

AS3932

3D Low Frequency Wakeup Receiver

1 General Description

The AS3932 is a 3-channel low power ASK receiver that is able to generate a wakeup upon detection of a data signal which uses a LF carrier frequency between 110 - 150 kHz. The integrated correlator can be used for detection of a programmable 16-bit wakeup pattern. The device can operate using one, two, or three active channels.

The AS3932 provides a digital RSSI value for each active channel, it supports a programmable data rate and Manchester decoding with clock recovery. The AS3932 offers a real-time clock (RTC), which is either derived from a crystal oscillator or the internal RC oscillator.

The programmable features of AS3932 enable to optimize its settings for achieving a longer distance while retaining a reliable wakeup generation. The sensitivity level of AS3932 can be adjusted in presence of a strong field or in noisy environments.

The device is available in 16 pin TSSOP and QFN 4x4 16LD packages.

2 Key Features

- 3-channel ASK wakeup receiver
- Carrier frequency range 110 - 150 kHz
- One, two, or three channel operation
- Reliable 1-, 2- or 3-D wakeup pattern detection
- Programmable wakeup pattern (16bits)
- Doubling of wakeup pattern supported
- Wakeup without pattern detection supported
- Wakeup sensitivity 100 μ VRMS (typ.)
- Adjustable sensitivity level
- Highly resistant to false wakeups
- False wakeup counter
- Periodical forced wakeup supported (1s – 2h)
- Low power listening modes
- Current consumption in 3-channel listening mode 1.7 μ A (typ.)
- Data rate adjustable from 0.5- 4 kbps (Manchester)
- Manchester decoding with clock recovery
- Digital RSSI values available for each channel
- Dynamic range 64dB
- 5 bit RSSI step (2dB per step)
- RTC based on 32kHz XTAL, RC-OSC, or External Clock
- Operating temperature range -40 to +85°C
- Operating supply voltage 2.4 - 3.6V (TA = 25°C)
- Bidirectional serial digital interface (SDI)
- Package option 16 pin TSSOP, QFN 4x4 16LD

3 Applications

The AS3932 is ideal for Active RFID tags, Real-time location systems, Operator identification, Access control, and Wireless sensors.

AIO: analog I/O

DI: digital input

DO: digital output

DO_T: digital output / tristate

5 Absolute Maximum Ratings

Stresses beyond those listed in [Table 3](#) may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions beyond those indicated in [Section 6 Electrical Characteristics on page 8](#) is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 3. Absolute Maximum Ratings

Parameter	Min	Max	Units	Notes
DC supply voltage (V _{DD})	-0.5	5	V	
Input pin voltage (V _{IN})	-0.5	5	V	
Input current (latch up immunity) (I _{SOURCE})	-100	100	mA	Norm: Jedec 78
Electrostatic discharge (ESD)	±2		kV	Norm: MIL 883 E method 3015 (HBM)
Total power dissipation (all supplies and outputs) (P _t)		0.07	mW	
Storage temperature (T _{strg})	-65	150	°C	
Package body temperature (T _{body})		260	°C	Norm: IPC/JEDEC J-STD-020C ¹
Humidity non-condensing	5	85	%	

1. The reflow peak soldering temperature (body temperature) is specified according IPC/JEDEC J-STD-020C "Moisture/Reflow Sensitivity Classification for Nonhermetic Solid State Surface Mount Devices".

