## **Features**

#### **CPU Features**

- · Operating voltage:
  - f<sub>SYS</sub>=16MHz: 3.3V~5.5V
- $0.25\mu s$  instruction cycle with 16MHz system clock at  $V_{DD}$ =5V
- · Power down and wake-up functions to reduce power consumption
- · Oscillator types:
  - External 16MHz Crystal -- HXT
  - External 32.768kHz Crystal -- LXT
  - Internal 32kHz RC -- LIRC
- Multi-mode operation: NORMAL, SLOW, IDLE and SLEEP
- · All instructions executed in one or two instruction cycles
- · Table read instructions
- 63 powerful instructions
- Up to 12-level subroutine nesting
- · Bit manipulation instruction

#### **Peripheral Features**

- Program Memory: Up to 16K×16
- RAM Data Memory: Up to 512×8
- True EEPROM Memory: Up to 256×8
- · Watchdog Timer function
- Up to 35 bidirectional I/O lines
- Two pin-shared external interrupts
- Multiple Timer Module for time measure, input capture, compare match output, PWM output or single pulse output function
- Serial Interface Module SIM (SPI/I<sup>2</sup>C)
- Individual SPI interface SPIA
- · Comparator function
- · Dual Time-Base functions for generation of fixed time interrupt signals
- Up to 16 channels 12-bit A/D Converter
- · Low voltage reset function
- · Low voltage detect function
- Package types: 32/40/46 pin QFN

## **RF Transceiver Features**

- Low Power High Performance 2.4GHz GFSK Transceiver
- 2400-2483.5MHz ISM band operation
- Support 250Kbps, 1Mbps and 2Mbps air data rate
- Programmable output power
- Variable payload length from 1 to 32 bytes
- · Automatic packet processing
- 6 data pipes for 1:6 star networks

# **General Description**

The devices are Flash Memory type 8-bit high performance RISC architecture microcontrollers. Offering users the convenience of Flash Memory multi-programming features, these devices also include a wide range of functions and features. Other memory includes an area of RAM Data Memory as well as an area of true EEPROM memory for storage of non-volatile data such as serial numbers, calibration data etc.

Analog features include a multi-channel 12-bit A/D converter and a comparator functions. Multiple and extremely flexible Timer Modules provide timing, pulse generation and PWM generation functions. Protective features such as an internal Watchdog Timer, Low Voltage Reset and Low Voltage Detector coupled with excellent noise immunity and ESD protection ensure that reliable operation is maintained in hostile electrical environments.

A full choice of HXT, LXT and LIRC oscillator functions are provided including a fully integrated system oscillator which requires no external components for its implementation. The ability to operate and switch dynamically between a range of operating modes using different clock sources gives users the ability to optimise microcontroller operation and minimize power consumption.

The inclusion of flexible I/O programming features, Time-Base functions along with many other features ensure that the devices will find excellent use in applications such as electronic metering, environmental monitoring, handheld instruments, household appliances, electronically controlled tools, motor driving in addition to many others.

Rev. 1.50 8 July 12, 2017

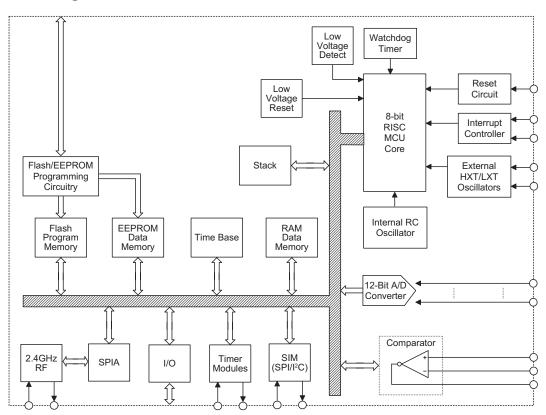

# **Selection Table**

Most features are common to all devices, the main feature distinguishing them are Memory capacity, I/O count, A/D Converter channels, TM features, stack capacity and package types. The following table summarises the main features of each device.

| Part No. | Program<br>Memory | Data<br>Memory | EEPROM<br>Memory | I/O | External<br>Interrupt | A/D Converter |
|----------|-------------------|----------------|------------------|-----|-----------------------|---------------|
| BC66F840 | 4k×16             | 256×8          | 128×8            | 21  | 2                     | 12-bit×8      |
| BC66F850 | 8k×16             | 384×8          | 256×8            | 29  | 2                     | 12-bit×16     |
| BC66F860 | 16k×16            | 512×8          | 256×8            | 35  | 2                     | 12-bit×16     |

