocessor interface sequence would be used.

Step	Address a[5:0]	Data d[15:0]	Description

PROGRAMMING	
VARIABLE	**DESCRIPTION**
crastarttap_cfir(4:0)	Number of DDC CFIR filter taps is 2 × gbl_ddc_writegbl_ddc_writegbl_ddc_write
mpu_ram_read	What set, the PFIR and CFIR coefficient rams are readable via the MPU control interface. *The AFE8405 signal path is not operational when this bit is set, it is intended for debug purposes only.*
cfir_gain	0 = $2e^{-19}$, 1 = $2e^{-18}$
The CFIR filter's 18-bit coefficients are loaded in two 32-word memories. **Note:** CFIR filter coefficients are shared between A and B channels of a DDC block in CDMA mode.	

7.2.8 DDC Programmable FIR Filter (PFIR)

The receive programmable FIR filter (PFIR) provides final pulse shaping of the baseband signal data. It does not perform any decimation. Filter coefficient size, input, and output data size is 18 bits. A special strapped mode can be employed for UMTS where two adjacent DDCs (2k and 2k + 1, k = 0 to 3) can be combined to yield a filter with twice the number of coefficients. This means the AFE8405 can support 4 UMTS DDC channels with double-length filter coefficients (up to 128 taps).

The filter is organized in four partial filter blocks, each containing a data RAM, a coefficient RAM and a dual multiplier, a common state machine and output accumulator.

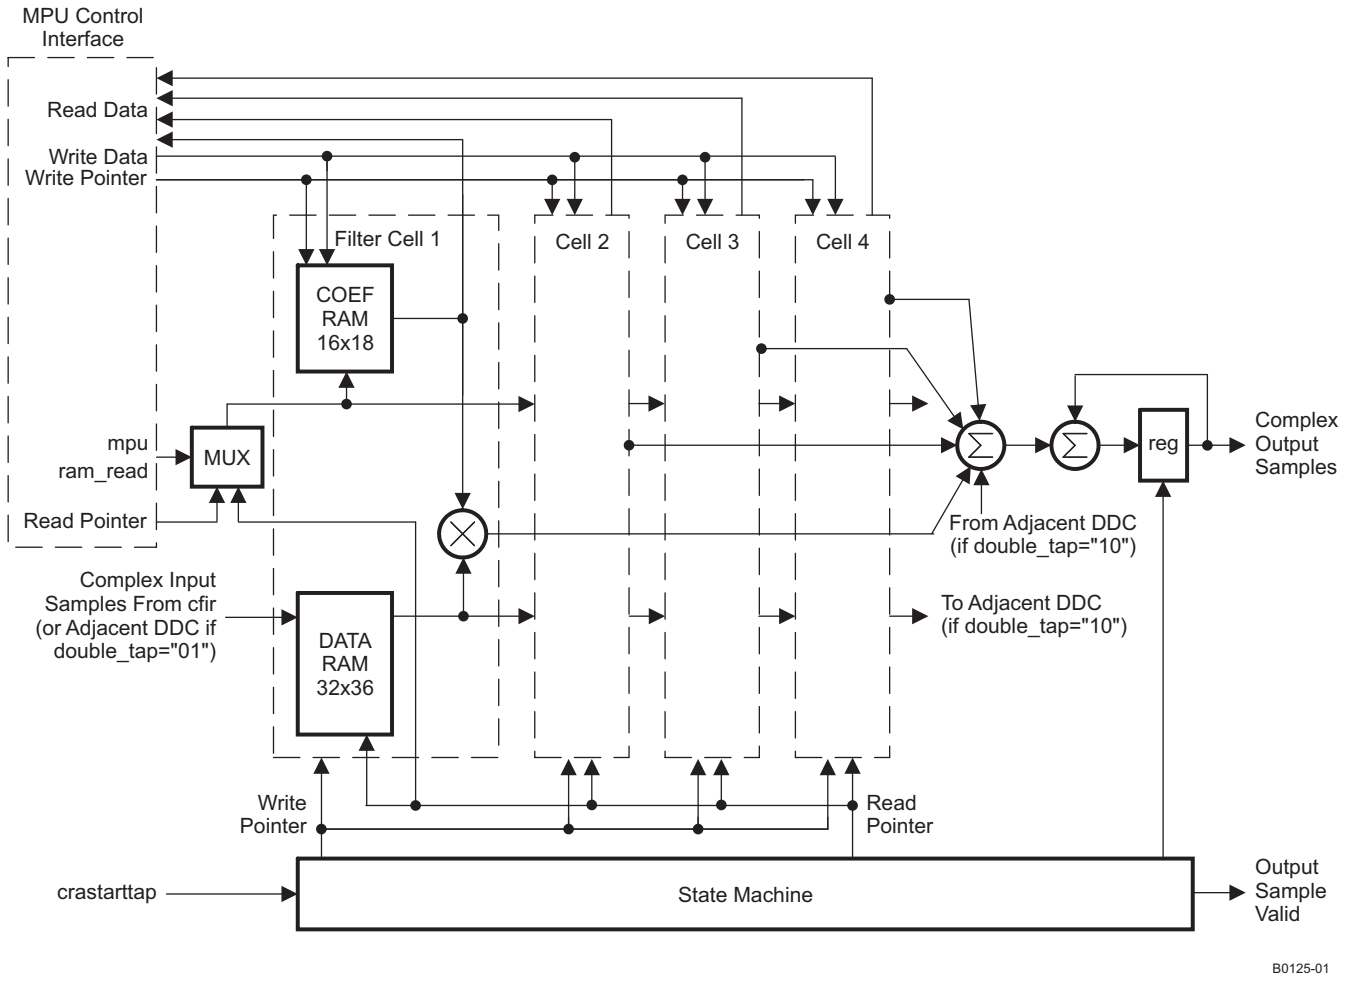

Figure 7-25. DDC PFIR Block Diagram

The PFIR length is programmable. This permits turning off taps and saving power if short filters are appropriate. The filter's output data can be shifted over a range of 0 to 7 bits where it is then rounded and hard-limited to 18 bits. The shift range results in a gain that ranges from $2e^{-19}$ to $2e^{-12}$.

The gain of the PFIR block is: sum(coefficients) $\times$ 2^{-shift}, where shift ranges from 12 to 19.

The maximum PFIR filter length is a function of AFE8405 clock rate and output sample rate and is limited by the number of coefficient memory registers. The maximum number of taps is 64 and the minimum number is 32 (for both CDMA and UMTS). Lengths between these limits can be specified in increments of 4. For strapped UMTS with double length filters, the range of taps available is 64 to 128 in increments of 8.

Subject to the above minimum and maximum values, the number of maximum taps available is:

UMTS mode: 4 $\times$ (rxclk $\div$ output + sample rate)

Strapped UMTS mode: 8 $\times$ (rxclk $\div$ output + sample rate)

CDMA mode: 2 $\times$ (rxclk $\div$ output + sample rate)

PFIR coefficients and gain shift values are shared between both A and B CDMA channels in a DDC block.

Example PFIR filter lengths available based on mode and rxclk frequency:

Mode	rxclk (MHz)	CIC DECIMATION	PFIR MAX LENGTH	PFIR MIN LENGTH	COMMENTS
UMTS	153.6	10	64	32	UMTS, 1 to 6 DDC channels
UMTS	122.88	8	64	32	UMTS, 1 to 6 DDC channels
UMTS	153.6	10	128	64	Strapped UMTS double length PFIR configuration; 1, 2, or 3 DDC channels.
UMTS	122.88	8	128	64	Strapped UMTS double length PFIR configuration; 1, 2, or 3 DDC channels
CDMA	157.2864	32	64	32	CDMA2000
CDMA	122.88	25	64	32	CDMA2000
CDMA	78.6432	16	64	32	CDMA2000 low power configuration
CDMA	153.6	30	64	32	TD-SCDMA
CDMA	81.92	16	64	32	TD-SCDMA
CDMA	76.8	15	60	32	TD-SCDMA low power configuration

Coefficients are organized in four groups of 16 words, each 18 bits wide. For fully utilized filters, the 64 coefficients are loaded 0 through 31 into the first and second RAMs, and 32 through 63 into the third and fourth RAMs. The 16-bit MSBs and 2-bit LSBs are written into the RAMs using different page register values. Shorter filters require the coefficients be loaded into the four RAMs equally, starting from address 0 and address 16.

For example, a CFIR coefficient set for a symmetric 60-tap TD-SCDMA PFIR is:

Taps	Coefficient	Taps	Coefficient
0 = 59	–2	15 = 44	420
1 = 58	1	16 = 43	–331
2 = 57	4	17 = 42	–319
3 = 56	–8	18 = 41	744
4 = 55	–2	19 = 40	–440
5 = 54	21	20 = 39	–1,005
6 = 53	–13	21 = 38	2,389
7 = 52	–28	22 = 37	514
8 = 51	46	23 = 36	–6,182
9 = 50	1	24 = 35	1,845
10 = 49	–85	25 = 34	12,959
11 = 48	96	26 = 33	–8,691
12 = 47	82	27 = 32	–27,246
13 = 46	–266	28 = 31	34,166
14 = 45	38	29 = 30	131,071

The first 15 coefficients are loaded into addresses 0 through 14 in the first coefficient RAM, the second group of 15 are loaded into addresses 16 through 30 corresponding to the second coefficient RAM, the third group of 15 are loaded into the third coefficient ram at addresses 0 through 14, and the fourth group of 15 are loaded into addresses 16 through 30 in the fourth coefficient RAM. Loading the 18-bit coefficients requires two writes per coefficient, one for the upper 16 bits and another for the lower 2 bits.

To program this coefficient set for the DDC2 PFIR, the following control microprocessor interface sequence would be used.

Step	Address a[5:0]	Data d[15:0]	Description

134	0x00	0x8EE0	DDC2 FIR_MODE register; cdma_mode enabled, 60-tap PFIR, 58-tap CFIR
135	0x01	0x2000	DDC2 PFIR gain = sum(taps) $\times 2^{-18}$ and CFIR gain = sum(taps) $\times 2^{-19}$

PROGRAMMING	
VARIABLE	**DESCRIPTION**
crastarttap_pfir(4:0)	Number of DDC PFIR filter taps is 4 × (crastartap + 1) For double length PFIR the number of taps is 8 × (crastartap + 1)
cdma_mode	When set, puts the CFIR & PFIR blocks in CDMA mode.
mpu_ram_read	What set, the PFIR and CFIR coefficient rams are readable via the MPU control interface. *The AFE8405 signal path is not operational when this bit is set, it is intended for debug purposes only.*
pfir_gain(2:0)	Sets the gain of the PFIR filter. The range is from $2e^{-19}$ to $2e^{-12}$; 000 = $2e^{-19}$ and 111 = $2e^{-12}$
double_tap(1:0)	When set, puts two adjacent DDC (2k and 2k + 1, k = 0 to 2) in double length (from 64- to 128-tap) UMTS mode. Set to 00 for normal mode. In double-tap mode, data out of the last PFIR RAM in the main DDC (DDC0, DDC2, DDC4, or DDC6) is sent to the adjacent secondary DDC (DDC1, DDC3, DDC5, or DDC7) PFIR as input, thus forming a 128-tap delay line. Data received from the adjacent PFIR summers is added into the main DDC's PFIR sum to form the final output. When using double-tap mode, set double_tap to 10 for the main DDC, and to 01 for the secondary DDC. When in double-tap mode, the first half of the coefficients should be loaded into the main DDC (DDC0, DDC2, DDC4, or DDC6), the remaining coefficients are loaded into the secondary DDC (DDC1, DDC3, DDC5, or DDC7). In double-tap mode, the main DDC must be turned on (ddc_ena = 1), and the secondary DDC must be turned **off** (ddc_ena = 0).
The PFIR filter's 18-bit coefficients are loaded in four 16-word memories.	
Note: PFIR filter coefficients are shared between A and B channels of a DDC block when in CDMA mode.	

7.2.9 DDC RMS Power Meter

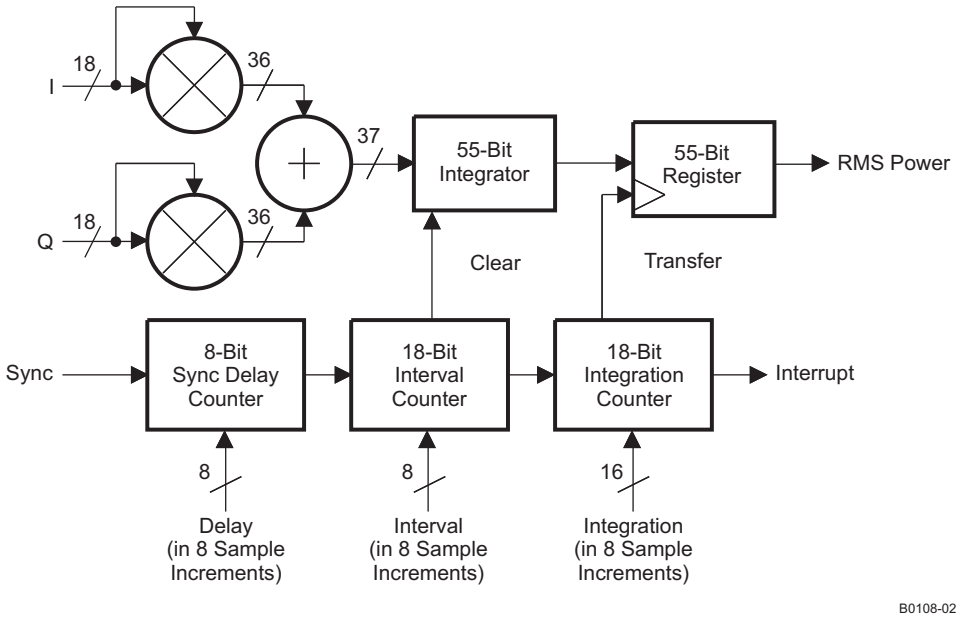

Figure 7-26. DDC RMS Power Meter Block Diagram

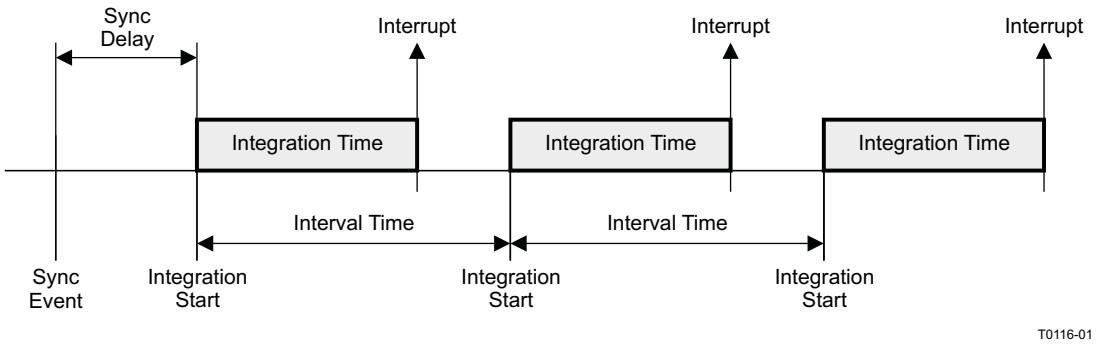

Figure 7-27. DDC RMS Power Meter Timing

Each DDC channel includes an RMS power meter which is used to measure the total power within the channel pass band.

The power meter samples the I and Q data stream after the PFIR filter. Both 18-bit I and Q data are squared, summed, and then integrated over a period determined by a programmable counter. The integration time is a 16-bit word which is programmed into the 18-bit counter.

There is a programmable 18-bit interval timer which sets the interval over which power measurements are made. The timer counts in increments of 1024 samples. This allows the user to select intervals from 1 $\times$ 1024 samples up to 256 $\times$ 1024 samples. For UMTS systems with sample rate rate at 7.68 MHz, the power meter interval range is from 133 μs to 34.1 ms. For a CDMA system with the sample rate at 2.4576 MHz, the power meter interval range is 417 μs to 107 ms.