8 Detailed Description

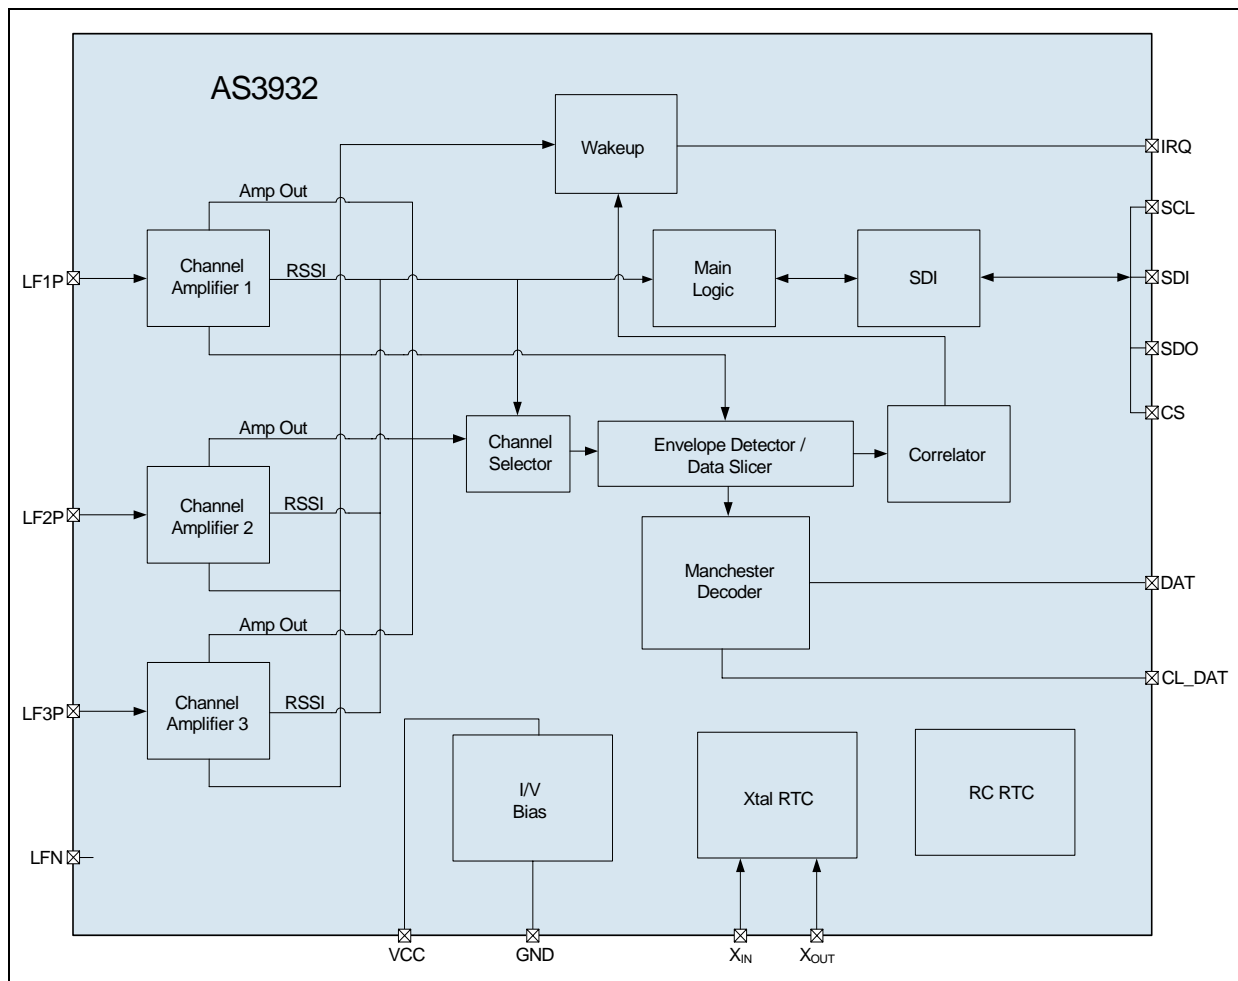

The AS3932 is a three-dimensional low power low-frequency wakeup receiver. The AS3932 is capable to detect the presence of an inductive coupled carrier and extract the envelope of the On-Off-Keying (OOK) modulated carrier. In case the carrier is Manchester coded the clock is recovered from the transmitted signal and the data can be correlated with a programmed pattern. If the detected pattern corresponds to the stored one a wake-up signal (IRQ) is risen up. The pattern correlation can be bypassed in case and the wake-up detection is based only on the frequency detection.

The AS3932 is made up by three independent receiving channels, one envelop detector, one data correlator, one Manchester decoder, 8 programmable registers with the main logic and a real time clock.

The digital logic can be accessed by an SPI. The real time clock can be based on a crystal oscillator or on an internal RC one. In case the second is used to improve its accuracy a calibration can be performed.

8.1 Block Diagram

Figure 10. Block Diagram

AS3932 needs the following external components:

- Power supply capacitor - CBAT – 100 nF
- 32.768 kHz crystal with its two pulling capacitors – XTAL and CL – (it is possible to omit these components if the internal RC oscillator is used instead of the crystal oscillator).
- One, two, or three LC resonators according to the number of used channels.

In case the internal RC-oscillator is used (no crystal oscillator is mounted), the pin XIN has to be connected to the supply, while pin XOUT should stay floating. Application diagrams with and without crystal are shown in [Figure 1](#) and [Figure 2](#)

8.2 Operating Modes

8.2.1 Power Down Mode

In Power Down Mode AS3932 is completely switched off. The typical current consumption is 400 nA.

8.2.2 Listening Mode

In listening mode only the active channel amplifiers and the RTC are running. In this mode the system detects the presence of a carrier. In case the carrier is detected the RSSI can be displayed.

If the three dimensional detection is not required it is possible to deactivate one or more channels. In case only two channels are required the deactivated channel must be the number three, while if only one channel detection is needed the active channel must be the number one.

Inside this mode it is possible to distinguish the following three sub modes:

8.2.2.1 Standard Listening mode

All channels are active at the same time

8.2.2.2 Scanning mode (Low Power mode 1)

All used channels are active, but only one per time slot, where the time slot T is defined as 1ms. If, for example all three channels are used in the first millisecond the only active channel is the number one, after the first millisecond the channel three will be active for the same period of time and at the end the channel two will be working for one millisecond, handing over to the channel one again. This channel rotation goes on until the presence of the carrier is detected by any of the channels; then immediately all three channels will become active at the same time. Now AS3932 can perform a simultaneous multidirectional evaluation (on all three channels) of the field and evaluate which channel has the strongest RSSI. The channel with the highest RSSI will be put through to the demodulator. In this way it is possible to perform multidirectional monitoring of the field with a current consumption of a single channel, keeping the sensitivity as good as if all channels are active at the same time.

Figure 11. Scanning Mode

8.2.2.3 ON/OFF mode (Low Power mode 2)

All active channels are on at the same time but not for the whole time (time slot T is defined as 1ms). An on-off duty-ratio is defined. This duty ratio is programmable see **R4<7:6>**.

Figure 12. ON/OFF Mode

For each of these sub modes it is possible to enable a further feature called Artificial Wake-up. The Artificial Wake-up is a counter based on the used RTC. Three bits define a time window see **R8<2:0>**. If no activity is seen within this time window the chip will produce an interrupt on the WAKE pin that lasts 128 μ s. With this interrupt the microcontroller (μ C) can get feedback on the surrounding environment (e.g. read the false wakeup register, see Correlator register **R13<7:0>**) and/or take actions in order to change the setup.

8.2.3 Preamble Detection / Pattern Correlation

The chip can go in to this mode after detecting a LF carrier only if the data correlator function is enabled see **R1<1>**. The correlator searches first for preamble frequency (constant frequency of Manchester clock defined according to bit-rate transmission) and then for data pattern.

If the pattern is matched the wake-up interrupt is displayed on the WAKE output and the chip goes in Data receiving mode. If the pattern fails the internal wake-up (on all active channels) is terminated and no IRQ is produced.

8.2.4 Data Receiving

The user can enable this mode allowing the pattern correlation or just on the base of the frequency detection. In this mode the chip can be retained a normal OOK receiver. The data is provided on the DAT pin and in case the Manchester decoder is enabled see **R1<3>**, the recovered clock is present on the CL_DAT. It is possible to put the chip back to listening mode either with a direct command (CLEAR_WAKE (see Table 12)) or by using the timeout feature. This feature automatically sets the chip back to listening mode after a certain time **R7<7:5>**.

