

TEXAS INSTRUMENTS

1 Introduction

1.1 FEATURES

- 14-Bit 85-MSPS High-Performance Dual ADC
- Dual ADC Can Be Configured Into Single ADC
- At f_{in} = 140 MHz, SNR \geq 71 dBFS, SFDR \geq 79 dBc
- At f_{in} = 70 MHz, SNR \geq 73 dBFS, SFDR \geq 85 dBc
- Independent Clocks for ADC and DDC With Built-In FIFO
- Programmable Closed Loop VGA Control With 6-Bit Outputs for Each ADC
- Received Total Wideband Power (RTWP)
 Measurement for the Composite Power Across
 Carriers With Programmable Time Window for
 Measurement
- 8 UMTS Digital Down Converter (DDC)
 Channels or 16 CDMA/TD-SCDMA DDC
 Channels With Programmable 18-Bit Filter
 Coefficients
- Each DDC Channel Provides:
 - Real or Complex DDC Inputs
 - UMTS Mode Rx Filtering: 6-Stage CIC (m = 1 or 2), up to 40-Tap CFIR, up to 64-Tap PFIR
 - CDMA Mode Rx Filtering: 6-Stage CIC (m = 1 or 2), up to 64-Tap CFIR, up to 64-Tap PFIR
 - Individual Channel Specific Power

Measurements

- A Dedicated Final AGC
- Test Bus to Monitor Data at Different Stages of the DDC Signal Path
- 3.3-V Analog Supplies, 1.5-V Digital Core Supply, 3.3-V Digital I/O Supply
- 484-Ball Plastic BGA (23 mm \times 23 mm) With 1,0-mm Pitch
- Power Dissipation (Eight Active DDC Channels): 2.7 W

1.2 APPLICATIONS

- Wireless Base Station Receiver
- Multi-Carrier Digital Receiver
- UMTS (4 Carriers-1 Sector With Diversity)
- CDMA (8 Carriers-1 Sector With Diversity)
 - TD-SCDMA (16 Carriers-1 Sector Without Diversity, 8 Carriers-1-Sector With Diversity)
- Digital Radio Receivers
- Wide Band Receivers
- Software Radios
- Wireless Local Loop
- Intelligent Antenna Systems

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this document.

2 General Description

The AFE8406 is a multichannel communications signal processor that provides analog-to-digital conversion and digital downconversion optimized for cellular base transceiver systems. The device supports UMTS, CDMA-1X and TD-SCDMA air interface cellular standards.

The AFE8406 provides up to 8 UMTS digital downconverter channels (DDC), 16 CDMA DDCs or 16 TD-SCDMA DDCs. The DDC channels are independent and operate simultaneously.

The AFE8406 DDCs have four input ports; two are hardwired to internal 14-bit analog-to-digital converters and two are 16-bit digital inputs. Each DDC channel can be programmed to accept data from any one of the four input ports.

3.2 ABSOLUTE MAXIMUM RATINGS(1)

| | | UNIT |
|------------------|--|-------------------------|
| Analog Ch | ip | |
| AVDD | Analog supply voltage | −0.3 V to 3.7 V |
| DRVDD | I/O ring supply voltage | −0.3 V to 3.7 V |
| | Ground difference DRVSS to AVSS | -0.1 V to 0.1 V |
| | Analog input voltage | –0.15 V to 3.6 V |
| | Digital input voltage | -0.3 V to DRVDD + 0.3 V |
| Digital Chi | p | |
| VDDS | Pad ring supply voltage | −0.3 V to 3.7 V |
| DVDD | Core supply voltage | −0.3 V to 1.8 V |
| | Digital input voltage | -0.3 V to VDDS + 0.3 V |
| Entire Chip |) | |
| | Clamp current for an input or output | –20 mA to 20 mA |
| T _{STG} | Storage temperature | −65°C to 140°C |
| T _J | Junction temperature | 105°C |
| | Lead soldering temperature (10 seconds) | 300°C |
| | ESD classification (tested to EIA/JESD22-A114-B) | Class 2 |

⁽¹⁾ Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

3.3 RECOMMENDED OPERATING CONDITIONS

| | | MIN | NOM | MAX | UNIT |
|-----------------|--|-------|-----|-------|----------|
| Analog C | Chip | | | | |
| AVDD | Analog supply voltage | 3 | 3.3 | 3.6 | V |
| DRVDD | I/O ring supply voltage | 3 | 3.3 | 3.6 | V |
| V _{ID} | Differential input voltage range | | 2.3 | | V |
| VCM | Common-mode input voltage | 1.5 | | 1.6 | V |
| | Differential clock inputs | | 3 | | V_{PP} |
| | Clock input duty cycle | | 50% | | |
| Digital C | hip | | | · | |
| VDDS | I/O ring supply voltage | 3.0 | | 3.6 | V |
| DVDD | Core supply voltage | 1.425 | | 1.575 | V |
| | Supply voltage difference, VDDS – DVDD | | | 2.0 | V |
| Entire Ch | nip | | | · | |
| T _A | Temperature ambient, no air flow | -40 | | 85 | °C |
| $T_J^{(1)}$ | Junction temperature | | | 105 | °C |

⁽¹⁾ Thermal management is required for full-rate operation. The circuit is designed for junction temperatures up to 125°C. Sustained operation at elevated temperatures reduces long-term reliability. Lifetime calculations based on maximum junction temperature of 105°C

14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www.ti.com

3.4 THERMAL CHARACTERISTICS

| | THERMAL CONDUCTIVITY ⁽¹⁾ | MIN | TYP | MAX | UNIT |
|---------------|--------------------------------------|-----|------|-----|------|
| | Theta junction-to-ambient (0 LFPM) | | 14 | | °C/W |
| 0 | Theta junction-to-ambient (100 LFPM) | | 13 | | °C/W |
| θ_{JA} | Theta junction-to-ambient (250 LFPM) | | 12.2 | | °C/W |
| | Theta junction-to-ambient (500 LFPM) | | 11.6 | | °C/W |
| θ_{JC} | Theta junction-to-case | | 2.8 | | °C/W |

⁽¹⁾ Air flow will reduce θ_{JA} and is highly recommended.

3.5 POWER DISSIPATION

Typical values at T_A = 25°C, UMTS mode, sampling rate = 61.44 MSPS, and rxclk = 122.88 MHz (unless otherwise noted)

| | PARAMETER | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|--------------------|--------------------------------|-------------------------|-----|-------|-----|------|
| I _{AVDD} | Analog supply current | Six active DDC channels | | 236 | | mA |
| I _{DRVDD} | Analog I/O supply current | | | 30 | | mA |
| I _{DVDD} | Digital core supply current | | | 959 | | mA |
| I _{VDDS} | Digital I/O supply current (1) | | | 100 | | mA |
| | Analog power dissipation | | | 878 | | mW |
| | Digital power dissipation (2) | | | 1.439 | | W |
| | Total power dissipation (2) | | | 2.3 | | W |
| I _{AVDD} | Analog supply current | Eight active DDC | | 236 | | mA |
| I _{DRVDD} | Analog I/O supply current | channels | | 30 | | mA |
| I _{DVDD} | Digital core supply current | | | 1.198 | | Α |
| I _{VDDS} | Digital I/O supply current (1) | | | 115 | | mA |
| | Analog power dissipation | | | 878 | | mW |
| | Digital power dissipation (2) | | | 1.797 | | W |
| | Total power dissipation (2) | | | 2.7 | | W |

⁽¹⁾ Current consumption on the digital I/O supply is primarily due to the external loads and follows C × V × F. Internal loads are estimated at 2 pF per terminal. Data outputs transition once every four clocks, whereas clock outputs transition every cycle. In general, I_{VDDS} = Σ (DataPad/4) × C × V × F + Σ ClockPad × C × V × F.

3.6 ANALOG ELECTRICAL CHARACTERISTICS

Typical values at T_A = 25°C, minimum and maximum values over full full temperature range of T_A = -40°C to +85°C, sampling rate = 80 MSPS, 50% clock duty cycle, AVDD = DRVDD = 3.3 V, -1dBFS differential input, internal reference, and 3-V_{PP} differential clock (unless otherwise noted)

| | PARAMETER | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|-----------------|----------------------------------|--------------------------------|-----|-----|-----|----------|
| | Resolution | | | 14 | | Bits |
| Analog | Inputs | | | | | |
| V _{ID} | Differential input voltage range | | | 2.3 | | V_{PP} |
| C _{ID} | Differential input capacitance | | | 3.2 | | pF |
| I _{IC} | Common-mode input current | 2 mA per input, 4 mA total | | 4 | | mA |
| | Analog input bandwidth | Source impedance = 50 Ω | | 750 | | MHz |

| Signal Name | Ball | Туре | Description | |
|---------------|------|--------|--|--|
| inpa | F3 | input | ADCA analog positive input | |
| inma | F4 | input | ADCA analog negative input | |
| inpb | V4 | input | ADCB analog positive input | |
| inmb | V3 | input | ADCB analog negative input | |
| clkpa | H1 | input | ADCA clock positive input | |
| clkma | J1 | input | ADCA clock negative input | |
| clkpb | R1 | input | ADCB clock positive input | |
| clkmb | T1 | input | ADCB clock negative input | |
| refpa | L3 | input | ADCA positive reference input. connect 0.1µF to AVSS. | |
| refma | К3 | input | ADCA negative reference input; connect 0.1μF to AVSS. | |
| refpb | P3 | input | ADCB positive reference input; connect 0.1µF to AVSS. | |
| refmb | N3 | input | ADCB negative reference input; connect 0.1µF to AVSS. | |
| cma | Н3 | output | ADCA common mode output reference | |
| cmb | Т3 | output | ADCB common mode output reference | |
| iref | МЗ | input | Current set; connect 56 kΩ to AVSS | |
| oea | L9 | input | Connect to AVDD, ADCA output enable; AVDD=enable, AVSS=disabled | |
| oeb | N9 | input | Connect to AVDD, ADCB output enable; AVDD=enable, AVSS=disabled | |
| ovra | G6 | output | ADCA over range indicator bit | |
| ovrb | N8 | output | ADCB over range indicator bit | |
| da(13:0) | n/a | output | ADCA output data; internally connected to rxin_a_15:2 | |
| db(13:0) | n/a | output | ADCB output data; internally connected to rxin_b_15:2 | |
| clkouta | n/a | output | ADCA output clock; internally connected to adcclka | |
| clkoutb | n/a | output | ADCB output clock; internally connected to adcclkb | |
| fuse_sel | H5 | input | Connect to AVSS; factory use only | |
| pin_configure | T5 | input | Connect to AVDD, factory use only | |
| dll_disable | N10 | input | connect to AVDD, factory use only | |
| pwdn | M9 | input | connect to AVSS, AVDD=powered down, AVSS = powered up | |
| ext_ref | M10 | input | connect to AVSS, AVDD=External reference, AVSS = internal reference. | |

4.7 Digital Supply Monitoring

| Signal Name | Ball | Description |
|-------------|------|--|
| dvddmon | L22 | It is recommended that this pin be brought to a probe point for monitoring and debugging purposes. |
| dvssmon | M22 | It is recommended that this pin be brought to a probe point for monitoring and debugging purposes. |

4.8 JTAG

The JTAG standard for boundary scan testing will be implemented for board testing purposes. Internal scan test will not be supported. Five device pins are dedicated for JTAG support: tdi, tdo, tms, tck, and trst_n. The JTAG bsdl configuration file is available at www.ti.com.

NOTE

The trst_n pin should be asserted after power up to insure the JTAG logic is properly initialized.

6 ANALOG-TO-DIGITAL CONVERTERS

The AFE8406 includes a high performance dual channel 14-bit 85-MSPS analog-to-digital converter (ADC). To provide a complete solution, each channel includes a high bandwidth linear sample-and-hold stage (S&H) and internal reference. An internal reference is provided, simplifying system design requirements, yet external reference can be used optionally to suit the accuracy and low drift requirements of the application.

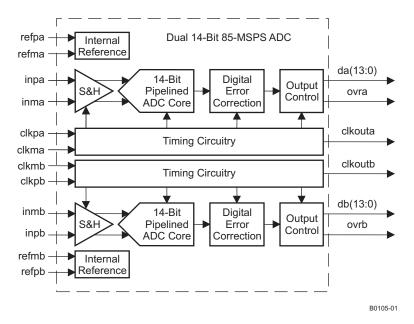

Figure 6-1. ADC Block Diagram

The ADC digital output data and output clocks are connected directly to the rxin_a and rxin_b ports of the AFE8406 digital section. The ovra and ovrb outputs connect directly to the AFE8406 digital section and also to package balls. The ADC outputs can be accessed through the test bus in a decimate by 32x mode only.

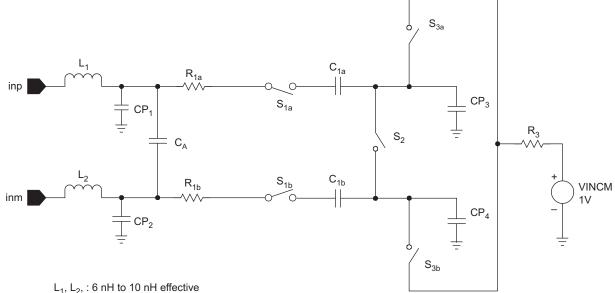

6.1 ADC Operation

The conversion process is initiated by a falling edge of the external input clocks. Once the signal is captured by the input S&H, the input sample is sequentially converted by a series of small resolution stages, with the outputs combined in a digital correction logic block. Both the rising and the falling clock edges are used to propagate the sample through the pipeline every half clock cycle. This process results in data latency of 16.5 clock cycles, after which the output data is available as a 14-bit parallel word, coded in binary two's complement format to the AFE8406 receive section.

6.2 ADC Input Configuration

The analog input for the ADC consists of a differential sample-and-hold architecture implemented using a switched capacitor technique shown in Figure 6-2.

 R_{1a} , R_{1b} : 5 Ω to 8 Ω C_{1a}, C_{1b}: 2.2 pF to 2.6 pF CP₁, CP₂: 1.8 pF to 2.2 pF CP₃, CP₄: 1.2 pF to 1.8 pF C_A: 0.8 pF to 1.2 pF R_3 : 80 Ω to 120 Ω

Switches : ${\rm S_{1a},\,S_{1b}}$: On Resistance : 35 Ω to 50 Ω \mbox{S}_2 : On Resistance : 7.5 Ω to 15 Ω S_{3a} , S_{3b} : On Resistance : 40 Ω to 60 Ω All switches Off Resistance : 10 G Ω

All switches are on in sampling phase which is approximately one half of a clock period.

S0175-01

Figure 6-2. Analog Input Stage

This differential input topology produces a high level of ac performance for high sampling rates. It also results in a high usable input bandwidth, especially important for high intermediate-frequency (IF) or undersampling applications. The ADC requires each of the analog inputs (inp, inm) to be externally biased around the common-mode level of the internal circuitry (cm). For a full-scale differential input, each of the differential lines of the input signal swings symmetrically between cm + 0.575 V and cm - 0.575 V. This means that each input is driven with a signal of up to cm ± 0.575 V, so that each input has a maximum differential signal of 1.15 V_{PP} for a total differential input signal swing of 2.3 V_{PP}. The maximum swing is determined by the two reference voltages, the top reference (refpa and refpb) and the bottom reference (refma and refmb).

The ADC obtains optimum performance when the analog inputs are driven differentially. The circuit shown in Figure 6-3 shows one possible configuration using an RF transformer.

SLWS168C-MAY 2005-REVISED OCTOBER 2008

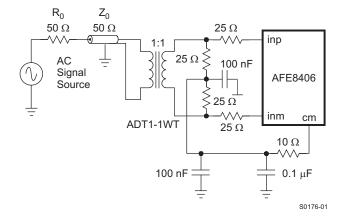

Figure 6-3. Transformer Input to Convert Single-Ended Signal to Differential Signal

The single-ended signal is fed to the primary winding of an RF transformer. Since the input signal must be biased around the common-mode voltage of the internal circuitry, the common-mode voltage (V_{CM}) from the ADC is connected to the center-tap of the secondary winding. To ensure a steady low-noise V_{CM} reference, best performance is obtained when the CM output is filtered to ground with a 10- Ω series resistor and parallel 0.1- μ F and 0.001- μ F low-inductance capacitors.

Output V_{CM} is designed to directly drive the ADC input. When providing a custom CM level, be aware that the input structure of the ADC sinks a common-mode current in the order of 200 μ A (100 μ A per input). Equation (1) describes the dependency of the common-mode current and the sampling frequency:

$$20 + \frac{400\mu\text{A} \times f_s(\text{in MSPS})}{125 \text{ MSPS}}$$
(6-1)

This equation helps to design the output capability and impedance of the driving circuit accordingly.

When it is necessary to buffer or apply a gain to the incoming analog signal, it is possible to combine single-ended operational amplifiers with an RF transformer, or to use a differential input/output amplifier without a transformer, to drive the input of the AFE8406 ADC. Texas Instruments offers a wide selection of single-ended operational amplifiers (including the THS3201, THS3202, OPA847, and OPA695) that can be selected depending on the application. An RF gain block amplifier, such as Texas Instruments THS9001, can also be used with an RF transformer for high input frequency applications. The THS4503/6/9 are recommended differential input/output amplifiers. Table 6-1 lists the recommended amplifiers.

Table 6-1. Recommended Amplifiers to Drive the Input of the AFE8406

| INPUT SIGNAL FREQUENCY | RECOMMENDED AMPLIFIER | TYPE OF AMPLIFIER | USE WITH TRANSFORMER? |
|------------------------|-----------------------|-------------------------------|-----------------------|
| DC to 20 MHz | THS4503/6/9 | Differential in/out amplifier | No |
| DC to 50 MHz | OPA847 | Operational amplifier | Yes |
| 10 MHz to 120 MHz | OPA695 | Operational amplifier | Yes |
| | THS3201 | Operational amplifier | Yes |
| | THS3202 | Operational amplifier | Yes |
| Over 100 MHz | THS9001 | RF gain block | Yes |

When using single-ended operational amplifiers (such as the THS3201, THS3202, OPA847, or OPA695) to provide gain, a three-amplifier circuit is recommended with one amplifier driving the primary of an RF transformer and one amplifier in each of the legs of the secondary driving the two differential inputs of the ADC. These three amplifier circuits minimize even-order harmonics. For high-frequency inputs, an RF gain block amplifier can be used to drive a transformer primary; in this case, the transformer secondary connections can drive the input of the ADC directly, as shown in Figure 6-3 or with the addition of the filter circuit shown in Figure 6-4.

Figure 6-4 illustrates how $R_{\rm IN}$ and $C_{\rm IN}$ can be placed to isolate the signal source from the switching inputs of the ADC and to implement a low-pass RC filter to limit the input noise in the ADC. It is recommended that these components be included in the AFE8406 circuit layout when any of the amplifier circuits discussed previously are used. The components allow fine-tuning of the circuit performance. Any mismatch between the differential lines of the ADC input produces a degradation in performance at high input frequencies, mainly characterized by an increase in the even-order harmonics. In this case, special care should be taken to keep as much electrical symmetry as possible between both inputs.

Another possible configuration for lower-frequency signals is the use of differential input/output amplifiers that can simplify the driver circuit for applications requiring dc coupling of the input. Flexible in their configurations (see Figure 6-5), such amplifiers can be used for single-ended-to-differential conversion, signal amplification.