The power measurement process starts with a sync event. The integration starts at sync event + 3 chips + sync_delay. The 8-bit delay register permits delays from 1 to 256 samples after sync. The integration continues until the integration count is met. At that point, the result in the 55-bit accumulator is transferred to the read holding register and an interrupt is generated indicating the power value is ready to read. The interval counter continues until the programmed interval count is reached. When reached, the integration counter and the interval counter start over again. Each time the integration count is reached, the 55 result bits are again transferred to the read register, overwriting the previous value, and an interrupt is generated signifying the data is ready to be read. Failure to read the data in time results in overwriting the previous interval measurement.

Sync starts the process. Whenever a sync is received, all the counters are reset to zero no matter what the status.

For UMTS, I and Q are calculated and the integrated power is read. When in CDMA mode, the power is calculated for both the A (signal) path and the B (diversity) signal. As a result, there are two 55-bit words representing the signal and diversity when in CDMA mode.

The power read is:

power = $[(I^2 + Q^2) \times (N \times 4 + 1)]$, where N is the integration count.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
pmeter_result_a(54:0)	55-bit UMTS or CDMA mode-A channel-power measurement result
pmeter_result_b(54:0)	55-bit CDMA mode-B channel-power measurement result
pmeter_sqr_sum_ddc(15:0)	Integration (square and sum) count in increments of four samples.
pmeter_sync_delay_ddc(7:0)	Sync delay count in samples.
pmeter_interval_ddc(7:0)	The measurement interval in increments of 2048 samples. This value must be greater than SQR_SUM.
ssel_pmeter(2:0)	Sync source selection.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
pmeter_sync_disable	Turns off the sync to the channel power meter. This can be used to individually turn off syncs to a channel power meter while still having syncs to other power meters on the chip.

7.2.10 DDC AGC

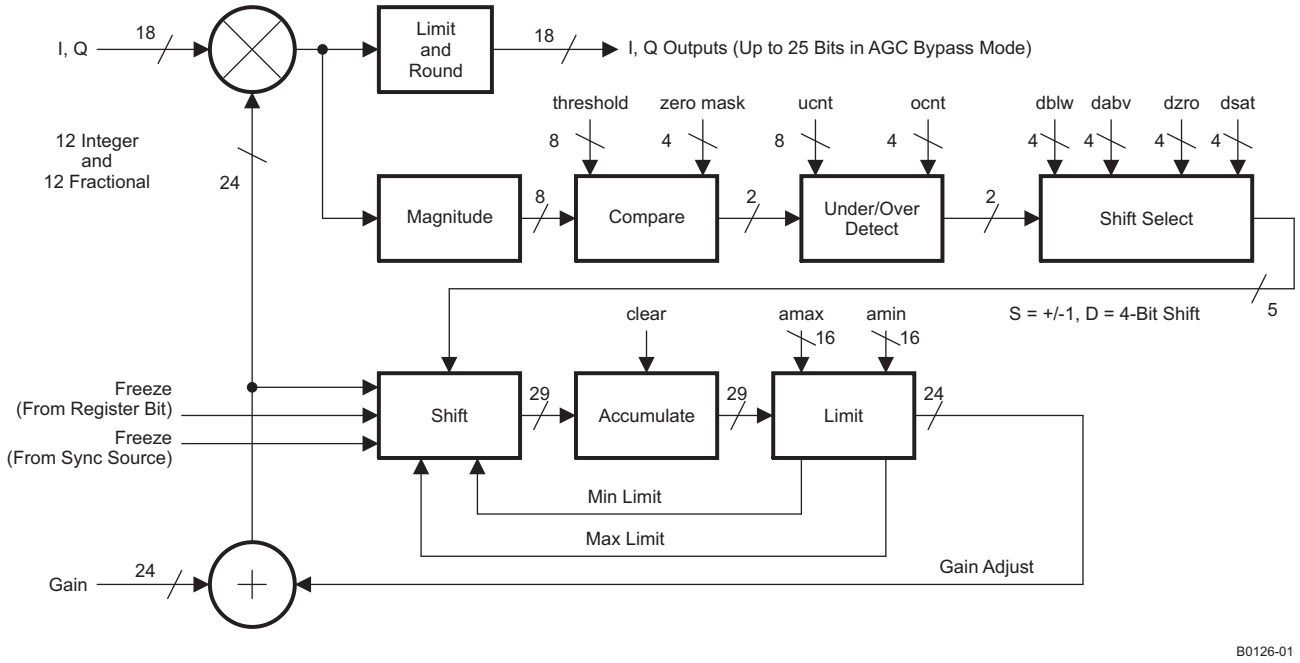

Figure 7-28. DDC AGC Block Diagram

The AFE8405 automatic gain control circuit is shown in Figure 7-28. The basic operation of the circuit is to multiply the 18-bit input data from the PFIR by a 24-bit gain word that represents a gain or attenuation in the range of 0 to 4096. The gain format is mixed integer and fraction. The 12-bit integer allows the gain to be boosted by up to factor of 4096 (72 dB). The 12-bit fractional part allows the gain to be adjusted up or down in steps of one part in 4096, or approximately 0.002 dB. If the integer portion is zero, then the circuit attenuates the signal. The gain-adjusted output data is saturated to full scale and then rounded to between 4 and 18 bits in steps of one bit.

The AGC portion of the circuit is used to adjust the gain automatically so that the *median* magnitude of the output data matches a target value, which is performed by comparing the magnitude of the output data with a target threshold. If the magnitude is greater than the threshold, then the gain is decreased, otherwise it is increased. The gain is adjusted as: G(t) = G + A(t), where G is the default user-supplied gain value and A(t) is the time-varying adjustment. A(t) is updated as $A(t) = A(t) + G(t) \times S \times 2^{-D}$, where S = 1 if the magnitude is less than the threshold and is –1 if the magnitude exceeds the threshold, and where D sets the adjustment step size. Note that the adjustment is a fraction of the current gain. This is designed to set the AGC noise level to a known and acceptable level while keeping the AGC convergence and tracking rate constant, independent of the gain level. The AGC noise is equal to 2^{-D}, and the AGC attack and decay rate is exponential, with a time constant equal to 2^{-D}. Hence, the AGC increases or decreases by 0.63 times G(t) in 2^{D} updates.

If one assumes the data is random with a Gaussian distribution, which is valid for UMTS if more than 12 users with different codes have been overlaid, then the relationship between the RMS level and the median is MEDIAN = 0.6745 × RMS, hence the threshold should be set to 0.6745 times the desired RMS level.

The gain step size can be set using four different values of *D*, each of which is a 4-bit integer. D can range from 3 to 18. The user can specify values of D for different situations, i.e., when the signal magnitude is below the user-specified threshold (Dblw), is above the threshold (Dabv), is consistently equal to zero (Dzro) or is consistently equal to maximum (Dsat). It is important to note that D represents a gain step size. Smaller values of D represent larger gain steps. The definition of *equal to zero* is any number when masked by zero_mask is considered to be zero. This permits consistently very small amplitude signals to have their gain increased rapidly.

Separate programmable D values allow the user to set different attack and decay time constants, and to set shorter time constants for when the signal falls too low (equal to zero), or is too high (saturates). The magnitude is considered to be consistently equal to zero by using a 4-bit counter that counts up every time the 8-bit magnitude value is zero, and counts down otherwise. If the counter value exceeds a user-specified threshold, then *Dabv* is used. Similarly the magnitude is considered too high by using a counter that counts up when the magnitude is maximum, and counts down otherwise. If this counter exceeds another user specified threshold, then *Dsat* is used.

As an example, if the AGC's current gain at a particular moment in time is 5.123, and the magnitude of the signal is greater than zero, but less than the user-programmed threshold. Step size Dblw is used to modify the gain for the next sample. This represents the AGC attack profile. If Dblw is set to a value of 5, then the gain for the next sample is $5.123 + 5.123 \times 2^{-5} = 5.123 + 0.160 = 5.283$. If the signal magnitude is still less than the user-programmed threshold, then the gain for the next sample is $5.283 + 5.283 \times 2^{-5} = 5.283 + 0.165 = 5.448$. This continues until the signal magnitude exceeds the user-programmed threshold. When the magnitude exceeds threshold (but is not saturated), then step size Dabv is automatically employed as a size rather than Dblw.

The AGC converges linearly in dB with a step size of $40 \log(1 + 2^{-D})$ when the error is greater than 12 dB (i.e., the gain is off by 12 dB or more). Within 6 dB, the behavior is approximately an exponential decay with a time constant of $2^{(D - 0.5)}$ samples.

The suggested value of D is 5 or 6 when the error is greater than 12 dB (i.e., in the fast range detected by consistently zero or saturated data). This gives a step size of 0.5 or 0.25 dB per sample.

The suggested value when the gain is off by less than 12 dB is D = 10, giving an exponential time constant for delay of around 724 samples (63% decay every 724 samples).

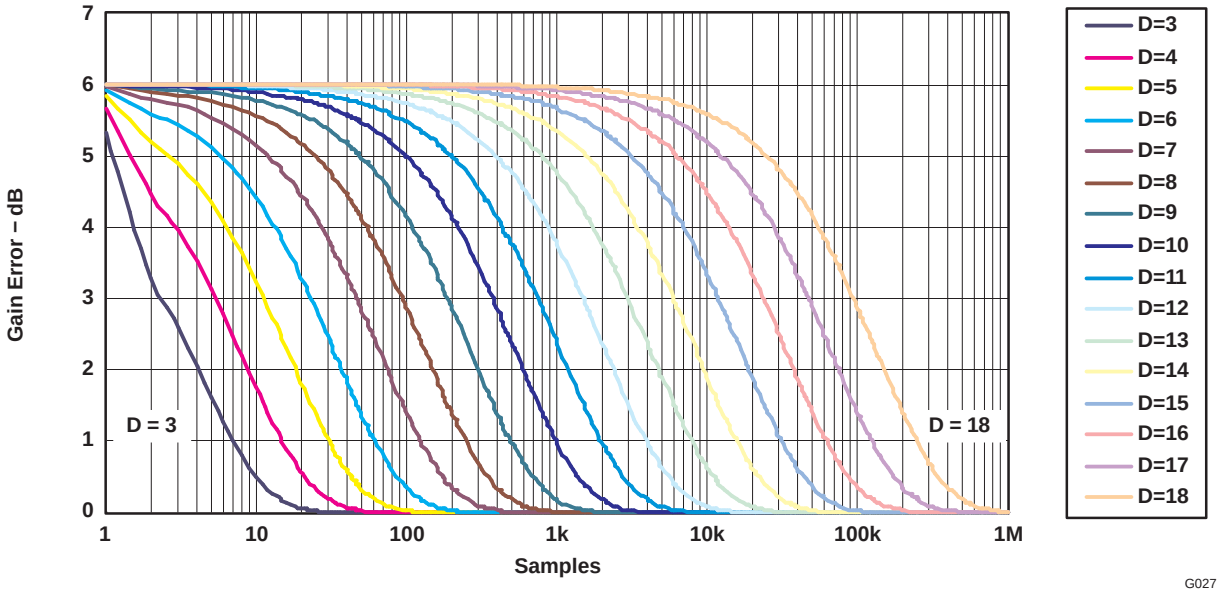

Figure 7-29. AGC Gain Error Over Time vs. D

The AGC noise once the AGC has converged is a random error of amplitude 2^{-D} relative to the RMS signal level. This means that the error level is $-6 \times D$ dB below the signal RMS level. At D = 10 (–60 dB) the error is negligible. The plot of Figure 7-29 shows the AGC response for vales of D ranging from 3 to 18. *Error dB* represents the distance the signal level is from the desired target threshold.

The AGC is also subject to user-specified upper and lower adjustment limits. The AGC stops incrementing the gain if the adjustment exceeds Amax. It stops decrementing the gain if the adjustment is less than Amin.

The input data is received with a valid flag that is high when a valid sample is received. For complex data, the I and Q samples are on the same data input line and are not treated independently. An adjustment is made for the magnitude of the I sample, and then another adjustment is made for the Q sample.

The AGC operates on UMTS and CDMA data. When in UMTS mode, the I and Q data are each used to produce the AGC level. There is no separate I path gain and Q path gain. When in CDMA mode there are separate gain levels for the signal and diversity I and Q data. The I and Q for A (or the signal) pair is calculated and then the I' and Q' for the B (or diversity) pair is calculated.

There is a freeze mode for holding the accumulator at its current level. This puts the AGC in a hold mode using the user-programmed gain along with the current gain_adjust value. To use only the user-programmed gain value as the gain, set the freeze bit and then clear the accumulator. When using the freeze bit, the full 25-bit output is sent out of the AGC block to support transferring up to 25 bits when the AGC is disabled.

For TDD applications, freeze mode can be controlled using a sync source. This allows rxsync_a/b/c/d to be assigned as an AGC hold signal to keep the AGC from responding during the transmit interval and run during the receive interval. The freeze register bit is logically ORed with the freeze sync source.

The current AGC gain and state can also be optionally output with the DDCs I and Q output data by setting the gain_mon variable. When in this mode, the top 14 bits of the current AGC gain word are appended to the 8-bit AGC-modified I and Q output data.

Output	Bits(17:10)	Bits(9:4)	Bits(3:2)	Bits(1:0)
I	I output data	Gain(23:16)		00
Q	Q output data	Gain(15:10)	AGC State(1:0)	00

PROGRAMMING	
VARIABLE	**DESCRIPTION**
agc_dblw(3:0)	**Below** threshold gain. Sets the value of gain step size Dblw (data x current gain below threshold). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = 0000, 4 = 0001, … 18 = 1111
agc_dabv(3:0)	**Above** threshold gain. Sets the value of gain step size Dabv (data x current gain above threshold). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = 0000, 4 = 0001, … 18 = 1111
agc_dzro(3:0)	**Zero** signal gain. Sets the value of gain step size Dzro (data x current gain consistently zero). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = 0000, 4 = 0001, … 18 = 1111
agc_dsat(3:0)	**Saturated** signal gain. Sets the value of gain step size Dsat (data x current gain consistently saturated). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = 0000, 4 = 0001, … 18 = 1111
agc_zero_msk(3:0)	Masks the lower 4 bits of signal data so as to be considered zeros.
agc_md(3:0)	AGC rounding. 0000 = 18 bits out, 1111 = 3 bits out.
agc_thresh(7:0)	AGC threshold. Compared with magnitude of 8 bits of input × gain.
agc_rnd_disable	AGC rounding is disabled when this bit is set.
agc_freeze	The AGC gain adjustment updates are disabled when set.
agc_clear	The AGC gain adjustment accumulator is cleared when set.
agc_gaina(23:0)	24-bit gain word for DDC A
agc_gainb(23:0)	24-bit gain word for DDC B (in CDMA mode)
agc_zero_cnt(3:0)	When the AGC output (input × gain) is zero-value this number of times, the shift value is changed to agc_dzero.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
agc_max_cnt(3:0)	When the AGC output (input × gain) is zero-value this number of times, the shift value is changed to agc_dsat.
agc_amax(15:0)	The maximum value that gain can be adjusted up to. Top 12 bits are integer, bottom 4 bits are fractional.
agc_amin(15:0)	The minimum value that gain can be adjusted down to. Top 12 bits are integer, bottom 4 bits are fractional.
gain_mon	When set, combines current AGC gain with I and Q data. The 18-bit output format thus becomes: I portion: 8 bits of AGC'd I data - Gain(23:16) - 00 Q portion: 8 bits of AGC'd Q data - Gain(15:10) - Status(1:0) - 00. **Note:** Bit 0 of Status, when set, indicates the data is saturated. Bit 1 of Status, when set, indicates the data is zero.
ssel_agc_freeze(2:0)	Sync selection for freeze mode, 1 of 8 sources. This source is ORed with the freeze register bit.
ssel_gain(2:0)	Sync selection for the double buffered agc_gaina and agc_gainb register.
ssel_ddc_agc(2:0)	Sync selection used to initialize the AGC, primarily for test purposes.

7.2.11 DDC Output Interface

The baseband I/Q sample interface can be configured as serial or parallel formatted data. The serial interface closely matches the GC5316-style interface. The parallel interface is provided to interface directly to the TMS320TCI110 when delayed antenna streams used to implement channel estimation buffering and/or transport format combination indicator (TFCI) buffering are not required.