R11<4:0>	RSSI3	R		RSSI channel 3	
R12<4:0>	RSSI2	R		RSSI channel 2	
R13<7:0>	F_WAK	WR		False wakeup register	

8.3.3 Serial Data Interface (SDI)

This 4-wires interface is used by the Microcontroller (μC) to program the AS3932. The clock operation frequency of the SDI is 1MHz.

Table 8. Serial Data Interface (SDI) pins

Name	Signal	Signal Level	Description
CS	Digital Input with pull down	CMOS	Chip Select
SDI	Digital Input with pull down	CMOS	Serial Data input for writing registers, data to transmit and/or writing addresses to select readable register
SDO	Digital Output	CMOS	Serial Data output for received data or read value of selected registers
SCLK	Digital Input with pull down	CMOS	Clock for serial data read and write

Note: SDO is set to tristate if CS is low. In this way more than one device can communicate on the same SDO bus.

8.3.3.1 SDI Command Structure

To program the SDI the CS signal has to go high. A SDI command is made up by a two bytes serial command and the data is sampled on the falling edge of SCLK. The [Table 9](#) shows how the command looks like, from the MSB (B15) to LSB (B0). The command stream has to be sent to the SDI from the MSB (B15) to the LSB (B0).

Table 9. SDI Command Structure

Mode		Register address / Direct Command						Register Data							
B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0

The first two bits (B15 and B14) define the operating mode. There are three modes available (write, read, direct command) plus one spare (not used), as shown in [Table 10](#).

Table 10. SDI Command Structure

B15	B14	Mode
0	0	WRITE
0	1	READ
1	0	NOT ALLOWED
1	1	DIRECT COMMAND

In case a write or read command happens the next 5 bits (B13 to B9) define the register address which has to be written respectively read, as shown in [Table 11](#).

Table 11. SDI Command Structure

B13	B12	B11	B10	B9	B8	Read/Write register
0	0	0	0	0	0	R0
0	0	0	0	0	1	R1
0	0	0	0	1	0	R2
0	0	0	0	1	1	R3
0	0	0	1	0	0	R4
0	0	0	1	0	1	R5
0	0	0	1	1	0	R6
0	0	0	1	1	1	R7
0	0	1	0	0	0	R8
0	0	1	0	0	1	R9
0	0	1	0	1	0	R10
0	0	1	0	1	1	R11
0	0	1	1	0	0	R12
0	0	1	1	0	1	R13

The last 8 bits are the data that has to be written respectively read. A CS toggle high-low-high terminates the command mode.

If a direct command is sent (B15-B14=11) the bits from B13 to B9 defines the direct command while the last 8 bits are omitted. The [Table 12](#) shows all possible direct commands:

Table 12. List of Direct Commands

COMMAND_MODE	B13	B12	B11	B10	B9	B8
clear_wake	0	0	0	0	0	0
reset_RSSI	0	0	0	0	0	1

Table 12. List of Direct Commands

COMMAND_MODE	B13	B12	B11	B10	B9	B8
trim_osc	0	0	0	0	1	0
clear_false	0	0	0	0	1	1
preset_default	0	0	0	1	0	0

All direct commands are explained below:

- clear_wake: clears the wake state of the chip. In case the chip has woken up (WAKE pin is high) the chip is set back to listening mode
- reset_RSSI: resets the RSSI measurement.
- trim_osc: starts the trimming procedure of the internal RC oscillator (see Figure 22)
- clear_false: resets the false wakeup register (R13=00)
- preset_default: sets all register in the default mode, as shown in Figure 7

8.3.3.2 Writing of Data to Addressable Registers (WRITE Mode)

The SDI is sampled at the falling edge of CLK (as shown in the following diagrams).

A CS toggling high-low-high indicates the end of the WRITE command after register has been written. The following example shows a write command.

Figure 13. Writing of a Single Byte (falling edge sampling)

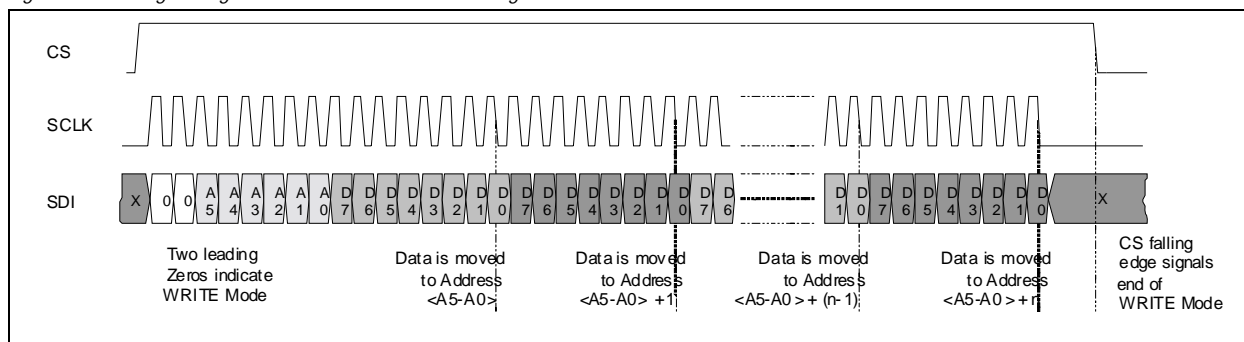

Figure 14. Writing of Register Data with Auto-incrementing Address

8.3.3.3 Reading of Data from Addressable Registers (READ Mode)

Once the address has been sent through SDI, the data can be fed through the SDO pin out to the microcontroller.

A CS LOW toggling high-low-high has to be performed after finishing the read mode session, in order to indicate the end of the READ command and prepare the Interface to the next command control Byte.

To transfer bytes from consecutive addresses, SDI master has to keep the CS signal high and the SCLK clock has to be active as long as data need to be read.

