COTS PEM

AS5SP512K18DQ

SSRAM

Plastic Encapsulated Microcircuit

9Mb, 512K x 18, Synchronous SRAM

Pipeline Burst, Single Cycle Deselect

Features

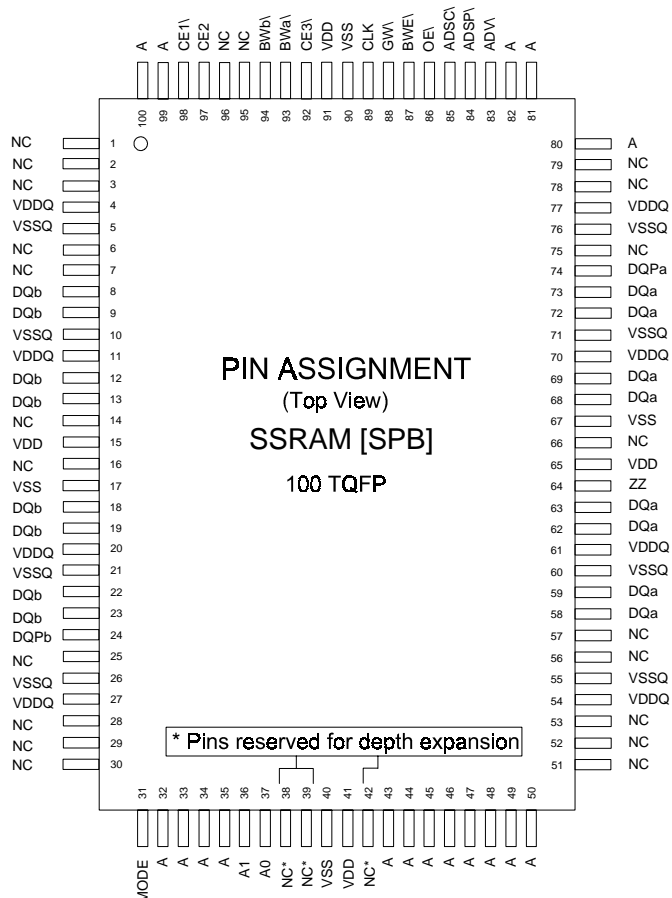

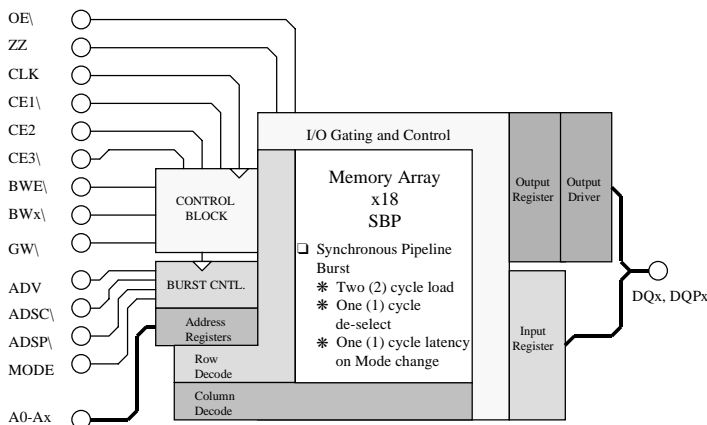

- Synchronous Operation in relation to the input Clock
- 2 Stage Registers resulting in Pipeline operation
- On chip address counter (base +3) for Burst operations
- Self-Timed Write Cycles
- On-Chip Address and Control Registers
- Byte Write support
- Global Write support
- On-Chip low power mode [powerdown] via ZZ pin
- Interleaved or Linear Burst support via Mode pin
- Three Chip Enables for ease of depth expansion without Data Contention.
- Two Cycle load, Single Cycle Deselect
- Asynchronous Output Enable (OE\)
- Three Pin Burst Control (ADSP\, ADSC\, ADV\)
- 3.3V Core Power Supply
- 3.3V/2.5V IO Power Supply
- JEDEC Standard 100 pin TQFP Package, MS026-D/BHA
- Available in **Industrial, Enhanced, and Mil-Temperature** Operating Ranges

Fast Access Times

Parameter	Symbol	200Mhz	166Mhz	133Mhz	Units

Block Diagram

General Description

ASI's AS5SP512K18DQ is a 9.0Mb High Performance Synchronous Pipeline Burst SRAM, available in multiple temperature screening levels, fabricated using High Performance CMOS technology and is organized as a 512K x 18. It integrates address and control registers, a two (2) bit burst address counter supporting four (4) double-word transfers. Writes are internally self-timed and synchronous to the rising edge of clock.