The DDC output data is 2s-complement format.

7.2.11.1 Serial Output Interface

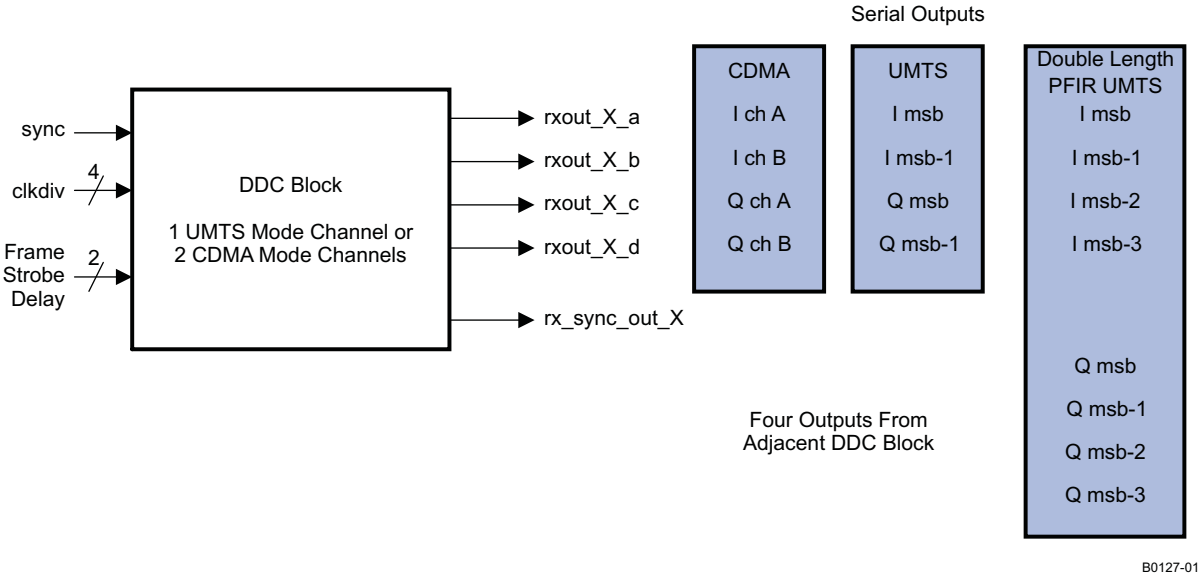

Figure 7-30. Serial Output Block Diagram and Output Pins for Each DDC Filter Mode

Each DDC block can be assigned four serial output data pins. These pins are used to transfer downconverted I/Q baseband data out of the AFE8405 for subsequent processing. The usage of these pins changes depending on how the DDC block is configured.

When the block is configured for two CDMA channels, a pair of serial data pins provides separate I and Q data output for the two DDC channels. Word size is selectable from 4 to 25 bits with the most-significant bit first.

When the DDC block is configured for a single UMTS channel, even and odd I and Q data drive the four serial pins separately, most-significant bit first.

Four serial pins each for I and Q data can be optionally employed (instead of two for I and two for Q) at half the output rate. This would most likely be used when two DDC channels (2k and 2k + 1, k = 0 to 5) are combined to support double-length PFIR filtering (a channel is sacrificed). Formatting for I data is then: Imsb, Imsb-1, Imsb-2, Imsb-3. Q data formatting is: Qmsb, Qmsb-1, Qmsb-2, Qmsb-3.

The frame strobe signal provided on the rx_sync_out_X pins can be programmed to arrive from 0 to 3 bit clocks early via a 2-bit control parameter. The frame interval can be programmed from 1 to 63 bits. A programmable 4-bit clock divider circuit is used to specify the serial bit rate. The clock divider circuit is synchronized using a sync block discussed later in this document.

Programming the serial port clock divider requires some thought and depends upon the channel's overall decimation ratio, frame sync interval, number of output bits, and CDMA-UMTS mode.

In general:

the serial clock divide ratio ↄ the frame sync interval = the total receive decimation

The relationship between the number of serial bits output, clock divide ratio, and overall decimation ratio is:

CDMA: [overall decimation ↄ(pser_recv_8pin + 1)] / (pser_recv_clkdiv + 1) ≥ pser_recv_bits + 1

UMTS: 2 ↄ[overall decimation ↄ(pser_recv_8pin + 1)] / (pser_recv_clkdiv + 1) ≥ pser_recv_bits + 1

where overall decimation = CIC DECIMATION × CFIR DECIMATION.

Decimation by 2 in the output interface can be achieved by setting the frame strobe interval and clock divider to 1/2 the PFIR output rate. The serial interface samples the PFIR output each time the transfer interval defined by these two settings has completed. The decimation moment can be controlled using the rxsync_X input signal selected as the sync source for the serial interface.

The timing diagram in Figure 7-31 shows the DDC serial output timing.

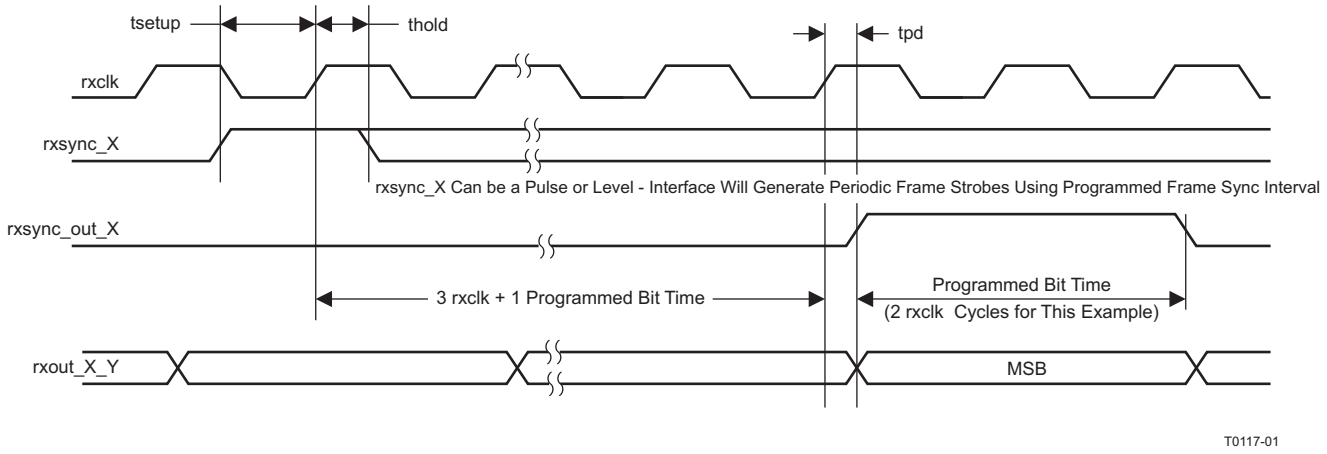

Figure 7-31. Serial Output Interface Timing Diagram

PROGRAMMING	
VARIABLE	**DESCRIPTION**
pser_recv_fsinvl(6:0)	Frame sync interval in bits
pser_recv_bits(4:0)	Number of data output bits – 1. e.g., 10001 = 18 bits
pser_recv_clkdiv(3:0)	Receive serial interface clock divider rate – 1. 0 = rcclk, 15 = rxclk/16
pser_recv_8pin	When set, configures the serial out pins for 4I and 4Q in UMTS mode. When cleared, the mode is 2I and 2Q. Used in conjunction with pser_recv_alt.
pser_recv_alt	When set, outputs Q data from adjacent DDC channel.
pser_recv_fsdel(1:0)	Number of bit clocks the frame sync is output early with respect to serial data.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ssel_serial(2:0)	Sync source selection, 1 of 8.
3-state(6:3)	3-state controls for the rx_sync_out_X and rxout_X_X pins. Pins are in the high-impedance state when the 3-state register bits are set.

7.2.11.2 Parallel Output Interface

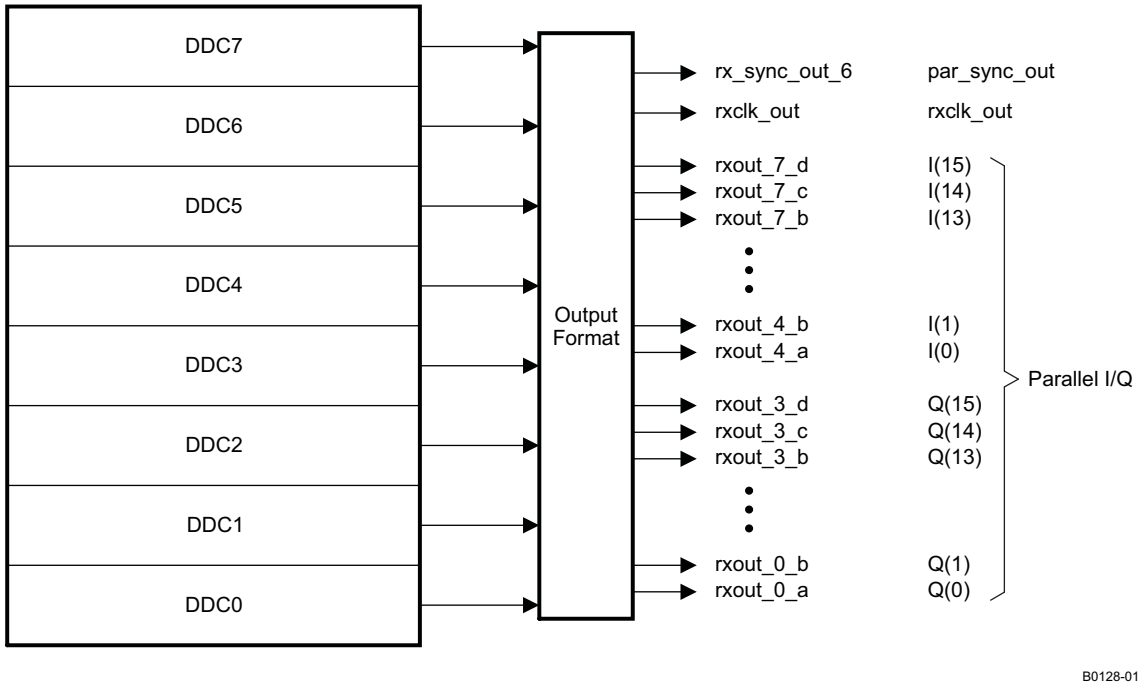

Figure 7-32. Parallel Output Interface Block Diagram and Output Pins

When a parallel I/Q interface is required, a 32-bit time-division-multiplexed output mode can be selected using the rxout_X_X pins. This interface is provided for direct connection to the TMS320TCI110 receive chip-rate ASSP when delayed antenna streams are not required. The output sample rate, rxclk_out clock polarity, par_sync_out position and number of channels to be output are all programmable.

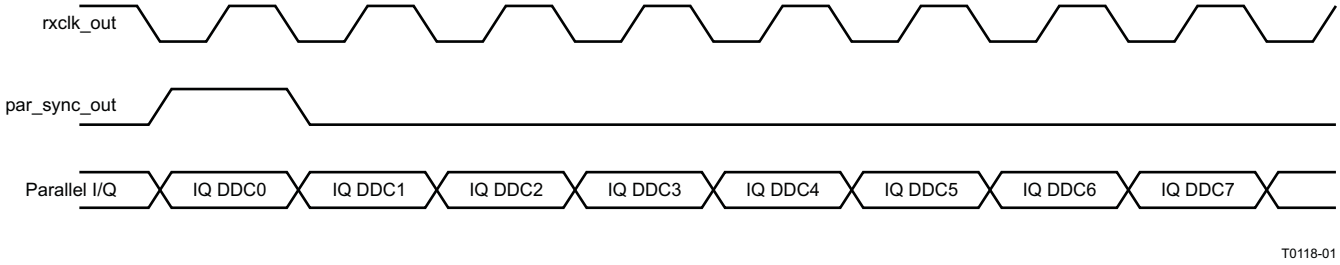

Figure 7-33. Parallel Output Interface Timing Diagram

The DDC channel serial interface synchronization source selections should all be programmed to the same value when using this parallel output interface (each DDC channel ssel_serial(2:0) in the SYNC_0 register should be programmed to the same rxsync_A/B/C/D value).

Decimation by 2 in the output interface can be achieved by setting the frame strobe interval and clock divider to 1/2 the PFIR output rate. The parallel interface samples the PFIR outputs each time the transfer interval defined by these two settings has completed.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
par_recv_fsinvl(6:0)	rx_sync_out (frame strobe) sync interval. 0 is 1 rxclk cycle and 127 is 128 rxclk cycles.
par_recv_clkdiv(6:0)	rxclk_out cycles per IQ channel sample; 1 is full rate, 2 is rxclk/2, etc.
par_recv_chan(3:0)	Number channels to be output. 0 is 1 channel, and 15 is 16 channels.
par_recv_sync_del(6:0)	Delays the DDC0 pser sync source to establish the timing of IQ DDC0. Increasing the value delays the par_sync_out location.
par_recv_syncout_del(3:0)	Delays the rx_sync_out position with respect to IQ DDC0. Setting to 0 moves the rx_sync_out pulse one rxclk_out cycle before the IQ DDC0 word, setting to 1 places it as shown above, lined up with IQ DDC0, etc.
par_recv_rxclk_pol	rxclk_out polarity. Outputs data on falling edges when cleared, rising edges when set.
par_recv_sync_pol	Parallel interface par_sync_out polarity. 0 is active-low, 1 for active-high
par_recv_ena	Parallel TCI110 style interface enabled when set, serial interface enabled when cleared.
ssel_serial(2:0)	DDC channel serial interface sync source selection. *All DDCs should be programmed to the same sync source when using this parallel output interface.*
gain_mon	When set, the parallel output data includes 8b I at I(15:8), 8b Q at Q(15:8), 14b AGC gain at I(7:0) and Q(7:2) and 2b AGC state at Q(1:0).
3-state(6:3)	3-state controls for the rx_sync_out_X and rxout_X_X pins. Pins are in the high-impedance state when the 3-state register bits are set.

7.2.12 DDC Checksum Generator

The checksum generator is used in conjunction with the input test signal generator to implement a self-test capability.