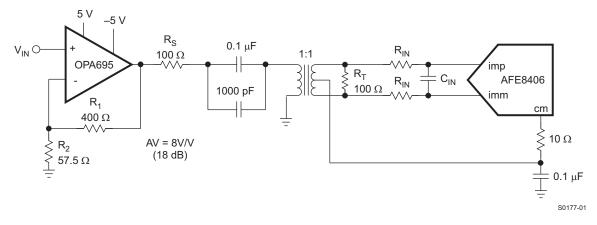

Figure 6-4. Converting a Single-Ended Input Signal to a Differential Signal Using an RF Transformer

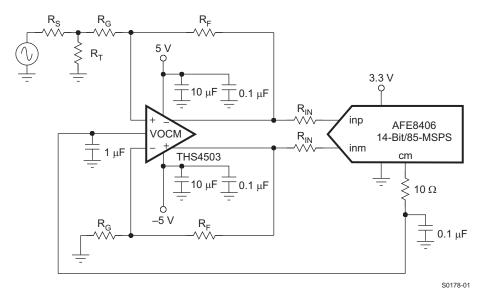

Figure 6-5. Using the THS4503 With the AFE8406

6.3 ADC Input Voltage Over-Stress

The AFE8406 ADC can handle absolute maximum voltages of 3.6 V DC on the input pins inp and inm. For DC inputs between 3.6 V and 3.8 V, a 25- Ω resistor is required in series with the input pins. For inputs above 3.8 V, the device can handle only transients, which need to have less than 5% duty cycle of

overstress. The input pins connect internally to an ESD diode to AVDD, as well as a switched capacitor circuit. The sampling capacitor of the switched capacitor circuit connects to the input pins through a switch in the sample phase. In this phase, an input larger then 2.65 V would cause the switched capacitor circuit to present an equivalent load of a forward biased diode to 2.65 V in series with a $60-\Omega$ impedance. Also, beyond the voltage on AVDD, the ESD diode to AVDD starts to become forward biased.

In the phase where the sampling switch is off, the diode loading from the input switched capacitor circuit is disconnected from the pin, while the ESD loading to AVDD is still present.

CAUTION

A violation of any of the previously stated conditions could damage the device (or reduce its lifetime) either due to electromigration or gate oxide integrity. Care should be taken not to expose the device to input over-voltage for extended periods of time as it may degrade device reliability.

6.4 ADC Reference Circuit

The AFE8406 ADC has built-in internal reference generation, requiring no external circuitry on the printed circuit board (PCB). For optimum performance, it is best to connect both refp and refm to ground with a $1-\mu F$ decoupling capacitor in series with a $20-\Omega$ resistor, as shown in the Figure 6-6. In addition, an external $56.2-k\Omega$ resistor should be connected from iref to AVSS to set the proper current for the operation of the ADC, as shown in Figure 6-6. No capacitor should be connected between these pins; only the $56.2-k\Omega$ resistor should be used.

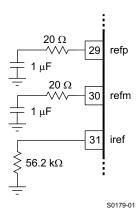

Figure 6-6. REFP, REFM, and IREF Connections for Optimum Performance

6.5 ADC Clock Input

The AFE8406 ADC clock input can be driven with either a differential clock signal or a single-ended clock input, with little or no difference in performance between both configurations. The common-mode voltage of the clock inputs is set internally to cm using internal 5-k Ω resistors that connect clkp and clkm to cm, as shown in Figure 6-7.

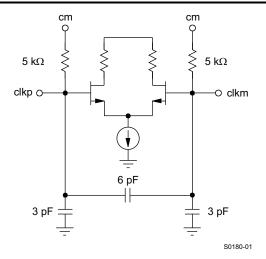

Figure 6-7. Clock Inputs

When driven with a single-ended CMOS clock input, it is best to connect clkm to ground with a $0.01-\mu F$ capacitor, while clkp is ac-coupled with a $0.01-\mu F$ capacitor to the clock source, as shown in Figure 6-8.

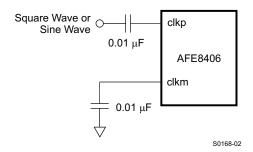

Figure 6-8. AC-Coupled, Single-Ended Clock Input

The ADC clock input can also be driven differentially, reducing susceptibility to common-mode noise. In this case, it is best to connect both clock inputs to the differential input clock signal with $0.01-\mu F$ capacitors, as shown in Figure 6-9.

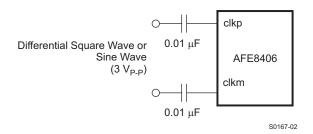

Figure 6-9. AC-Coupled, Differential Clock Input

For high input frequency sampling, it is recommended to use a clock source with low jitter. Additionally, the internal ADC core uses both edges of the clock for the conversion process. This means that, ideally, a 50% duty cycle should be provided.

Bandpass filtering of the source can help produce a 50% duty cycle clock and reduce the effect of jitter. When using a sinusoidal clock, the clock jitter further improves as the amplitude is increased. In that sense, using a differential clock allows for the use of larger amplitudes without exceeding the supply rails and absolute maximum ratings of the ADC clock input.

SLWS168C-MAY 2005-REVISED OCTOBER 2008 www.ti.com

7 RECEIVE DIGITAL SIGNAL PROCESSING

The down conversion section of the AFE8406 consists of the receive input interface, the rx_distribution bus, and 8 digital downconverter blocks.

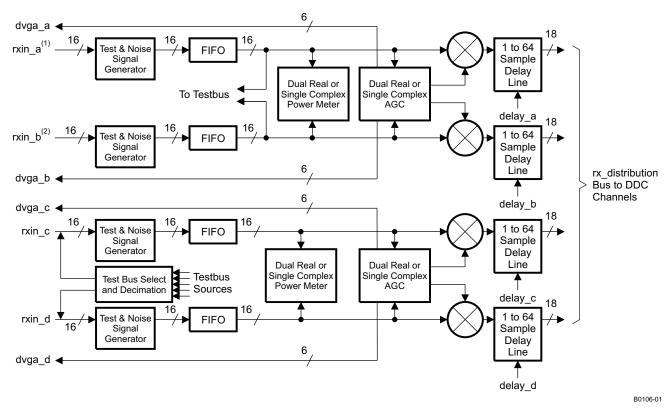

The purpose of the receive input interface is to accept signal data from four 16-bit input ports, measure the input signal power, control the digital VGA and to distribute the data to the DDC blocks. The input interface also has a user-controlled test generator and noise source.

The rx_distribution bus distributes the four channels of signal data to each of the 8 DDC blocks.

Each DDC block selects one of the four channels (or 2 for complex input data) from the rx_distribution bus and then performs downconversion tuning, programmable delay, channel filtering with decimation, power measurement, fixed gain adjust and/or automatic gain control. Each DDC block can support 1 UMTS channel, 2 CDMA channels or 2 TD-SCDMA channels. An optional mode permits stacking two DDC blocks in UMTS mode to provide double-length final pulse shaping filtering.

Tuned, filtered, and decimated signal data is output in bit serial or parallel format.

7.1 Receive Input Interface

- Hard-wired to internal ADCA
- (2) Hard-wired to internal ADCB

Figure 7-1. Receive Data Input Interface

The AFE8406's receive input data interface accepts data from several sources:

- Signal data from the two integrated 14-bit ADCs
- Signal data presented at the two 16-bit digital data input ports.
- An LFSR test signal generator allows the AFE8406 to be tested using a known repetitive data sequence.

AFE8406 14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www ti com

For the rxin_c and rxin_d input ports, signal data can be provided in binary or 2s complement form. The location of the ADC's MSB can be programmed to allow additional AGC headroom if desired. For example, a 14-bit ADC may be connected with the MSBs aligned or shifited down to allow the AGC additional gain range before clipping the signal.

Signal data can be accepted at rates up to rxclk in UMTS mode for either 8 normal channels or 4 double length final pulse shaping filter channels. In CDMA mode the maximum input rate is rxclk for real inputs, or rxclk/2 for complex inputs. For maximum filter performance, higher clock rates generally allow longer filters.

Complex signal data is input with I data driving one input port and Q data driving another. This means that there are only two signal data ports available when using complex input mode. The mapping of I and Q data onto the four input ports is programmable.

Signal input data is clocked into 8-stage FIFOs using a matching external clock signal adcclk_a/b/c/d. Signal data is clocked out of the FIFO from a gated rxclk (the AFE8406 receive section clock). The FIFO allows arbitrary phase relationship between adcclk_a/b/c/d and rxclk. The frequency relationship is mandated by the programmed configuration.

The test and noise generator can supply test sequences or add noise to the input signal data. The test sequences, when combined with the checksum generators, are useful for initial board debug or power-on self-test.

For applications that require receiver desensitization, the noise generator can add noise to input data streams.

The two ADC input ports, rxin_a and rxin_b, can be passed to the testbus control block, decimated by 32x, and routed directly to the AFE8406 testbus output pins. The key requirement of this function is to be able to verify the performance of the ADC by reconstructing the samples, while limiting the output sample rate to less than 5 MHz using an 85-MHz ADC sample rate.

Many other internal chip signals can be routed to the testbus for evaluation and debug purposes. When the testbus is enabled, the rxin c and rxin d ports are driven as digital outputs.

Each of the four outputs to the DDC channels includes a 1- to 64-sample delay line.

| PROGRAMMING | | | | |
|----------------|--|--|--|--|
| VARIABLE | DESCRIPTION | | | |
| ssel_ddc(2:0) | Selects the sync source for the DDC data input mux and mixer. This sets the sync source for DDC input clock generation and synchronization for all DDC channels. | | | |
| offset_bin_X | Selects offset binary input when set, 2s complement input when cleared. X={a,b,c,d}. Note that the internal ADCs use 2s complement format, so offset_bin_a and offset_bin_b must be set. | | | |
| msb_pos_X(2:0) | Identifies the connection location of the ADC's MSB. Programmed values of {07} corresponds to msb at {rxin_x_15 rxin_x_8}. X={a,b,c,d} | | | |

7.1.1 Receive FIFO

The receive FIFO consists of an 8 stage memory and 2 counters generating the input write pointer and output read pointer. When the FIFO receives a sync signal, the input and output pointers are initialized with a write to read pointer offset of four samples. Input samples from rxin_X (writes) are clocked with the adcclk_X input clock rising edges, and the input pointer advances on each clock rising edge. Output samples (reads) and the output pointer are clocked with the rxclk input signal rising edges, divided by the programmed sample rate loaded into the rate sel(1:0) control register.

| PROGRAMMING | | |
|--------------------|--|--|
| VARIABLE | DESCRIPTION | |
| adc_fifo_bypass | When set, bypasses the input FIFOs and input data is latched directly using the rxclk. When cleared, input data is latched using the adcclk_a/b/c/d inputs. | |
| ssel_adc_fifo(2:0) | Selects the sync source for the FIFO state machines. This sync signal initializes the FIFO input and output pointers. | |
| rate_sel(1:0) | This selects the FIFO input and output rate; {rxclk, rxclk/2, rxclk/4 or rxclk/8 }. For example, with rxclk at 153.6MHz, set rate_sel to 0, 1, 2 or 3 respectively for adcclk_a/b/c/d 153.6, 76.8, 38.4 or 19.2MHz. Must be set the same as register ch_rate_sel(1:0). | |
| adc_fifo_strap_ab | When set, the rxin_a and rxin_b FIFO input and output pointers are synchronized to support complex input signals. | |
| adc_fifo_strap_cd | When set, the rxin_c and rxin_d FIFO input and output pointers are synchronized to support complex input signals. | |

7.1.2 Receive Input Power Meters

SLWS168C-MAY 2005-REVISED OCTOBER 2008

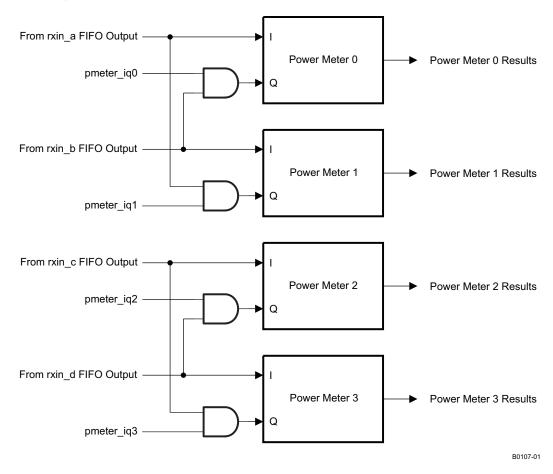

Figure 7-2. Receive Input Power Meters

Four Receive Input RMS power meters are provided. For real inputs, the four power meters can be used to measure the RMS power of the combined carriers in each of the four input signals (the Q input is held at zero). For complex inputs, two power meters can be use to measure the combined complex power and two can be disabled.

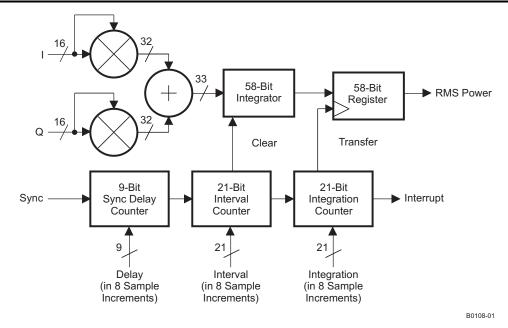

Figure 7-3. Detailed Functionality of Receive Input Power Meter

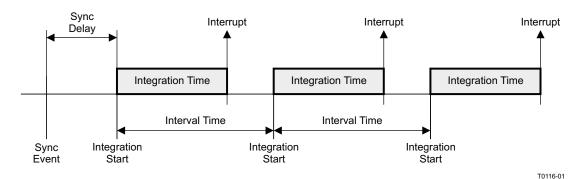

Figure 7-4. Receive Input Power Meter Timing

Power is calculated by squaring each 16-bit I (I and Q for complex inputs) sample, summing, and then integrating the summed-squared results into a 58-bit accumulator over a programmable integration period. The integration period is programmed into the 21-bit counter, in 8 sample increments. The power read is:

power = [
$$(I^2) \times (N \times 8 + 1)$$
] for real inputs where N is the integration count.
power = [$(I^2 + Q^2) \times (N \times 8 + 1)$] for complex inputs where N is the integration count.

A programmable 21-bit interval counter sets the power measurement interval (how often power will be measured) in 8 sample increments. A measurement integration period is started at the beginning of each interval period.

The process begins with a sync event starting the 9-bit delay counter. After $(8 \times \text{sync_delay} + 2)$ samples, the integration interval is started. Integration continues until the integration count is met, at which point the 58-bit integrator results are transferred to the read-only register and an interrupt is generated. A new measurement period starts at the end of the interval period.

The 21-bit counters in 8 sample increments allow up to 104.8 mS interval times at 160-MHz clock.

14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

NOTE

Each of the four composite RMS power meter blocks has its own delay sync, interval, and integration period counters, as well as separate sync source registers.

| PROGRAMMING | | | |
|--------------------------------|--|--|--|
| VARIABLE | DESCRIPTION | | |
| recv_pmeterX (57:0) | 58-bit power measurement result. X= {0,1,2,3}. | | |
| recv_pmeterX_sqr_sum(20:0) | 21-bit integration (square and sum) period. X= {0,1,2,3}. | | |
| recv_pmeterX_sync_delay(8:0) | Power meter delay sync period. X= {0,1,2,3}. | | |
| recv_pmeterX_strt_intrvl(20:0) | 21-bit measurement interval. X= {0,1,2,3}. The strt_intrvl value must be greater than the sqr_sum value. | | |
| ssel_recv_pmeter_X(2:0) | Sync source. X= {0,1,2,3}. | | |
| pmeterX_iq | Selects complex power measurement input mode when set. X= {0,1,2,3}. | | |
| recv_pmeterX_ena | Enables power meter when set. X= {0,1,2,3}. | | |

7.1.3 Receive Input AGC (RAGC)

Input signals from the ADCs can be used to create a front end composite AGC loop when combined with a digitally controlled variable gain amplifier (DVGA) connected before the ADCs. The AGC system operates by integrating the square of the ADC samples over a programmable interval and applying a table driven error signal to a loop integrator based on the squared integration output. The error table maps the signal power to a user programmed error value. The loop integrator output is used to drive map tables to control the DVGA output pins and a gain adjustment multiplier. Fast updates can be enabled if desired, to cause the loop integrator to quickly adjust to interfering signals. The ADC input signals can also be passed through a high pass filter to remove DC offset before squaring the input.

The programmable error table, integrator mapping tables, and clip thresholds, when combined with the user programmable interval timers provide a highly flexible AGC function.

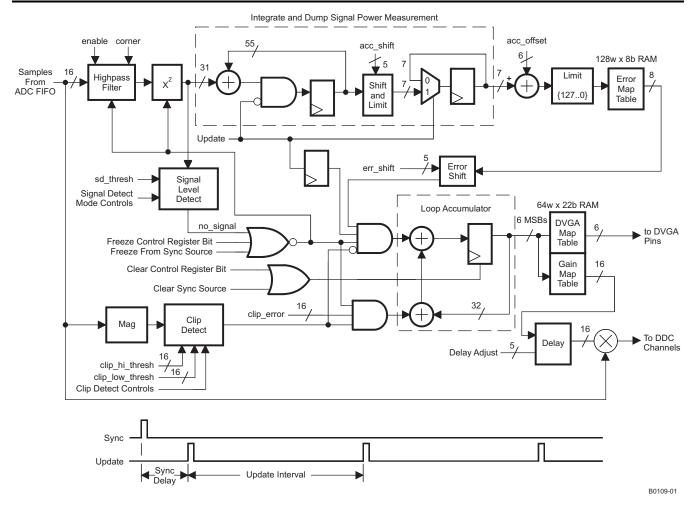

Figure 7-5. Receive Input AGC

The AGC measurement interval timer is a 24-bit timer initialized by a sync after a programmable 8-bit delay. During the integration interval, the squared input signal is shifted by the programmed value and accumulated. At the end of the interval time, an update pulse is generated, and the selected 7 bits of the 55-bit accumulated power is upper limit checked and transferred to the power holding register. A programmable offset is applied, and the following limit check produces a 7-bit address value for the error map table RAM. The user programmable error map table and following gain shift setting are used to determine the loop error signal to be added to the 32-bit AGC loop accumulator. The error value is only added to the loop accumulator once per update. The loop accumulator upper 6 MSBs are used as the address for the programmable DVGA map table and gain map table. The gain map table address can be delayed from 0 to 31 clock cycles to align DVGA changes to signal level changes at the output of the AGC.

The AGC includes four sources for freezing the loop and holding the loop accumulator constant. A general sync source can be used to directly control the freeze; when the selected sync source is high, the AGC will be held, and when low, the AGC will operate. A control register bit freezes the AGC in the same fashion; when the bit is set, the AGC is held, and when cleared, the AGC will operate. A signal level detector is provided that can be used to automatically freeze the AGC loop in the event of input signal loss. A programmable signal detection threshold value, number of samples below the signal detection threshold, and window timer are used to determine when no signal is present. Finally, a programmable number of AGC updates after sync can be programmed, and the AGC will he held until the next sync event. Freeze holds the loop accumulator constant, the integrate and dump accumulator constant and the interval timer constant. When freeze is released, the interval timer will resume counting.

A sync event will always reinitialize the integrate and dump interval timer, and terminate the pending update to the loop accumulator from the current integrate and dump measurement interval. For example, if a sync event occurs during an integrate and dump interval, that interval will be terminated without updating the loop, and the integrate and dump accumulator will be cleared. After the programmed sync delay, a new interval will start.