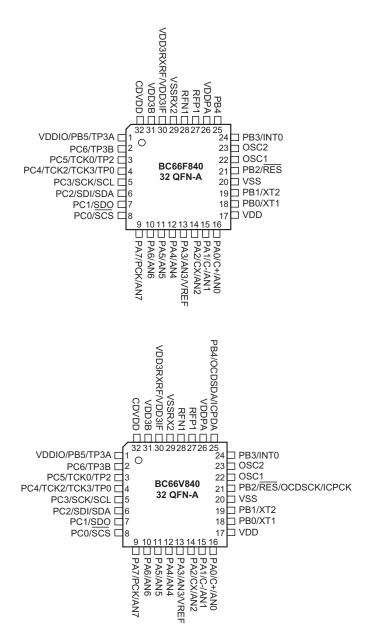

| Part No. | Timer Module                                 | SIM      | SPIA     | Time Base | Comparator | Stacks | Package |

# **Pin Descriptions**

With the exception of the power pins, all pins on these devices can be referenced by their Port name, e.g. PA0, PA1, etc, which refer to the digital I/O function of the pins. However some of these Port pins are also shared with other function such as the Analog to Digital Converter, Timer Module pins etc. The function of each pin is listed in the following table, however the details behind how each pin is configured is contained in other sections of the datasheet.

The BC66V8x0 device is the corresponding EV chip of the BC66F8x0 device. It supports the "On-Chip Debug" function for debugging during development using the OCDSDA and OCDSCK pins connected to the Holtek HT-IDE development tools.

2.4GHz RF Transceiver IP Control Diagram

Rev. 1.50 18 July 12, 2017

# **Absolute Maximum Ratings**

| Supply Voltage          | V <sub>SS</sub> -0.3V to V <sub>SS</sub> +6.0V |
|-------------------------|--|
| Storage Temperature     | -50°C to 150°C                                 |
| Input Voltage           | $V_{SS}$ -0.3V to $V_{DD}$ +0.3V               |
| Operating Temperature   | -40°C to 85°C                                  |
| I <sub>OL</sub> Total   | 100mA  |
| I <sub>OH</sub> Total   | -100mA   |
| Total Power Dissipation | 500mW  |
| ESD HBM                 | ±1.5KV   |
| ESD MM                  | ±100V  |

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

\*Device is ESD sensitive. HBM (Human Body Mode) is based on MIL-STD-883H Method 3015.8. MM (Machine Mode) is based on JEDEC EIA/JESD22-A115.

## **D.C. Characteristics**

Rev. 1.50 24 July 12, 2017

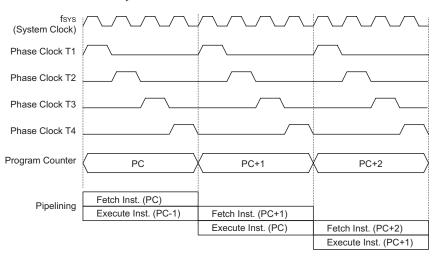

# **System Architecture**

A key factor in the high-performance features of the Holtek range of microcontrollers is attributed to their internal system architecture. The range of devices take advantage of the usual features found within RISC microcontrollers providing increased speed of operation and enhanced performance. The pipelining scheme is implemented in such a way that instruction fetching and instruction execution are overlapped, hence instructions are effectively executed in one cycle, with the exception of branch or call instructions. An 8-bit wide ALU is used in practically all instruction set operations, which carries out arithmetic operations, logic operations, rotation, increment, decrement, branch decisions, etc. The internal data path is simplified by moving data through the Accumulator and the ALU. Certain internal registers are implemented in the Data Memory and can be directly or indirectly addressed. The simple addressing methods of these registers along with additional architectural features ensure that a minimum of external components is required to provide a functional I/O and A/D control system with maximum reliability and flexibility. This makes the devices suitable for low-cost, high-volume production for controller applications.

#### Clocking and Pipelining

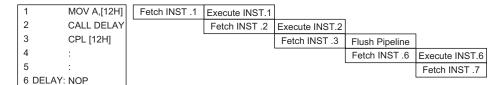

The main system clock, derived from either a HXT, LXT or LIRC oscillator is subdivided into four internally generated non-overlapping clocks, T1~T4. The Program Counter is incremented at the beginning of the T1 clock during which time a new instruction is fetched. The remaining T2~T4 clocks carry out the decoding and execution functions. In this way, one T1~T4 clock cycle forms one instruction cycle. Although the fetching and execution of instructions takes place in consecutive instruction cycles, the pipelining structure of the microcontroller ensures that instructions are effectively executed in one instruction cycle. The exception to this are instructions here the contents of the Program Counter are changed, such as subroutine calls or jumps, in which case the instruction will take one more instruction cycle to execute.