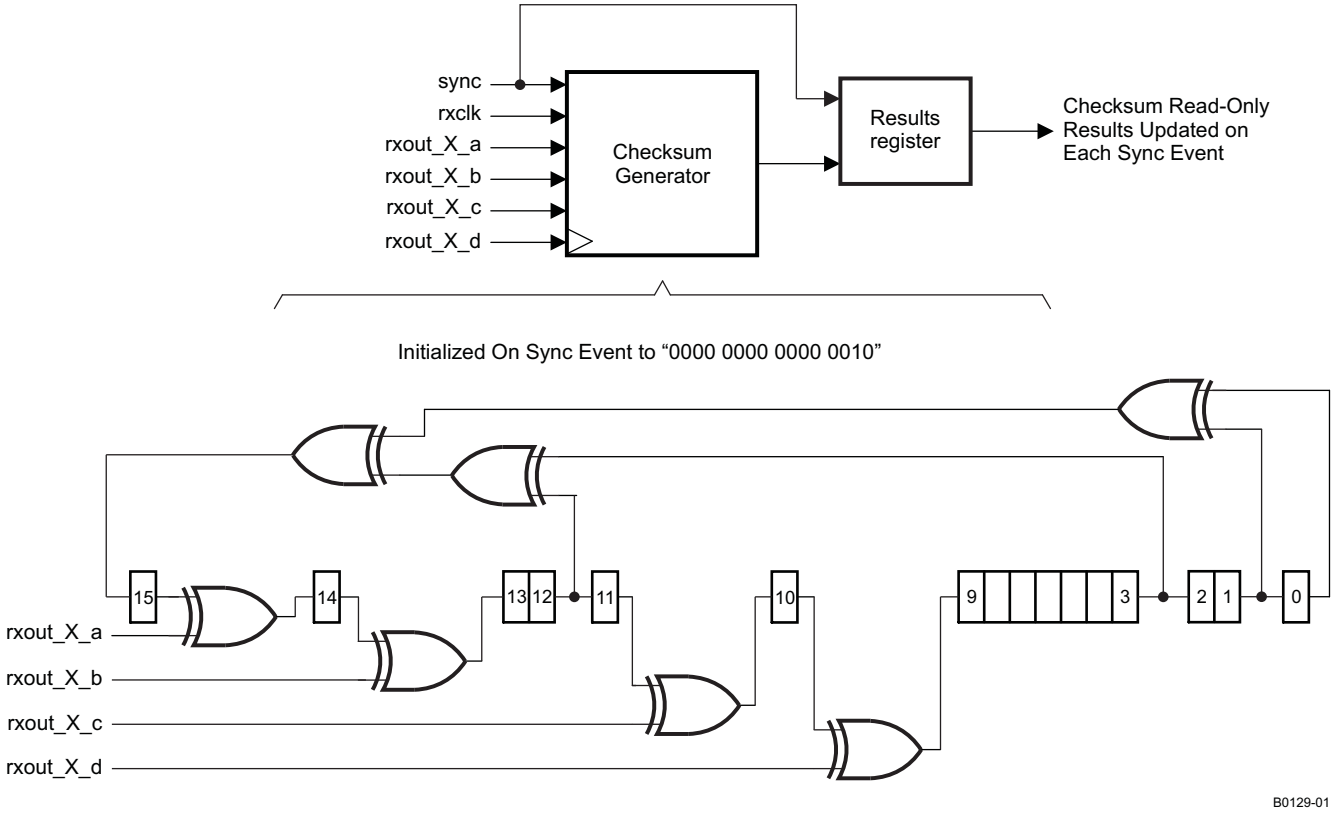

Figure 7-34. DDC Checksum Generator Block Diagram

The sync for the checksum generator is internally connected to the ddc_counter output.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ddc_chk_sum(15:0)	Read-only DDC channel checksum results

8 AFE8405 GENERAL CONTROL

The AFE8405 is configured over a bidirectional 16-bit parallel-data microprocessor control port. The control port permits access to the control registers which configure the chip. The control registers are organized using a paged-access scheme using 6 address lines. Half of the 64 addresses (address 32 through address 63) represent global registers. The other 32 (address 0 through address 31) are paged registers. This arrangement permits accessing a large number of control registers using relatively few address lines.

Global registers (address 32 through address 63) are used to read/write AFE8405 parameters that are global in nature and can benefit from single read/write operations. Examples include chip status, reset, sync options, checksum ramp parameters, interrupt sources, interrupt masks, 3-state controls and the page register.

Global address 33 is the page register. Writing a 16-bit value to this register sets the page to which future write or read operations performed. These paged registers contain the actual parameters that configure the chip and are accessed by writing/reading address 0 through address 31.

The global 3-state register can be used to place the output drivers on the AFE8405 in the high-impedance state, and also includes the capability of disabling the internal rxclk of the chip.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
rxclk_ena	Enables the internal rxclk when set. When cleared, the AFE8405 ignores the rxclk input signal and hold the internal clock low.
3-state(10:0)	Various output pins are forced into the high-impedance state when these bits are asserted. See the GBL_3STATE register description for pin groups to bit assignments.
arst_func	When asserted, the internal data path is held reset. The control register programming is not affected.

8.1 Microprocessor Interface Control Data, Address, and Strobes

The microprocessor control bus consists of 16 bidirectional control data lines **d[15:0]**, 6 address lines **a[5:0]**, a read enable line **rd_n**, a write enable line **wr_n**, and a chip enable line **ce_n**. These lines usually interface to a microprocessor or DSP chip and are intended to look like a block of memory.

The interface can be operated in a three-pin control mode (using rd_n, wr_n and ce_n) or two-pin control mode (using wr_n and ce_n with rd_n always low).

8.1.1 MPU Timing Diagrams

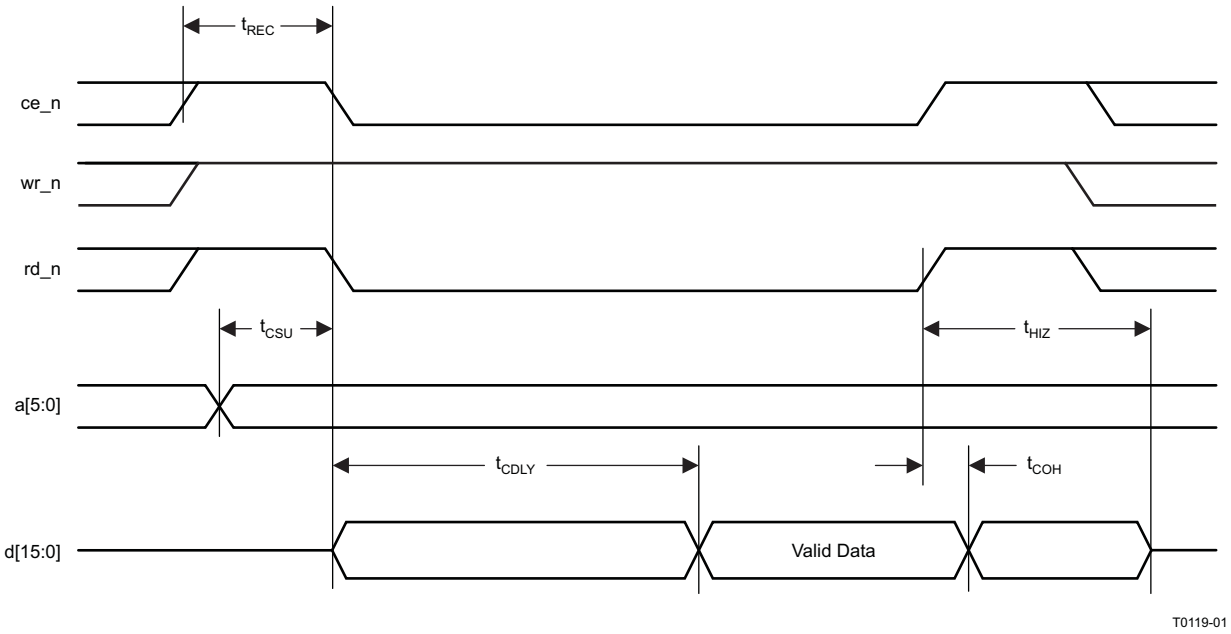

Figure 8-1. Read Operation—Three-Pin Control Mode

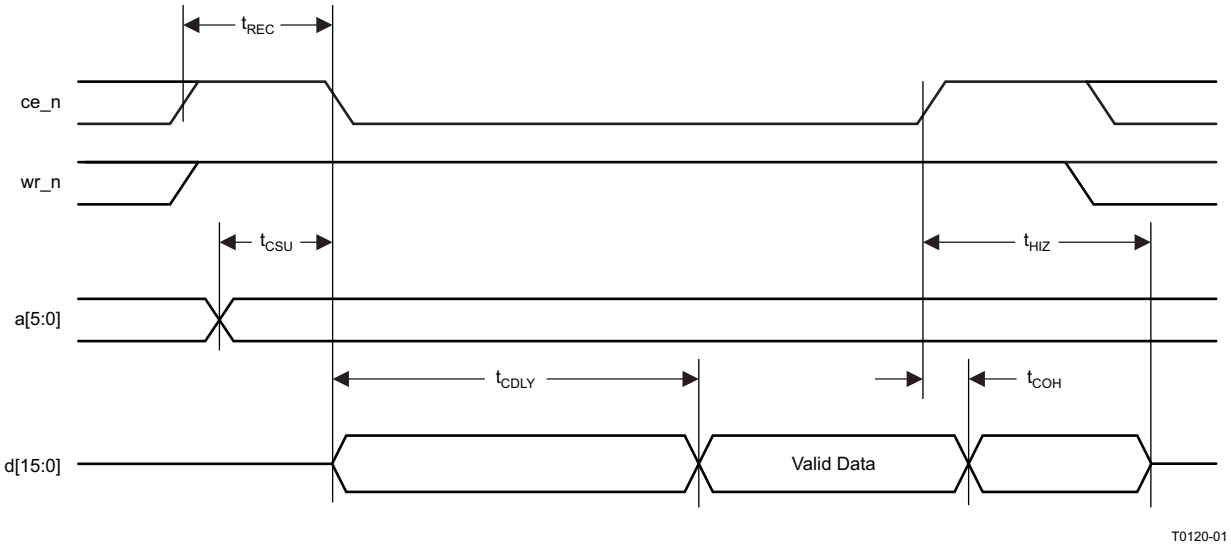

Figure 8-2. Read Operation—Two-Pin Control Mode (rd_n Tied Low)

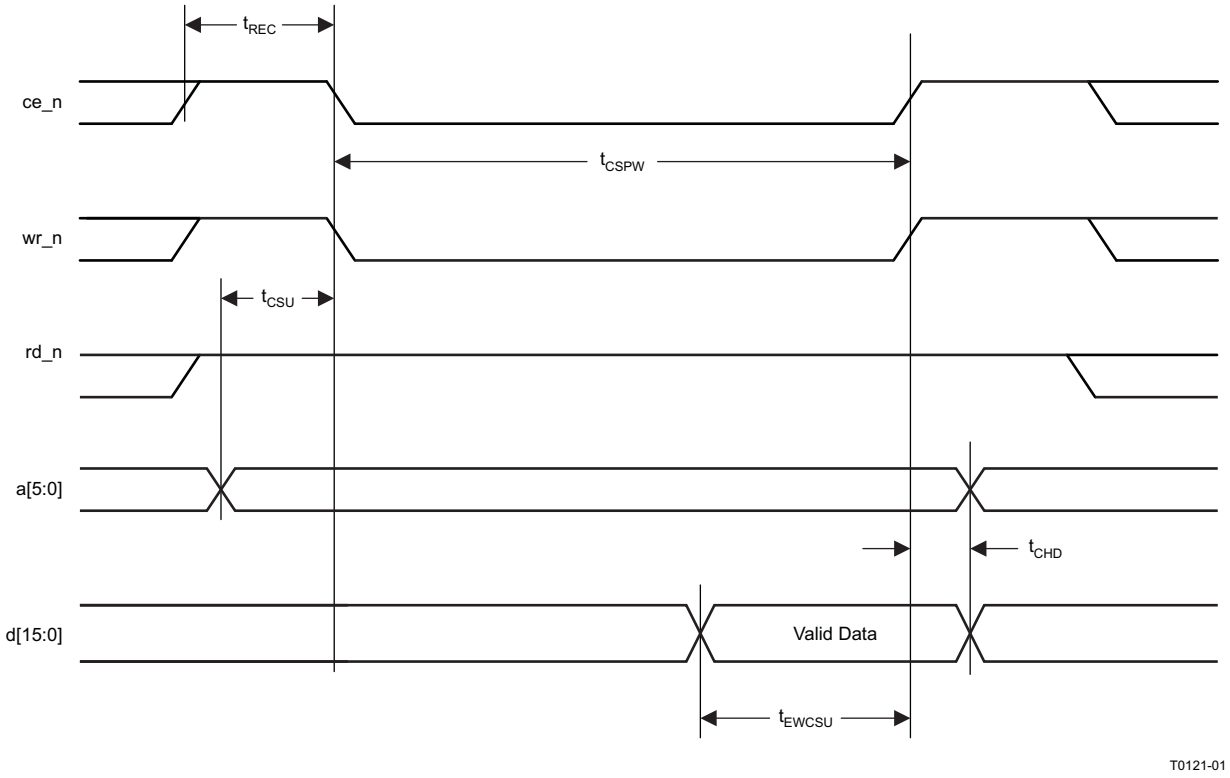

Figure 8-3. Write Operation—Three-Pin Control Mode

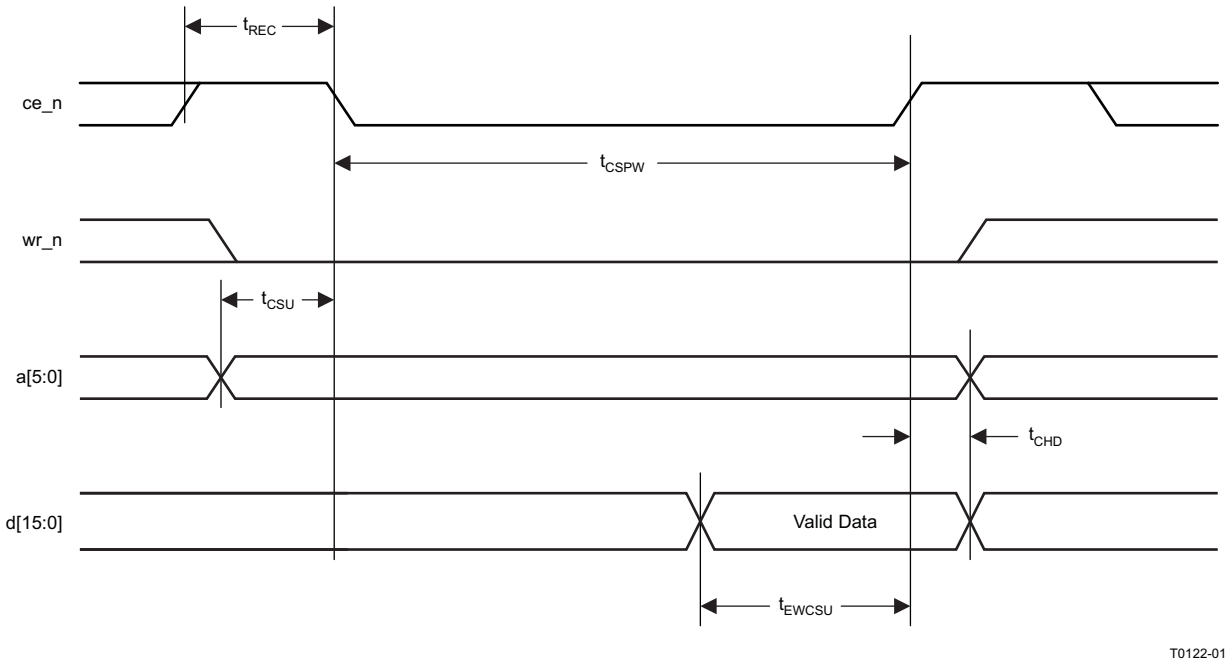

Figure 8-4. Write Operation—2-Pin Control Mode (rd_n Tied Low)

8.2 Synchronization Signals

Various function blocks within the AFE8405 must be synchronized in order to realize predictable results. The AFE8405 provides a flexible system where each function block that requires synchronization can be independently synchronized from either device pins or from a software *one-shot*. The one-shot option is setup and triggered through control registers. The four sync input pins, rxsync_a, rxsync_b, rxsync_c and rxsync_d are qualified on the rxclk rising clock edge. Table 8-1 shows the different sync modes available.

Table 8-1. Different Sync Modes Available

SYNC SELECT CODE	RECEIVE SYNC SOURCE
000	rxsync_a
001	rxsync_b
010	rxsync_c
011	rxsync_d
100	ddc sync counter terminal count
101	ddc sync triggered by software one-shot (register bit)
110	0 (always off)
111	1 (always on)

Table 8-2 and Table 8-3 summarizes the blocks which have functions that can be synchronized using the eight sync source options listed in Table 8-1.