The AGC includes a dual threshold clip detect function, using two programmable 16-bit thresholds and programmable counters. The clip detector will cause immediate loop accumulator updates while the clip event is active. The 16-bit clip error value is aligned at the MSBs of the loop accumulator. Clip events are qualified when a programmed number of samples are above the high clip threshold during the programmable clip window time. For example, a clip event can be defined as 8 samples above the clip high threshold in a 256 sample window; the clip high threshold, the number of samples above the high clip threshold and the sample window time are programmable. Once the clip event has occurred, the clip duration is controlled by the clip low threshold value, clip low samples value and clip low timer. The clip event is cleared when the number of samples below the low clip threshold exceeds the programmed value within the clip low timer window. The clip low threshold, number of clip low samples and the clip low window timer are programmable.

The AGC blocks can be paired together, rxin_a with rxin_b, and rxin_c with rxin_d, to produce a complex input AGC mode. The clip detector output from the rxin_b/d AGCs is logically OR'ed with the rxin_a/c clip detect outputs. The squared input function before the integrate and dump and signal level detector is replaced with a $I^2 + Q^2$ power calculation. The accumulator MSBs from the rxin_a/c AGCs are connected to the rxin_c/d DVGA map table and gain map table inputs. This arrangement allows the AGCs to operate in a direct conversion receiver system by controlling the $I^2 + Q^2$ complex signal level.

The highpass filter is a 32-bit accumulator followed by an adjustable shift to control the corner frequency, a subtractor to remove the accumulated offset and a final limiter to produce a 16-bit result. The highpass filter function is enabled by setting hp_ena; clearing hp_ena holds the accumulator reset.

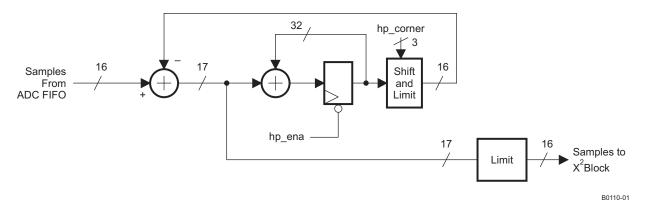

Figure 7-6. High Pass Filter in Receive Input AGC

| PROGRAMMING | | |
|---------------------------|--|--|
| VARIABLE | DESCRIPTION | |
| ragc_bypass_X | Bypasses the entire receive AGC circuit when set. $\times = \{0,1,2,3\}$ | |
| hp_ena_X | Enables high pass filter when set | |
| hp_corner_X(2:0) | Adjusts the corner frequency of the high pass filter | |
| integ_interval_X(23:0) | Integrate and dump signal power measurement interval in samples. | |
| acc_shift_X(4:0) | Shift down amount following the integrate and dump accumulator. | |
| acc_offset_X(5:0) | Offset value applied to the shifted integrate and dump output. | |
| ragc_sync_delay_X(7:0) | AGC sync delay interval, from 1 to 256 samples. | |
| ssel_ragc_interval_X(2:0) | Sync source selection for the interval timer. | |
| ssel_ragc_freeze_X(2:0) | Sync source selection for AGC freeze | |

SLWS168C-MAY 2005-REVISED OCTOBER 2008

| PROGRAMMING | | | | | | |
|------------------------|---|--|--|--|--|--|
| VARIABLE | DESCRIPTION | | | | | |
| ssel_ragc_clear_X(2:0) | Sync source selection for the AGC loop accumulator clear | | | | | |
| ragc_freeze_X | Register bit to freeze the AGC when set | | | | | |
| ragc_clear_X | Register bit to clear the AGC accumulator when set | | | | | |
| ragc_update_X(7:0) | Sets the number of updates per sync event, after which no further updates will occur until the next sync event. Program to 0x00 to continually update. | | | | | |
| sd_ena_X | Enables freezing the AGC with the signal detector when set | | | | | |
| sd_thresh_X(15:0) | Signal detection threshold for AGC channel X. This 16-bit word is lined up with bits 23 down to 8 of the square output. The smallest signal level is that can be programmed is therefore 16 LSBs on the ADC input, and the largest is 4095 LSBs at the ADC input. | | | | | |
| sd_samples_X(15:0) | The number of samples below the signal detect threshold within the signal detect sample timer window required to freeze on the AGC. | | | | | |
| sd _timer_X(15:0) | Window timer to qualify signal detection. | | | | | |
| clip_hi_thresh_X(15:0) | Clip detector high threshold | | | | | |
| clip_lo_thresh_X(15:0) | Clip detector low threshold | | | | | |
| clip_hi_samples_X(7:0) | A clip event is detected when this number of samples above the clip high threshold within the clip high sample timer window exceeds this value. | | | | | |
| clip_lo_samples_X(7:0) | A clip event ends when th5is number of samples below the clip low threshold within the clip low sample timer window exceeds this value. | | | | | |
| clip_hi_timer_X(15:0) | Window timer to qualify clip events. | | | | | |
| clip_lo_timer_X(15:0) | Window timer to determine when the clip event ends. | | | | | |
| clip_error_X(15:0) | Error signal applied to the AGC accumulator when a clip event is active. This data is MSB aligned, and therefore can cause immediate changes to the accumulator. | | | | | |
| ragc_error_map_X | 128w × 8b memory holding the log to error look up table. | | | | | |
| dvga_map_X | 64w × 6b memory holding the accumulator to DVGA look up table | | | | | |
| gain_map_X | $64\text{w} \times 16\text{b}$ memory holding the accumulator to GAIN look up table (256 decibels is unity gain). | | | | | |
| delay_adj_X(4:0) | Delay between DVGA output updates and gain map updates to compensate for ADC pipeline delays, etc. | | | | | |
| err_shift_X(4:0) | Error map table output shift up before adding to loop accumulator | | | | | |
| complex01 | Enables complex AGC mode on inputs rxin_a and rxin_b when set | | | | | |
| complex23 | Enables complex AGC mode on inputs rxin_c and rxin_d when set | | | | | |
| ragcX_accum(31:0) | 32-bit read only register holding the current contents of the loop accumulator. | | | | | |
| 3-state(10:7) | 3-state controls for the dvga_d/c/b/a output pins; pins are in the high-impedance state when the 3-state bits are set. | | | | | |
| ragc_mpu_ram_read | When set, the receive AGC map rams are readable via the MPU control interface. The AFE8406 signal path is not operational when this bit is set, it is intended for debug purposes only. | | | | | |

7.1.4 Test and Noise Signal Generator

The test and noise generator can generate test signals to replace the rxin_a/b/c/d inputs as a tool for debug, evaluation and self test. Checksum generators included in the individual DDC channels at the outputs can be used in conjunction with the noise generator and the internal sync timer block to create the built in self test function.

The test and noise signal source included in this block is a 23-bit linear feedback shift register (LFSR) with a fixed polynomial and fixed initialization state. A sync input is required to initialize the LFSR, and the sync source is connected to the ddc_counter output signal.

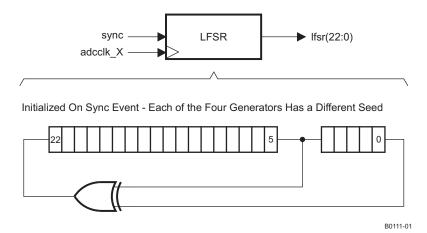

Figure 7-7. Noise Signal Generator

| Receive Input Port | LFSR Seed Value, MSB to LSB |
|--------------------|---|
| rxin_a | 100 0000 0000 0000 0001 0000 (0x400010) |
| rxin_b | 010 0110 1110 0110 1100 1110 (0x26E6CE) |
| rxin_c | 110 1110 1010 0010 1001 1000 (0x6EA298) |
| rxin_d | 000 1011 0001 1110 1011 0111 (0x0B1EB7) |

The 23-bit LFSR output signal if used to create a 16-bit "dout(15:0)" test signal using XOR combinations of the LFSR bits.

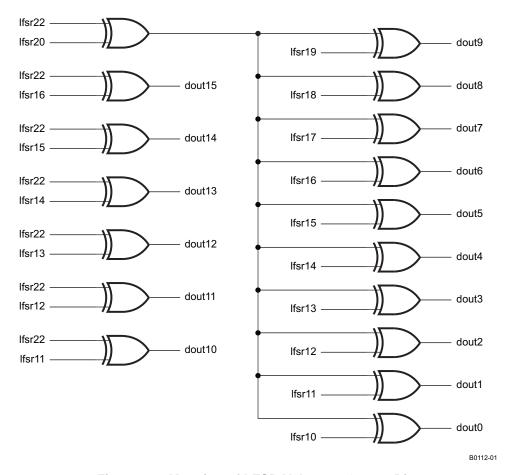

Figure 7-8. Mapping of LFSR Values to Output Bits

To enable the test signal generator, the slf_tst_ena control bit is set. The rxin_a/b/c/d signals will be then replaced by the four generator output streams. To use this test signal generator as a signal source for self test, the user must also set the adc_fifo_bypass control bit. Setting the adc_fifo_bypass control bit causes the adcclk_a/b/c/d input clocks to be internally replaced with rxclk/N, where N is as programmed with the rate_sel(1:0) control bits to {1,2,4 or 8}.

The test signal generators can also output a programmable constant value. All four test signal generators output the same programmable constant value.

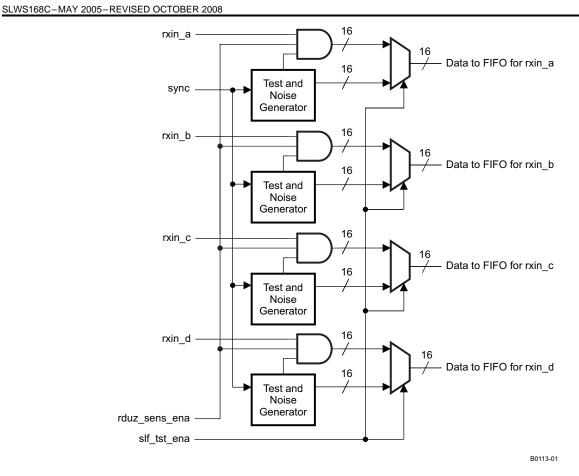

Figure 7-9. Block diagram of Noise Generator Input Options

The LFSR circuits can also be used to add noise to the rxin_a/b/c/d input signals by setting the rduz_sens_ena control register bit. The magnitude of the noise added can be adjusted by programming the nz_pwr_mask(15:0) control register. In Figure 7-10, \times = {a,b,c or d}.

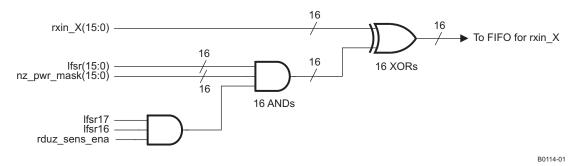

Figure 7-10. Detail Circuit for Adding Noise Generator Signal to rxin Signal

www.ti.com

AFE8406 14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

PROGRAMMING VARIABLE DESCRIPTION slf_tst_ena When set, the test signal generators replace the rxin_a/b/c/d input signals with internally generated psuedo random sequences. The fifo_bypass bit must be set when this bit is set. rduz_sens_ena Enables the LFSR, adding noise to the ADC input data when set. Selects the power of the noise added to the ADC input data. nz_pwr_mask(15:0) When set, the FIFO is essentially bypassed, and the adcclk_a/b/c/d clock input ports are ignored. adc_fifo_bypass ddc_counter(31:0) 32-bit general purpose counter interval ddc_counter_width(7:0) 8-bit general purpose counter timeout width pulse ssel_ddc_counter(2:0) Sync source selection for the general purpose counter self_test_constant(17:0) 18-bit self test constant value applied to all 4 rxin_a/b/c/d inputs when self_test_const_ena is set.

Enables the self test constant value for rxin a/b/c/d

7.1.5 Sample Delay Lines

self_test_const_ena

The four sample delay line blocks each consist of a 64 register memory and a state machine. The state machine uses a counter to control the write (input) pointer, and the programmed read offset register data to create the read (output) pointer. Programming larger read offset register values increases the effective delay at a resolution equal to the sample rate.

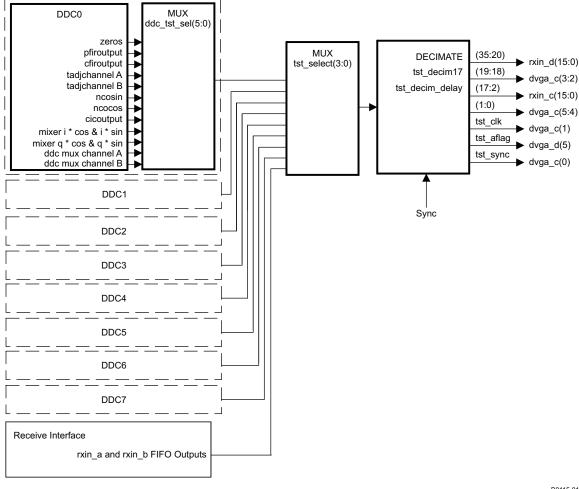

The read offset registers, delay_line_X, are double buffered. Writes to these registers may occur anytime, but the actual values used by the circuit will not be updated until a delay line sync event occurs.

| PROGRAMMING | | | | | | |
|------------------------|---|--|--|--|--|--|
| VARIABLE | VARIABLE DESCRIPTION | | | | | |
| delay_line_X(5:0) | Read offset into the 64 element memory for each delay line. X= {0,1,2,3}. | | | | | |
| ssel_delay_line_X(2:0) | Selects the sync source used to update the double buffered delay line register. | | | | | |

7.1.6 Test Bus

When the test bus is enabled, the rxin_c(15:0) and rxin_d(15:0) ports become outputs, and the dvga_c and dvga_d pins are combined with these pins to allow 36-bit wide signals from the DDC channels and the receive input interface to be multiplexed to this test output port. Many of these sources can be decimated to reduce the output sample rates.

B0115-01

Figure 7-11. Test Bus Output Circuit Showing Options for Selecting Signal

| PROGRAMMING | | | | | | |
|----------------------|---|--|--|--|--|--|
| VARIABLE | VARIABLE DESCRIPTION | | | | | |
| ssel_tst_decim(2:0) | Selects the sync source for the testbus decimator | | | | | |
| tst_decim_delay(3:0) | Sets the testbus decimator delay from sync | | | | | |
| tst_decim17 | Must be cleared | | | | | |
| tst_on | Enables the test bus; rxin_c(15:0) and rxin_d(15:0) are changed from inputs to outputs, dvga_c(5:0) and dvga_d(5) are used as part of the test bus. | | | | | |
| tst_select(3:0) | Selects the source block for the testbus output; DDC0-7 or Receive Interface. | | | | | |
| ddc_tst_sel(5:0) | Selects the signal to be output from the DDC block | | | | | |
| tst_rate_sel(4:0) | Sets the testbus output clock tst_clk period to (tst_rate_sel + 1) rxclk cycles. When the testbus source is set to the ADC FIFO, tst_rate_sel(4:0) must be set to 0 for an output. | | | | | |
| tst_clk_pol | Selects the polarity of the test clock output at dvga_c(1) when the test bus is enabled; 0 for rising edge in the center of valid data, 1 for falling edge in the center of valid data. No effect when tst_rate_sel is "00000". | | | | | |

7.2 DDC Organization

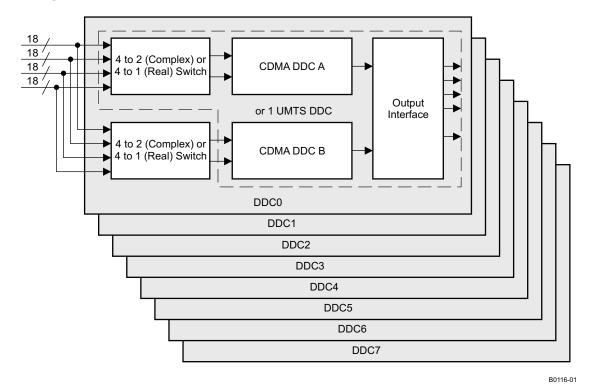

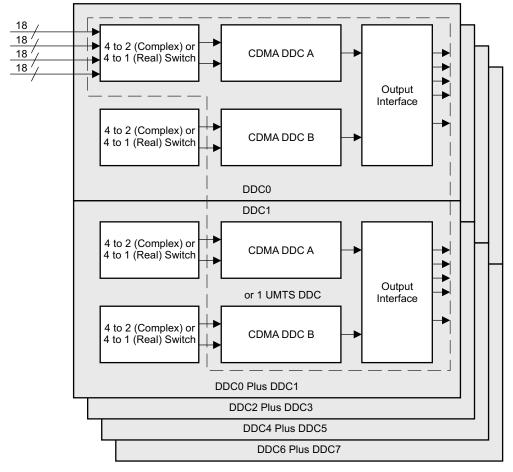

Figure 7-12. DDC Organization for Single Length Filter Mode

The AFE8406 provides downconversion for up to 8 UMTS receive channels, 16 CDMA2000 receive channels or 16 TD-SCDMA receive channels. Downconversion channels are organized into 8 DDC blocks. Each individual DDC block provides 2 CDMA2000 or 2 TD-SCDMA DDC channels, A and B, or 1 UMTS channel.

Both CDMA DDC channels in a DDC block can be independently tuned, though they would likely be used as diversity pairs and tuned to the same frequency. Filter coefficients are shared between the two CDMA DDC channels within a block.

Two adjacent DDC blocks (for example, DDC0 and DDC1) can be strapped together to form a single UMTS DDC channel with double-length final pulse shaping filtering. The AFE8406 can therefore provide 4 UMTS DDC channels with double-length final PFIR filtering as shown in the following diagram.

B0117-01

Figure 7-13. DDC Organization for Double Length Filter Mode

| PROGRAMMING | | | | |
|----------------------|--|--|--|--|
| VARIABLE DESCRIPTION | | | | |
| ddc_ena | When set, turns on the DDC. | | | |
| cdma_mode | cdma_mode When set, puts the DDC block in dual channel CDMA mode. | | | |
| gbl_ddc_write | When set, all subsequent programming (writes only) for DDC0 and DDC1 is also written to DDC2/4/6 and DDC3/5/7. | | | |

7.2.1 Downconverter Function Blocks

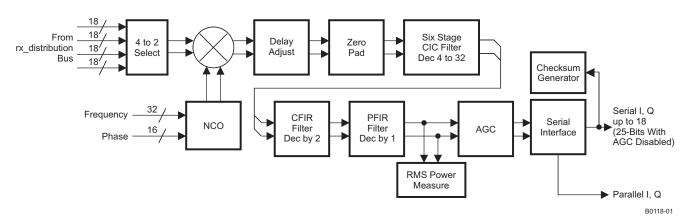

Figure 7-14. DDC Functional Block Diagram

INSTRUMENTS

www.ti.com

Each AFE8406 downconversion block can process two CDMA carriers or a single UMTS carrier. Signal data is selected from one of four ports for real inputs, or two of four ports for complex inputs. Data from the selected port(s) is multiplied with a complex, programmable numerically controlled oscillator (NCO) which tunes the signal of interest to baseband. The delay adjust and zero pad blocks permits adjustment of the delay in the end-to-end channel. Zero padding interpolates the signal to the rxclk rate. Filtering consists of a six stage CIC filter which decimates the tuned data by a factor from 4 to 32, a compensating FIR filter (CFIR) which decimates by a factor of two, followed by a programmable FIR filter (PFIR) which does not decimate. The output interface block can be programmed to decimate by 2 if desired.