System Clocking and Pipelining

# BC66F840/BC66F850/BC66F860 2.4GHz Flash RF TX/RX MCU

For instructions involving branches, such as jump or call instructions, two machine cycles are required to complete instruction execution. An extra cycle is required as the program takes one cycle to first obtain the actual jump or call address and then another cycle to actually execute the branch. The requirement for this extra cycle should be taken into account by programmers in timing sensitive applications.

Instruction Fetching

#### **Program Counter**

During program execution, the Program Counter is used to keep track of the address of the next instruction to be executed. It is automatically incremented by one each time an instruction is executed except for instructions, such as "JMP" or "CALL" that demand a jump to a non-consecutive Program Memory address. Only the lower 8 bits, known as the Program Counter Low Register, are directly addressable by the application program.

When executing instructions requiring jumps to non-consecutive addresses such as a jump instruction, a subroutine call, interrupt or reset, etc., the manages program control by loading the required address into the Program Counter. For conditional skip instructions, once the condition has been met, the next instruction, which has already been fetched during the present instruction execution, is discarded and a dummy cycle takes its place while the correct instruction is obtained.

| Davisa   | Program Counter |                         |
|----------|-----------------|-------------------------|
| Device   | High Byte       | Low Byte (PCL Register) |
| BC66F840 | PC11~PC8        | PCL7~PCL0               |
| BC66F850 | PC12~PC8        | PCL7~PCL0               |
| BC66F860 | PC13~PC8        | PCL7~PCL0               |

**Program Counter** 

The lower byte of the Program Counter, known as the Program Counter Low register or PCL, is available for program control and is a readable and writeable register. By transferring data directly into this register, a short program jump can be executed directly, however, as only this low byte is available for manipulation, the jumps are limited to the present page of memory, that is 256 locations. When such program jumps are executed it should also be noted that a dummy cycle will be inserted. Manipulating the PCL register may cause program branching, so an extra cycle is needed to pre-fetch.

Rev. 1.50 26 July 12, 2017

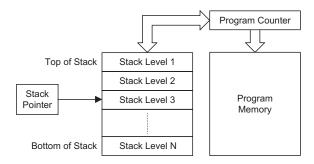

#### **Stack**

This is a special part of the memory which is used to save the contents of the Program Counter only. The stack has multiple levels depending upon the device and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the Stack Pointer, and is neither readable nor writeable. At a subroutine call or interrupt acknowledge signal, the contents of the Program Counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction, RET or RETI, the Program Counter is restored to its previous value from the stack. After a device reset, the Stack Pointer will point to the top of the stack.

If the stack is full and an enabled interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the Stack Pointer is decremented, by RET or RETI, the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. However, when the stack is full, a CALL subroutine instruction can still be executed which will result in a stack overflow. Precautions should be taken to avoid such cases which might cause unpredictable program branching.

If the stack is overflow, the first Program Counter save in the stack will be lost.

| Device   | Stack Level N |
|----------|---------------|
| BC66F840 | 8             |
| BC66F850 | 8             |
| BC66F860 | 12            |

## Arithmetic and Logic Unit - ALU

The arithmetic-logic unit or ALU is a critical area of the that carries out arithmetic and logic operations of the instruction set. Connected to the main data bus, the ALU receives related instruction codes and performs the required arithmetic or logical operations after which the result will be placed in the specified register. As these ALU calculation or operations may result in carry, borrow or other status changes, the status register will be correspondingly updated to reflect these changes. The ALU supports the following functions:

- · Arithmetic operations: ADD, ADDM, ADC, ADCM, SUB, SUBM, SBC, SBCM, DAA
- · Logic operations: AND, OR, XOR, ANDM, ORM, XORM, CPL, CPLA
- Rotation RRA, RR, RRCA, RRC, RLA, RL, RLCA, RLC
- · Increment and Decrement INCA, INC, DECA, DEC
- Branch decision, JMP, SZ, SZA, SNZ, SIZ, SDZ, SIZA, SDZA, CALL, RET, RETI

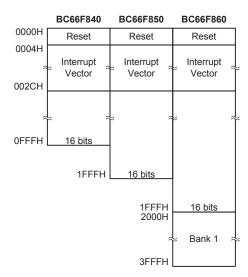

# **Flash Program Memory**

The Program Memory is the location where the user code or program is stored. For these devices serie the Program Memory is Flash type, which means it can be programmed and re-programmed a large number of times, allowing the user the convenience of code modification on the same device. By using the appropriate programming tools, these Flash devices offer users the flexibility to conveniently debug and develop their applications while also offering a means of field programming and updating.