Figure 15. Reading of Single Register Byte

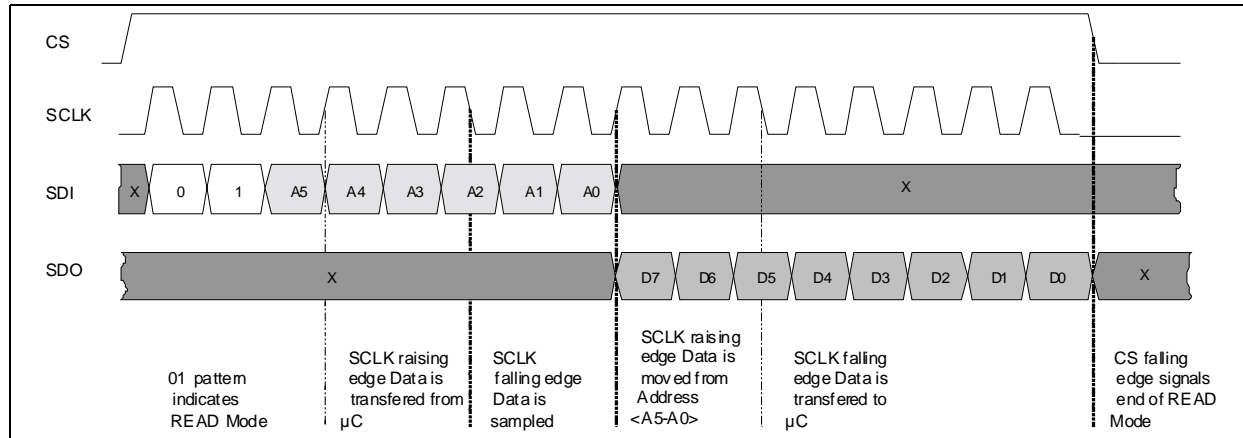

Figure 16. Send Direct COMMAND byte

8.4 Channel Amplifier and Frequency Detector

Each of the 3 channels consists of a variable gain amplifier, an automatic gain control and a frequency detector. The latter detects the presence of a carrier. As soon as the carrier is detected the AGC is enabled, the gain of the VGA is reduced and set to the right value and the RSSI can be displayed.

It is possible to enable/disable individual channels, in case not all three channels are needed. This enables to reduce the current consumption by 1.5 μA (typ.) per channel.

8.4.1 Frequency Detector / AGC

The frequency detection uses the RTC as time base. In case the internal RC oscillator is used as RTC, it must be calibrated, but the calibration is guaranteed for a 32.768 kHz crystal oscillator only. The frequency detection criteria can be tighter or more relaxed according to the setup described in R2<1:0> (see Table 13).

Table 13. Tolerance Settings for Wakeup

R2<1>	R2<0>	Tolerance
0	0	relaxed
0	1	tighter (medium)
1	0	stringent
1	1	Reserved

The AGC can operate in two modes:

- AGC down only (R1<5>=0)
- AGC up and down (R1<5>=1)

As soon as the AGC starts to operate, the gain in the VGA is set to maximum. If the AGC down only mode is selected, the AGC can only decrease the gain. Since the RSSI is directly derived from the VGA gain, the system holds the RSSI peak.

When the AGC up and down mode is selected, the RSSI can follow the input signal strength variation in both directions.

Regardless which AGC operation mode is used, the AGC needs maximum 35 carrier periods to settle.

The RSSI is available for all 3 channels at the same time and it is stored in 3 registers (R10<4:0>, R11<4:0>, R12<4:0>)

Both AGC modes (only down or down and up) can also operate with time limitation. This option allows AGC operation only in time slot of 256µs following the internal wake-up. Then the AGC (RSSI) is frozen till the wake-up or RSSI reset occurs.

The RSSI is reset either with the direct command 'clear_wakeup' or 'reset_RSSI'. The 'reset_RSSI' command resets only the AGC setting but does not terminate wake-up condition. This means that if the signal is still present the new AGC setting (RSSI) will appear not later than 300µs (35 LF carrier periods) after the command was received. The AGC setting is reset if for duration of 3 Manchester half symbols no carrier is detected. If the wake-up IRQ is cleared the chip will go back to listening mode.

In case the maximum amplification at the beginning is a drawback (e.g. in noisy environment) it is possible to set a smaller starting gain on the amplifier, according to the [Table 14](#). In this way it is possible to reduce the false frequency detection.

Table 14. Bit Setting of Gain Reduction

R4<3>	R4<2>	R4<1>	R4<0>	Gain reduction
0	0	0	0	no gain reduction
0	0	0	1	n.a.
0	0	1	0 or 1	n.a.
0	1	0	0 or 1	-4dB
0	1	1	0 or 1	-8dB
1	0	0	0 or 1	-12dB
1	0	1	0 or 1	-16dB
1	1	0	0 or 1	-20dB
1	1	1	0 or 1	-24dB

8.4.2 Antenna Damper

The antenna damper allows the chip to deal with higher field strength, it is enabled by register R1<4>. It consists of shunt resistors which degrade the quality factor of the resonator by reducing the signal at the input of the amplifier. In this way the resonator sees a smaller parallel resistance (in the band of interest) which degrades its quality factor in order to increase the linear range of the channel amplifier (the amplifier doesn't saturate in presence of bigger signals). [Table 15](#) shows the bit setup.

Table 15. Antenna Damper Bit Setup

R4<5>	R4<4>	Shunt resistor (parallel to the resonator at 125 kHz)
0	0	1 kΩ
0	1	3 kΩ
1	0	9 kΩ
1	1	27 kΩ

8.5 Channel Selector / Demodulator / Data Slicer

When at least one of three gain channel enters initial wake-up state the channel selector makes a decision which gain channel to connect to the envelope detector. If only one channel is in wake-up state the selection is obvious. If more than one channel enters wake-up state in 256µs following the first active channel the channel with highest RSSI value is selected. The output signal (amplified LF carrier) of selected channel is connected to the input of the demodulator.