The RMS power meter measures the power within the channel's bandwidth. The AGC automatically drives the gain and keeps the magnitude of the signal at a user-specified level. This allows fewer bits to represent the signal. The serial output interface formats and rounds the output data. Each of the above blocks is described in greater detail in the following sections.

7.2.2 DDC Mixer

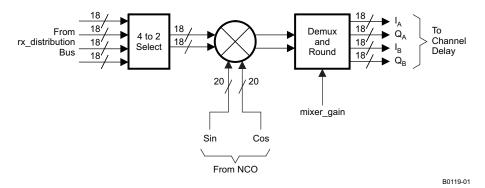

Figure 7-15. Mixer Functional Block Diagram

The receive mixer translates the input (from one of the input signal sources) to baseband where subsequent filtering is performed to isolate the signal of interest. The mixer is a complex multiplier that accepts 18-bit I and 18-bit Q signal data from the receive input interface and 20-bit sine and cosine sequences from the NCO. The NCO generates a mixing frequency (sometimes referred to as a local oscillator, or LO) specified by the user so that the desired signal of interest is tuned to 0 Hz.

A DDC channel can support one UMTS signal directly, or two CDMA channels at half the input rate. When in CDMA mode, each channel may be set independently; the path selection and the mixer tuning and phase. The mixer output produces two complex streams; one representing the signal path for the A-side DDC, the other the B-side. Each of these streams drives a channel delay and zero pad block.

The maximum input rate for UMTS is rxclk for either real or complex input data.

The maximum input rate in CDMA mode with real inputs is rxclk (remix_only is set, see the following).

The maximum input rate in CDMA mode with complex inputs is rxclk/2 due to sharing of multiplier resources.

| PROGRAMMING | | | | | |
|-------------------|---|--|--|--|--|
| VARIABLE | DESCRIPTION | | | | |
| ddcmux_sel_a(3:0) | Programs the I and Q complex input data routing onto two of the four input ports for stream A of CDMA DDC | | | | |
| ddcmux_sel_b(3:0) | Programs the I and Q complex input data routing onto two of the four input ports for stream B of CDMA DDC | | | | |
| remix_only | For CDMA mode only, set this bit for real input data at the rxclk rate. | | | | |
| | For complex inputs in CDMA mode, the maximum input data rate is rxclk/2, and this bit must be cleared. | | | | |
| | For CDMA mode with real inputs at the rxclk/2 rate or lower, this bit must be cleared | | | | |
| zero_qsample | When set, the Q samples used by the mixer are always zero. This bit should be set for real only inputs in UMTS mode, or real only inputs in CDMA mode when the input sample rate is rxclk/2 or lower. | | | | |
| ch_rate_sel(1:0) | Specifies the input channel data rate (rxclk, rxclk/2, rxclk/4, or rxclk/8 MSPS). MUST BE SET THE SAME AS REGISTER rate_sel(1:0). | | | | |
| mixer_gain | When asserted, adds 6dB of gain in the mixer. This gain is highly recommended. | | | | |

7.2.3 DDC Number Controlled Oscillator (NCO)

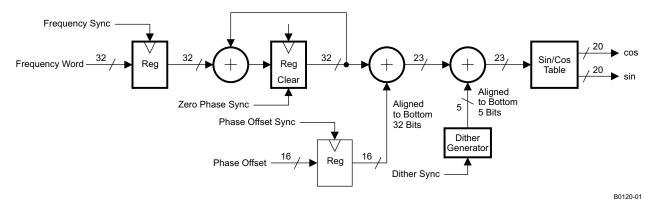

Figure 7-16. Detailed NCO Circuit

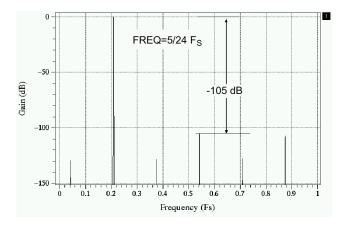

The NCO is a digital complex oscillator that is used to translate (or downconvert) an input signal of interest to baseband. The block produces programmable complex digital sinusoids by accumulating a frequency word which is programmed by the user. The output of the accumulator is a phase argument that indexes into a sin/cos ROM table which produces the complex sinusoid. A phase offset can be added prior to indexing if desired for channel calibration purposes. This will change the sin/cos phase with respect to other channels' NCOs.

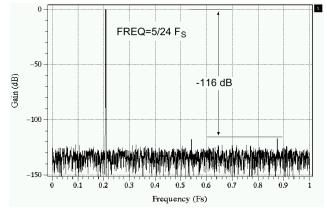

A 5-bit dither generator is provided and generates a small level of digital pseudo-noise that is added to the phase argument below the bottom bits and is useful for reducing NCO spurious outputs. This dither generation is enabled by setting the dither_ena bit; the magnitude of the dither can be reduced by setting one or both of the dither_mask bits.

| DITHER PROGRAMMING | | | | | | |
|--|--|--|--|--|--|--|
| VARIABLE | VARIABLE DESCRIPTION | | | | | |
| dither_ena | ither_ena When set turns dither on. Clearing turns dither off. | | | | | |
| ither_mask(1:0) Masks the MSB and MSB-1 dither bits, respectively, when set. | | | | | | |

The NCO spurious levels are better than -115 dBc. Added phase dither randomizes the periodic nature of the phase accumulation process and reduces low-level spurious energy. For some frequencies (N \times Fs/24, where N = {1,2, . . . 23}) dither is ineffective – in these cases an initial phase of 4 reduces NCO spurs. Figure 7-17 show the spur level performance of the NCO without dither, with dither, and with a phase offset value.

a) Worst Case Spectrum Without Dither

b) Spectrum With Dither (Tuned to Same Frequency

Figure 7-17. NCO SFDR - Without Dither

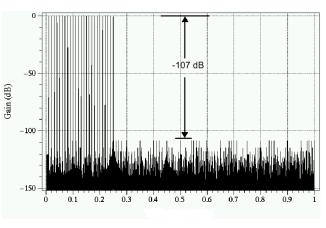

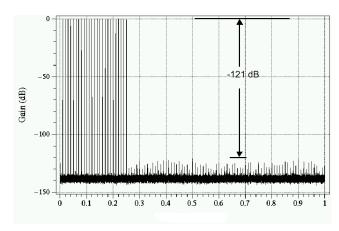

Figure 7-18. NCO SFDR - With Dither

a) Plot Without Dither or Phase Initialization

b) Plot With Dither or Phase Initialization

Figure 7-19. NCO Spectra (0 and Fs/4) - Without Dither or Phase Initialization

Figure 7-20. NCO Spectra (0 and Fs/4) - With Dither or Phase Initialization

The tuning frequency is specified as a 32-bit frequency word and is programmed as two sequential 16-bit words over the control port. The NCO frequency resolution is Fclk/ 2³², where Fclk is the ADCCLK frequency. As an example, at an input clock rate of 61.44 MHz, the frequency step size would be approximately 14 milli-Hertz. The Frequency Word is determined by the formula:

Frequency Word (in decimal)= $2^{32} \times \text{Tuning Frequency} / F_{clk}$

Note that frequency tuning words can be positive or negative valued. Specifying a positive frequency value translates complex negative frequencies upwards towards 0 Hertz. Specifying a negative tuning frequency translates complex positive frequencies downwards towards 0 Hertz.

| FREQUENCY PROGRAMMING | | | | | | |
|-----------------------|---|--|--|--|--|--|
| VARIABLE | VARIABLE DESCRIPTION | | | | | |
| phase_add_a(31:0) | 32-bit tuning frequency word for the A-side DDC when in CDMA mode. Also for UMTS mode. | | | | | |
| phase_add_b(31:0) | 32-bit tuning frequency word for the B-side DDC when in CDMA mode. Not used in UMTS mode. | | | | | |

INSTRUMENTS

Each of the 16 CDMA DDC channels can be loaded with unique frequency words.

The phase of the NCO's Sin/Cos output can be adjusted relative to the phase of other channel NCOs by specifying a Phase Offset. The Phase Offset is programmed as a 16-bit word, yielding a step size of about 5.5 m°. The Phase Offset Word is determined by the formula:

Phase Offset Word = 2¹⁶ × Offset_in_Degrees / 360 or,

Phase Offset Word = $2^{16} \times Offset_in_Radians / 2\pi$

| PHASE PROGRAMMING | | | | | |
|----------------------|---|--|--|--|--|
| VARIABLE DESCRIPTION | | | | | |
| phase_offset_a(15:0) | 16-bit phase offset word for the A-side DDC when in CDMA mode. Also for UMTS mode. | | | | |
| phase_offset_b(15:0) | 16-bit phase offset word for the B-side DDC when in CDMA mode. Not used in UMTS mode. | | | | |

Each of the 16 CDMA DDC channels can be loaded with unique phase offset words.

Various synchronization signals are available which are used to synchronize the NCOs of all channels with respect to each other. Frequency Sync and Phase Offset Sync determine when frequency and phase offset changes occur. For example, generating a Frequency Sync after programming the two frequency words will cause the NCO (or multiple NCOs) to change frequency at that time, rather than after each of the three frequency words is programmed over the control bus. The Zero Phase Sync signal is used to force the sine and cosine oscillators to their zero phase state. Dither Sync can be used to synchronize the dither generators of multiple NCOs. The NCOs used in the transmit section are identical to what is described for the receive section. Note that there is one set of sync's provided for each DDC. When one DDC is used to process two CDMA signals, the syncs are shared between them.

| SYNC PROGRAMMING | | | | | |
|----------------------|--|--|--|--|--|
| VARIABLE DESCRIPTION | | | | | |
| ssel_nco(2:0) | Sync source for NCO accumulator reset | | | | |
| ssel_dither(2:0) | Sync source for NCO dither reset | | | | |
| ssel_freq(2:0) | Sync source for NCO frequency register loading | | | | |
| ssel_phase(2:0) | Sync source for NCO phase register loading | | | | |

7.2.4 DDC Filtering and Decimation

The purpose of the receive filter chain is to isolate the signal of interest (and reject all others) that has been previously translated to baseband via the mixer and NCO. The overall decimation through the chain needs to be considered. The goal, generally, is to output the isolated signal at a rate that is twice (2X) the signal's chip rate. For UMTS this would be 7.68 MSPS and for CDMA the output rate should be 2.4576 MSPS. TD-SCDMA systems require the output rate be the chip rate of 1.28 MSPS. The output interface is programmed to decimate by 2 for the TD-SCDMA case.

Receive filtering and decimation is performed in several stages:

- Zero padding to interpolate the input sample rate (if needed) up to the rxclk rate
- High rate decimation (4 to 32) using a six stage cascade-integrate-comb filter (CIC)
- Decimate by two compensation filtering using the programmable compensating FIR filter (CFIR)
- Pulse-shape filtering via the programmable FIR filter (PFIR) with no decimation
- Output interface, serial or parallel format, with no decimation or decimate by 2

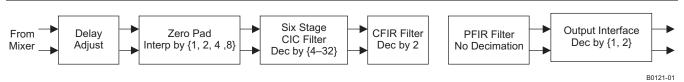

Figure 7-21. DDC Filtering Functional Block Diagram

Table 7-1 contains some examples of decimation and sample rates at the output of each block for UMTS, CDMA and TD-SCDMA standards at various supported input samples. For each example, the differential ADC clocks are provided to the AFE8406 at the input sample rate and the rxclk is provided at the zero pad output rate.

| | Input Sample Rate (MSPS) | Zeros Added | rxclk(MHz) and Zero Pad Output Rate (MSPS) | CIC Decimation | CIC Output Rate (MSPS) | CFIR Decimation | CFIR Output Rate (MSPS) | PFIR Decimation | PFIR Output Rate (MSPS) | Output Decimation |
|----------|-----------------------------------|----------------|---|-------------------|---------------------------------|--------------------|----------------------------------|--------------------|----------------------------------|----------------------|
| UMTS | 76.80 | 1 | 153.6 | 10 | 15.36 | 2 | 7.68 | 1 | 7.68 | 1 |

7.2.5 DDC Channel Delay Adjust and Zero Insertion

153.6

122.88

30

24

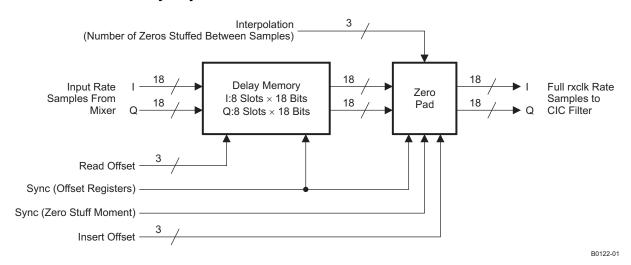

Figure 7-22. DDC Delay and Zero Insertion Block

The Receive Channel Delay Adjust function is used to add programmable delays in the channel downconvert path. Adjusting channel delay can be used to compensate for analog elements external to the AFE8406 digital downconversion such as cables, splitters, analog downconverters, filters, etc.

TD-SCDMA

TD-SCDMA

76.80

61.44

⁽¹⁾ The DDC output interfaces, both serial and parallel formats, can be programmed to decimate by 2. For the TD-SCDMA examples listed above, the DDC output rate is 1.28Msps (1x chip rate).

The Delay Memory block consists of an 8 register memory and a state machine. The state machine uses a counter to control the write (input) pointer, and the programmed read offset register data to create a read (output) pointer. Programming larger read offset register values increases the effective delay at a resolution equal to the input sample rate.

The Zero Pad block is used in conjunction with the Delay Memory for delay adjustments. For example, with input rates of rxclk/8, the Zero Pad block interpolates the input data to rxclk by inserting 7 zeros. The Zero Pad's sync insert offset 3-bit control specifies when the zeros are inserted relative to the Sync signal. This permits a fine adjustment at the rxclk resolution.

The read offset register, tadf_offset_course_a/b, and the insert offset register, tadj_offset_fine_a/b, are double buffered. Writes to these registers may occur anytime, but the actual values used by the circuit will not be updated until a register sync.

| PROGRAMMING | | | | |
|---------------------------|--|--|--|--|
| VARIABLE | DESCRIPTION | | | |
| tadj_offset_coarse_a(2:0) | Read offset into the 8 element memory for the UMTS or CDMA mode A channel DDC. | | | |
| tadj_offset_coarse_b(2:0) | Read offset into the 8 element memory for the CDMA mode B channel DDC when in CDMA mode. | | | |
| tadj_offset_fine_a(2:0) | Controls the zero pad (or stuff) insert offset (fine adjust) for the UMTS or CDMA mode A channel of the DDC. | | | |
| tadj_offset_fine_b(2:0) | Controls the zero pad (or stuff) insert offset (fine adjust) for the CDMA mode B channel of the DDC when in CDMA mode. | | | |
| tadj_interp(2:0) | The interpolation value (1, 2, 4, or 8). Same used for both the A and B channels when in CDMA mode. Selects the number of zeros to be inserted. | | | |
| ssel_tadj_fine(2:0) | Selects the sync source for the fine time adjust zero stuff moment. Same for A and B channels when in CDMA mode. | | | |
| ssel_tadj_reg(2:0) | Selects the sync source used to update the double buffer course and fine delay selection registers. Same for A and B channels when in CDMA mode. | | | |

7.2.6 DDC CIC Filter

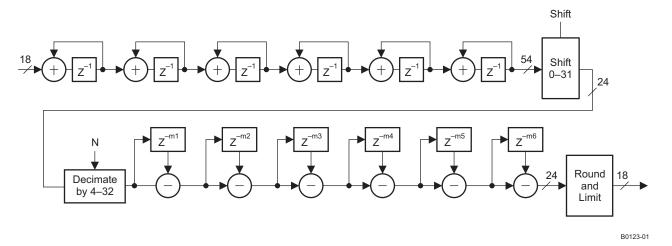

Figure 7-23. DDC CIC Filter Block Diagram

The CIC filter provides the first stage of filtering and large-value decimation. The filter consists of six stages and decimates over a range from 4 to 32.

I data and Q data are handled separately with two CIC filters. In addition, when in CDMA mode (two CDMA channels processed within a single DDC), another pair of CIC filters handles the B-side channel.

14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www.ti.com

The filter response is 6x(Sin(x)/x) in character where the key attribute is that the resulting response nulls reject signal aliases from decimation. A consequence of this desirable behavior is that only a small portion of the passband can be used, less than 25% generally. This means that the CIC decimation value should be chosen so that the signal exiting the CIC filter is oversampled by at least a factor of four.

The filter is equivalent to 6 stages of a FIR filter with uniform coefficients (6 combined boxcar filter stages). Each filter would be of length N if m=1, or 2N if m=2.

The filter is made up of six banks of 54-bit accumulator sections followed by six banks of 24-bit subtractor sections. Each of the subtractor sections can be independently programmed with a differential delay of either one or two. A shift block follows the last integration stage and can shift the 54-bit accumulated data down by 36-rcic_shift (a programmable factor from 0 to 31 bits).

The CIC filter exhibits a droop across its frequency response. The following CFIR filter compensates for the CIC droop with a gradually rising frequency response. It is also possible to compensate for CIC droop in the PFIR filter.

The gain of the receive CIC filter is:

 $Ncic^6 \times 2^{(number of stages where M=2)} \times 2^{(-36+RCIC_SHIFT)}$ where RCIC_SHIFT is 0 to 31.

There is no rollover protection internal to the CIC or at the final round so the user must guarantee no sample exceeds full scale prior to rounding. For practical purposes this means the CIC gain can only compensate for peak gain less than one or must be less than or equal to one. A fixed gain of +12 dB at the output of the CIC can also be programmed.

| PROGRAMMING | | | | |
|--------------------|--|--|--|--|
| VARIABLE | DESCRIPTION | | | |
| cic_decim(4:0) | The CIC decimation ratio (4 to 32). The ratio is cic_decim + 1. This ratio applies to both A and B channels of the DDC block in CDMA mode. | | | |
| cic_scale_a(4:0) | The shift value for the A channel. A value of 0 is no shift, each increment in value increases the amplitude of the shifter output by a factor of 2. | | | |
| cic_scale_b(4:0) | The shift value for the B channel. A value of 0 is no shift, each increment in value increases the amplitude of the shifter output by a factor of 2. | | | |
| cic_gain_ddc | When asserted, adds a gain of 12 dB at the CIC output. | | | |
| cic_m2_ena_a(5:0) | Sets the differential delay value M for each of the CIC subtractor stages for the UMTS or CDMA mode A channel. | | | |
| cic_m2_ena_b (5:0) | Sets the differential delay value M for each of the CIC subtractor stages for the CDMA mode B channel. | | | |
| cic_bypass | Bypasses the CIC filter when set, for factory use only. | | | |
| ssel_cic(2:0) | Sets syncing (1 of 8 sources) for the CIC decimation moment. | | | |

7.2.7 DDC Compensating FIR Filter (CFIR)

The receive compensating FIR filter (CFIR) decimates the output of the CIC filter by a fixed factor of two. Filter coefficient size, input data size, and output data size are 18 bits. The CFIR length can be programmed. This permits "turning off" taps and saving power if shorter filters are appropriate (the CFIR power dissipation is proportional to its length).