Table 8-2. Receive Common Syncs

Sync Name	Purpose
sync_ddc_counter	Initializes the receive sync counter
sync_ddc	Initializes the receive ADC interface and clock generation circuits
sync_rxsync_out	Selects sync signal to be output on the rx_sync_out pin.
sync_adc_fifo	Initializes the input and output pointers in the ADC fifo circuits.
sync_tst_decim	Initializes the testbus decimation counter.
sync_recv_pmeterX	Initializes the rxin power meters. {X = 0, 1, 2, or 3}
sync_ragc_interval_X	Initializes the rxin receive AGC timers. {X = 0, 1, 2, or 3}
sync_ragc_freeze_X	rxin receive AGC freeze mode control. {X = 0, 1, 2, or 3}
sync_ragc_clear_X	Initializes the receive AGC error accumulator. {X = 0, 1, 2, or 3}

Table 8-3. DDC Channel Syncs

Sync Name	Purpose
sync_ddc_tadj	Selects zero stuff moment in the tadj fine-adjustment section
sync_ddc_tadj_reg	Updates the tadj output pointer register delay in the tadj coarse-adjustment section
sync_ddc_nco	Resets the NCO accumulator
sync_ddc_freq	Updates the NCO freq registers
sync_ddc_phase	Updates the NCO phase register
sync_ddc_dither	Initializes the NCO dither circuits
sync_ddc_cic	Selects the CIC decimation moment
sync_ddc_pmeter	Initializes the receive channel power meters
sync_ddc_gain	Updates the DDC channel AGC gain registers
sync_ddc_agc	Initializes the AGC accumulator
sync_ddc_agc_freeze	AGC freeze mode control
sync_ddc_serial	Initializes the receive serial interface

A 32-bit general-purpose timer is included in the synchronization function. The timer loads the user-programmed terminal count on a sync event and counts down to zero using rxclk. The duration of the terminal-count pulse can also be programmed up to rxclk cycles. The timer output can be used as a sync source for any other circuits requiring a sync if desired, and can also be routed to the rx_sync_out pin.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
ddc_counter(31:0)	32-bit programmable terminal count
ddc_counter_width(7:0)	8-bit programmable terminal-count pulse duration
ssel_ddc_counter(2:0)	Sync source selection for the ddc counter
ssel_rxsync_out(2:0)	Sync source selection for the rx_sync_out pin
3-state(0)	When set, the interrupt and rx_sync_out pins are placed in the high-impedance state.
rx_oneshot	Register bit used to generate the S/W oneshot signal for sync. This bit must be programmed from cleared to set in order to generate a rising edge sync signal.

8.3 Interrupt Handling

When an AFE8405 block sets an interrupt, the interrupt pin goes active if the interrupt source is not masked. The microprocessor should then read the interrupt register to determine the source of the interrupt. The microprocessor then must write the interrupt register to clear the interrupt pin and the interrupt source. The interrupt register and interrupt mask are located in the global registers section of the control registers.

The AFE8405 has 16 interrupt sources; power meters in each of the eight DDC blocks, power meters in the four receive input interface, and four rxin_X_ovr (adc overflow) input pins where X = {a, b, c, d}.

PROGRAMMING	
VARIABLE	**DESCRIPTION**
pmeterX_im(7:0)	Channel pmeter interrupt mask bits. Interrupt source is masked when set.
recv_pmeterX_im(3:0)	Receive input power meter interrupt masks.
rxin_X_ovr_im	ADC overflow input pin interrupt masks.
pmeterX(7:0)	Channel pmeter interrupt status.
recv_pmeterX(3:0)	Receive input power meter interrupt status.
rxin_X_ovr	ADC overflow input pin interrupt status.
intr_clr	When asserted, holds all interrupt status bits cleared. The interrupt pin is inactive (always low) when this bit is set. Intended for lab/debug use only
3-state(0)	When set, the interrupt and rx_sync_out pins are placed in the high-impedance state.

8.4 AFE8405 Programming

The AFE8405 includes over 2000 internal configuration registers and therefore implements a paged addressing scheme. The register map includes a *global control variables* register address space that is accessed directly when the a5 signal is high. This *global control variables* address space includes the page register. All other registers are addressed using a combination of an address consisting of the internal page register contents and the 6-bit external address: a5, a4, a3, a2, a1, and a0.

The page register is accessed when the 6-bit address a5:a0 is 0x21 (or 10 0001b).

Page Register Contents in Hex	Address Pin a5	Registers Addressed With 5-Bit Address Space, Pins (a4:a0)
Don't care	1	Global control variables 0x00 through 0x1F
0x0000	0	DDC0 PFIR taps 0 through 31 coefficient lsbs(1:0)

Page Register Contents in Hex	Address Pin a5	Registers Addressed With 5-Bit Address Space, Pins (a4:a0)
0x0020	0	DDC0 PFIR taps 32 through 63 coefficient lsbs(1:0)
0x0040	0	DDC0 PFIR taps 0 through 31 coefficient msbs(17:2)
0x0060	0	DDC0 PFIR taps 32 through 63 coefficient msbs(17:2)

8.4.2 Global Control Variables

These registers are accessed directly without page address extension; when pin a5 is high during a read or write access, this block of 32 registers is accessed.

8.4.2.1 VER Register

Register name: VER **Address: 0x00** **Read-only**

BIT 15 BIT 8

Unused	Unused	Unused	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	Unused	Unused	Unused	VER3	VER2	VER1	VER0
0	0	0	0	0	0	*	*

VER(3:0): A hardwired read-only register that returns the version of the chip
* A valid version code is 0010.

8.4.2.2 PAGE Register

Register name: PAGE **Address: 0x01**

BIT 15 BIT 8

Unused	Unused	Unused	W(2:0)			X	Y(2)
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Y(1)	Y(0)	Zp	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

W(2:0): Selects which dual-DDC block to address.

X: The DDC modules are configured as dual DDCs; an even-numbered DDC and odd-numbered DDC are contained in each dual-DDC module, the X bit selects which DDC gets address. (DDC0/2/4/6=0, DDC1/3/5/7=1)

W(2:0)	X bit	Selected Block
000	0	DDC0
000	1	DDC1
001	0	DDC2
001	1	DDC3
010	0	DDC4
010	1	DDC5
011	0	DDC6
011	1	DDC7
100	0	Receive AGC0/1 RAMs
101	0	Receive AGC2/3 RAMs
110	0	Receive input interface

Y(2:0): Within each major block, there are up to 8 different zones that can be addressed using the Y bits.

Y(2:0)	DDC Zone	Receive Input Interface Zone	Receive AGC RAMs Zone
000	PFIR coeffient lower 2 bits	CHIPS control registers	RAGC0/2 ERRMAP
001	PFIR coeffient upper 16 bits	RAGC control registers	RAGC0/2 DVGAMAP
010	CFIR coeffient lower 2 bits	Not assigned	RAGC0/2 GAINMAP
011	CFIR coeffient upper 16 bits	Not assigned	Not assigned
100	Control registers	Not assigned	RAGC1/3 ERRMAP
101	Not assigned	Not assigned	RAGC1/3 DVGAMAP
110	Not assigned	Not assigned	RAGC1/3 GAINMAP
111	Not assigned	Not assigned	Not assigned

Zp: The Zp bit is the MSB of the address word sent to the registers and RAMs. This bit can be thought of as an upper/lower selector of the 64-word addressing.

8.4.2.3 CONFIG Register

Register name: CONFIG **Address: 0x02**

BIT 15 BIT 8

slf_ tst_ena	rduz_sens_ena	arst_ func	tst_rate_sel(4:0)				
0	0	0	0	0	0	0	0

BIT 7 BIT 0

par_recv_ena	gbl_ ddc_write	intr_ clr	tst_select(3:0)				tst_ on
0	0	0	1	1	1	0	0

slf_tst_ena: Turns on the checksum LFSR for the receivers. They are located in the RECEIVE INPUT INTERFACE and DDC blocks.

rduz_sens_ena: When enabled, adds noise to the LSBs of the ADC inputs.

arst_func: When asserted, resets the functional portion of the circuits. The MPU registers are not reset and retain their programmed value.

tst_rate_sel(4:0): Sets the rate of the output test data and clock. The length of the clock cycle is the value in tst_rate_sel+1 multiplied by the RXCLK period. When the test bus source is set to 1000 (rxin_a and rxin_b FIFO outputs), tst_rate_sel(4:0) must be set to 0 for output. Otherwise, it does not output a clock at the decimated test-bus rate.

par_recv_ena: When asserted, the rxout_*_* serial pins join to form a 32-bit parallel output using 32 pins as a data bus, one pin as an output clock, and one pin as a sync. This is used to connect to the TCI110 Chip rate processor from TI.

gbl_ddc_write: Factory use only. When asserted, the mpu writes are global. This means that DDC0/2/4/6 or DDC1/3/5/7 can be programmed simultaneously with the same values. This is an effort to reduce the amount of time spent programming the device. A common setup can be used to program DDC0/2/4/6, then DDC1/3/5/7. Afterwards, just individual writes to the registers which differ between DDCs can be done. To use this feature, this bit must be asserted and the DDC0/1 must be addressed. Any other DDC address does not work.

intr_clr: When asserted, this bit forces all interrupts to be cleared. To allow the interrupts to be set again, this bit must be programmed to zero. This does not stop blocks from generating interrupts, but rather just keeps the interrupts from being reported.

tst_select(3:0): This selects which block the test output comes from:

tst_select(3:0)	Test Data Sent to Output
0000	DDC 0
0001	DDC 1
0010	DDC 2
0011	DDC 3
0100	DDC 4
0101	DDC 5
0110	DDC 6
0111	DDC 7
1000	rxin_a and rxin_b FIFO outputs
Others	None selected

tst_on: When asserted, the testbus is active. The ADC input ports rxin_c(15:0), rxin_d(15:0), dvga_c(5:0) and dvga_d(5:0) become the testbus output ports. When this bit is set, the rxin_c(15:0) and rxin_d(15:0) ports become chip outputs. The dvga_c(5:0) and dvga_d(5:0) ports are enabled separately using the GBL_3STATE register.

8.4.2.4 GBL_PAR_CONFIG0 Register

Register name: GBL_PAR_CONFIG0 **Address: 0x03**

BIT 15 BIT 8

par_recv_sync_del(6:0)							tst_clk_pol
0	0	0	0	0	0	0	0

BIT 7 BIT 0

par_recv_clkdiv(6:0)							par_recv_ rxclk_pol
0	0	0	0	0	0	0	0

par_recv_sync_del(6:0): Delays the sync source from the DDC0 AGC output by (par_recv_sync_del+1) rxclk cycles.

tst_clk_pol: Selects the polarity of the test clock output at dvga_c(1) when the test bus is enabled; 0 for rising edge in the center of valid data, 1 for falling edge in the center of valid data. *No effect when tst_rate_sel is 0 0000.*

par_recv_clkdiv(6:0): Selects the parallel interface output clock rate.

par_recv_rxclk_pol: Selects the polarity of the rxclk_out clock output; 0 for rising edge in the center of valid data, 1 for falling edge in the center of valid data.

8.4.2.5 GBL_PAR_CONFIG1 Register

Register name: GBL_PAR_CONFIG1 **Address: 0x04**

BIT 15 BIT 8

par_recv_syncout_del(3:0)				par_recv_chan(3:0)			
0	0	0	0	0	0	0	0

BIT 7 BIT 0

par_recv_fsinvl(6:0)							par_recv_ sync_pol
0	0	0	0	0	0	0	0

par_recv_syncout_del(3:0): Changes the rx_sync_out position with respect to IQ DDC0. Setting to 0 causes rx_sync_out to lead IQ DDC0 by 1 output sample, setting to 1 causes rx_sync_out to line up with IQ DDC0, setting to 2 causes rx_sync_out to trail IQ DDC0 by 1 output sample, etc.

par_recv_chan(3:0): Selects the number of channels to be output over the parallel interface, from 1 to 16 channels.

par_recv_fsinvl(6:0): Selects the number of rxclk cycles per parallel interface frame, from 1 to 128 cycles.

par_recv_sync_pol: Selects the polarity of the parallel interface sync pulse; 0 for active-low, 1 for active-high.

8.4.2.6 GBL_3STATE Register

Register name: GBL_3STATE **Address: 0x05**

BIT 15 BIT 8

rxclk_ena	Unused	Unused	Unused	Unused	3-state(10)	3-state(9)	3-state(8)
1	0	0	0	0	1	1	1

BIT 7 BIT 0

3-state(7)	3-state(6)	3-state(5)	3-state(4)	3-state(3)	3-state(2)	3-state(1)	3-state(0)
1	1	1	1	1	1	1	1

rxclk_ena: *Master rxclk enable.* When set, the chip's rxclk is enabled, when cleared, rxclk is disabled.

All 3-states are ACTIVE-LOW so a 0 turns on the output and a 1 places it in the high-impedance state.

3-state(10): This bit turns on the dvga_d outputs.

3-state(9): This bit turns on the dvga_c outputs.

3-state(8): This bit turns on the dvga_b outputs.

3-state(7): This bit turns on the dvga_a outputs.

3-state(6): This bit turns on the rx_sync_out_6/7 and the rxout_6/7_a/b/c/d outputs. (For parallel interface use only)

3-state(5): This bit turns on the rx_sync_out_4/5 and the rxout_4/5_a/b/c/d outputs.

3-state(4): This bit turns on the rx_sync_out_2/3 and the rxout_2/3_a/b/c/d outputs.

3-state(3): This bit turns on the rx_sync_out_0/1 and the rxout_0/1_a/b/c/d outputs.

3-state(2): Unused

3-state(1): rxclk_out

3-state(0): interrupt and rx_sync_out.

8.4.2.7 GBL_ONESHOT Register

Register name: GBL_ONESHOT **Address: 0x06**

BIT 15 BIT 8

Unused	Unused	Unused	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

BIT 7 BIT 0

rx_oneshot	Unused	Unused	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

rx_oneshot: When set, a one-shot pulse is sent to the receive blocks for syncing. This only works if the blocks are programmed to use the one-shot as the sync source. To use the one-shot again, it must be programmed to a 0 and then back to a 1.

8.4.2.8 GBL_IMASK0 Register

Register name: GBL_IMASK0 **Address: 0x07**

BIT 15 BIT 8

0	0	0	0	0	0	0	0

pmeterX: Asserted when an interrupt has been generated by this DDC pmeterX block, X = {0, 1, 2, 3, 4, 5, 6, 7}

recv_pmeterX: Asserted when an interrupt has been generated by this receive input pmeter, X = {0, 1, 2, 3}.

rxin_X_ovr: Asserted when a logic high input from the rxin_X_ovr pin occurs, X={a,b,c,d}.

8.4.3 Receive Input Interface Controls

8.4.3.1 SYNC_DDC_CNTR_LSB Register

Register name: SYNC_DDC_CNTR_LSB **Page: 0x1800** **Address: 0x00**

BIT 15 BIT 8

ddc_counter(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

ddc_counter(7:0)							
0	0	0	0	0	0	0	0

8.4.3.2 SYNC_DDC_CNTR_MSB

Register name: SYNC_DDC_CNTR_MSB **Page: 0x1800** **Address: 0x01**

BIT 15 BIT 8

ddc_counter(31:24)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

ddc_counter(23:16)							
0	0	0	0	0	0	0	0

ddc_counter(32:0): 32-bit interval timer common to all DDC sync inputs. This timer may be programmed to any interval count, and each DDC synchronization input can select this counter as a source. The value programmed into the counter is: (desired number – 1). The counter increments on each RX clock rising edge.

8.4.3.3 SSEL_DDC_CNTR Register

Register name: SSEL_DDC_CNTR **Page: 0x1800** **Address: 0x02**

BIT 15 BIT 8

rxinab_mux	rxincd_mux	Unused	Unused	Unused	ssel_ddc_counter(2:0)		
0	0	0	0	0	0	0	0

BIT 7 BIT 0

ddc_counter_width(7:0)							
0	0	0	0	0	0	0	0

rxinab_mux: When asserted, the rxin_a and rxin_b inputs are internally driven by the rxin_c and rxin_d ports, respectively (factory-test use only).

rxincd_mux: When asserted, the rxin_c and rxin_d inputs are internally driven by the rxin_a and rxin_b ports, respectively (factory-test use only).

ssel_ddc_counter(2:0): Selects the sync source for the DDC sync counter

ddc_counter_width(7:0): Sets the duration of the counter-generated sync pulse in RX clock cycles, from 1 to 256.