## **Structure**

The Program Memory has a capacity of up to 16Kx16 bits. The Program Memory is addressed by the Program Counter and also contains data, table information and interrupt entries. Table data, which can be setup in any location within the Program Memory, is addressed by a separate table pointer register.

| Device   | Capacity | Program Memory Banks |
|----------|----------|----------------------|
| BC66F840 | 4K×16    | 0                    |
| BC66F850 | 8K×16    | 0                    |
| BC66F860 | 16K×16   | 0~1                  |

**Program Memory Structure** 

Rev. 1.50 28 July 12, 2017

#### **Special Vectors**

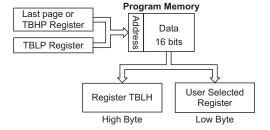

Within the Program Memory, certain locations are reserved for the reset and interrupts. The location 0000H is reserved for use by the device reset for program initialisation. After a device reset is initiated, the program will jump to this location and begin execution.

#### Look-up Table

Any location within the Program Memory can be defined as a look-up table where programmers can store fixed data. To use the look-up table, the table pointer must first be setup by placing the address of the look up data to be retrieved in the table pointer register, TBLP and TBHP. These registers define the total address of the look-up table.

After setting up the table pointer, the table data can be retrieved from the Program Memory using the "TABRD[m]" or "TABRDL[m]" instructions, respectively. When the instruction is executed, the lower order table byte from the Program Memory will be transferred to the user defined Data Memory register [m] as specified in the instruction. The higher order table data byte from the Program Memory will be transferred to the TBLH special register. Any unused bits in this transferred higher order byte will be read as "0".

The accompanying diagram illustrates the addressing data flow of the look-up table.

#### **Table Program Example**

The following example shows how the table pointer and table data is defined and retrieved from the microcontroller. This example uses raw table data located in the Program Memory which is stored there using the ORG statement. The value at this ORG statement is "0F00H" which refers to the start address of the last page within the 4K Program Memory of the BC66F840 device. The table pointer is setup here to have an initial value of "06H". This will ensure that the first data read from the data table will be at the Program Memory address "0F06H" or 6 locations after the start of the last page. Note that the value for the table pointer is referenced to the first address of the present page if the "TABRD [m]" instruction is being used. The high byte of the table data which in this case is equal to zero will be transferred to the TBLH register automatically when the "TABRD [m]" instruction is executed.

Because the TBLH register is a read-only register and cannot be restored, care should be taken to ensure its protection if both the main routine and Interrupt Service Routine use table read instructions. If using the table read instructions, the Interrupt Service Routines may change the value of the TBLH and subsequently cause errors if used again by the main routine. As a rule it is recommended that simultaneous use of the table read instructions should be avoided. However, in situations where simultaneous use cannot be avoided, the interrupts should be disabled prior to the execution of any main routine table-read instructions. Note that all table related instructions require two instruction cycles to complete their operation.

#### **Table Read Program Example:**

```
tempreg1 db ?
                  ; temporary register #1
tempreg2 db ?
                  ; temporary register #2
mov a,06h
                  ; initialise low table pointer - note that this address is referenced
mov tblp,a
mov a,0Fh
                  ; initialise high table pointer
mov tbhp, a
:
tabrd
        tempreq1 ; transfers value in table referenced by table pointer data at program
                  ; memory address "OFO6H" transferred to tempreg1 and TBLH
dec tblp
                 ; reduce value of table pointer by one
tabrd tempreg2
                  ; transfers value in table referenced by table pointer data at program
                  ; memory address "OFO5H" transferred to tempreg2 and TBLH in this
                  ; example the data "1AH" is transferred to tempreg1 and data "OFH" to
                   ; register tempreg2
org OFOOh
                  ; sets initial address of program memory
    00Ah, 00Bh, 00Ch, 00Dh, 00Eh, 00Fh, 01Ah, 01Bh
```

## In Circuit Programming

The provision of Flash type Program Memory provides the user with a means of convenient and easy upgrades and modifications to their programs on the same device.