The performance of the demodulator can be optimized according to bit rate and preamble length as described in [Table 16](#) and [Table 17](#).

Table 16. Bit Setup for the Envelop Detector for Different Symbol Rates

R3<2>	R3<1>	R3<0>	Symbol rate [Manchester symbols/s]
0	0	0	4096
0	0	1	2184
0	1	0	1490
0	1	1	1130
1	0	0	910
1	0	1	762
1	1	0	655
1	1	1	512

If the bit rate gets higher the time constant in the envelop detector must be set to a smaller value, this means that higher noise is injected because of the wider band. The next table is a rough indication of how the envelop detector looks like for different bit rates. By using proper data slicer settings it is possible to improve the noise immunity paying the penalty of a longer preamble. In fact if the data slicer has a bigger time constant it is possible to reject more noise, but every time a transmission occurs, the data slicer need time to settle. This settling time will influence the length of the preamble. [Table 17](#) gives a correlation between data slicer setup and minimum required preamble length.

Table 17. Bit Setup for the Data Slicer for Different Preamble Length

R3<5>	R3<4>	R3<3>	Minimum preamble length [ms]
0	0	0	0.8
0	0	1	1.15
0	1	0	1.55
0	1	1	1.9
1	0	0	2.3
1	0	1	2.65
1	1	0	3
1	1	1	3.5

Note: These times are minimum required, but it is recommended to prolong the preamble.

The comparator of the data slicer can work only with positive or with symmetrical threshold (R3<6>). In addition the threshold can be 20 or 40 mV (R3<7>)

In case the length of the preamble is an issue the data slicer can also work with an absolute threshold (R1<7>). In this case the bits R3<2:0> would not influence the performance. It is even possible to reduce the absolute threshold in case the environment is not particularly noisy (R2<7>).

8.6 Correlator

After frequency detection the data correlation is only performed if the correlator is enabled ($R1<1>=1$).

The data correlation consists of checking the presence of a preamble (ON/OFF modulated carrier) followed by a certain pattern.

After the frequency detection the correlator waits 16 bits (see bit rate definition in [Table 18](#)) and if no preamble is detected the chip is set back to listening mode and the false-wakeup register ($R13<7:0>$) is incremented by one.

To get started with the pattern correlation the correlator needs to detect at least 4 bits of the preamble (ON/OFF modulated carrier).

The bit duration is defined in the register $R7<4:0>$ according to the [Table 18](#) as function of the Real Time Clock (RTC) periods.

Table 18. Bit Rate Setup

R7<4>	R7<3>	R7<2>	R7<1>	R7<0>	Bit duration in RTC clock periods	Bit rate (bits/s)	Symbol rate (Manchester symbols/s)
0	0	0	1	1	4	8192	4096
0	0	1	0	0	5	6552	3276
0	0	1	0	1	6	5460	2730
0	0	1	1	0	7	4680	2340
0	0	1	1	1	8	4096	2048
0	1	0	0	0	9	3640	1820
0	1	0	0	1	10	3276	1638
0	1	0	1	0	11	2978	1489
0	1	0	1	1	12	2730	1365
0	1	1	0	0	13	2520	1260
0	1	1	0	1	14	2340	1170
0	1	1	1	0	15	2184	1092
0	1	1	1	1	16	2048	1024
1	0	0	0	0	17	1926	963
1	0	0	0	1	18	1820	910
1	0	0	1	0	19	1724	862
1	0	0	1	1	20	1638	819
1	0	1	0	0	21	1560	780
1	0	1	0	1	22	1488	744
1	0	1	1	0	23	1424	712
1	0	1	1	1	24	1364	682
1	1	0	0	0	25	1310	655
1	1	0	0	1	26	1260	630
1	1	0	1	0	27	1212	606
1	1	0	1	1	28	1170	585
1	1	1	0	0	29	1128	564
1	1	1	0	1	30	1092	546
1	1	1	1	0	31	1056	528
1	1	1	1	1	32	1024	512

If the preamble is detected correctly the correlator keeps searching for a data pattern. The duration of the preamble plus the pattern should not be longer than 40 bits (see bit rate definition in [Table 18](#)). The data pattern can be defined by the user and consists of two bytes which are stored in the registers R5<7:0> and R6<7:0>. The two bytes define the pattern consisting of 16 half bit periods. This means the pattern and the bit period can be selected by the user. The only limitation is that the pattern (in combination with preamble) must obey Manchester coding and timing. It must be noted that according to Manchester coding a down-to-up bit transition represents a symbol "0", while a transition up-to-down represents a symbol "1". If the default code is used (96 [hex]) the binary code is (10 01 01 10 01 10 10 01). MSB has to be transmitted first.

The user can also select (R1<2>) if single or double data pattern is used for wake-up. In case double pattern detection is set, the same pattern has to be repeated 2 times.

Additionally it is possible to set the number of allowed missing zero bits (not symbols) in the received bitstream (R2<6:5>), as shown in the [Table 19](#).

Table 19. Allowed Pattern Detection Errors

R2<6>	R2<5>	Maximum allowed error in the pattern detection
0	0	No error allowed
0	1	1 missed zero
1	0	2 missed zeros
1	1	3 missed zeros

If the pattern is matched the wake-up interrupt is displayed on the WAKE output. In case the Manchester decoder is enabled (R1<3>) the data coming out from the DAT pin are decoded and the clock is recovered on the pin DAT_CL.

The data coming out from the DAT pin are stable (and therefore can be acquired) on the rising edge of the CL_DAT clock, as shown in [Figure 17](#).

Figure 17. Synchronization of Data with Recovered Manchester Clock

If the pattern detection fails the internal wake-up (on all active channels) is terminated with no signal sent to MCU and the false wakeup register will be incremented (R13<7:0>).