The filter is organized in two partial filter blocks, each containing a data RAM, a coefficient RAM and a dual multiplier, a common state machine and output accumulator.

www.ti.com

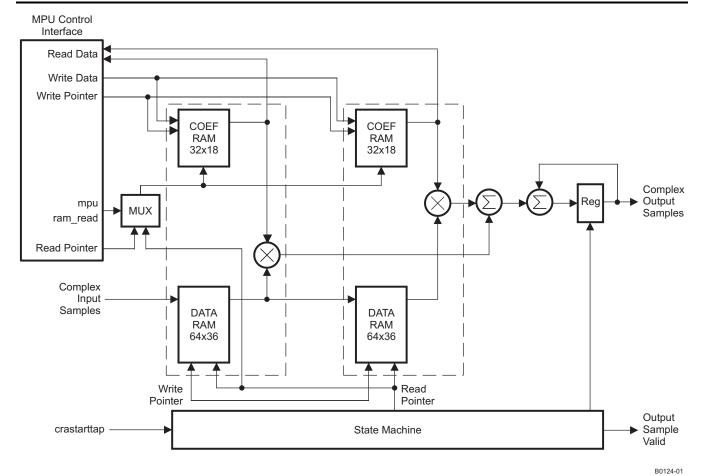

Figure 7-24. DDC CFIR Block Diagram

The maximum CFIR filter length is a function of AFE8406 rxclk clock rate, output sample rate and the number of coefficient memory registers. The maximum number of taps is 64 and the minimum number is 14. Lengths between these limits can be specified in increments of 2.

Subject to the above minimum and maximum values, in the general case, the number of taps available is:

UMTS Mode: 2 × (rxclk ÷ output sample rate)

CDMA Mode if cic_decim is even (decimating by an odd number): 2 × (cic_decim)

CDMA Mode if cic decim is odd (decimating by an even number): 2 × (cic decim + 1)

Example CFIR filter lengths available based on mode and rxclk frequency:

| Mode | rxclk (MHz) | CIC DECIMATION | cic_decim | CFIR MAX LENGTH | CFIR MIN LENGTH | COMMENTS |
|------|----------------|-------------------|-----------|--------------------|--------------------|----------------------------------|
| UMTS | 153.60 | 10 | 9 | 40 | 14 | UMTS |
| UMTS | 122.88 | 8 | 7 | 32 | 14 | UMTS |
| CDMA | 157.2864 | 32 | 31 | 64 | 14 | CDMA2000 |
| CDMA | 122.88 | 25 | 24 | 48 | 14 | CDMA2000 |
| CDMA | 78.6432 | 16 | 15 | 32 | 14 | CDMA2000 low power configuration |
| CDMA | 153.60 | 30 | 29 | 60 | 14 | TD-SCDMA |
| CDMA | 81.92 | 16 | 15 | 32 | 14 | TD-SCDMA |
| CDMA | 76.80 | 15 | 14 | 28 | 14 | TD-SCDMA low power configuration |

www.ti.com

A single set of programmed tap values are used for both the A-side and B-side DDC channels (two CDMA channels) within a single DDC block when in CDMA mode.

After the CFIR filter performs the convolution, gain is applied at full precision, the signal is rounded, and then hard limited. A shifter at the output of the filter then scales the data by either 2e-19 or 2e-18. The gain through the filter is therefore:

Sum(CFIR coefficients) × 2 -(18 or 19)

Coefficients are organized in two groups of 32 words, each 18 bits wide. For fully utilized filters, the 64 coefficients are loaded 0 through 31 into the first RAM, and 32 through 63 into the second RAM. The 16-bit MSBs and 2-bit LSBs are written into the RAMs using different page register values. Shorter filters require the coefficients be loaded into the 2 rams equally, starting from address 0.

For example, a CFIR coefficient set for a symmetric 58 tap TD-SCDMA CFIR is:

| Taps | Coefficient | Taps | Coefficient |
|---------|-------------|---------|-------------|
| 0 = 57 | -13 | 15 = 42 | -4975 |
| 1 = 56 | -20 | 16 = 41 | -4649 |
| 2 = 55 | 14 | 17 = 40 | -232 |
| 3 = 54 | 101 | 18 = 39 | 6581 |
| 4 = 53 | 184 | 19 = 38 | 11266 |
| 5 = 52 | 133 | 20 = 37 | 8917 |
| 6 = 51 | -147 | 21 = 36 | -1957 |
| 7 = 50 | -562 | 22 = 35 | -16736 |
| 8 = 49 | -768 | 23 = 34 | -25469 |
| 9 = 48 | -364 | 24 = 33 | -17599 |
| 10 = 47 | 719 | 25 = 32 | 11560 |
| 11 = 46 | 1905 | 26 = 31 | 56455 |
| 12 = 45 | 2126 | 27 = 30 | 102215 |
| 13 = 44 | 567 | 28 = 29 | 131071 |
| 14 = 43 | -2416 | | |

The first 29 coefficients are loaded into addresses 0 through 28 in the first coefficient RAM, and the remaining 29 are loaded into addresses 0 through 28 in the second coefficient RAM. Loading the 18-bit coefficients requires 2 writes per coefficient, one for the upper 16 bits and another for the lower 2 bits.

To program this coefficient set for the DDC2 CFIR, the following control microprocessor interface sequence would be used.

| Step | Address a[5:0] | Data d[15:0] | Description |
|------|-------------------|-----------------|---|

|---|---|--|--|--|
| VARIABLE | DESCRIPTION | | | |
| crastarttap_cfir(4:0) | Number of DDC CFIR filter taps is 2x(crastarttap + 1) | | | |
| mpu_ram_read | What set, the PFIR and CFIR coefficient rams are readable via the MPU control interface. The AFE8406 signal path is not operational when this bit is set, it is intended for debug purposes only. | | | |
| cfir_gain | cfir_gain $0 = 2e^{-19}$, $1 = 2e^{-18}$ | | | |
| The CFIR filter's 18-bit coefficients are loaded in two 32 word memories. | | | | |
| Note: CFIR filter coefficier | nts are shared between A and B channels of a DDC block in CDMA mode. | | | |

7.2.8 DDC Programmable FIR Filter (PFIR)

The receive programmable FIR filter (PFIR) provides final pulse shaping of the baseband signal data. It does not perform any decimation. Filter coefficient size, input, and output data size is 18 bits. A special strapped mode can be employed for UMTS where two adjacent DDCs (2k & 2k+1, k=0 to 3) can be combined to yield a filter with twice the number of coefficients. This means the AFE8406 can support 4 UMTS DDC channels with double-length filter coefficients (up to 128 taps).

The filter is organized in four partial filter blocks, each containing a data RAM, a coefficient RAM and a dual multiplier, a common state machine and output accumulator.

Instruments

Texas

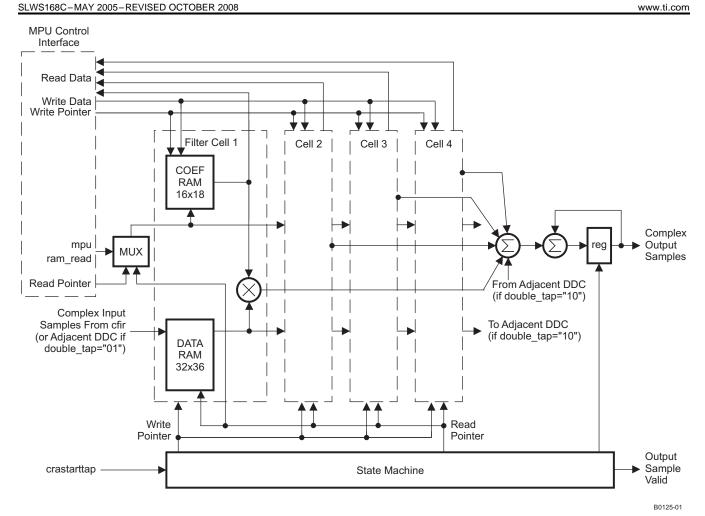

Figure 7-25. DDC PFIR Block Diagram

The PFIR length is programmable. This permits turning off taps and saving power if short filters are appropriate. The filter's output data can be shifted over a range of 0 to 7 bits where it is then rounded and hard-limited to 18 bits. The shift range results in a gain that ranges from $2e^{-19}$ to $2e^{-12}$.

The gain of the PFIR block is: sum(coefficients) \times 2^{-shift}, where shift ranges from 12 to 19.

The maximum PFIR filter length is a function of AFE8406 clock rate and output sample rate and is limited by the number of coefficient memory registers. The maximum number of taps is 64 and the minimum number is 32 (for both CDMA and UMTS). Lengths between these limits can be specified in increments of 4. For strapped UMTS with double length filters, the range of taps available is 64 to 128 in increments of 8.

Subject to the above minimum and maximum values, the number of maximum taps available is:

UMTS Mode: $4 \times (rxclk \div output + sample rate)$

Strapped UMTS Mode: 8 × (rxclk ÷ output + sample rate)

CDMA Mode: 2 × (rxclk ÷ output + sample rate)

PFIR coefficients and gain shift values are shared between both A and B CDMA channels in a DDC block.

Example PFIR filter lengths available based on mode and rxclk frequency:

www.ti.com SLWS168C-MAY 2005-REVISED OCTOBER 2008

| Mode | rxclk (MHz) | CIC DECIMATIO N | PFIR MAX LENGTH | PFIR MIN LENGTH | COMMENTS |
|------|----------------|-----------------------|--------------------|--------------------|---|
| UMTS | 153.60 | 10 | 64 | 32 | UMTS, 1 to 6 DDC channels |
| UMTS | 122.88 | 8 | 64 | 32 | UMTS, 1 to 6 DDC channels |
| UMTS | 153.60 | 10 | 128 | 64 | Strapped UMTS double length PFIR configuration; 1, 2 or 3 DDC channels. |
| UMTS | 122.88 | 8 | 128 | 64 | Strapped UMTS double length PFIR configuration; 1, 2 or 3 DDC channels |
| CDMA | 157.2864 | 32 | 64 | 32 | CDMA2000 |
| CDMA | 122.88 | 25 | 64 | 32 | CDMA2000 |
| CDMA | 78.6432 | 16 | 64 | 32 | CDMA2000 low power configuration |
| CDMA | 153.60 | 30 | 64 | 32 | TD-SCDMA |
| CDMA | 81.92 | 16 | 64 | 32 | TD-SCDMA |
| CDMA | 76.80 | 15 | 60 | 32 | TD-SCDMA low power configuration |

Coefficients are organized in four groups of 16 words, each 18 bits wide. For fully utilized filters, the 64 coefficients are loaded 0 through 31 into the first and second RAMs, and 32 through 63 into the third and fourth RAMs. The 16-bit MSBs and 2-bit LSBs are written into the RAMs using different page register values. Shorter filters require the coefficients be loaded into the 4 rams equally, starting from address 0 and address 16.

For example, a CFIR coefficient set for a symmetric 60 tap TD-SCDMA PFIR is:

| Taps | Coefficient | Taps | Coefficient |
|---------|-------------|---------|-------------|
| 0 = 59 | -2 | 15 = 44 | 420 |
| 1 = 58 | 1 | 16 = 43 | -331 |
| 2 = 57 | 4 | 17 = 42 | -319 |
| 3 = 56 | -8 | 18 = 41 | 744 |
| 4 = 55 | -2 | 19 = 40 | -440 |
| 5 = 54 | 21 | 20 = 39 | -1005 |
| 6 = 53 | -13 | 21 = 38 | 2389 |
| 7 = 52 | -28 | 22 = 37 | 514 |
| 8 = 51 | 46 | 23 = 36 | -6182 |
| 9 = 50 | 1 | 24 = 35 | 1845 |
| 10 = 49 | -85 | 25 = 34 | 12959 |
| 11 = 48 | 96 | 26 = 33 | -8691 |
| 12 = 47 | 82 | 27 = 32 | -27246 |
| 13 = 46 | -266 | 28 = 31 | 34166 |
| 14 = 45 | 38 | 29 = 30 | 131071 |

The first 15 coefficients are loaded into addresses 0 through 14 in the first coefficient RAM, the second group of 15 are loaded into addresses 16 through 30 corresponding to the second coefficient RAM, the third group of 15 are loaded into the third coefficient ram at addresses 0 through 14, and the fourth group of 15 are loaded into addresses 16 through 30 in the fourth coefficient RAM. Loading the 18-bit coefficients requires 2 writes per coefficient, one for the upper 16 bits and another for the lower 2 bits.

To program this coefficient set for the DDC2 PFIR, the following control microprocessor interface sequence would be used.

| 135 | 0x01 | 0x2000 | DDC2 PFIR gain = sum(taps)x2^-18 and CFIR gain = sum(taps)x2^-19 |

| PROGRAMMING | | |
|--|---|--|
| VARIABLE | DESCRIPTION | |
| crastarttap_pfir(4:0) | Number of DDC PFIR filter taps is 4x(crastartap+1) For double length PFIR the number of taps is 8x(crastartap+1) | |
| cdma_mode | When set, puts the CFIR & PFIR blocks in CDMA mode. | |
| mpu_ram_read | What set, the PFIR and CFIR coefficient rams are readable via the MPU control interface. The AFE8406 signal path is not operational when this bit is set, it is intended for debug purposes only. | |
| pfir_gain(2:0) | Sets the gain of the PFIR filter. The range is from $2e^{-19}$ to $2e^{-12}$; "000"= $2e^{-19}$ and "111"= $2e^{-12}$ | |
| double_tap(1:0) | When set, puts two adjacent DDC (2k and 2k+1, k=0 to 2) in double length (from 64 to128 tap) UMTS mode. | |
| | Set to "00" for normal mode. | |
| | In double tap mode, data out of the last PFIR ram in the main DDC (DDC0, DDC2, DDC4 or DDC6) is sent to the adjacent secondary DDC (DDC1, DDC3, DDC5 or DDC7) PFIR as input thus forming a 128-tap delay line. Data received from the adjacent PFIR summers is added into the Main DDC's PFIR sum to form the final output. | |
| | When using double tap mode, set double_tap to "10" for the main DDC, and to "01" for the secondary DDC. | |
| | When in double tap mode, the first half of the coefficients should be loaded into the main DDC (DDC0, DDC2, DDC4 or DDC6), the remaining coefficients are loaded into the secondary DDC (DDC1, DDC3, DDC5 or DDC7). | |
| | In double tap mode, the main DDC must be turned on (ddc_ena=1), and the secondary DDC must be turned off (ddc_ena=0). | |
| The PFIR filter's 18-bit coeffic | cients are loaded in four 16-word memories. | |
| Note: PFIR filter coefficients are shared between A and B channels of a DDC block when in CDMA mode. | | |

7.2.9 DDC RMS Power Meter

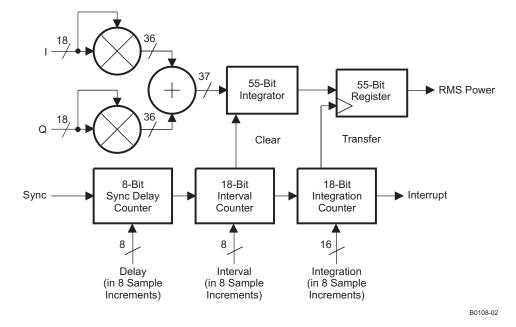

Figure 7-26. DDC RMS Power Meter Block Diagram

www.ti.com

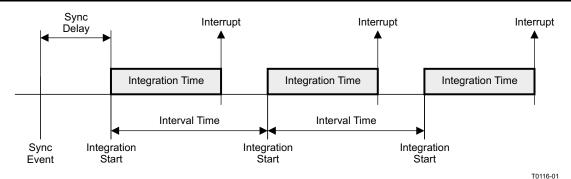

Figure 7-27. DDC RMS Power Meter Timing

Each DDC channel includes an RMS power meter which is used to measure the total power within the channel pass band.

The power meter samples the I and Q data stream after the PFIR filter. Both 18-bit I and Q data are squared, summed, and then integrated over a period determined by a programmable counter. The integration time is a 16-bit word which is programmed into the 18-bit counter.

There is a programmable 18-bit interval timer which sets the interval over which power measurements are made. The timer counts in increments of 1024 samples. This allows the user to select intervals from 1 \times 1024 samples up to 256 \times 1024 samples. For UMTS systems with sample rate rate at 7.68 MHz, the power meter interval range is from 133 μ s to 34.1 ms. For a CDMA system with the sample rate at 2.4576 MHz, the power meter interval range is 417 μ s to 107 ms.

The power measurement process starts with a sync event. The integration will start at sync event +3 chips + sync_delay. The 8-bit delay register permits delays from 1 to 256 samples after sync. The integration will continue until the integration count is met. At that point, the result in the 55-bit accumulator is transferred to the read holding register and an interrupt is generated indicating the power value is ready to read. The interval counter continues until the programmed interval count is reached. When reached, the integration counter and the interval counter start over again. Each time the integration count is reached, the 55 result bits are again transferred to the read register overwriting the previous value and an interrupt is generated signifying the data is ready to be read. Failure to read the data timely will result in overwriting the previous interval measurement.

Sync starts the process. Whenever a sync is received, all the counters are reset to zero no matter what the status.

For UMTS, I and Q are calculated and the integrated power is read. When in CDMA mode the power is calculated for both the A (Signal) path and the B (Diversity) signal. As a result, there are two 55-bit words representing the Signal and Diversity when in CDMA mode.

The power read is:

power = $[(I^2 + Q^2) \times (N \times 4 + 1)]$ where N is the integration count.

| PROGRAMMING | | |
|----------------------------|--|--|
| VARIABLE | DESCRIPTION | |
| pmeter_result_a(54:0) | 55-bit UMTS or CDMA mode A channel power measurement result. | |
| pmeter_result_b(54:0) | 55-bit CDMA mode B channel power measurement result. | |
| pmeter_sqr_sum_ddc(15:0) | Integration (square and sum) count in increments of four samples. | |
| pmeter_sync_delay_ddc(7:0) | Sync delay count in samples. | |
| pmeter_interval_ddc(7:0) | The measurement interval in increments of 2048 samples. This value must be greater than SQR_SUM. | |
| ssel_pmeter(2:0) | Sync source selection. | |

AFE8406 14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

| PROGRAMMING | | |
|---------------------|--|--|
| VARIABLE | DESCRIPTION | |
| pmeter_sync_disable | Turns off the sync to the channel power meter. This can be used to individually turn off syncs to a channels power meter while still having syncs to other power meters on the chip. | |

7.2.10 DDC AGC

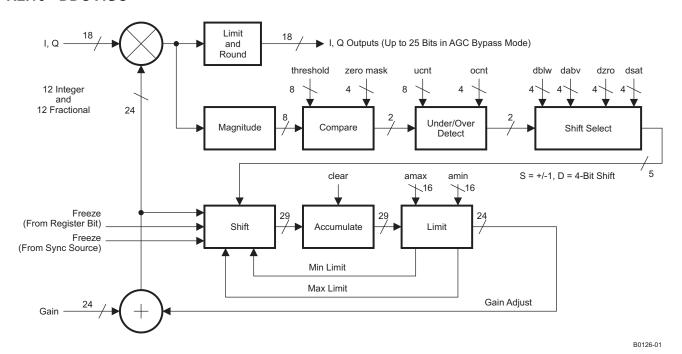

Figure 7-28. DDC AGC Block Diagram

The AFE8406 automatic gain control circuit is shown above. The basic operation of the circuit is to multiply the 18-bit input data from the PFIR by a 24-bit gain word that represents a gain or attenuation in the range of 0 to 4096. The gain format is mixed integer and fraction. The 12-bit integer allows the gain to be boosted by up to factor of 4096 (72 dB). The 12-bit fractional part allows the gain to be adjusted up or down in steps of one part in 4096, or approximately 0.002 dB. If the integer portion is zero, then the circuit attenuates the signal. The gain adjusted output data is saturated to full scale and then rounded to between 4 and 18 bits in steps of one bit.