As an additional convenience, Holtek has provided a means of programming the microcontroller in-circuit using a 4-pin interface. This provides manufacturers with the possibility of manufacturing their circuit boards complete with a programmed or un-programmed microcontroller, and then programming or upgrading the program at a later stage. This enables product manufacturers to easily keep their manufactured products supplied with the latest program releases without removal and re-insertion of the device.

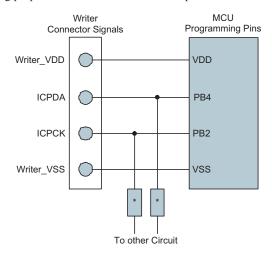

| Holtek Writer Pins | MCU Programming Pins | Function                |
|--------------------|----------------------|-------------------------|
| ICPDA              | PB4                  | Programming Serial Data |
| ICPCK              | PB2                  | Programming Clock       |
| VDD                | VDD                  | Power Supply            |
| VSS                | VSS                  | Ground                  |

The Program Memory can be programmed serially in-circuit using this 4-wire interface. Data is downloaded and uploaded serially on a single pin with an additional line for the clock. Two additional lines are required for the power supply and one line for the reset. The technical details regarding the in-circuit programming of the devices are beyond the scope of this document and will be supplied in supplementary literature.

Rev. 1.50 30 July 12, 2017

During the programming process, the user must take care of the ICPDA and ICPCK pins for data and clock programming purposes to ensure that no other outputs are connected to these two pins.

Note: \* may be resistor or capacitor. The resistance of \* must be greater than  $1k\Omega$  or the capacitance of \* must be less than 1nF.

## On-Chip Debug Support - OCDS

There is an EV chip named BC66V8x0 which is used to emulate the BC66F8x0 device respectively. The BC66V8x0 device also provides the "On-Chip Debug" function to debug the corresponding BC66F8x0 device during development process. The devices, BC66F8x0 and BC66V8x0, are almost functional compatible except the "On-Chip Debug" function. Users can use the BC66V8x0 device to emulate the BC66F8x0 device behaviors by connecting the OCDSDA and OCDSCK pins to the Holtek HT-IDE development tools. The OCDSDA pin is the OCDS Data/Address input/output pin while the OCDSCK pin is the OCDS clock input pin. When users use the BC66V8x0 EV chip for debugging, the corresponding pin functions shared with the OCDSDA and OCDSCK pins in the BC66F8x0 device will have no effect in the BC66V8x0 EV chip. However, the two OCDS pins which are pin-shared with the ICP programming pins are still used as the Flash Memory programming pins for ICP. For more detailed OCDS information, refer to the corresponding document named "Holtek e-Link for 8-bit MCU OCDS User's Guide".

| Holtek e-Link Pins | EV Chip Pins | Pin Description                                 |
|--------------------|--------------|---|
| OCDSDA             | OCDSDA       | On-Chip Debug Support Data/Address input/output |
| OCDSCK             | OCDSCK       | On-Chip Debug Support Clock input               |
| VDD                | VDD          | Power Supply                                    |

# **RAM Data Memory**

The Data Memory is a volatile area of 8-bit wide RAM internal memory and is the location where temporary information is stored.

#### Structure

Divided into two sections, the first of these is an area of RAM, known as the Special Function Data Memory. Here are located registers which are necessary for correct operation of the device. Many of these registers can be read from and written to directly under program control, however, some remain protected from user manipulation.

**Data Memory Structure** 

## **General Purpose Data Memory**

All microcontroller programs require an area of read/write memory where temporary data can be stored and retrieved for use later. It is this area of RAM memory that is known as General Purpose Data Memory. This area of Data Memory is fully accessible by the user programming for both reading and writing operations. By using the bit operation instructions individual bits can be set or reset under program control giving the user a large range of flexibility for bit manipulation in the Data Memory.

| Device   | Capacity | Banks  |
|----------|----------|--|
| BC66F840 | 256×8    | 0: 80H~FFH<br>1: 80H~FFH                             |
| BC66F850 | 384×8    | 0: 80H~FFH<br>1: 80H~FFH<br>2: 80H~FFH               |
| BC66F860 | 512×8    | 0: 80H~FFH<br>1: 80H~FFH<br>2: 80H~FFH<br>3: 80H~FFH |

Rev. 1.50 32 July 12, 2017

## **Special Purpose Data Memory**

This area of Data Memory is where registers, necessary for the correct operation of the microcontroller, are stored. Most of the registers are both readable and writeable but some are protected and are readable only, the details of which are located under the relevant Special Function Register section. Note that for locations that are unused, any read instruction to these addresses will return the value "00H".