8.7 Wakeup Protocol - Carrier Frequency 125 kHz

The wake-up state is terminated with the direct command 'clear_wake' [Table 12](#). This command terminates the MCU activity. The termination can also be automatic in case there is no response from MCU. The time out for automatic termination is set in a register R7<7:5>, as shown in the [Table 20](#).

Table 20. Timeout Setup

R7<7>	R7<6>	R7<5>	Time out
0	0	0	0 sec
0	0	1	50 msec
0	1	0	100 msec
0	1	1	150 msec
1	0	0	200 msec
1	0	1	250 msec

Table 20. Timeout Setup

R7<7>	R7<6>	R7<5>	Time out
1	1	0	300 msec
1	1	1	350 msec

8.7.1 Without Pattern Detection (Manchester decoder disabled)

Figure 18. Wakeup Protocol Overview without Pattern Detection (only carrier frequency detection, Manchester decoder disabled)

In case the data correlation is disabled ($R1<1>=0$) the AS3932 wakes up upon detection of the carrier frequency only as shown in Figure 18. In order to ensure that AS3932 wakes up the carrier burst has to last longer than 550 μ s. To set AS3932 back to listening mode there are two possibilities: either the microcontroller sends the direct command clear_wake via SDI or the time out option is used ($R7<7:5>$). In case the latter is chosen, AS3932 is automatically set to listening mode after the time defined in T_OUT ($R7<7:5>$), counting starts at the low-to-high WAKE edge on the WAKE pin.

8.7.2 Single Pattern Detection (Manchester decoder disabled)

The Figure 19 shows the wakeup protocol in case the pattern correlation is enabled ($R1<1>=1$) for a 125 kHz carrier frequency. The initial carrier burst has to be longer than 550 μ s and can last maximum 16 bits (see bit rate definition in Table 18). If the ON/OFF mode is used ($R1<5>=1$), the minimum value of the maximum carrier burst duration is limited to 10 ms. This is summarized in Table 21. In case the carrier burst is too long the internal wakeup will be set back to low and the false wakeup counter ($R13<7:0>$) will be incremented by one. The carrier burst must be followed by a preamble (0101... modulated carrier with a bit duration defined in Table 18) and the wakeup pattern stored in the registers $R5<7:0>$ and $R6<7:0>$. The preamble must have at least 4 bits and the preamble duration together with the pattern should not be longer than 40 bits. If the wakeup pattern is correct the signal on the WAKE pin is set to high and the data transmission can get started. To set the chip back to listening mode the direct command clear_false, as well as the time out option ($R7<7:5>$) can be used.

Figure 19. Wakeup Protocol Overview with Single Pattern Detection (Manchester decoder disabled)

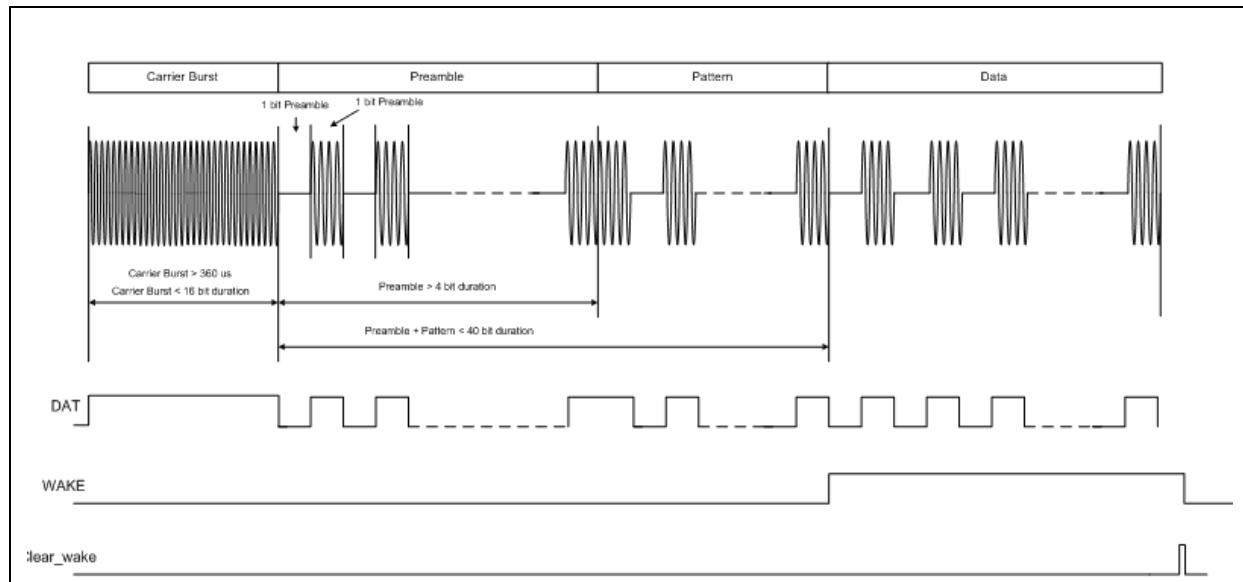

Table 21. Preamble Requirements in Standard Mode, Scanning Mode and ON/OFF Mode

Bit rate (bit/s)	Maximum duration of the carrier burst in Standard Mode and Scanning Mode (ms)	Maximum duration of the carrier burst in ON/OFF Mode (ms)
8192	1.95	10

8.7.3 Single Pattern Detection (Manchester decoder enabled)

The [Figure](#) shows the wakeup protocol in case both the pattern correlation and the Manchester decoder are enabled ($R1<1>=1$ and $R1<3>=1$) for a 125 kHz carrier frequency. The initial carrier burst has to be at least 42 Manchester symbols long and has to be followed by a separation bit (one bit of no-carrier). The carrier burst must be followed by a minimum 4 Manchester symbol preamble (10101010) and the pattern stored in the $R5<7:0>$ and $R6<7:0>$. The preamble can only be made up by integer Manchester symbol and the preamble duration together with the pattern should not be longer than 40 bits. If the pattern is correct the signal on the WAKE pin is set to high, the data are internally decoded and the Manchester clock is recovered. To set the AS3932 back to listening mode the direct command `clear_false` or the time out option ($R7<7:5>$) can be used.