Sync sources are contained in this and many of the following registers. For all sync source selections:

ssel_ddc_XXXXX(2:0)	Selected Sync Source
000	rxsyncA
001	rxsyncB
010	rxsyncC
011	rxsyncD
100	DDC sync counter
101	One-shot (register write triggered)
110	Always 0
111	Always 1

8.4.3.4 SSEL_RX_0 Register

Register name: SSEL_RX_0 **Page: 0x1800** **Address: 0x03**

BIT 15 BIT 8

Unused	ssel_adc_fifo(2:0)			Unused	ssel_tst_decim(2:0)		
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	ssel_rxsync_out(2:0)			Unused	ssel_ddc(2:0)		
0	0	0	0	0	0	0	0

ssel_adc_fifo(2:0): Selects the sync source for the adc FIFO blocks. Sync reinitializes the read and write pointers of the FIFO.

ssel_tst_decim(2:0): Selects the sync source for the test bus decimator block.

ssel_rxsync_out(2:0): Selects the sync source for the RXSYNC_OUT pin.

ssel_ddc(2:0): Selects the sync source for the DDC data input multiplexer and mixer. *Controls clock generation in each DDC block (before the CIC input), which must match because the FIFO output clock is common for all DDC blocks.*

8.4.3.5 RECV_CONFIG0 Register

Register name: RECV_CONFIG0 **Page: 0x1800** **Address: 0x04**

BIT 15 BIT 8

rate_sel(1:0)		adc_ fifo_strap_ab	adc_ fifo_strap_cd	self_test_ const_ena	adc_ fifo_bypass	ragc_mpu_ram _read	tst_ decim17
0	0	0	0	0	0	0	0

BIT 7 BIT 0

tst_decim_delay(3:0)				pmeter3_iq	pmeter2_iq	pmeter1_iq	pmeter0_iq
0	0	0	0	0	0	0	0

rate_sel(1:0): Tells RECV_CDRV the input rate. This is the rxin_a/b/c/d input rate and the rate that the receive input interface block sends data to the DDCs.

rate_sel	Input clock rate
00	rxclk
01	rxclk/2
10	rxclk/4
11	rxclk/8

adc_fifo_strap_ab: When asserted, the input pointers of the rxin_a FIFO and rxin_b FIFO are hooked together in lock-step configuration. This is used for maintaining FIFO delay consistency when complex inputs are driven on rxin_a(I) and rxin_b(Q). rxin_a is the master.

adc_fifo_strap_cd: When asserted, the input pointers of the rxin_c FIFO and rxin_d FIFO are hooked together in lock-step configuration. This is used for maintaining FIFO delay consistency when complex inputs are driven on rxin_c(I) and rxin_d(Q). rxin_c is the master.

self_test_const_ena: When asserted, (with slf_tst_ena also asserted), a constant value is output by the test and noise generator instead of the pseudorandom sequence. The constant value is programmable.

adc_fifo_bypass: When asserted, the ADC FIFO circuits are bypassed. Input data is then clocked in directly using the rxclk input. *The ssel_ddc selection value controls the location of the internally generated sample clock when this bit is asserted, where rate_sel is rxclk/2, rxclk/4, or rxclk/8.*

ragc_mpu_ram_read: When asserted, the RAMs in the RAGC blocks can be read. This bit should only be set when reading the RAGC map RAMs via the MPU interface, and must be cleared for proper RAGC operation.

tst_decim17: Must be cleared

tst_decim_delay(3:0): These bits set the delay from the occurrence of sync until the decimator samples. In other words, the moment of the decimator is set by this delay value.

pmeter3_iq: When asserted, the pmeter3 block takes input from both rxin_c and rxin_d as a complex sample pair. When de-asserted, only input from rxin_d is used for the power measurement.

pmeter2_iq: When asserted, the pmeter2 block takes input from both rxin_c and rxin_d as a complex sample pair. When de-asserted, only input from rxin_c is used for the power measurement.

pmeter1_iq: When asserted, the pmeter1 block takes input from both rxin_a and rxin_b as a complex sample pair. When de-asserted, only input from rxin_b is used for the power measurement.

pmeter0_iq: When asserted, the pmeter0 block takes input from both rxin_a and rxin_b as a complex sample pair. When de-asserted, only input from rxin_a is used for the power measurement.

8.4.3.6 RECV_CONFIG1 Register

Register name: RECV_CONFIG1 **Page: 0x1800** **Address: 0x05**

BIT 15 BIT 8

msb_pos_d(2:0)			offset_bin_d	msb_pos_c(2:0)			offset_bin_c
0	0	0	0	0	0	0	0

BIT 7 BIT 0

msb_pos_b(2:0)			offset_bin_b	msb_pos_a(2:0)			offset_bin_a
0	0	0	0	0	0	0	0

msb_pos_X(2:0): Places the MSB of the input word from the ADC. The value programmed into these 3 bits is the MSB location in bit positions to the left of bit 16 of the input word. For example, if a 14-bit input word is driving rxin_a input and is aligned with rxin_a_0, then msb_pos_a is programmed to 010 meaning the MSB is shifted down 2 bits from bit 16. X = {a, b, c, d}.

offset_bin_X: rxin_X input data is in 2s complement and not offset binary. If cleared, the input value is converted to 2s complement using the MSB from the corresponding msb_pos_X value. X = {a, b, c, d}. **Note that the internal ADCs use 2s complement format, so offset_bin_A and offset_bin_B must be cleared.**

8.4.3.7 NZ_PWR_MASK Register

Register name: NZ_PWR_MASK **Page: 0x1800** **Address: 0x06**

BIT 15 BIT 8

nz_pwr_mask(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

nz_pwr_mask(7:0)							
0	0	0	0	0	0	0	0

nz_pwr_mask(15:0): Used with rduz_sens_ena, it selects the noise bits to be added to the ADC input sample when asserted.

8.4.3.8 RECV_PMETER_SYNC Register

Register name: RECV_PMETER_SYNC **Page: 0x1800** **Address: 0x07**

BIT 15 BIT 8

0	0	0	0	0	0	0	0

recv_pmeter0_ena: Enables the receive input interface pmeter0 block when set

recv_pmeter1_ena: Enables the receive input interface pmeter1 block when set

recv_pmeter2_ena: Enables the receive input interface pmeter2 block when set

recv_pmeter3_ena: Enables the receive input interface pmeter3 block when set

ssel_ recv_pmeter0(2:0): Selects the sync source for the receive input interface pmeter0 block

ssel_ recv_pmeter1(2:0): Selects the sync source for the receive input interface pmeter1 block

ssel_ recv_pmeter2(2:0): Selects the sync source for the receive input interface pmeter2 block

ssel_ recv_pmeter3(2:0): Selects the sync source for the receive input interface pmeter3 block

8.4.3.9 RECV_PMETER0_SQR_SUM_LSB Register

Register name: RECV_PMETER0_SQR_SUM_LSB **Page: 0x1800** **Address: 0x08**

BIT 15							BIT 8
recv_pmeter0_sqr_sum(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
recv_pmeter0_sqr_sum(7:0)							
0	0	0	0	0	0	0	0

recv_pmeter0_sqr_sum(15:0): The sqr_sum register controls the number of samples to accumulate for a power measurement. Ia is (or Ia and Qa are) if complex mode is selected squared and accumulated. Eight Ia samples (or eight pairs of Ia and Qa samples) equal one sqr_sum count. The accumulation interval is initiated when sync is asserted and the programmed (8 × sync_delay + 2) samples have expired or when the interval start time is reached. When the (8 × sqr_sum + 1) sample time is reached, the accumulated powers are made available for MPU access and an interrupt is generated.

8.4.3.10 RECV_PMETER0_STRT_INTVL_LSB Register

Register name: RECV_PMETER0_STRT_INTVL_LSB **Page: 0x1800** **Address: 0x09**

BIT 15							BIT 8
recv_pmeter0_strt_intrvl(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
recv_pmeter0_strt_intrvl(7:0)							
0	0	0	0	0	0	0	0

recv_pmeter0_strt_intrvl(15:0): The start interval timer is the interval over which sqr_sum is restarted. The timer value is (8 × strt_intrvl + 1) samples and must be larger than (8 × sqr_sum + 1) samples. The interval start counter and RMS power accumulation is started at the sync pulse after the programmed delay and every time the STRT_INTRVL counter reaches its limit.

8.4.3.11 RECV_PMETER0_SYNC_DLY Register

Register name: RECV_PMETER0_SYNC_DLY **Page: 0x1800** **Address: 0x0A**

BIT 15							BIT 8
delay_line_0(5:0)						Unused	recv_pmeter0_ sync_delay(8)

complex01	complex23	ssel_ragc_interval_0(2:0)			ssel_ragc_interval_1(2:0)		
0	0	0	0	0	0	0	0

ragc_freeze_X: Freezes the receive AGC block when set.

ragc_clear_X: Clears the loop error accumulator when set.

complex01: When set, receive AGC 0 uses complex input with the second sample stream coming from receive AGC 1. The clip detect, high pass, and squarer from receive AGC 1 are used to generate inputs for receive AGC 0.

complex23: When set, receive AGC 2 uses complex input with the second sample stream coming from receive AGC 3. The clip detect, high pass, and squarer from receive AGC 3 are used to generate inputs for receive AGC 2.

ssel_ragc_interval_0(2:0): Selects the sync source for receive AGC 0. After a programmed delay from sync, the interval update timer is started.

ssel_ragc_interval_1(2:0): Selects the sync source for receive AGC 1. After a programmed delay from sync, the interval update timer is started.

8.4.4.3 RAGC_CONFIG2 Register

Register name: RAGC_CONFIG2 **Page: 0x1840** **Address: 0x02**

0	0	0	0	0	0	0	0

ssel_agc_clear_X(2:0: Controls the selection of the sync that clears the receive AGC error accumulator.

ssel_agc_interval_3(2:0): Selects the sync source for receive AGC 3. After a programmed delay from sync, the interval update timer is started.

8.4.4.5 RAGC0_INTEGINVL_LSB Register

Register name: RAGC0_INTEGINVL_LSB **Page: 0x1840** **Address: 0x04**

BIT 15 BIT 8

integ_interval_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

integ_interval_0(7:0)							
0	0	0	0	0	0	0	0

integ_interval_0(15:0): The 16 LSBs of the integration time for receive AGC 0.

8.4.4.6 RAGC0_INTEGINVL_MSB Register

Register name: RAGC0_INTEGINVL_MSB **Page: 0x1840** **Address: 0x05**

BIT 15 BIT 8

ragc_update_0(7:0)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

integ_interval_0(23:16)							
0	0	0	0	0	0	0	0

ragc_update_0(7:0): Sets the number of receive AGC updates per sync event (0x00 is infinite).

integ_interval_0(23:16): The eight MSBs of the integration time for receive AGC 0.

8.4.4.7 RAGC0_CONFIG0 Register

Register name: RAGC0_CONFIG0 **Page: 0x1840** **Address: 0x06**

BIT 15 BIT 8

ragc_sync_delay_0(7:0)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

hp_corner_0(2:0)			acc_shift_0(4:0)				
0	0	0	0	0	0	0	0

ragc_sync_delay_0(7:0): The input sync to the receive AGC block is delayed by this number of samples.

hp_corner_0(2:0): Sets the corner frequency of the high-pass filter. Larger values result in higher corner frequencies

acc_shift_0(4:0): Selects the integrated power measurements result bits to be used as the error lookup table address. A larger number means fewer samples must be integrated to achieve the same result.

8.4.4.8 RAGC0_CONFIG1 Register

Register name: RAGC0_CONFIG1 **Page: 0x1840** **Address: 0x07**

BIT 15 BIT 8

acc_offset_0(5:0)						err_shift_0(4:3)	
0	0	0	0	0	0	0	0

BIT 7 BIT 0

err_shift_0(2:0)			delay_adj_0(4:0)				
0	0	0	0	0	0	0	0

acc_offset_0(5:0): Constant subtracted from the integrated power measurement result before the error lookup table.

err_shift_0(4:0): Adjusts the loop gain by controlling the amount of shifting applied to the error lookup table output. Larger values result in higher gain.

delay_adj_0(4:0): Sets the delay difference, in samples, between the DVGA outputs and the value applied to the sample multiplier.

8.4.4.9 RAGC0_SD_THRESH Register

Register name: RAGC0_SD_THRESH **Page: 0x1840** **Address: 0x08**

BIT 15							BIT 8
sd_thresh_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
sd_thresh_0(7:0)							
0	0	0	0	0	0	0	0

sd_thresh_0(15:0): This is the threshold used by the signal-detect block to determine if there is a signal on the inputs. The comparison is done to the output of the squarer block, which is a 32-bit word. Because of this, these bits are aligned with bits 24 down to 8 of the 32-bit squared value.

8.4.4.10 RAGC0_SD_TIMER Register

Register name: RAGC0_SD_TIMER **Page: 0x1840** **Address: 0x09**

BIT 15							BIT 8
sd _timer_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
sd _timer_0(7:0)							
0	0	0	0	0	0	0	0

sd_timer_0(15:0): Qualification window timer for loss of input signal.

8.4.4.11 RAGC0_SD_SAMPLES Register

Register name: RAGC0_SD_SAMPLES **Page: 0x1840** **Address: 0x0A**

BIT 15							BIT 8
sd_samples_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
sd_samples_0(7:0)							
0	0	0	0	0	0	0	0

sd_samples_0(15:0): Number of samples that must be below the sd_thresh_X within the sd_timer_X timer value for the loss-of-signal condition to occur.

8.4.4.12 RAGC0_CLIP_HITHRESH Register

Register name: RAGC0_CLIP_HITHRESH **Page: 0x1840** **Address: 0x0B**

BIT 15 BIT 8

clip_hi_thresh_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

clip_hi_thresh_0(7:0)							
0	0	0	0	0	0	0	0

clip_hi_thresh_0(15:0): The high threshold value for clip detection

8.4.4.13 RAGC0_CLIP_LOTHRESH Register

Register name: RAGC0_CLIP_LOTHRESH **Page: 0x1840** **Address: 0x0C**

BIT 15 BIT 8

BIT 7 BIT 0

clip_hi_timer_0(7:0)							
0	0	0	0	0	0	0	0

clip_hi_timer_0(15:0): The high timer value in samples

8.4.4.15 RAGC0_CLIP_LOTIMER Register

Register name: RAGC0_CLIP_LOTIMER **Page: 0x1840** **Address: 0x0E**

BIT 15 BIT 8

clip_lo_timer_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

clip_lo_timer_0(7:0)							
0	0	0	0	0	0	0	0

clip_lo_timer_0(15:0): The low timer value in samples

8.4.4.16 RAGC0_CLIP_SAMPLES Register

Register name: RAGC0_CLIP_SAMPLES **Page: 0x1840** **Address: 0x0F**

BIT 15 BIT 8

clip_hi_samples_0(7:0)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

clip_lo_samples_0(7:0)							
0	0	0	0	0	0	0	0

clip_hi_samples_0(7:0): Number of samples above the high threshold within the clip high time to enable the clip event

clip_lo_samples_0(7:0): Number of samples below the low threshold within the clip low time to disable the clip event

8.4.4.17 RAGC0_CLIP_ERROR Register

Register name: RAGC0_CLIP_ERROR **Page: 0x1840** **Address: 0x10**

BIT 15 BIT 8

clip_error_0(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

clip_error_0(7:0)							
0	0	0	0	0	0	0	0

clip_error_0(15:0): This is the error value that is added into the loop accumulator when a clip is detected.

8.4.4.18 RAGC1_INTEGINVL_LSB Register

Register name: RAGC1_INTEGINVL_LSB **Page: 0x1840** **Address: 0x11**

BIT 15 BIT 8

integ_interval_1(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

integ_interval_1(7:0)							
0	0	0	0	0	0	0	0

integ_interval_1(15:0): The LSBs of the integration time for receive AGC 1

8.4.4.19 RAGC1_INTEGINVL_MSB Register

Register name: RAGC1_INTEGINVL_MSB **Page: 0x1840** **Address: 0x12**

BIT 15 BIT 8

ragc_update_1(7:0)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

integ_interval_1(23:16)							
0	0	0	0	0	0	0	0

ragc_update_1(7:0): Sets the number of receive AGC updates per sync event (0x00 is infinite).

integ_interval_1(23:16): The MSBs of the integration time for receive AGC 1

8.4.4.20 RAGC1_CONFIG0 Register

Register name: RAGC1_CONFIG0 **Page: 0x1840** **Address: 0x13**

BIT 15 BIT 8

ragc_sync_delay_1(7:0)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

hp_corner_1(2:0)			acc_shift_1(4:0)				
0	0	0	0	0	0	0	0

ragc_sync_delay_1(7:0): The input sync to the receive AGC block is delayed by this value of samples.

hp_corner_1(2:0): This sets the corner frequency of the high-pass filter. Larger values result in higher corner frequencies.

acc_shift_1(4:0): Selects the integrated power measurements result bits to be used as the error lookup table address. A larger number means fewer samples must be integrated to achieve the same result.