Special Purpose Data Memory Structure - BC66F860

# **Special Function Register Description**

Most of the Special Function Register details will be described in the relevant functional section, however several registers require a separate description in this section.

## Indirect Addressing Registers - IAR0, IAR1

The Indirect Addressing Registers, IAR0 and IAR1, although having their locations in normal RAM register space, do not actually physically exist as normal registers. The method of indirect addressing for RAM data manipulation uses these Indirect Addressing Registers and Memory Pointers, in contrast to direct memory addressing, where the actual memory address is specified. Actions on the IAR0 and IAR1 registers will result in no actual read or write operation to these registers but rather to the memory location specified by their corresponding Memory Pointers, MP0 or MP1. Acting as a pair, IAR0 and MP0 can together access data from Bank 0 while the IAR1 and MP1 register pair can access data from any bank. As the Indirect Addressing Registers are not physically implemented, reading the Indirect Addressing Registers indirectly will return a result of "00H" and writing to the registers indirectly will result in no operation.

#### Memory Pointers - MP0, MP1

Two Memory Pointers, known as MP0 and MP1 are provided. These Memory Pointers are physically implemented in the Data Memory and can be manipulated in the same way as normal registers providing a convenient way with which to address and track data. When any operation to the relevant Indirect Addressing Registers is carried out, the actual address that the microcontroller is directed to, is the address specified by the related Memory Pointer. MP0, together with Indirect Addressing Register, IAR0, are used to access data from Bank 0, while MP1 and IAR1 are used to access data from all banks according to BP register. Direct Addressing can only be used with Bank 0, all other Banks must be addressed indirectly using MP1 and IAR1. Note that for this series of devices, the Memory Pointers, MP0 and MP1, are both 8-bit registers and used to access the Data Memory together with their corresponding indirect addressing registers IAR0 and IAR1.

The following example shows how to clear a section of four Data Memory locations already defined as locations adres1 to adres4.

#### Indirect Addressing Program Example

```
data .section data
adres1 db ?
adres2 db ?
adres3 db ?
adres4 db ?
block db?
code .section at 0 code
org 00h
start:
mov a,04h
                      ; setup size of block
mov block, a
mov a, offset adres1 ; Accumulator loaded with first RAM address
mov mp0,a
                      ; setup memory pointer with first RAM address
loop:
clr IAR0
                      ; clear the data at address defined by MPO
inc mp0
                      ; increment memory pointer
sdz block
                      ; check if last memory location has been cleared
jmp loop
continue:
```

The important point to note here is that in the example shown above, no reference is made to specific RAM addresses.

Rev. 1.50 36 July 12, 2017

### Bank Pointer - BP

For this series of devices, the Data Memory is divided into up to four banks depending upon which device is selected while the Program Memory is divided into two banks for the BC66F860 device. Selecting the required Data or Program Memory area is achieved using the Bank Pointer. Bit 1~0 are used to select Data Memory Banks while the bit 5 is used to select Program Memory Banks.

The Data Memory is initialised to Bank 0 after a reset, except for a WDT time-out reset in the Power Down Mode, in which case, the Data Memory bank remains unaffected. It should be noted that the Special Function Data Memory is not affected by the bank selection, which means that the Special Function Registers can be accessed from within any bank. Directly addressing the Data Memory will always result in Bank 0 being accessed irrespective of the value of the Bank Pointer. Accessing data from banks other than Bank 0 must be implemented using indirect addressing.

00: Bank 0 01: Bank 1 10: Bank 2 11: Bank 3

### Accumulator - ACC

The Accumulator is central to the operation of any microcontroller and is closely related with operations carried out by the ALU. The Accumulator is the place where all intermediate results from the ALU are stored. Without the Accumulator it would be necessary to write the result of each calculation or logical operation such as addition, subtraction, shift, etc., to the Data Memory resulting in higher programming and timing overheads. Data transfer operations usually involve the temporary storage function of the Accumulator; for example, when transferring data between one user defined register and another, it is necessary to do this by passing the data through the Accumulator as no direct transfer between two registers is permitted.

### Program Counter Low Register - PCL

To provide additional program control functions, the low byte of the Program Counter is made accessible to programmers by locating it within the Special Purpose area of the Data Memory. By manipulating this register, direct jumps to other program locations are easily implemented. Loading a value directly into this PCL register will cause a jump to the specified Program Memory location, however, as the register is only 8-bit wide, only jumps within the current Program Memory page are permitted. When such operations are used, note that a dummy cycle will be inserted.