In case the On/OFF mode is enabled the Manchester decoder can not be used.

Figure 20. Wakeup Protocol Overview with Single Pattern Detection (Manchester decoder enabled)

8.8 False Wakeup Register

The wakeup strategy in the AS3932 is based on 2 steps:

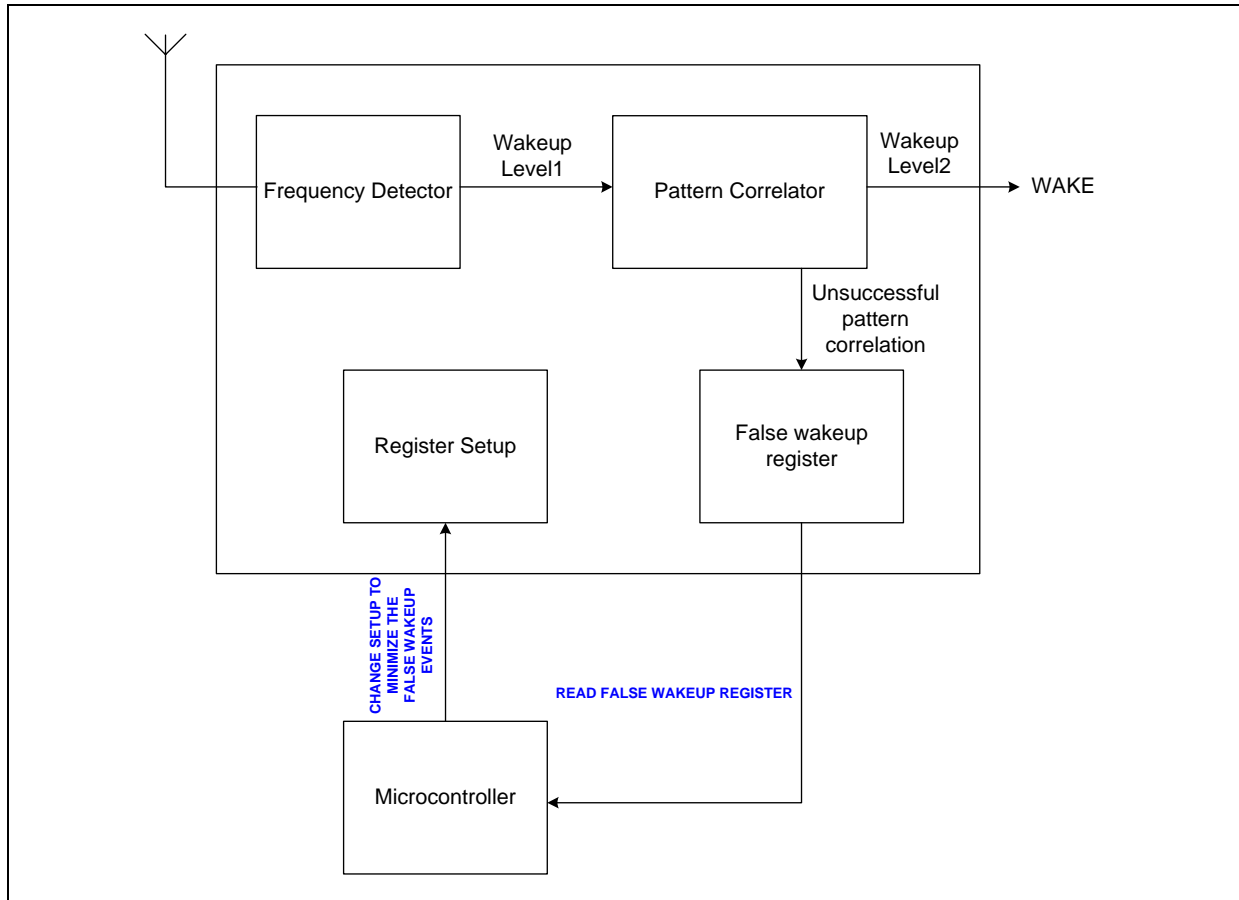

1. Frequency Detection: in this phase the frequency of the received signal is checked.
2. Pattern Correlation: here the pattern is demodulated and checked whether it corresponds to the valid one.

If there is a disturber or noise capable to overcome the first step (frequency detection) without producing a valid pattern, then a false wakeup call happens. Each time this event is recognized a counter is incremented by one and the respective counter value is stored in a memory cell (false wakeup register). Thus, the microcontroller can periodically look at the false wakeup register, to get a feeling how noisy the surrounding environment is and can then react accordingly (e.g. reducing the gain of the LNA during frequency detection, set the AS3932 temporarily to power down etc.), as shown in the [Figure 21](#). The false wakeup counter is a useful tool to quickly adapt the system to any changes in the noise environment and thus avoid false wakeup events.

Most wakeup receivers have to deal with environments that can rapidly change. By periodically monitoring the number of false wakeup events it is possible to adapt the system setup to the actual characteristics of the environment and enables a better use of the full flexibility of AS3932.

Note: If the Manchester decoder is enabled, the false wakeup register is not able anymore to store the false wakeup events.

Figure 21. Concept of the False Wakeup Register together with the system

8.9 Real Time Clock (RTC)

The RTC can be based on a crystal oscillator ($R1<0>=1$), the internal RC-oscillator ($R1<0>=0$), or an external clock source ($R1<0>=1$). The crystal oscillator has higher precision of the frequency with higher current consumption and needs three external components (crystal plus two capacitors). The RC-oscillator is completely integrated and can be calibrated if a reference signal is available for a very short time to improve the frequency accuracy. The calibration gets started with the trim_osc direct command. Since no non-volatile memory is available on the chip, the calibration must be done every time after battery replacement. Since the RTC defines the time base of the frequency detection, the selected frequency (frequency of the crystal oscillator or the reference frequency used for calibration of the RC oscillator) should be about one fourth of the carrier frequency:

$$F_{RTC} \sim F_{CAR} * 0.25 \quad (EQ 1)$$

Where: F_{CAR} is the carrier frequency and F_{RTC} is the RTC frequency

The third option for the RTC is the use of an external clock source, which must be applied directly to the XIN pin (XOUT floating).