8.4.4.21 RAGC1_CONFIG1 Register

Register name: RAGC1_CONFIG1 **Page: 0x1840** **Address: 0x14**

BIT 15 BIT 8

acc_offset_1(5:0)						err_shift_1(4:3)	
0	0	0	0	0	0	0	0

BIT 7 BIT 0

err_shift_1(2:0)			delay_adj_1(4:0)				
0	0	0	0	0	0	0	0

acc_offset_1(5:0): Constant subtracted from the integrated power measurement result before the error lookup table

err_shift_1(4:0): Controls the loop gain by left-shifting the error output. Larger values result in higher gain.

delay_adj_1(4:0): Sets the delay difference, in samples, between the DVGA outputs and the value applied to the sample multiplier.

8.4.4.22 RAGC1_SD_THRESH Register

Register name: RAGC1_SD_THRESH **Page: 0x1840** **Address: 0x15**

BIT 15 BIT 8

BIT 15 BIT 8

cdma_mode	Unused	Unused	crastarttap_pfir(4:0)				
0	0	0	0	0	0	0	0

BIT 7 BIT 0

crastarttap_cfir(4:0)					Unused	Unused	Unused
0	0	0	0	0	0	0	0

cdma_mode: When asserted, the DDC block is in CDMA mode (2 streams per DDC block).

crastarttap_pfir: These bits define the number of taps that PFIR uses for the filtering.

crastarttap_cfir: These bits define the number of taps that CFIR uses for the filtering.

Formulas for the number of taps, in the different FIRs, using the crastarttap word.

DDC PFIR: 4 × (crastarttap_pfir + 1)

DDC PFIR long mode: 8 × (crastarttap_pfir + 1)

DDC CFIR: 2 × (crastarttap_cfir + 1)

8.4.5.2 FIR_GAIN Register

Register name: FIR_GAIN **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x01**

BIT 15 BIT 8

pfir_gain(2:0)			Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	Unused	Unused	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

pfir_gain(2:0): PFIR gain, from 2e–19 to 2e–12 for the receive PFIR. (000 = 2e–19 and 111 = 2e–12)

cfir_gain: When 0, then the gain of the CFIR is 2e-19; when set to 1, the gain is 2e-18.

8.4.5.3 SQR_SUM Register

Register name: SQR_SUM **Page: 0x0%00** **Address: 0x02**
where:
% = 2 × (DDC channel #) + 1

BIT 15							BIT 8
pmeter_sqr_sum_ddc(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
pmeter_sqr_sum_ddc(7:0)							
0	0	0	0	0	0	0	0

pmeter_sqr_sum_ddc(15:0): The sqr_sum register is the number of four-sample sets to accumulate for a power measurement. In CDMA mode, one sample set is the I & Q of the signal and diversity. Ia & Qa (signal) are each squared and accumulated and Ib & Qb (diversity) are squared and accumulated. In UMTS mode, each I and Q pair is squared and accumulated. Four samples are equal to one SQR_SUM count. The count is initiated when sync is asserted or when the interval start time is reached. When the SQR_NUM number is reached, the accumulated powers are made available for MPU access and an interrupt is generated.

8.4.5.4 STRT_INTRVL Register

Register name: STRT_INTRVL **Page: 0x0%00** **Address: 0x03**
where:
% = 2 × (DDC channel #) + 1

BIT 15							BIT 8
pmeter_sync_delay_ddc(7:0)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
pmeter_interval_ddc(7:0)							
0	0	0	0	0	0	0	0

pmeter_sync_delay_ddc(7:0): The delay from selected sync source to when the power calculation starts. The actual value is *sync_delay + 1*.

pmeter_interval_ddc(7:0): The start interval timer is the interval over which the SQR_SUM is restarted and must be greater than the SQR_SUM. **The actual interval is interval +1, and must be greater than the sqr_sum interval.** The interval start counter and RMS power accumulation is started at the sync pulse after the programmed delay and every time the interval counter reaches its limit. This value is in 1024-sample units.

8.4.5.5 CIC_MODE1 Register

Register name: CIC_MODE1 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x04**

BIT 15 BIT 8

cic_scale_a(4:0)					cic_scale_b(4:2)		
0	0	0	0	0	0	0	0

BIT 7 BIT 0

cic_scale_b(1:0)		cic_gain_ ddc	cic_decim(4:0)				
0	0	0	0	0	0	0	0

cic_scale_a(4:0): This sets the gain shift at the output of the A channel CIC. 0x00 is no shift; each increment by 1 increases the signal amplitude by 2X.

cic_scale_b(4:0): This sets the gain shift at the output of the B channel CIC. 0x00 is no shift; each increment by 1 increases the signal amplitude by 2X.

cic_gain_ddc: Adds a fixed gain of 12 dB at the CIC output when asserted.

cic_decim(4:0): Sets the CIC decimation rate, where decimation is cic_decim + 1.

8.4.5.6 CIC_MODE2 Register

Register name: CIC_MODE2 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x05**

BIT 15 BIT 8

cic_m2_ena_a(5:0)						cic_m2_ena_b(5:4)	
0	0	0	0	0	0	0	0

BIT 7 BIT 0

cic_m2_ena_b(3:0)				Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

cic_m2_ena_a(5:0): Programs the A channel CIC fir sections M value to 2 when set, 1 when cleared. cic_m2_ena_a(0) controls the M value for the first comb section and cic_m2_ena_a(5) controls the M value for the last comb section.

cic_m2_ena_b(5:0): Programs the B channel CIC fir sections M value to 2 when set, 1 when cleared. cic_m2_ena_b(0) controls the M value for the first comb section and cic_m2_ena_b(5) controls the M value for the last comb section.

8.4.5.7 TADJC Register

Register name: TADJC **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x06** **Double buffered, requires sync for loading**

BIT 15 BIT 8

Unused	Unused	Unused	tadj_offset_coarse_a(2:0)			Unused	Unused
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	tadj_offset_coarse_b(2:0)			Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

tadj_offset_coarse_a(2:0): This is the coarse time adjustment offset and acts as an offset from the write address in the delay RAM. This value affects the A-data in the path if CDMA mode is being used. Each LSB is one more offset between input to the caurse delay block and the output of the coarse block.

tadj_offset_coarse_b(2:0): Affects the B-channel in CDMA, just as tadj_offset_coarse_a(2:0) affects the A-channel.

8.4.5.8 TADJF Register

Register name: TADJF **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x07** **Double buffered, requires sync for loading**

BIT 15 BIT 8

tadj_offset_fine_a(2:0)			tadj_offset_fine_b(2:0)			tadj_interp(2:1)	
0	0	0	0	0	0	0	0

BIT 7 BIT 0

tadj_interp(0)	Unused	Unused	Unused	Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

tadj_offset_fine_a(2:0): This is the fine-adjust (zero stuff offset) value. It adjusts the time delay at the rxclk rate. This value affects the A-channel data in the path if CDMA mode is being used.

tadj_offset_fine_b(2:0): Same as tadj_offset_fine_a(2:0) except this value affects the B-channel data in CDMA mode.

tadj_interp(2:0): This is the interpolation (zero stuff) value for the fine time adjust block. Interpolation can be from 1 to 8 (tadj_interp + 1). This value affects the A and B data in the path if CDMA mode is being used.

8.4.5.9 PHASEADD0A Register

Register name: PHASEADD0A **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x08** **Double buffered, requires sync for loading**

phase_offset_b(15:0): This is the fixed phase offset added to the output of the frequency accumulator for sinusoid generation in the NCO. *(B channel in CDMA mode)*

8.4.5.15 CONFIG1 Register

Register name: CONFIG1 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x0E**

BIT 15 BIT 8

dither_ena	dither_mask(1:0)		pmeter_ sync_ disable	ddc_ena	muxed _data	mixer_gain	mpu_ram_read
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	Unused	Unused	Unused	Unused	zero_ qsample	mux_pos	mux_factor
0	0	0	0	0	0	0	0

dither_ena: This bit controls whether dither is turned on (1) or off (0).

dither_mask(1): This bit controls the MASKing of the dither word MSB. (1 = MASKed, 0 = used in dither word).

dither_mask(0): This bit controls the MASKing of the dither word MSB-1. (1 = MASKed, 0 = used in dither word).

pmeter_sync_disable: Turns off the sync to the channel power meter. This can be used to turn off syncs individually to a channel power meter while still having syncs available to other power meters.

ddc_ena: When set, this turns on the DDC. When cleared, the clocks to this block are turned off. For the DDC blocks used as the second half in the long PFIR configuration, this bit should be cleared.

muxed_data: When asserted the DDC multiplexer block assumes that multiple channels are multiplexed together on one input data stream. *For factory use only*.

For a 2× multiplexed stream it would look like: Sa0, Sb0, Sa1, Sb1, Sa2, Sb2 …. etc...

mixer_gain: Adds a fixed 6 dB of gain to the mixer output(before round and limiting) when asserted.

mpu_ram_read: (TESTING PURPOSES) Allows the coefficient RAMs in the PFIR/CFIR to be read out the MPU data bus. Unfortunately, this cannot be done during normal operation and must be done when the state of the output data is not important. **THIS BIT MUST BE SET ONLY DURING THE MPU READ OPERATION AND MUST BE CLEARED FOR NORMAL DDC OPERATION.**

zero_qsample: When asserted, the Q sample into the mixer is held to zero. For UMTS mode at any input rate, and CDMA mode with input rates of rxclk/2 or lower, this bit must be set for real-only input data mode (also for multiplexed input data stream modes). For real-only inputs at the full rxclk rate in CDMA mode, the remix_only bit must be set in the DDCCONFIG1 register.

mux_pos: These bits set the position for selection in the multiplexed data stream. This value must be less than or equal to the mux_factor bits.

mux_factor: These two bits set the number of channels in the data stream. 0 = one stream, 1 = two streams. The ch_rate_sel bits for the DDC should be programmed to rxclk/2 for the two-stream mode.

8.4.5.16 CONFIG2 Register

Register name: CONFIG2 **Page: 0x0%00** **Address: 0x0F**
where:
% = 2 × (DDC channel #) + 1

BIT 15 BIT 8

8.4.5.17 AGC_CONFIG1 Register

Register name: AGC_CONFIG1 **Page: 0x0%00** **Address: 0x10**
where:
% = 2 × (DDC channel #) + 1

BIT 15 BIT 8

agc_dblw(3:0)				agc_dabv(3:0)			
0	0	0	0	0	0	0	0

BIT 7 BIT 0

agc_dzro(3:0)				agc_dsat(3:0)			
0	0	0	0	0	0	0	0

agc_dblw(3:0): The value to shift the gain that is then added to the accumulator when the value of the incoming data * current gain value is **below** the threshold.

agc_dabv(3:0): The value to shift the gain that is then subtracted from the accumulator when the value of the incoming data * the current gain value is **above** the threshold.

agc_dzro(3:0): The value to shift the gain that is then added to the accumulator when the value of the incoming data * current gain value is **consistently equal to zero** (usually a smaller number than agc_dblw).

agc_dsat(3:0): The value to shift the gain that is then subtracted form the accumulator when the value of the incoming data * the current gain value is **consistently equal to maximum (saturation)**.

NOTE: The larger the number in the foregoing words, the smaller the step size. The preceding values control the AGC gain shifting (range is from 3 to 18).

8.4.5.18 AGC_CONFIG2 Register

Register name: AGC_CONFIG2 **Page: 0x0%00** **Address: 0x11**
where:
% = 2 × (DDC channel #) + 1

BIT 7 BIT 0

Unused	Unused	Unused	agc_ clear	agc_zero_cnt(3:0)			
0	0	0	0	0	0	0	0

agc_freeze: Freezes the agc when set. This should be asserted when the AGC algorithm is bypassed or held constant.

agc_max_cnt(3:0): When the agc_output (input × gain) is at full scale for this number of samples, then the gain shift value is changed to agc_dsat.

agc_clear: Clears the AGC accumulator when set. Assert this when the AGC is in bypass mode.

agc_zero_cnt(3:0): when the agc_output (input × gain) is zero value for this number of samples, then the gain shift value is changed to agc_dzro.

8.4.5.20 AGC_GAINMSB Register

Register name: AGC_GAINMSB **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x13** **Double buffered, requires sync for loading**

0	0	0	0	0	0	0	0

BIT 7							BIT 0
agc_gaina(7:0)							
0	0	0	0	0	0	0	0

agc_gaina(15:0): This is the lower 16 bits of the total 24 bits of programmable gain. The gain value is always positive with the upper 12 bits being the integer value and the lower 12 bits being the fractional. This gain value is used for all UMTS operations and for A-channel data when in CDMA mode. A 24-bit value of 0000 000 0001.0000 0000 0000 is unity gain.

8.4.5.22 AGC_GAINB Register

Register name: AGC_GAINB **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x15** **Double buffered, requires sync for loading**

BIT 15							BIT 8
agc_gainb(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
agc_gainb(7:0)							
0	0	0	0	0	0	0	0

agc_gainb(15:0): This is the lower 16 of the total of 24 bits of programmable gain. The gain value is always positive with the upper 12 bits being the integer value and the lower 12 bits being the fractional. This gain value is used for B-channel data when in CDMA. A 24-bit value of 0000 0000 0001.0000 0000 0000 is unity gain.

8.4.5.23 AGC_AMAX Register

Register name: AGC_AMAX **Page: 0x0%00** **Address: 0x16**
where:
% = 2 × (DDC channel #) + 1

BIT 15							BIT 8
agc_amax(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
agc_amax(7:0)							
0	0	0	0	0	0	0	0

agc_amax(15:0): This is the maximum gaina or gainb can be adjusted up. The value programmed is a positive value that is used to generate the most-positive AGC gain adjust. For example, if 512 is programmed, the maximum gain is the programmed gain (AGC_GAINA/B) + 512.

8.4.5.24 AGC_AMIN Register

Register name: AGC_AMIN **Page: 0x0%00** **Address: 0x17**
where:
% = 2 × (DDC channel #) + 1

BIT 15							BIT 8
agc_amin(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
agc_amin(7:0)							
0	0	0	0	0	0	0	0

agc_amin(15:0): This is the minimum gaina or gainb can be adjusted down. The value programmed is a positive value that is inverted internally to generate the most-negative AGC gain adjust. For example, if 512 is programmed, the minimum gain is the programmed gain (AGC_GAINA/B) – 512.

8.4.5.25 PSER_CONFIG1 Register

Register name: PSER_CONFIG1 **Page: 0x0%00** **Address: 0x18**
where:
% = 2 × (DDC channel #) + 1

BIT 15 BIT 8

Unused	pser_recv_fsinvl(6:0)						
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	Unused	Unused	pser_recv_bits(4:0)				
0	0	0	0	0	0	0	0

pser_recv_fsinvl(6:0): Receive serial interface frame sync interval in bit clocks.

pser_recv_bits(4:0): Number of output bits per sample – 1; for 18 bits, this is set to 1 0001.