ASI's AS5SP512K18DQ includes advanced control options including Global Write, Byte Write as well as an Asynchronous Output enable. Burst Cycle controls are handled by three (3) input pins, ADV, ADSP\ and ADSC\. Burst operation can be initiated with either the Address Status Processor (ADSP\ or Address Status Cache controller (ADSC\)) inputs. Subsequent burst addresses are generated internally in the system's burst sequence control block and are controlled by Address Advance (ADV) control input.

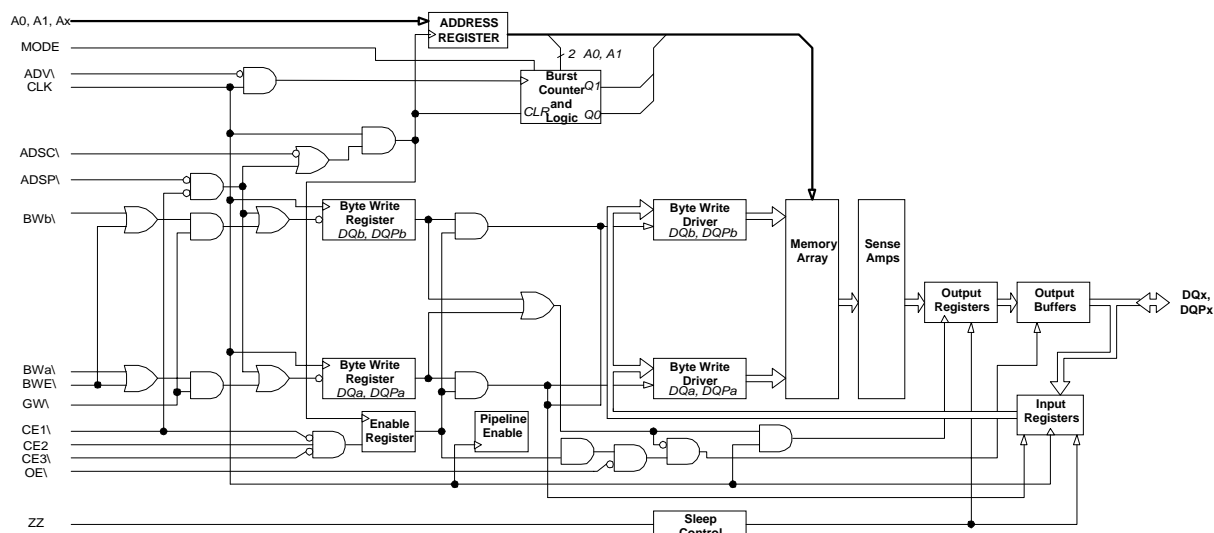

Pin Description/Assignment Table

Signal Name	Symbol	Type	Pin	Description
Clock	CLK	Input	89	This input registers the address, data, enables, Global and Byte writes as well as the burst control functions
Address	A0, A1	Input	37, 36	Low order, Synchronous Address Inputs and Burst counter address inputs
Address	A	Input(s)	35, 34, 33, 32, 31, 100, 99, 82, 81, 44, 45, 46, 47, 48, 49, 50, 43, 83	Synchronous Address Inputs
Chip Enable	CE1\, CE3\	Input	98, 92	Active Low True Chip Enables
Chip Enable	CE2	Input	97	Active High True Chip Enable
Global Write Enable	GW\	Input	88	Active Low True Global Write enable. Write to all bits
Byte Enables	BWa\, BWb\	Input	93, 94	Active Low True Byte Write enables. Write to byte segments
Byte Write Enable	BWE\	Input	87	Active Low True Byte Write Function enable
Output Enable	OE\	Input	86	Active Low True Asynchronous Output enable
Address Strobe Controller	ADSC\	Input	85	Address Strobe from Controller. When asserted LOW, Address is captured in the address registers and A0-A1 are loaded into the Burst Counter. When ADSP\ and ADSC are both asserted, only ADSP\ is recognized
Address Strobe from Processor	ADSP\	Input	84	Synchronous Address Strobe from Processor. When asserted LOW, Address is captured in the Address registers, A0-A1 is registered in the burst counter. When both ADSP\ and ADSC\ or both asserted, only ADSP\ is recognized. ADSP\ is ignored when CE1\ is HIGH
Address Advance	ADV	Input	83	Advance input Address. When asserted HIGH, address in burst counter is incremented.
Power-Down	ZZ	Input	64	Asynchronous, non-time critical Power-down Input control. Places the chip into an ultra low power mode, with data preserved.
Data Parity Input/Outputs	DQPa, DQPb	Input/Output	74, 24	Bidirectional I/O Parity lines. As inputs they reach the memory array via an input register, the address stored in the register on the rising edge of clock. As an output, the line delivers the valid data stored in the array via an output register and output driver. The data delivered is from the previous clock period of the READ cycle.
Data Input/Outputs	DQa, DQb, DQc, DQd	Input/Output	58, 59, 62, 63, 68, 69, 72, 73, 8, 9, 12, 13, 18, 19, 22, 23	Bidirectional I/O Data lines. As inputs they reach the memory array via an input register, the address stored in the register on the rising edge of clock. As an output, the line delivers the valid data stored in the array via an output register and output driver. The data delivered is from the previous clock period of the READ cycle.
Burst Mode	MODE	Input	31	Interleaved or Linear Burst mode control
Power Supply [Core]	VDD	Supply	91, 15, 41, 65	Core Power Supply
Ground [Core]	VSS	Supply	90, 17, 40, 67	Core Power Supply Ground