The AGC portion of the circuit is used to automatically adjust the gain so that the *median* magnitude of the output data matches a target value, which is performed by comparing the magnitude of the output data with a target threshold. If the magnitude is greater than the threshold, then the gain is decreased, otherwise it is increased. The gain is adjusted as: G(t) = G + A(t), where G is the default, user supplied gain value, and A(t) is the time varying adjustment. A(t) is updated as $A(t) = A(t) + G(t)xSx2^{-D}$, where S=1 if the magnitude is less than the threshold and is -1 if the magnitude exceeds the threshold, and where D sets the adjustment step size. Note that the adjustment is a fraction of the current gain. This is designed to set the AGC noise level to a known and acceptable level while keeping the AGC convergence and tracking rate constant, independent of the gain level. The AGC noise will be equal to 2^{-D} and the AGC attack and decay rate will be exponential, with a time constant equal to 2^{-D} . Hence, the AGC will increase or decrease by 0.63 times G(t) in 2^{D} updates.

If one assumes the data is random with a Gaussian distribution, which is valid for UMTS if more than 12 users with different codes have been overlaid, then the relationship between the RMS level and the median is MEDIAN = 0.6745xRMS, hence the threshold should be set to 0.6745 times the desired RMS level.

The gain step size can be set using four different values of *D*, each of which is a 4-bit integer. D can range from 3 to 18. The user can specify values of D for different situations, i.e., when the signal magnitude is below the user-specified threshold (Dblw), is above the threshold (Dabv), is consistently equal to zero (Dzro) or is consistently equal to maximum (Dsat). It is important to note that D represents a gain step size. Smaller values of D represent larger gain steps. The definition of *equal to zero* is any number when masked by zero_mask is considered to be zero. This permits consistently very small amplitude signals to have their gain increased rapidly.

Separate programmable D values allow the user to set different attack and decay time constants, and to set shorter time constants for when the signal falls too low (equal to zero), or is too high (saturates). The magnitude is considered to be consistently equal to zero by using a 4-bit counter that counts up every time the 8-bit magnitude value is zero, and counts down otherwise. If the counter's value exceeds a user specified threshold, then *Dabv* is used. Similarly the magnitude is considered too high by using a counter that counts up when the magnitude is maximum, and counts down otherwise. If this counter exceeds another user specified threshold, then *Dsat* is used.

As an example, if the AGC's current gain at a particular moment in time is 5.123, and the magnitude of the signal is greater than zero, but less than the user-programmed threshold. Step size Dblw will be used to modify the gain for the next sample. This represents the AGC attack profile. If Dblw is set to a value of 5, then the gain for the next sample will be $5.123 + 5.123 \times 2^{-5} = 5.123 + 0.160 = 5.283$. If the signal's magnitude is still less than the user-programmed threshold, then the gain for the next sample will be $5.283 + 5.283 \times 2^{-5} = 5.283 + 0.165 = 5.448$. This continues until the signal's magnitude exceeds the user-programmed threshold. When the magnitude exceeds threshold (but is not saturated), then step size Dabv is automatically employed as a size rather than Dblw.

The AGC converges linearly in dB with a step size of $40\log(1+2^{-D})$ when the error is greater than 12 dB (i.e. the gain is off by 12 dB or more). Within 6 dB the behavior is approximately a exponential decay with a time constant of $2^{(D-0.5)}$ samples.

The suggested value of D is 5 or 6 when the error is greater than 12dB (i.e., in the fast range detected by consistently zero or saturated data). This gives a step size of 0.5 or 0.25 dB per sample.

The suggested value when the gain is off by less than 12 dB is D=10, giving a exponential time constant for delay of around 724 samples (63% decay every 724 samples).

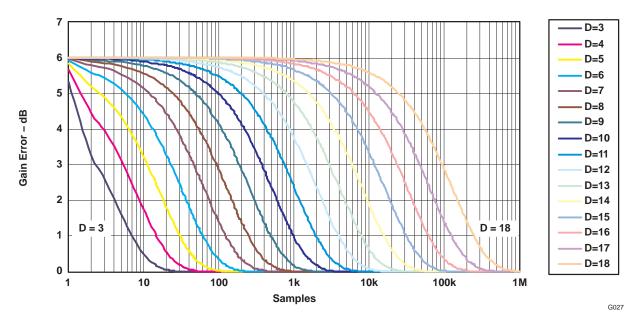

Figure 7-29. AGC Gain Error Over Time vs. D

14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www.ti.com

The AGC noise once the AGC has converged is a random error of amplitude 2^{-D} relative to the RMS signal level. This means that the error level is –6xD dB below the signal RMS level. At D=10 (–60 dB) the error is negligible. The plot above shows the AGC response for vales of D ranging from 3 to 18. *Error dB* represents the distance the signal level is from the desired target threshold.

The AGC is also subject to user specified upper and lower adjustment limits. The AGC stops incrementing the gain if the adjustment exceeds Amax. It stops decrementing the gain if the adjustment is less than Amin.

The input data is received with a valid flag that is high when a valid sample is received. For complex data the I and Q samples are on the same data input line and are not treated independently. An adjustment is made for the magnitude of the I sample, and then another adjustment is made for the Q sample.

The AGC operates on UMTS and CDMA data. When in UMTS mode the I and Q data are each used to produce the AGC level. There is no separate I path gain and Q path gain. When in CDMA mode there are separate gain levels for the Signal and Diversity I and Q data. The I and Q for A (or the Signal) pair is calculated and then the I' and Q' for the B (or Diversity) pair is calculated.

There is a freeze mode for holding the accumulator at its current level. This will put the AGC in a hold mode using the user-programmed gain along with the current gain_adjust value. To only use the user programmed gain value as the gain, set the freeze bit and then clear the accumulator. When using the freeze bit, the full 25-bit output is sent out of the AGC block to support transferring up to 25 bits when the AGC is disabled.

For TDD applications, freeze mode can be controlled using a sync source. This allows rxsync_a/b/c/d to be assigned as a AGC hold signal to keep the AGC from responding during the transmit interval and run during the receive interval. The freeze register bit is logically ORed with the freeze sync source.

The current AGC gain and state can also be optionally output with the DDCs I and Q output data by setting the gain_mon variable. When in this mode, the top 14 bits of the current AGC gain word are appended to the 8-bit AGC-modified I and Q output data.

| Output | Bits(17:10) | Bits(9:4) | Bits(3:2) | Bits(1:0) |
|--------|---------------|-------------|----------------|-----------|
| 1 | I output data | Gain(| 23:16) | "00" |
| Q | Q output data | Gain(15:10) | AGC State(1:0) | "00" |

| PROGRAMMING | | |
|-------------------|--|--|
| VARIABLE | DESCRIPTION | |
| agc_dblw(3:0) | Below threshold gain. Sets the value of gain step size Dblw (data × current gain below threshold). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = "0000", 4= "0001", 18= "1111" | |
| agc_dabv(3:0) | Above threshold gain. Sets the value of gain step size Dabv (data × current gain above threshold). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = "0000", 4= "0001", 18= "1111" | |
| agc_dzro(3:0) | Zero signal gain. Sets the value of gain step size Dzro (data × current gain consistently zero). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = "0000", 4= "0001", 18= "1111" | |
| agc_dsat (3:0) | Saturated signal gain. Sets the value of gain step size Dsat (data × current gain consistently saturated). Ranges from 3 to 18, and maps to a 4-bit field. For example: 3 = "0000", 4= "0001", 18= "1111" | |
| agc_zero_msk(3:0) | Masks the lower 4 bits of signal data so as to be considered zeros. | |
| agc_md(3:0) | AGC rounding. 0000= 18 bits out, 1111= 3 bits out. | |
| agc_thresh(7:0) | AGC threshold. Compared with magnitude of 8 bits of input × gain. | |
| agc_rnd_disable | AGC rounding is disabled when this bit is set. | |
| agc_freeze | The AGC gain adjustment updates are disable when set. | |
| agc_clear | The AGC gain adjustment accumulator is cleared when set | |
| agc_gaina(23:0) | 24-bit gain word for DDC A | |
| agc_gainb(23:0) | 24-bit gain word for DDC B (in CDMA mode) | |
| agc_zero_cnt(3:0) | When the AGC output (input \times gain) is zero value this number of times, the shoft value is changed to agc_dzero. | |

| PROGRAMMING | | |
|----------------------|---|--|
| VARIABLE | DESCRIPTION | |
| agc_max_cnt(3:0) | When the AGC output (input × gain) is zero value this number of times, the shift value is changed to agc_dsat. | |
| agc_amax(15:0) | The maximum value that gain can be adjusted up to. Top 12 bits are integer, bottom 4 bits are fractional. | |
| agc_amin(15:0) | The minimum value that gain can be adjusted down to. Top 12 bits are integer, bottom 4 bits are fractional. | |
| gain_mon | When set, combines current AGC gain with I and Q data. The 18-bit output format thus becomes: | |
| | I Portion: 8 bits of AGC'd I data - Gain(23:16) - 00 | |
| | Q Portion: 8 bits of AGC'd Q data - Gain(15:10) - Status(1:0) - 00. | |
| | Note: Bit 0 of Status, when set, indicates the data is saturated. Bit 1 of Status, when set, indicates the data is zero. | |
| ssel_agc_freeze(2:0) | Sync selection for freeze mode, 1 of 8 sources. This source is ORed with the freeze register bit | |
| ssel_gain(2:0) | Sync selection for the double buffered agc_gaina and agc_gainb register. | |
| ssel_ddc_agc(2:0) | Sync selection used to initialize the AGC, primarily for test purposes. | |

7.2.11 DDC Output Interface

SLWS168C-MAY 2005-REVISED OCTOBER 2008

The baseband I/Q sample interface can be configured as serial or parallel formatted data. The serial interface closely matches the GC5316 style interface. The parallel interface is provided to interface directly to the TMS320TCI110 when delayed antenna streams used to implement channel estimation buffering and/or transport format combination indicator (TFCI) buffering are not required.

The DDC output data is 2's complement format.

7.2.11.1 Serial Output Interface

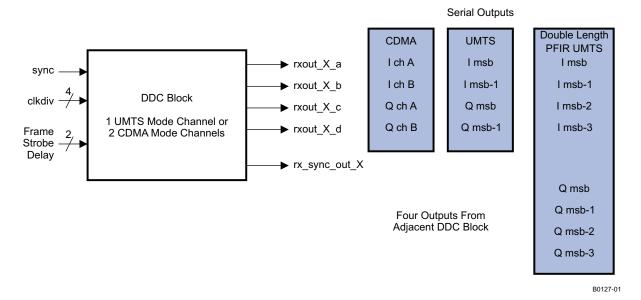

Figure 7-30. Serial Output Block Diagram and Output Pins for Each DDC Filter Mode

Each DDC block can be assigned four serial output data pins. These pins are used to transfer downconverted I/Q baseband data out of the AFE8406 for subsequent processing. The usage of these pins changes depending on how the DDC block is configured.

When the block is configured for two CDMA channels, a pair of serial data pins provides separate I and Q data output for the two DDC channels. Word size is selectable from 4 to 25 bits with the most-significant bit first.

When the DDC block is configured for a single UMTS channel, even and odd I and Q data drive the four serial pins separately, most-significant bit first.

www ti com

Four serial pins each for I and Q data can be optionally employed (instead of two for I and two for Q) at half the output rate. This would most likely be used when two DDC channels (2k and 2k + 1, k = 0 to 5) are combined to support double-length PFIR filtering (a channel is sacrificed). Formatting for I data is then: Imsb, Imsb-1, Imsb-2, Imsb-3. Q data formatting is: Qmsb, Qmsb-1, Qmsb-2, Qmsb-3.

The frame strobe signal provided on the rx_sync_out_X pins can be programmed to arrive from 0 to 3 bit clocks early via a 2-bit control parameter. The frame interval can be programmed from 1 to 63 bits. A programmable 4-bit clock divider circuit is used to specify the serial bit rate. The clock divider circuit is synchronized using a sync block discussed later in this document.

Programming the serial port clock divider requires some thought and depends upon the channel's overall decimation ratio, frame sync interval, number of output bits, and CDMA-UMTS mode.

In general:

the serial clock divide ratio 1 the frame sync interval = the total receive decimation

The relationship between the number of serial bits output, clock divide ratio, and overall decimation ratio is:

CDMA: [overall decimation \times (pser_recv_8pin + 1)] / (pser_recv_clkdiv + 1) \ge pser_recv_bits + 1 UMTS: $2 \times$ [overall decimation \times (pser_recv_8pin + 1)] / (pser_recv_clkdiv + 1) \ge pser_recv_bits + 1 where overall decimation = CIC DECIMATION \times CFIR DECIMATION.

Decimation by 2 in the output interface can be achieved by setting the frame strobe interval and clock divider to 1/2 the PFIR output rate. The serial interface samples the PFIR output each time the transfer interval defined by these two settings has completed. The decimation moment can be controlled using the rxsync_X input signal selected as the sync source for the serial interface.

The timing diagram in Figure 7-31 shows the DDC serial output timing.

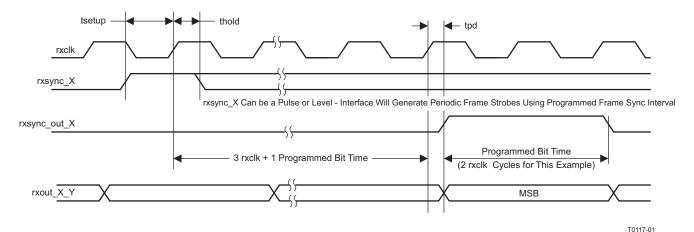

Figure 7-31. Serial Output Interface Timing Diagram

| PROGRAMMING | | |
|-----------------------|---|--|
| VARIABLE | DESCRIPTION | |
| pser_recv_fsinvl(6:0) | Frame sync interval in bits | |
| pser_recv_bits(4:0) | Number of data output bits - 1. i.e.: 10001= 18 bits | |
| pser_recv_clkdiv(3:0) | Receive serial interface clock divider rate – 1. 0= rcclk, 15= rxclk/16 | |
| pser_recv_8pin | When set, configures the serial out pins for 4I and 4Q in UMTS mode. When clear, the mode is 2I and 2Q. Used in conjunction with pser_recv_alt. | |
| pser_recv_alt | When set, outputs Q data from adjacent DDC channel. | |
| pser_recv_fsdel(1:0) | Number of bit clocks the frame sync is output early with respect to serial data. | |

7.2.11.2 Parallel Output Interface

SLWS168C-MAY 2005-REVISED OCTOBER 2008

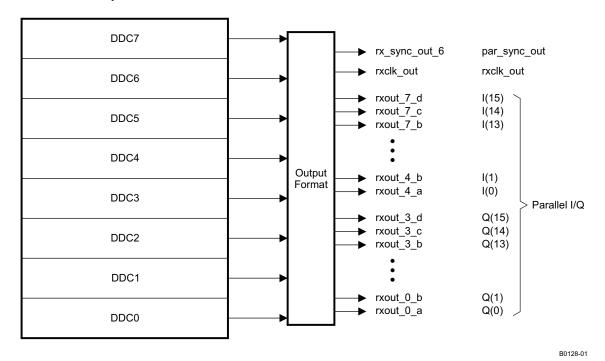

Figure 7-32. Parallel Output Interface Block Diagram and Output Pins

When a parallel I/Q interface is required, a 32-bit time-division-multiplexed output mode can be selected using the rxout_X_X pins. This interface is provided for direct connection to the TMS320TCI110 Receive Chip Rate ASSP when delayed antenna streams are not required. The output sample rate, rxclk out clock polarity, par_sync_out position and number of channels to be output are all programmable.

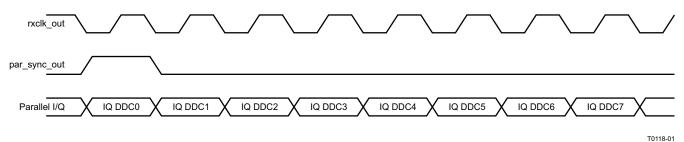

Figure 7-33. Parallel Output Interface Timing Diagram

The DDC channel serial interface synchronization source selections should all be programmed to the same value when using this parallel output interface (each DDC channel ssel serial(2:0) in the SYNC 0 register should be programmed to the same rxsync_A/B/C/D value).

Decimation by 2 in the output interface can be achieved by setting the frame strobe interval and clock divider to 1/2 the PFIR output rate. The parallel interface samples the PFIR outputs each time the transfer interval defined by these two settings has completed.

www.ti.com

| PROGRAMMING | | |
|---------------------------|---|--|
| VARIABLE | DESCRIPTION | |
| par_recv_fsinvl(6:0) | rx_sync_out (frame strobe) sync interval. 0 is 1 rxclk cycle and 127 is 128 rxclk cycles. | |
| par_recv_clkdiv(6:0) | rxclk_out cycles per IQ channel sample; 1 is full rate, 2 is rxclk/2, etc. | |
| par_recv_chan(3:0) | Number channels to be output. 0 is 1 channel, and 15 is 16 channels. | |
| par_recv_sync_del(6:0) | Delays the DDC0 pser sync source to establish the timing of IQ DDC0. Increasing the value delays the par_sync_out location. | |
| par_recv_syncout_del(3:0) | Delays the rx_sync_out position with respect to IQ DDC0. Setting to 0 moves the rx_sync_out pulse one rxclk_out cycle before the IQ DDC0 word, setting to 1 places it as shown above, lined up with IQ DDC0, etc. | |
| par_recv_rxclk_pol | rxclk_out polarity. Outputs data on falling edges when cleared, rising edges when set. | |
| par_recv_sync_pol | Parallel interface par_sync_out polarity. 0 is active low, 1 for active high | |
| par_recv_ena | Parallel TCI110 style interface enabled when set, serial interface enabled when cleared. | |
| ssel_serial(2:0) | DDC channel serial interface sync source selection. All DDCs should be programmed to the same sync source when using this parallel output interface. | |
| gain_mon | When set, the parallel output data includes 8b I at I(15:8), 8b Q at Q(15:8), 14b AGC gain at I(7:0) and Q(7:2) and 2b AGC state at Q(1:0). | |
| 3-state(6:3) | 3-state controls for the rx_sync_out_X and rxout_X_X pins. Pins are in the high-impedance state when the 3-state register bits are set. | |

7.2.12 DDC Checksum Generator

The checksum generator is used in conjunction with the input test signal generator to implement a self test capability.

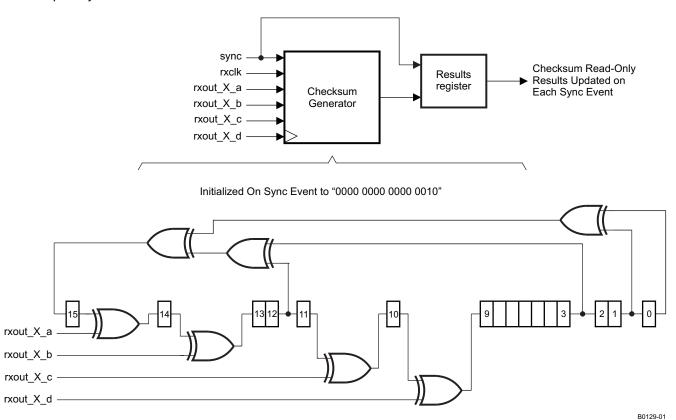

Figure 7-34. DDC Checksum Generator Block Diagram

The sync for the checksum generator is internally connected to the ddc_counter output.