8.4.5.26 PSER_CONFIG2 Register

Register name: PSER_CONFIG2 **Page: 0x0%00** **Address: 0x19**
where:
% = 2 × (DDC channel #) + 1

BIT 15 BIT 8

pser_recv_clkdiv(3:0)				Unused	Unused	Unused	Unused
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pser_recv_8pin	pser_recv_alt	Unused	Unused	Unused	Unused	pser_recv_fsdel(1:0)	
0	0	0	0	0	0	0	0

pser_recv_clkdiv(3:0): Receive serial interface clock divider rate – 1; 0 is full-rate and 15 divides the clock by 16. For example, to run the receive serial interface at 1/4 the AFE8405 clock, set pser_recv_clkdiv(3:0) = 0011.

pser_recv_8pin: When set, four pins are used for I and four pins for Q in UMTS mode. When cleared, two pins are used for I and two pins for Q. This is used in combination with the pser_recv_alt bit. When this bit is set, it would be set in two adjacent DDC channels; one would also set the pser_recv_alt bit in the adjacent DDC. This causes the I channel to be serialized on four pins and the Q channel to be serialized on the four adjacent-channel pins.

pser_recv_alt: When set, this channel's receive serial interface outputs the Q data from the adjacent DDC channel.

pser_recv_fsdel(1:0): Delay between the receive frame sync output and the MSB of serial data {3, 2, 1, 0}. This number is in serial output bit times, not rxclk periods.

8.4.5.27 DDCCONFIG1 Register

Register name: DDCCONFIG1 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x1A**

BIT 15 BIT 8

ddcmux_sel_a(3:0)				agc_rnd_ disable	gain_mon	ch_rate_sel(1:0)	
0	0	0	0	0	0	0	0

BIT 7 BIT 0

ddcmux_sel_b(3:0)				remix_only	cic_ bypass	double_tap(1:0)	
0	0	0	0	0	0	0	0

ddcmux_sel_X(3:0): Controls which samples go to the mixer for I/Q. Because in CDMA there are two streams, an A and B stream, two multiplex select values are used.

Select Value	I data from X input(1)	Q data from X input(1)
0000	RXINA	RXINA
0001	RXINB	RXINB
0010	RXINC	RXINC
0011	RXIND	RXIND
0100	RXINA	RXINB
0101	RXINA	RXINC
0110	RXINA	RXIND
0111	RXINB	RXINA
1000	RXINB	RXINC
1001	RXINB	RXIND
1010	RXINC	RXINA
1011	RXINC	RXINB
1100	RXINC	RXIND
1101	RXIND	RXINA
1110	RXIND	RXINB
1111	RXIND	RXINC

(1) RXINA = internal A-side ADC, RXINB not used, RXINC = external input C, RXIND = external input D

agc_rnd_disable: When set, the agc_rnd bits have no effect. The whole 29 bits are used in the rounding and the round bit is bit 4.

gain_mon: Combines the gain with the I/Q output signals when asserted.

OUTPUT	Bits(17:10)	Bits(9:4)	Bits(3:2)	Bits(1:0)
I	Gained I value	Gain(18:11)		00
Q	Gained Q value	Gain(10:5)	Shift status(1:0)	00

ch_rate_sel(1:0): Sets the DDC channel input data rate. The value set here should match the value in the receive input interface rate-select bits (rate_sel).

ch_rate_sel	Input data rate
00	rxclk
01	rxclk/2
10	rxclk/4
11	rxclk/8

When muxed_data is set (Factory Use Only), rate_sel should be set to rxclk 00 and ch_rate_sel should be set to rxclk/2 01.

remix_only: Assert this when real only, full rxclk rate input data is used in CDMA mode. The signal on the Q bus selected by the ddcmux_sel_X(3:0) bits above is ignored (functions as if the Q data is 0).

cic_bypass: *Factory Use Only.* If asserted, then the data from the rxin_a(15:0) and rxin_b(15:0) are fed directly into the cfir input as I and Q respectively. rxin_a(0) also functions as the sync_cfir signal and should rise at the beginning of input data.

ONLY DDC0, DDC2, DDC4 and DDC6 can be the UMTS double-tap (64- to 128-tap) PFIR mode. DDC1, DDC3, DDC5 and DDC7 PFIRs are used to lengthen the DDC0, DDC2, DDC4 and DDC6 PFIRs.

double_tap(1): When set, the DDC is in double-length PFIR mode, which sends the data out of the last PFIR sample RAM in this DDC (DDC0, DDC2, DDC4, DDC6) to the adjacent secondary DDC (DDC1, DDC3, DDC5, DDC7) PFIR forming a 128-tap delay line. Output data received from the adjacent secondary DDC PFIR summer is added into the main DDC PFIR sum to form the final output.

double_tap(0): When set, the PFIR input comes from the adjacent (main) PFIR. When cleared, PFIR input is from the CFIR connected directly to this PFIR. **Only valid in DDC1, DDC3, DDC5 and DDC7. The ddc_ena bit in the CONFIG1 register should be cleared for DDC1, DDC3, DDC5 and DDC7 when double_tap(0) is set.**

NOTE: To put 2 DDCs into 128 tap mode:

Program DDC0/DDC2/DDC4/DDC6 double_tap(1:0) to 10 and ddc_ena to 1.

Program DDC1/DDC3/DDC5/DDC7 double_tap(1:0) to 01 and ddc_ena to 0.

8.4.5.28 SYNC_0 Register

Register name: SYNC_0 **Page: 0x0%00** **Address: 0x1B**

where:

% = 2 × (DDC channel #) + 1

BIT 15 BIT 8

Unused	ssel_cic(2:0)			Unused	ssel_pmeter(2:0)		
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	ssel_agc_freeze(2:0)			Unused	ssel_serial(2:0)		
0	1	1	0	0	0	0	0

ssel_cic(2:0): Selects the sync source for the DDC CIC filter, thus setting the decimation moment

ssel_pmeter(2:0): Selects the sync source for the channel power meter

ssel_agc_freeze(2:0): Selects the sync that is used to hold the AGC in freeze mode. With this functionality the user can program the AGC freeze control to look at the state of an input sync, or the one-shots. It defaults to being off or not looking at any syncs and not driving the freeze control. This way, on startup, the chip looks at the MPU register bit for AGC freezing and not the syncs.

ssel_serial(2:0): Selects the sync source for the DDC serial interface state machines.

Sync sources are contained in this and many of the following registers. For all sync source selections:

ssel_XXXX(2:0)	Selected sync source for DDC
000	rxsyncA
001	rxsyncB
010	rxsyncC
011	rxsyncD
100	DDC sync counter
101	one shot (register write triggered)
110	always 0
111	always 1

8.4.5.29 SYNC_1 Register

Register name: SYNC_1 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x1C**

ssel_tadj_fine(2:0): Selects the sync source for the fine time adjust zero stuff moment.

ssel_tadj_reg(2:0): Selects the sync source for the fine and coarse time adjust register updates.

ssel_gain(2:0): Selects the sync source for the DDC AGC gain register.

ssel_ddc_agc(2:0): Selects the sync source to initialize the AGC, primarily for test purposes.

8.4.5.30 SYNC_2 Register

Register name: SYNC_2 **Page: 0x0%00 where: % = 2 × (DDC channel #) + 1** **Address: 0x1D**

BIT 15 BIT 8

Unused	ssel_nco(2:0)			Unused	ssel_dither(2:0)		
0	0	0	0	0	0	0	0

BIT 7 BIT 0

Unused	ssel_freq(2:0)			Unused	ssel_phase(2:0)		
0	0	0	0	0	0	0	0

ssel_nco: Selects the sync source for the NCO accumulator reset.

ssel_dither: Selects the sync source for the NCO phase dither generator reset.

ssel_freq: Selects the sync source for the NCO frequency register.

ssel_phase: Selects the sync source for the NCO phase offset register.

8.4.5.31 DDC_CHK_SUM Register

Register name: DDC_CHK_SUM **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x00** **Read-only**

BIT 15							BIT 8
ddc_chk_sum(15:0)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
ddc_chk_sum(7:0)							
0	0	0	0	0	0	0	0

ddc_chk_sum: The DDC self test checksum value

8.4.5.32 PMETER_RESULT_A_LSB Register

Register name: PMETER_RESULT_A_LSB **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x01** **Read-only**

BIT 15							BIT 8
pmeter_result_a(15:8)							
0	0	0	0	0	0	0	0

BIT 7							BIT 0
pmeter_result_a(7:0)							
0	0	0	0	0	0	0	0

pmeter_result_a(15:0): Lower 16 bits of the UMTS-mode or CDMA-mode A-channel power measurement.

8.4.5.33 PMETER_RESULT_A_MID Register

Register name: PMETER_RESULT_A_MID **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x02** **Read-only**

BIT 15 BIT 8

pmeter_result_a(31:24)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_a(23:16)							
0	0	0	0	0	0	0	0

pmeter_result_a(31:16): Mid 16 bits of the UMTS-mode or CDMA-mode A-channel power measurement.

8.4.5.34 PMETER_RESULT_A_MSB Register

Register name: PMETER_RESULT_A_MSB **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x03** **Read-only**

BIT 15 BIT 8

pmeter_result_a(47:40)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_a(39:32)							
0	0	0	0	0	0	0	0

pmeter_result_a(47:32): Upper mid 16 bits of the UMTS-mode or CDMA-mode A-channel power measurement.

8.4.5.35 PMETER_RESULT_B_LSB Register

Register name: PMETER_RESULT_B_LSB **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x04** **Read-only**

BIT 15 BIT 8

pmeter_result_b(15:8)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_b(7:0)							
0	0	0	0	0	0	0	0

pmeter_result_b(15:0): Lower 16 bits of the CDMA-mode B-channel power measurement

8.4.5.36 PMETER_RESULT_B_MID Register

Register name: PMETER_RESULT_B_MID **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x05** **Read-only**

BIT 15 BIT 8

pmeter_result_b(31:24)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_b(23:16)							
0	0	0	0	0	0	0	0

pmeter_result_b(31:16): Mid 16 bits of the CDMA-mode B-channel power measurement.

8.4.5.37 PMETER_RESULT_B_MSB Register

Register name: PMETER_RESULT_B_MSB **Page: 0x0%20 where: % = 2 × (DDC channel #) + 1** **Address: 0x06** **Read-only**

BIT 15 BIT 8

pmeter_result_b(47:40)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_b(39:32)							
0	0	0	0	0	0	0	0

pmeter_result_b(47:32): Upper mid 16 bits of the CDMA-mode B-channel power measurement.

8.4.5.38 PMETER_RESULT_AB_UMSB Register

Register name: PMETER_RESULT_AB_UMSB **Page: 0x0%20**
where:
% = 2 × (DDC channel #) + 1
Address: 0x07 **Read-only**

BIT 15 BIT 8

pmeter_result_a(54:48)							
0	0	0	0	0	0	0	0

BIT 7 BIT 0

pmeter_result_b(54:48)							
0	0	0	0	0	0	0	0

pmeter_result_a(54:48): Most-significant 7 bits of the 55-bit UMTS- or CDMA-mode A-channel power measurement. Bits 15–9 are used, bit 8 is not used.

pmeter_result_b(54:48): Most-significant 7 bits of the 55-bit CDMA-mode B-channel power measurement. Bits 7–1 are used, bit 0 is not used.

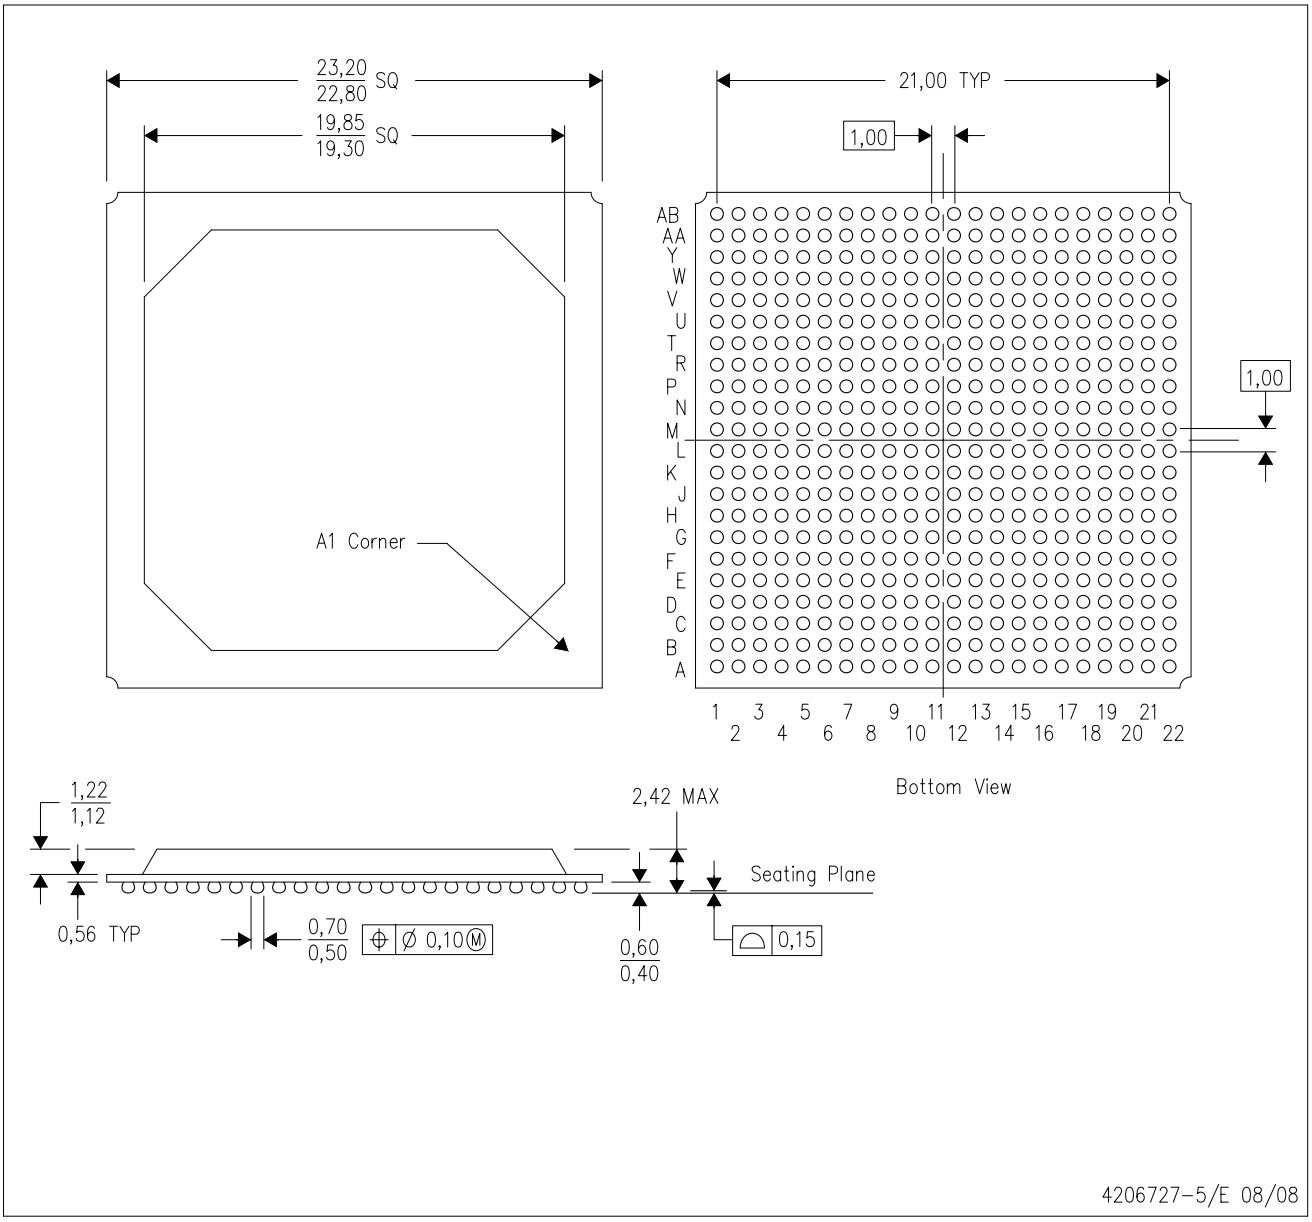
PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish	MSL Peak Temp (3)	Samples (Requires Login)
AFE8405IZDQ	NRND	BGA	ZDQ	484	60	Pb-Free (RoHS)	SNAGCU	Level-3-260C-168 HR	

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.
TBD: The Pb-Free/Green conversion plan has not been defined.
Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.



NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Falls within JEDEC MO–151
D. This is a Pb–free solder ball design.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have ***not*** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