Power Supply I/O	VDDQ	Supply	4, 11, 20, 27, 54, 61, 70, 77	Isolated Input/Output Buffer Supply
I/O Ground	VSSQ	Supply	5, 10, 21, 26, 55, 60, 71, 76	Isolated Input/Output Buffer Ground
No Connection(s)	NC	NA	1, 2, 3, 6, 7, 14, 16, 25, 28, 29, 30, 38, 39, 42, 51, 52, 53, 56, 57, 66, 75, 78, 79, 95, 96	No connections to internal silicon

Logic Block Diagram

Functional Description

Austin Semiconductor's AS5SP512K18DQ Synchronous SRAM is manufactured to support today's High Performance platforms utilizing the Industries leading Processor elements including those of Intel and Motorola. The AS5SP512K18DQ supports Synchronous SRAM READ and WRITE operations as well as Synchronous Burst READ/WRITE operations. All inputs with the exception of OE\, MODE and ZZ are synchronous in nature and sampled and registered on the rising edge of the devices input clock (CLK). The type, start and the duration of Burst Mode operations is controlled by MODE, ADSC\, ADSP\ and ADV as well as the Chip Enable pins CE1\, CE2, and CE3\. All synchronous accesses including the Burst accesses are enabled via the use of the multiple enable pins and wait state insertion is supported and controlled via the use of the Advance control (ADV).

The ASI AS5SP512K18DQ supports both Interleaved as well as Linear Burst modes therefore making it an architectural fit for either the Intel or Motorola CISC processor elements available on the Market today.

The AS5SP512K18DQ supports Byte WRITE operations and enters this functional mode with the Byte Write Enable (BWE\), and the Byte Write Select pin(s) (BWA\, BWb\, BWc\, BWD\). Global Writes are supported via the Global Write Enable (GW\), and Global Write Enable will override the Byte Write inputs and will perform a Write to all Data I/Os.

The AS5SP512K18DQ provides ease of producing very dense arrays via the multiple Chip Enable input pins and Tri-state outputs.

www.DataSheet4U.com

Single Cycle Access Operations

A Single READ operation is initiated when all of the following conditions are satisfied at the time of Clock (CLK) HIGH: [1] ADSP\ or ADSC\ is asserted LOW, [2] Chip Enables are all asserted active, and [3] the WRITE signals (GW\, BWE\), are in their FALSE state (HIGH). ADSP\ is ignored if CE1\ is HIGH. The address presented to the Address inputs is stored within the Address Registers and Address Counter/Advancement Logic and then passed or presented to the array core. The corresponding data of the addressed location is propagated to the Output Registers and passed to the data bus on the next rising clock via the Output Buffers. The time at which the data is presented to the Data bus is as specified by either the Clock to Data valid specification or the Output Enable to Data Valid spec for the device speed grade chosen. The only exception occurs when the device is recovering from a deselected to select state where its outputs are tristated in the first machine cycle and controlled by its Output Enable (OE\), on following cycle. Consecutive single

cycle READS are supported. Once the READ operation has been completed and deselected by use of the Chip Enable(s) and either ADSP\ or ADSC\, its outputs will tri-state immediately.