8 AFE8406 GENERAL CONTROL

The AFE8406 is configured over a bidirectional 16-bit parallel data microprocessor control port. The control port permits access to the control registers which configure the chip. The control registers are organized using a paged-access scheme using 6 address lines. Half of the 64 addresses (Address 32 through Address 63) represent global registers. The other 32 (Address 0 through Address 31) are paged registers. This arrangement permits accessing a large number of control registers using relatively few address lines.

Global registers (Address 32 through Address 63) are used to read/write AFE8406 parameters that are global in nature and can benefit from single read/write operations. Examples include chip status, reset, sync options, checksum ramp parameters, interrupt sources, interrupt masks, 3-state controls and the page register.

Global Address 33 is the page register. Writing a 16-bit value to this register sets the page to which future write or read operations performed. These paged-registers contain the actual parameters that configure the chip and are accessed by writing/reading address 0 through address 31.

The global 3-state register can be used to 3-state the output drivers on the AFE8406, and also includes the capability of disabling the chip's internal rxclk.

| PROGRAMMING | | |
|----------------------|---|--|
| VARIABLE DESCRIPTION | | |
| rxclk_ena | Enables the internal rxclk when set. When cleared, the AFE8406 will ignore the rxclk input signal and hold the internal clock low. | |
| 3-state(10:0) | Various output pins are forced into the high-impedance state when these bits are asserted. See the GBL_3STATE register description for pin groups to bit assignments. | |
| arst_func | When asserted, the internal datapath is held reset. The control register programming is not affected. | |

8.1 Microprocessor Interface Control Data, Address, and Strobes

The microprocessor control bus consists of 16 bi-directional control data lines **d[15:0]**, 6 address lines **a[5:0]**, a read enable line **rd_n**, a write enable line **wr_n**, and a chip enable line **ce_n**. These lines usually interface to a microprocessor or DSP chip and is intended to look like a block of memory.

The interface can be operated in a 3 pin control mode (using rd_n, wr_n and ce_n) or 2 pin control mode (using wr_n and ce_n with rd_n always low).

8.2 Synchronization Signals

Various function blocks within the AFE8406 need to be synchronized in order to realize predictable results. The AFE8406 provides a flexible system where each function block that requires synchronization can be independently synchronized from either device pins or from a software "one-shot". The one-shot option is setup and triggered through control registers. The four sync input pins, rxsync_a, rxsync_b, rxsync_c and rxsync_d are qualified on the rxclk rising clock edge.

Table 8-1 shows the different sync modes available.

Table 8-1. Different Sync Modes Available

| SYNC SELECT CODE | RECEIVE SYNC SOURCE | | |
|------------------|--|--|--|
| 000 | rxsync_a | | |
| 001 | rxsync_b | | |
| 010 | rxsync_c | | |
| 011 | rxsync_d | | |
| 100 | ddc sync counter terminal count | | |
| 101 | ddc sync triggered by s/w oneshot (register bit) | | |
| 110 | 0 (always off) | | |
| 111 | 1 (always on) | | |

Table 8-2 and Table 8-3 summarizes the blocks which have functions that can be synchronized using the above eight sync source options.

Table 8-2. Receive Common Syncs

| Sync Name | Purpose | | |
|----------------------|---|--|--|
| sync_ddc_counter | Initializes the receive sync counter | | |
| sync_ddc | Initializes the receive ADC interface and clock generation circuits | | |
| sync_rxsync_out | selects sync signal to be output on the rx_sync_out pin. | | |
| sync_adc_fifo | Initializes the input and output pointers in the ADC fifo circuits. | | |
| sync_tst_decim | Initializes the testbus decimation counter. | | |
| sync_recv_pmeterX | Initializes the rxin power meters. {X = 0,1,2 or 3} | | |
| sync_ragc_interval_X | Initializes the rxin receive AGC timers. {X = 0,1,2 or 3} | | |
| sync_ragc_freeze_X | rxin receive AGC freeze mode control. {X = 0,1,2 or 3} | | |
| sync_ragc_clear_X | Initializes the receive AGC error accumulator. {X = 0,1,2 or 3} | | |

Table 8-3. DDC Channel Syncs

| Sync Name | Purpose | | |
|---------------------|---|--|--|
| sync_ddc_tadj | Selects zero stuff moment in the tadj fine adjustment section. | | |
| sync_ddc_tadj_reg | Updates the tadj output pointer register delay in the tadj coarse adjustment section. | | |
| sync_ddc_nco | Resets the NCO accumulator. | | |
| sync_ddc_freq | Updates the NCO freq registers. | | |
| sync_ddc_phase | Updates the NCO phase register. | | |
| sync_ddc_dither | Initializes the NCO dither circuits. | | |
| sync_ddc_cic | Selects the CIC decimation moment. | | |
| sync_ddc_pmeter | Initializes the receive channel power meters. | | |
| sync_ddc_gain | Updates the DDC channel AGC gain registers | | |
| sync_ddc_agc | Initializes the AGC accumulator. | | |
| sync_ddc_agc_freeze | AGC freeze mode control. | | |
| sync_ddc_serial | Initializes the receive serial interface. | | |

AFE8406 GENERAL CONTROL

SLWS168C-MAY 2005-REVISED OCTOBER 2008

77

A 32-bit general purpose timer is included in the synchronization function. The timer loads the user programmed terminal count on a sync event, and counts down to zero using rxclk. The width of the terminal count pulse can also be programmed up to rxclk cycles. The timers output can be used as a sync source for any other circuits requiring a sync if desired, and can also be routed to the rx_sync_out pin.

| PROGRAMMING | | | |
|------------------------|--|--|--|
| VARIABLE | DESCRIPTION | | |
| ddc_counter(31:0) | 32-bit programmable terminal count | | |
| ddc_counter_width(7:0) | 8-bit programmable terminal count pulse width | | |
| ssel_ddc_counter(2:0) | Sync source selection for the ddc counter | | |
| ssel_rxsync_out(2:0) | Sync source selection for the rx_sync_out pin | | |
| 3-state(0) | When set, the interrupt and rx_sync_out pins are in high-impedance state. | | |
| rx_oneshot | Register bit used to generate the S/W oneshot signal for sync. This bit must be programmed from cleared to set in order to generate a rising edge sync signal. | | |

8.3 Interrupt Handling

When an AFE8406 block sets an interrupt, the interrupt pin will go active if the interrupt source is not masked. The microprocessor should then read the interrupt register to determine the source of the interrupt. The microprocessor will then have to write the interrupt register to clear the interrupt pin and the interrupt source. The interrupt register and interrupt mask are located in the global registers section of the control registers.

The AFE8406 has 16 interrupt sources; power meters in each of the eight DDC blocks, power meters in the four receive input interface, and four rxin_X_ovr (adc overflow) input pins where X={a,b,c,d}.

| PROGRAMMING | | | |
|----------------------|---|--|--|
| VARIABLE | DESCRIPTION | | |
| pmeterX_im(7:0) | Channel pmeter interrupt mask bits. Interrupt source is masked when set. | | |
| recv_pmeterX_im(3:0) | Receive input power meter interrupt masks. | | |
| rxin_X_ovr_im | ADC overflow input pin interrupt masks. | | |
| pmeterX(7:0) | Channel pmeter interrupt status. | | |
| recv_pmeterX(3:0) | Receive input power meter interrupt status. | | |
| rxin_X_ovr | ADC overflow input pin interrupt status. | | |
| intr_clr | When asserted, holds all interrupt status bits cleared. The interrupt pin will be inactive (always low) when this bit is set. Intended for lab/debug use only | | |
| 3-state(0) | When set, the interrupt and rx_sync_out pins are in high-impedance state. | | |

8.4 AFE8406 Programming

The AFE8406 includes over 2000 internal configuration registers and therefore implements a paged addressing scheme. The register map includes a *global control variables* register address space that is accessed directly when the a5 signal is high. This *global control variables* address space includes the page register. All other registers are addressed using a combination of an address comprised of the internal page register contents and the 6-bit external address; a5, a4, a3, a2, a1 and a0.

The page register is accessed when the 6-bit address a5:a0 is 0x21 (or binary "100001").

8.4.2 Global Control Variables

These registers are accessed directly without page address extension; when pin a5 is high during a read or write access, this block of 32 registers are accessed.

8.4.2.1 VER Register

| Register name: | VER | Address: 0x00 | | READ_ONLY | | | |
|----------------|--------|---------------|--------|-----------|--------|--------|--------|
| BIT 15 | | | | | | | BIT 8 |
| unused | unused | unused | unused | unused | unused | unused | unused |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | | | | | | | |
| BIT 7 | | | | | | | BIT 0 |
| unused | unused | unused | unused | VER3 | VER2 | VER1 | VER0 |
| 0 | 0 | 0 | 0 | 0 | 0 | * | * |

VER(3:0): A hardwired read-only register that returns the version of the chip

^{*} A valid version code is 0010.

SLWS168C-MAY 2005-REVISED OCTOBER 2008

8.4.2.2 PAGE Register

Register name: PAGE Address: 0x01

| BIT 15 | BIT 15 | | | | | | | | | |
|--------|--------|--------|---|--------|---|------|---|--|--|--|
| unused | unused | unused | | W(2:0) | X | Y(2) | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | |

| BIT 7 | | | | | | | BIT 0 |
|-------|------|----|--------|--------|--------|--------|--------|
| Y(1) | Y(0) | Zp | unused | unused | unused | unused | unused |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

W(2:0): Selects which dual DDC block to address.

X: The DDC modules are configured as dual DDCs; an even numbered DDC and odd numbered DDC are contained in each dual DDC module, the X bit selects which DDC gets address. (DDC0/2/4/6=0, DDC1/3/5/7=1)

| W(2:0) | X bit | Selected Block |
|--------|-------|-------------------------|
| 000 | 0 | DDC0 |
| 000 | 1 | DDC1 |
| 001 | 0 | DDC2 |
| 001 | 1 | DDC3 |
| 010 | 0 | DDC4 |
| 010 | 1 | DDC5 |
| 011 | 0 | DDC6 |
| 011 | 1 | DDC7 |
| 100 | 0 | Receive AGC0/1 RAMs |
| 101 | 0 | Receive AGC2/3 RAMs |
| 110 | 0 | Receive Input Interface |

Y(2:0): Within each major block, there are up to 8 different Zones that can be addressed using the Y

| Y(2:0) | DDC Zone | DC Zone Receive Input Interface Zone | | |
|--------|------------------------------|--------------------------------------|-----------------|--|
| 000 | PFIR coeffient lower 2 bits | CHIPS control registers | RAGC0/2 ERRMAP | |
| 001 | PFIR coeffient upper 16 bits | RAGC control registers | RAGC0/2 DVGAMAP | |
| 010 | CFIR coeffient lower 2 bits | Not assigned | RAGC0/2 GAINMAP | |
| 011 | CFIR coeffient upper 16 bits | Not assigned | Not assigned | |
| 100 | Control registers | Not assigned | RAGC1/3 ERRMAP | |
| 101 | Not assigned | Not assigned | RAGC1/3 DVGAMAP | |
| 110 | Not assigned | Not assigned | RAGC1/3 GAINMAP | |
| 111 | Not assigned | Not assigned | Not assigned | |

Zp: The Zp bit is the MSB of the address word sent to the registers and rams. This bit can be thought of as an upper/lower selector of the 64-word addressing.

8.4.2.3 CONFIG Register

Register name: CONFIG Address: 0x02

| BIT 15 | | | | | | | BIT 8 |
|--------------|---------------|------------|-------------------|---|---|---|-------|
| slf_ tst_ena | rduz_sens_ena | arst_ func | tst_rate_sel(4:0) | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| BIT 7 | | | | | | | BIT 0 | |
|--------------|----------------|-----------|---|-----------------|---|---|-------|--|
| par_recv_ena | gbl_ ddc_write | intr_ clr | | tst_select(3:0) | | | | |
| 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | |

slf_tst_ena: Turns on the checksum LFSR for the receivers. They are located in the RECEIVE INPUT INTERFACE and DDC blocks

rduz_sens_ena: When enabled, adds noise to the LSB's of the ADC inputs.

arst_func : When asserted, resets the functional portion of the circuits. The MPU registers do not get reset and retain their programmed value

tst_rate_sel(4:0): Sets the rate of the output test data and clock. The length of the clock cycle is the value in tst_rate_sel+1 multiplied by the RXCLK period. When the test bus source is set to 1000 (rxin_a and rxin_b FIFO outputs), tst_rate_sel(4:0) must be set to 0 for output. Otherwise, it will not output a clock at the decimated test bus rate.

par_recv_ena: When asserted, the rxout_*_* serial pins join to form a 32-bit parallel output using 32 pins as a data bus, one pin as a output clock and one pin as a sync. This is used to connect to the TCI110 Chip rate processor from TI.

gbl_ddc_write: Factory Use Only. When asserted, the mpu writes are global. This means that DDC0/2/4/6 or DDC1/3/5/7 can be programmed simultaneously with the same values. This is an effort to reduce the amount of time spent programming the device. A common setup can be used to program the DDC0/2/4/6, then all the DDC1/3/5/7. Afterwards, just individual writes to the registers which differ between DDCs can be done. To use this feature, this bit must be asserted and the DDC0/1 must be addressed. Any other DDC address will not work.

intr_clr: When asserted, this bit forces all interrupts to be cleared. To allow the interrupts to be set again, this bit must be programmed to zero. This does not stop blocks from generating interrupts, but rather just keeps the interrupts from being reported.

tst_select(3:0): This selects which block the test output comes from:

| tst_select(3:0) | Test Data Sent to Output | | | | |
|-----------------|--------------------------------|--|--|--|--|
| 0000 | DDC 0 | | | | |
| 0001 | DDC 1 | | | | |
| 0010 | DDC 2 | | | | |
| 0011 | DDC 3 | | | | |
| 0100 | DDC 4 | | | | |
| 0101 | DDC 5 | | | | |
| 0110 | DDC 6 | | | | |
| 0111 | DDC 7 | | | | |
| 1000 | rxin_a and rxin_b FIFO outputs | | | | |
| others | none selected | | | | |

tst_on: When asserted, the testbus is active. The ADC input ports rxin_c(15:0), rxin_d(15:0), dvga_c(5:0) and dvga_d(5:0) become the testbus output ports. When this bit is set, the rxin_c(15:0) and rxin_d(15:0) ports become chip outputs. The dvga_c(5:0) and dvga_d(5:0) ports are enabled separately using the GBL_3STATE register

8.4.2.6 GBL_3STATE Register

Register name: GBL_3STATE Address: 0x05

| BIT 15 | | | | | | | BIT 8 |
|-----------|--------|--------|--------|--------|-------------|------------|------------|
| rxclk_ena | unused | unused | unused | unused | 3-state(10) | 3-state(9) | 3-state(8) |
| 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |

| BIT 7 | | | | | | | BIT 0 |
|------------|------------|------------|------------|------------|------------|------------|------------|
| 3-state(7) | 3-state(6) | 3-state(5) | 3-state(4) | 3-state(3) | 3-state(2) | 3-state(1) | 3-state(0) |
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

rxclk_ena: Master rxclk enable. When set, the chip's rxclk is enabled, when cleared, rxclk is disabled.

All 3-states are ACTIVE-LOW so a 0 turns on the output and a 1 places it in the high-impedance state.

3-state(10): This bit turns on the dvga_d outputs.

 $\textbf{3-state(9):} \quad \text{This bit turns on the dvga_c outputs.}$

3-state(8): This bit turns on the dvga_b outputs.

3-state(7): This bit turns on the dvga_a outputs.

3-state(6): This bit turns on the rx_sync_out_6/7, and the rxout_6/7_a/b/c/d outputs. (For parallel

interface use only)

3-state(5): This bit turns on the rx_sync_out_4/5, and the rxout_4/5_a/b/c/d outputs.

3-state(4): This bit turns on the rx_sync_out_2/3, and the rxout_2/3_a/b/c/d outputs.

3-state(3): This bit turns on the rx_sync_out_0/1, and the rxout_0/1_a/b/c/d outputs.

3-state(2): unused

3-state(1): rxclk_out

3-state(0): interrupt, and rx_sync_out.

8.4.2.7 GBL_ONESHOT Register

Register name: GBL_ONESHOT Address: 0x06

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | |

ddc_counter(32:0): 32-bit interval timer common to all DDC sync inputs. This timer may be programmed to any interval count, and each DDC synchronization input can select this counter as a source. The value programmed into the counter is: (desired number -1). The counter increments on each RX clock rising edge.

TEXAS INSTRUMENTS

8.4.3.5 RECV_CONFIG0 Register

Register name: RECV_CONFIG0 Page: 0x1800 Address: 0x04

| BIT 15 | | | | | | | BIT 8 |
|------------|---------|-----------------------|-----------------------|-------------------------|---------------------|-----------------------|--------------|
| rate_s | el(1:0) | adc_ fifo_strap_ab | adc_ fifo_strap_cd | self_test_ const_ena | adc_ fifo_bypass | ragc_mpu_ram _read | tst_ decim17 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| BIT 7 | | | BIT 0 |
|-------|---|--|-------|
| | • | | |

| | tst_decim_ | _delay(3:0) | | pmeter3_iq | pmeter2_iq | pmeter1_iq | pmeter0_iq |
|---|------------|-------------|---|------------|------------|------------|------------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

rate_sel(1:0): Tells the RECV_CDRV the input rate. This is the rxin_a/b/c/d input rate and the rate that the RECEIVE INPUT INTERFACE block sends data to the DDCs.

| rate_sel | Input clock rate |
|----------|------------------|
| 00 | rxclk |
| 01 | rxclk/2 |
| 10 | rxclk/4 |
| 11 | rxclk/8 |

- adc_fifo_strap_ab: When asserted, the input pointers of the rxin_a FIFO and rxin_b FIFO are hooked together in lock step configuration. This is used for maintaining FIFO delay consistency when complex inputs are driven on rxin_a(I) and rxin_b(Q). rxin_a is the Master.
- adc_fifo_strap_cd : When asserted, the input pointers of the rxin_c FIFO and rxin_d FIFO are hooked together in lock step configuration. This is used for maintaining FIFO delay consistency when complex inputs are driven on rxin_c(I) and rxin_d(Q). rxin_c is the Master.
- **self_test_const_ena**: When asserted, (with slf_tst_ena also asserted), a constant value is output by the test and noise generator instead of the pseudo random sequence. The constant value is programmable.
- adc_fifo_bypass: When asserted, the ADC FIFO circuits are bypassed. Input data is then clocked in directly using the rxclk input. The ssel_ddc selection value will control the location of the internally generated sample clock when this bit is asserted where rate_sel is rxclk/2, rxclk/4 or rxclk/8.
- ragc_mpu_ram_read: When asserted, the RAMs in the RAGC blocks can be read. This bit should only be set when reading the RAGC map rams via the mpu interface and must be cleared for proper RAGC operation.
- tst decim17: Must be cleared
- **tst_decim_delay(3:0)**: These bits set the delay from the sync occurring until the decimator samples. In other words, the moment of the decimator is set by this delay value.
- pmeter3_iq : When asserted, the pmeter3 block takes input from both rxin_c and rxin_d as a complex sample pair. When de-asserted, only input from rxin_d is used for the power measurement.
- **pmeter2_iq:** When asserted, the pmeter2 block takes input from both rxin_c and rxin_d as a complex sample pair. When de-asserted, only input from rxin_c is used for the power measurement.
- pmeter1_iq : When asserted, the pmeter1 block takes input from both rxin_a and rxin_b as a complex sample pair. When de-asserted, only input from rxin_b is used for the power measurement.
- **pmeter0_iq**: When asserted, the pmeter0 block takes input from both rxin_a and rxin_b as a complex sample pair. When de-asserted, only input from rxin_a is used for the power measurement.