### Look-up Table Registers - TBLP, TBHP, TBLH

These three special function registers are used to control operation of the look-up table which is stored in the Program Memory. TBLP and TBHP are the table pointer and indicates the location where the table data is located. Their value must be setup before any table read commands are executed. Their value can be changed, for example using the "INC" or "DEC" instructions, allowing for easy table data pointing and reading. TBLH is the location where the high order byte of the table data is stored after a table read data instruction has been executed. Note that the lower order table data byte is transferred to a user defined location.

Rev. 1.50 38 July 12, 2017

## Status Register - STATUS

This 8-bit register contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). These arithmetic/logical operation and system management flags are used to record the status and operation of the microcontroller.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition, operations related to the status register may give different results due to the different instruction operations. The TO flag can be affected only by a system power-up, a WDT time-out or by executing the "CLR WDT" or "HALT" instruction. The PDF flag is affected only by executing the "HALT" or "CLR WDT" instruction or during a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

- C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
- AC is set if an operation results in a carry out of the low nibbles in addition, or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
- **Z** is set if the result of an arithmetic or logical operation is zero; otherwise Z is cleared.
- OV is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.
- **PDF** is cleared by a system power-up or executing the "CLR WDT" instruction. PDF is set by executing the "HALT" instruction.
- TO is cleared by a system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.

In addition, on entering an interrupt sequence or executing a subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status registers are important and if the subroutine can corrupt the status register, precautions must be taken to correctly save it.

# BC66F840/BC66F850/BC66F860 2.4GHz Flash RF TX/RX MCU

# **STATUS Register**

| Bit  | 7 | 6 | 5  | 4   | 3   | 2   | 1   | 0   |
|------|---|---|----|-----|-----|-----|-----|-----|
| Name | _ | _ | TO | PDF | OV  | Z   | AC  | С   |
| R/W  | _ | _ | R  | R   | R/W | R/W | R/W | R/W |
| POR  | _ | _ | 0  | 0   | х   | Х   | х   | Х   |

"x" unknown

Bit 7, 6 Unimplemented, read as "0"

Bit 5 **TO:** Watchdog Time-Out flag

0: After power up or executing the "CLR WDT" or "HALT" instruction

1: A watchdog time-out occurred.

Bit 4 **PDF:** Power down flag

0: After power up or executing the "CLR WDT" instruction

1: By executing the "HALT" instruction

Bit 3 **OV:** Overflow flag

0: No overflow

1: An operation results in a carry into the highest-order bit but not a carry out of the highest-order bit or vice versa.

Bit 2 **Z:** Zero flag

0: The result of an arithmetic or logical operation is not zero

1: The result of an arithmetic or logical operation is zero

Bit 1 AC: Auxiliary flag

0: No auxiliary carry

1: An operation results in a carry out of the low nibbles in addition, or no borrow from the high nibble into the low nibble in subtraction

Bit 0 C: Carry flag

0: No carry-out

1: An operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation

C is also affected by a rotate through carry instruction.

Rev. 1.50 40 July 12, 2017

# **EEPROM Data Memory**

The devices contain an area of internal EEPROM Data Memory. EEPROM, which stands for Electrically Erasable Programmable Read Only Memory, is by its nature a non-volatile form of re-programmable memory, with data retention even when its power supply is removed. By incorporating this kind of data memory, a whole new host of application possibilities are made available to the designer. The availability of EEPROM storage allows information such as product identification numbers, calibration values, specific user data, system setup data or other product information to be stored directly within the product microcontroller. The process of reading and writing data to the EEPROM memory has been reduced to a very trivial affair.

## **EEPROM Data Memory Structure**

The EEPROM Data Memory capacity is up to 256×8 bits for this series of devices. Unlike the Program Memory and RAM Data Memory, the EEPROM Data Memory is not directly mapped into memory space and is therefore not directly addressable in the same way as the other types of memory. Read and Write operations to the EEPROM are carried out in single byte operations using an address and data register in Bank 0 and a single control register in Bank 1.

| Device               | Capacity | Address |
|----------------------|----------|---------|
| BC66F840             | 128×8    | 00H~7FH |
| BC66F850<br>BC66F860 | 256×8    | 00H~FFH |

**EEPROM Data Memory Structure** 

## **EEPROM Registers**

Three registers control the overall operation of the internal EEPROM Data Memory. These are the address register, EEA, the data register, EED and a single control register, EEC. As both the EEA and EED registers are located in Bank 0, they can be directly accessed in the same was as any other Special Function Register. The EEC register however, being located in Bank1, cannot be addressed directly and can only be read from or written to indirectly using the MP1 Memory Pointer and Indirect Addressing Register, IAR1. Because the EEC control register is located at address 40H in Bank 1, the MP1 Memory Pointer must first be set to the value 40H and the Bank Pointer register, BP, set to the value, 01H, before any operations on the EEC register are executed.