A Single ADSP\ controlled WRITE operation is initiated when both of the following conditions are satisfied at the time of Clock (CLK) HIGH: [1] ADSP\ is asserted LOW, and [2] Chip Enable(s) are asserted ACTIVE. The address presented to the address bus is registered and loaded on CLK HIGH, then presented to the core array. The WRITE controls Global Write, and Byte Write Enable (GW\, BWE\), as well as the individual Byte Writes (BWA\, BWb\, BWc\, and BWD\), and ADV\ are ignored on the first machine cycle. ADSP\ triggered WRITE accesses require two (2) machine cycles to complete. If Global Write is asserted LOW on the second Clock (CLK) rise, the data presented to the array via the Data bus will be written into the array at the corresponding address location specified by the Address bus. If GW\ is HIGH (inactive) then BWE\ and one or more of the Byte Write controls (BWA\, BWb\, BWc\, and BWD\), controls the write operation. All WRITES that are initiated in this device are internally self timed.

A Single ADSC\ controlled WRITE operation is initiated when the following conditions are satisfied: [1] ADSC\ is asserted LOW, [2] ADSP\ is de-asserted (HIGH), [3] Chip Enable(s) are asserted (TRUE or Active), and [4] the appropriate combination of the WRITE inputs (GW\, BWE\, BWx\), are asserted (ACTIVE). Thus completing the WRITE to the desired Byte(s) or the complete data-path. ADSC\ triggered WRITE accesses require a single clock (CLK) machine cycle to complete. The address presented to the input Address bus pins at time of clock HIGH will be the location that the WRITE occurs. The ADV pin is ignored during this cycle, and the data WRITTEN to the array will either be a BYTE WRITE or a GLOBAL WRITE depending on the use of the WRITE control functions GW\ and BWE\, as well as the individual BYTE CONTROLS (BWx\).

Deep Power-Down Mode (SLEEP)

The AS5SP512K18DQ has a Deep Power-Down mode and is controlled by the ZZ pin. The ZZ pin is an Asynchronous input and asserting this pin places the SSRAM in a deep power-down mode (SLEEP). While in this mode, Data integrity is guaranteed. For the device to be placed successfully into this operational mode the device must be deselected and the Chip Enables, ADSP\ and ADSC\ remain inactive for the duration of tZZREC after the ZZ input returns LOW. Use of this deep power-down mode conserves power and is very useful in multiple memory page designs where the mode recovery time can be hidden.

Notes to Switching Specifications:

1. Measured as HIGH when above VIH and Low when below VIL
2. This parameter is measured with the output loading shown in AC Test Loads
3. This parameter is sampled
4. Transition is measured +500mV from steady state voltage
5. Critical specification(s) when Design Considerations are being reviewed/analyzed for Bus Contentention
6. OE_\ is a Don't Care when a Byte or Global Write is sampled LOW
7. A READ cycle is defined by Byte or Global Writes sampled LOW and ADSP_\ is sampled HIGH for the required SET-UP and HOLD times
8. This is a Synchronous device. All addresses must meet the specified SET-UP and HOLD times for all rising edges of CLK when either ADSP_\ or ADSC_\ is sampled LOW while the device is enabled. All other synchronous inputs must meet the SET-UP and HOLD times with stable logic levels for all rising edges of clock (CLK) during device operation (enabled). Chip Enable (Cex_\, CE₂) must be valid at each rising edge of clock (CLK) when either ADSP_\ or ADSC_\ is LOW to remain enabled.

Power Down (SNOOZE MODE)

Power Down or Snooze is a Power conservation mode which when building large/very dense arrays, using multiple devices in a multi-banked or paged array, can greatly reduce the Operating current requirements of your total memory array solution.

The device is placed in this mode via the use of the ZZ pin, an asynchronous control pin which when asserted, places the array into the lower power or Power Down mode. Awakening the array or leaving the Power Down (SNOOZE) mode is done so by de-asserting the ZZ pin .

While in the Power Down or Snooze mode, Data integrity is guaranteed. Accesses pending when the device entered the mode are not considered valid nor is the completion of the operation guaranteed. The device must be de-selected prior to entering the Power Down mode, all Chip Enables, ADSP\ and ADSC\ must remain inactive for the duration of ZZ recovery time (tZZREC).