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www.ti.com

8.4.3.6 RECV_CONFIG1 Register

Register name: RECV_CONFIG1 Page: 0x1800 Address: 0x05

| _ | | | | _ | | | |

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

msb_pos_X(2:0): Places the MSB of the input word from the ADC. The value programmed into the 3 bits is the number of bit positions to the left of bit 16 in the input word, that the MSB is located. For example, if a 14-bit input word is driving rxin_a input and is aligned with rxin_a_0, then msb pos a is programmed to "010" meaning 2 bits shifted down from bit 16 is the MSB. $X=\{a,b,c,d\}.$

offset_bin_X:rxin_X input data is in 2s complement and not offset binary. If clear, the input value will be converted to 2s complement using the MSB from the corresponding msb_pos_X value. X={a,b,c,d}. Note that the internal ADCs use 2s complement format, so offset_bin_A and offset bin B must be clear.

| | recv_pmeter0_sqr_sum (7:0) | | | | | | | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | | |

recv_pmeter0_sqr_sum(15:0): The sqr_sum register controls the number of samples to accumulate for a power measurement. Ia is (or la & Qa if complex mode is selected are) squared and accumulated. Eight la samples (or eight sample pairs of la and Qa samples) equal to one sqr_sum count. The accumulation interval is initiated when the sync is asserted and the programmed (8*sync_delay+2) samples has expired or when the interval start time is reached. When the (8*sqr_sum+1) sample time is reached, the accumulated powers are made available for MPU access and an interrupt is generated.

8.4.3.10 RECV_PMETER0_STRT_INTVL_LSB Register

Register name: RECV_PMETER0_STRT_INTVL_LSB Page: 0x1800 Address: 0x09

| BIT 7 | | | | | | | BIT 0 | | | | | |
| BIT 7 | | | recv_pmeter0_ | _strt_intrvl (7:0) | | | BIT 0 | | | | | |

recv_pmeter0_strt_intrvl(15:0): The start interval timer is the interval over which the sqr_sum is restarted. The timer value is (8*strt_intrvl + 1) samples and must be larger than (8*sqr_sum+1) samples. The interval start counter and RMS power accumulation is started at the sync pulse after the programmed delay and every time the STRT_INTRVL counter reaches its limit.

ragc_freeze_X : Freezes the receive AGC block when set.

ragc_clear_X : Clears the loop error accumulator when set.

complex01 : When set, receive AGC 0 uses complex input with the second sample stream coming from receive AGC 1. The clip detect, high pass, and squarer from receive AGC 1 are used to generate inputs for receive AGC 0.

complex23: When set, receive AGC 2 uses complex input with the second sample stream coming from receive AGC 3. The clip detect, high pass, and squarer from receive AGC 3 are used to generate inputs for receive AGC 2.

ssel_ragc_interval_0(2:0): Selects the sync source for receive AGC 0. After a programmed delay from sync, the interval update timer is started.

ssel_ragc_interval_1(2:0): Selects the sync source for receive AGC 1. After a programmed delay from sync, the interval update timer is started.

BIT 7 BIT 0

| crastarttap_cfir(4:0) | | | | | unused | unused | unused |
|-----------------------|---|---|---|---|--------|--------|--------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

cdma_mode: When asserted the DDC block is in CDMA mode (2 streams per DDC block).

crastarttap_pfir: These bits define the number of taps that PFIR will use for the filtering.

crastarttap_cfir: These bits define the number of taps that CFIR will use for the filtering.

Formulas for the number of taps, in the different FIR's, using the crastarttap word.

DDC PFIR: 4*(crastarttap_pfir+1)

DDC PFIR long mode: 8*(crastarttap_pfir+1)

DDC CFIR: 2*(crastarttap cfir+1)

8.4.5.2 FIR_GAIN Register

Register name: FIR_GAIN Page: 0x0%00 Address: 0x01

where:

% = 2×(DDC channel #)+1

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

pfir_gain(2:0): PFIR gain, from 2e-19 to 2e-12 for the receive PFIR. ("000" = 2e-19 and "111" = 2e-12)

cfir_gain: When '0' then the gain of the CFIR is 2e-19, otherwise when set to '1' the gain is 2e-18.

SLWS168C-MAY 2005-REVISED OCTOBER 2008

www.ti.com

8.4.5.3 SQR_SUM Register

| Register name: SQR_SUM | Page: 0x0%00 | Address: 0x02 |
|------------------------|-------------------------|---------------|
| | where: | |
| | % = 2×(DDC channel #)+1 | |
| | | |

| BIT 15 | | | | | | | BIT 8 | | | | |
|--------|--------------------------|---|---|---|---|---|-------|--|--|--|--|
| | pmeter_sqr_sum_ddc(15:8) | | | | | | | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | | |

| | pmeter_sqr_sum_ddc(7:0) | | | | | | | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | | |

pmeter_sqr_sum_ddc(15:0): The sqr_sum register is the number of 4 sample sets to accumulate for a power measurement. In CDMA mode, one sample set is the I & Q of the signal and diversity. Ia & Qa (signal) are each squared and accumulated and Ib & Qb (diversity) are squared and accumulated. In UMTS mode, each I and Q pair are squared and accumulated. 4 samples is equal to one SQR_SUM count. The count is initiated when the sync is asserted or when the interval start time is reached. When the SQR_NUM number is reached, the accumulated powers are made available for MPU access and an interrupt is generated.

8.4.5.4 STRT_INTRVL Register

| Register name: STRT_INTRVL | Page: 0x0%00 | Address: 0x03 |
|----------------------------|----------------------------------|---------------|
| | where: | |

| | pmeter_interval_ddc(7:0) | | | | | | | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | | |

pmeter_interval_ddc(7:0): The start interval timer is the interval over which the SQR_SUM is restarted and must be greater than the SQR_SUM. The actual interval is interval +1, and must be greater than the sqr_sum interval. The interval start counter and RMS power accumulation is started at the sync pulse after the programmed delay and every time the interval counter reaches its limit. This value is in 1024 sample units.

SLWS168C-MAY 2005-REVISED OCTOBER 2008

8.4.5.5 CIC_MODE1 Register

Register name: CIC_MODE1 Page: 0x0%00 Address: 0x04

where:

% = 2×(DDC channel #)+1

| | | | | | | BIT 8 |
|---|------------------|----------------------|------------------------|--------------------------|------------------------|---|

| cic_scal | e_b(1:0) | cic_gain_ ddc | | | cic_decim(4:0) | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

cic_scale_a(4:0): This sets the gain shift at the output of the A channel CIC. 0x00 is no shift, each increment by 1 increases the signal amplitude by 2X.

cic_scale_b(4:0): This sets the gain shift at the output of the B channel CIC. 0x00 is no shift, each increment by 1 increases the signal amplitude by 2X.

cic_gain_ddc: Adds a fixed gain of 12dB at the CIC output when asserted.

cic_decim(4:0): Sets the CIC decimation rate, where decimation is cic_decim + 1.

8.4.5.6 CIC_MODE2 Register

cic_m2_ena_a(5:0): Programs the A channel CIC fir sections M value to 2 when set, 1 when cleared.
cic_m2_ena_a(0) controls the M value for the first comb section and cic_m2_ena_a(5) controls the M value for the last comb section.

0

cic_m2_ena_b(5:0): Programs the B channel CIC fir sections M value to 2 when set, 1 when cleared. cic_m2_ena_b(0) controls the M value for the first comb section and cic_m2_ena_b(5) controls the M value for the last comb section.

www.ti.com

8.4.5.7 TADJC Register

Register name: TADJC Page: 0x0%00 Address: 0x06 DOUBLE BUFFERED, REQUIRES SYNC FOR where:

LOADING % = 2×(DDC channel #)+1

BIT 15 BIT 8 unused offset_coarse_a(2:0) unused unused unused tadj_ unused 0 0 0 0 0 0 0 0

BIT 7 BIT 0 tadj_offset_coarse_b(2:0) unused unused unused unused unused 0 0 0

tadj_offset_coarse_a(2:0): This is the coarse time adjustment offset and acts as an offset from the write address in the delay ram. This value affects the A data in the path if CDMA mode is being used. Each LSB is one more offset between input to the course delay block and the output of the course block.

dj_offset_coarse_b(2:0): Effects the B channel in CDMA, just as the above effects the A channel.

8.4.5.8 TADJF Register

Register name: TADJF Page: 0x0%00 Address: 0x07 DOUBLE BUFFERED, REQUIRES SYNC FOR **LOADING** where:

% = 2×(DDC channel #)+1

BIT 15 BIT 8 tadj_offset_fine_a(2:0) tadj_offset_fine_b(2:0) tadj_interp(2:1) 0 0 0 0 0 0 0 0

14-BIT, 85 MSPS DUAL ADC, 8-CHANNEL WIDEBAND RECEIVER

SLWS168C-MAY 2005-REVISED OCTOBER 2008

135

8.4.5.15 CONFIG1 Register

Register name: CONFIG1 Page: 0x0%00 Address: 0x0E

where:

% = 2×(DDC channel #)+1

| BIT 15 | | | | | | | BIT 8 |
|------------|------------------|---|--------------------------|---------|-------------|------------|--------------|
| dither_ena | dither_mask(1:0) | | pmeter_ sync_ disable | ddc_ena | muxed _data | mixer_gain | mpu_ram_read |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| BIT 7 | | | | | | | BIT 0 |
|--------|--------|--------|--------|--------|---------------|---------|------------|
| unused | unused | unused | unused | unused | zero_ qsample | mux_pos | mux_factor |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

dither_ena: This bit controls whether dither is turned on(1) or off(0).

dither_mask(1): This bit controls the MASKing of the dither word's MSB. (1= MASKed, 0=used in dither word)

dither_mask(0): This bit controls the MASKing of the dither word's MSB-1. (1= MASKed, 0=used in dither word)

pmeter_sync_disable: Turns off the sync to the channel power meter. This can be used to individually turn off syncs to a channels power meter while still having syncs to other power meters available.

ddc_ena: When set this turns on the DDC. When cleared, the clocks to this block are turned off. For the DDC blocks used as the second half in the long PFIR configuration, this bit should be cleared.

muxed_data: When asserted the DDC mux block assumes that multiple channels are muxed together on one input data stream. For factory use only.

For a 2X muxed stream it would look like: Sa0, Sb0, Sa1, Sb1, Sa2, Sb2 etc...

mixer gain: Adds a fixed 6 dB of gain to the mixer output (before round and limiting) when asserted.

mpu_ram_read:(TESTING PURPOSES) Allows the coefficient RAMs in the PFIR/CFIR to be read out the mpu data bus. Unfortunately, this cannot be done during normal operation and must be done when the state of the output data is not important. THIS BIT MUST ONLY BE SET DURING THE MPU READ OPERATION AND MUST BE CLEARED FOR NORMAL DDC OPERATION.

zero_qsample: When asserted, the Q sample into the mixer is held to zero. For UMTS mode at any input rate, and CDMA mode with input rates of rxclk/2 or lower, this bit must be set for real only input data mode (also for muxed input data stream modes). For real only inputs at the full rxclk rate in CDMA mode, the remix_only bit must be set in the DDCCONFIG1 register.

mux_pos : These bits set the position for selection in the muxed data stream. This value must be less than or equal to the mux_factor bits.

mux_factor: These two bits set the number of channels in the data stream. 0=1 stream, 1=2 streams. The ch_rate_sel bits for the DDC should be programmed to rxclk/2 for the 2 streams mode.

www.ti.com

|--------|--------|---|------------------|---|---|---|---|--|--|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | |

ddc_tst_sel(5:0): This is the selection of which signal comes out the test bus. When a constant '0' is selected this also reduces power by preventing the data at the input of the tst_blk from changing. It does not stop the clock however. The 36 bits for the test bus are routed to the rxin_c, rxin_d, dvga_c and dvga_d pins on the chip.

| | aut uz | zro(3:0) | | agc_dsat(3:0) | | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |

- agc_dblw(3:0): The value to shift the gain that is then added to the accumulator when the value of the incoming data * current gain value is below the Threshold.
- agc_dabv(3:0): The value to shift the gain that is then subtracted from the accumulator when the value of the incoming data * the current gain value is above the Threshold.
- agc_dzro(3:0): The value to shift the gain that is then added to the accumulator when the value of the incoming data * current gain values consistently equal to zero. (Usually a smaller number than agc_dblw).
- agc_dsat(3:0): The value to shift the gain that is then subtracted form the accumulator when the value of the incoming data * the current gain value is consistently equal to maximum (saturation).

NOTE: The larger the number in the above words, the smaller the step size. The above values control the AGC gain shifting (range is from 3 to 18).

8.4.5.18 AGC_CONFIG2 Register

Register name: AGC_CONFIG2 Page: 0x0%00 Address: 0x11 where:

| unused | unused | unused | | | pser_recv_bits(4:0 |) | | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | |

pser recv fsinvl(6:0): Receive serial interface frame sync interval in bit clocks.

pser_recv_bits(4:0): Number of output bits per sample-1; for 18 bits, this is set to {10001}.

8.4.5.26 PSER_CONFIG2 Register

Register name: PSER_CONFIG2

Page: 0x0%00

Address: 0x19

where:

% = 2×(DDC channel #)+1

| BIT 15 | | | | | | | BIT 8 |
|----------------|---------------|--------------|--------|--------|--------|-----------|-------------|
| | pser_recv_ | _clkdiv(3:0) | | unused | unused | unused | unused |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| BIT 7 | | | | | | | BIT 0 |
| pser_recv_8pin | pser_recv_alt | unused | unused | unused | unused | pser_recv | _fsdel(1:0) |

pser_recv_clkdiv(3:0): Receive serial interface clock divider rate-1; 0 is full rate and 15 divides the clock by 16. For example, to run the receive serial interface at 1/4 the AFE8406 clock, set pser_recv_clkdiv(3:0) = 0011.

pser_recv_8pin: When set, 4 pins are used for I and 4 pins for Q in UMTS mode. When cleared, 2 pins are used for I and 2 pins for Q. This is used in combination with the pser_recv_alt bit. When this bit is set, it would be set in 2 adjacent DDC channels; one would also set the pser_recv_alt bit in the adjacent DDC. This causes the I channel to be serialized on 4 pins and the Q channel to be serialized on the adjacent channels 4 pins.

pser_recv_alt: When set, this channel's receive serial interface will output the Q data from the adjacent DDC channel.

pser_recv_fsdel(1:0): Delay between the receive frame sync output and the MSB of serial data {3,2,1,0}. This number is in serial output bit times, not rxclk periods.

| 1100 | RXINC | RXIND |
| 1101 | RXIND | RXINA |
| 1110 | RXIND | RXINB |
| 1111 | RXIND | RXINC |

⁽¹⁾ RXINA = internal A-side ADC, RXINB = internal B-side ADC, RXINC = external input C, RXIND = external input D

agc_rnd_disable : When set, the agc_rnd bits have no effect. The whole 29 bits are used in the rounding and the round bit is bit 4.

gain_mon: Combines the gain with the I/Q output signals when asserted.

| OUTPUT | Bits(17:10) | Bits(9:4) Bits(3:2) | | Bits(1:0) |
|--------|----------------|---------------------|-------------------|-----------|
| I | Gained I value | Gain(18:11) | | "00" |
| Q | Gained Q value | Gain(10:5) | Shift status(1:0) | "00" |

ch_rate_sel(1:0): Sets the DDC channel input data rate. The value set here should match the value in the Receive Input Interface rate select bits (rate_sel).

| ch_rate_sel | Input data rate |
|-------------|-----------------|
| 00 | rxclk |
| 01 | rxclk/2 |
| 10 | rxclk/4 |
| 11 | rxclk/8 |

SLWS168C-MAY 2005-REVISED OCTOBER 2008

When muxed_data is set (Factory Use Only) rate_sel should be set to rxclk "00" and ch_rate_sel should be set to rxclk/2 "01".

- **remix_only**: Assert this when real only, full rxclk rate input data is used in CDMA mode. The signal on the Q bus selected by the ddcmux_sel_X(3:0) bits above is ignored (functions as if the Q data is 0).
- cic_bypass: Factory Use Only. If asserted then the data from the rxin_a(15:0) and rxin_b(15:0) are fed directly into the cfir input as I and Q respectively. rxin_a(0) also functions as the "sync_cfir" signal and should rise at the beginning of input data.
- ONLY DDC0, DDC2, DDC4 and DDC6 can be the UMTS double tap (64 to 128 tap) PFIR Mode. DDC1, DDC3, DDC5 and DDC7 PFIRs are used to lengthen the DDC0, DDC2, DDC4 and DDC6 PFIRs.
- double_tap(1): When set, the DDC is in double length PFIR mode which sends the data out of the last PFIR sample ram in this DDC (DDC0, DDC2, DDC4, DDC6) to the adjacent secondary DDC (DDC1, DDC3, DDC5, DDC7) PFIR forming a 128-tap delay line. Output data received from the adjacent secondary DDC PFIR summer is added into the Main DDC's PFIR sum to form the final output.
- double_tap(0): When set, the PFIR input comes from the adjacent(Main) PFIR. When cleared, PFIR input is from the CFIR connected directly to this PFIR. Only valid in DDC1, DDC3, DDC5 and DDC7. The ddc_ena bit in the CONFIG1 register should be cleared for the DDC1, DDC3, DDC5 and DDC7 when double_tap(0) is set.

NOTE: to put 2 DDCs in to 128 tap mode:

Program DDC0/DDC2/DDC4/DDC6 double_tap(1:0) to "10" and ddc_ena to "1".

Program DDC1/DDC3/DDC5/DDC7 double tap(1:0) to "01" and ddc ena to "0".

| 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |

ssel_cic(2:0): Selects the sync source for the DDC CIC filter, thus setting the decimation moment.

ssel_pmeter(2:0): Selects the sync source for the channel power meter.

ssel_agc_freeze(2:0): Selects the sync that is used to hold the AGC in freeze mode. With this functionality the user can program the AGC freeze control to look at the state of an input sync, or the one shots. It defaults to being off or not looking at any syncs and not driving the freeze control. This way, upon startup, the chip looks at the MPU register bit for AGC freezing and not the syncs.

ssel serial(2:0): Selects the sync source for the DDC serial interface state machines.

Sync sources are contained in this and many of the following registers. For all sync source selections:

| ssel_XXXX(2:0) | Selected sync source for DDC |
|----------------|-------------------------------------|
| 000 | rxsyncA |
| 001 | rxsyncB |
| 010 | rxsyncC |
| 011 | rxsyncD |
| 100 | DDC sync counter |
| 101 | one shot (register write triggered) |
| 110 | always 0 |
| 111 | always 1 |

PACKAGING INFORMATION

| Orderable Device | Status ⁽¹⁾ | Package Type | Package Drawing | Pins I | Package Qty | Eco Plan ⁽²⁾ | Lead/Ball Finish | MSL Peak Temp ⁽³⁾ |
|------------------|-----------------------|-----------------|--------------------|--------|----------------|-------------------------|------------------|------------------------------|
| AFE8406IZDQ | ACTIVE | BGA | ZDQ | 484 | 60 | Pb-Free (RoHS) | SNAGCU | Level-3-260C-168 HR |

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