8.9.1 Crystal Oscillator

Table 22. Characteristics of XTAL

Symbol	Parameter	Conditions	Min	Typ	Max	Units
	Crystal accuracy (initial)	Overall accuracy			±120	p.p.m.
	Crystal motional resistance				60	KΩ
	Frequency			32.768		kHz
	Contribution of the oscillator to the frequency error			±5		p.p.m
	Start-up Time	Crystal dependent		1		s
	Duty cycle		45	50	55	%
	Current consumption			1		μA

8.9.2 RC-Oscillator

Table 23. Characteristics of RCO

Symbol	Parameter	Conditions	Min	Typ	Max	Units
	Frequency	If no calibration is performed	27	32.768	42	kHz
		If calibration is performed	31	32.768	34.5	kHz
	Calibration time	Periods of reference clock			65	cycles
	Current consumption			200		nA

To trim the RC-Oscillator, set the chip select (CS) to high before sending the direct command trim_osc over SDI. Then 65 digital clock cycles of the reference clock (e.g. 32.768 kHz) have to be sent on the clock bus (SCL), as shown in Figure 22. After that the signal on the chip select (CS) has to be pulled down.

The calibration is effective after the 65th reference clock edge and it will be stored in a volatile memory. In case the RC-oscillator is switched off or a power-on-reset happens (e.g. battery change) the calibration has to be repeated.

Figure 22. RC-Oscillator Calibration via SDI

8.9.3 External Clock Source

To clock the AS3932 with an external signal the crystal oscillator has to be enabled ($R1 < 1 > = 1$). As shown in the [Figure 3](#) the clock must be applied on the pin XIN while the pin XOUT must stay floating. The RC time constant has to be $100\mu\text{s}$ with a tolerance of $\pm 10\%$ (e.g. $R=680\text{ k}\Omega$ and $C=22\text{pF}$). In the [Table 24](#) the clock characteristics are summarized.

Table 24. Characteristics of External Clock

Symbol	Parameter	Conditions	Min	Typ	Max	Units
Vl	Low level		0		0.1 * V _{DD}	V
Vh	High level		0.9 * V _{DD}		V _{DD}	V
Tr	Rise-time				3	μs
Tf	Fall-time				3	μs
$T=1/2\pi RC$	RC Time constant		90	100	110	μs

Note: In power down mode the external clock has to be set to V_{DD}.

8.10 Channel Selection in Scanning Mode and ON/OFF Mode

In case only 2 channels are active and one of the Low Power modes is enabled, then the channels 1 and 3 have to be active. If the chip works in On-Off mode and only one channel is active then the active channel has to be the channel 1.

Both Low Power modes are not allowed to be enabled at the same time.

e	0.65 BSC			AE/AET	9.60	9.70	9.80	5.5	3.0	28

Note:

1. Die thickness allowable is 0.279 ± 0.0127 .
2. Dimensioning and tolerances conform to *ASME Y14.5M-1994*.
3. Datum plane H located at mold parting line and coincident with lead, where lead exits plastic body at bottom of parting line.
4. Datum A-B and D to BE determined where center line between leads exits plastic body at datum plane H.
5. D & E1 are reference datum and do not include mold flash or protrusions, and are measured at the bottom parting line. Mold lash or protrusions shall not exceed 0.15mm on D and 0.25mm on E per side.
6. Dimension is the length of terminal for soldering to a substrate.
7. Terminal positions are shown for reference only.
8. Formed leads shall be planar with respect to one another within 0.076mm at seating plane.
9. The lead width dimension does not include dambar protrusion. Allowable dambar protrusion shall be 0.07mm total in excess of the lead width dimension at maximum material condition. Dambar cannot be located on the lower radius or the foot. Minimum space between protrusions and an adjacent lead should be 0.07mm for 0.65mm pitch.
10. Section B-B to be determined at 0.10mm to 0.25mm from the lead tip.
11. Dimensions P and P1 are thermally enhanced variations. Values shown are maximum size of exposed pad within lead count and body size. End user should verify available size of exposed pad for specific device application.
12. All dimensions are in millimeters, angle is in degrees.
13. N is the total number of terminals.

Figure 24. Package Diagram QFN 4x4 16LD

Table 26. Package Dimensions QFN 4x4 16LD

Disclaimer

Devices sold by austriamicrosystems AG are covered by the warranty and patent indemnification provisions appearing in its Term of Sale. austriamicrosystems AG makes no warranty, express, statutory, implied, or by description regarding the information set forth herein or regarding the freedom of the described devices from patent infringement. austriamicrosystems AG reserves the right to change specifications and prices at any time and without notice. Therefore, prior to designing this product into a system, it is necessary to check with austriamicrosystems AG for current information. This product is intended for use in normal commercial applications. Applications requiring extended temperature range, unusual environmental requirements, or high reliability applications, such as military, medical life-support or life-sustaining equipment are specifically not recommended without additional processing by austriamicrosystems AG for each application. For shipments of less than 100 parts the manufacturing flow might show deviations from the standard production flow, such as test flow or test location.

The information furnished here by austriamicrosystems AG is believed to be correct and accurate. However, austriamicrosystems AG shall not be liable to recipient or any third party for any damages, including but not limited to personal injury, property damage, loss of profits, loss of use, interruption of business or indirect, special, incidental or consequential damages, of any kind, in connection with or arising out of the furnishing, performance or use of the technical data herein. No obligation or liability to recipient or any third party shall arise or flow out of austriamicrosystems AG rendering of technical or other services.