| POR  | _ | _ | _ | _ | 0    | 0   | 0    | 0   |

Bit 7~4 Unimplemented, read as "0"

Bit 3 WREN: Data EEPROM Write Enable

0: Disable 1: Enable

This is the Data EEPROM Write Enable Bit which must be set high before Data EEPROM write operations are carried out. Clearing this bit to zero will inhibit Data EEPROM write operations.

Bit 2 WR: EEPROM Write Control

0: Write cycle has finished1: Activate a write cycle

This is the Data EEPROM Write Control Bit and when set high by the application program will activate a write cycle. This bit will be automatically reset to zero by the hardware after the write cycle has finished. Setting this bit high will have no effect if the WREN has not first been set high.

Bit 1 RDEN: Data EEPROM Read Enable

0: Disable 1: Enable

This is the Data EEPROM Read Enable Bit which must be set high before Data EEPROM read operations are carried out. Clearing this bit to zero will inhibit Data EEPROM read operations.

Bit 0 **RD**: EEPROM Read Control

0: Read cycle has finished1: Activate a read cycle

This is the Data EEPROM Read Control Bit and when set high by the application program will activate a read cycle. This bit will be automatically reset to zero by the hardware after the read cycle has finished. Setting this bit high will have no effect if the RDEN has not first been set high.

Note: The WREN, WR, RDEN and RD can not be set to "1" at the same time in one instruction. The WR and RD can not be set to "1" at the same time.

## Reading Data from the EEPROM

To read data from the EEPROM, the read enable bit, RDEN, in the EEC register must first be set high to enable the read function. The EEPROM address of the data to be read must then be placed in the EEA register. If the RD bit in the EEC register is now set high, a read cycle will be initiated. Setting the RD bit high will not initiate a read operation if the RDEN bit has not been set. When the read cycle terminates, the RD bit will be automatically cleared to zero, after which the data can be read from the EED register. The data will remain in the EED register until another read or write operation is executed. The application program can poll the RD bit to determine when the data is valid for reading.

# Writing Data to the EEPROM

The EEPROM address of the data to be written must first be placed in the EEA register and the data placed in the EED register. To write data to the EEPROM, the write enable bit, WREN, in the EEC register must first be set high to enable the write function. After this, the WR bit in the EEC register must be immediately set high to initiate a write cycle. These two instructions must be executed consecutively. The global interrupt bit EMI should also first be cleared before implementing any write operations, and then set again after the write cycle has started. Note that setting the WR bit high will not initiate a write cycle if the WREN bit has not been set. As the EEPROM write cycle is controlled using an internal timer whose operation is asynchronous to microcontroller system clock, a certain time will elapse before the data will have been written into the EEPROM. Detecting when the write cycle has finished can be implemented either by polling the WR bit in the EEC register or by using the EEPROM interrupt. When the write cycle terminates, the WR bit will be automatically cleared to zero by the microcontroller, informing the user that the data has been written to the EEPROM. The application program can therefore poll the WR bit to determine when the write cycle has ended.

# **Write Protection**

Protection against inadvertent write operation is provided in several ways. After the devices are powered-on the Write Enable bit in the control register will be cleared preventing any write operations. Also at power-on the Bank Pointer, BP, will be reset to zero, which means that Data Memory Bank 0 will be selected. As the EEPROM control register is located in Bank 1, this adds a further measure of protection against spurious write operations. During normal program operation, ensuring that the Write Enable bit in the control register is cleared will safeguard against incorrect write operations.

### **EEPROM Interrupt**

The EEPROM write interrupt is generated when an EEPROM write cycle has ended. The EEPROM interrupt must first be enabled by setting the DEE bit in the relevant interrupt register. However as the EEPROM is contained within a Multi-function Interrupt, the associated Multi-function Interrupt enable bit must also be set. When an EEPROM write cycle ends, the DEF request flag and its associated Multi-function Interrupt request flag will both be set. If the global, EEPROM and Multi-function interrupts are enabled and the stack is not full, a jump to the associated Multi-function Interrupt vector will take place. When the interrupt is serviced only the Multi-function interrupt flag will be automatically reset, the EEPROM interrupt flag must be manually reset by the application program. More details can be obtained in the Interrupt section.

Rev. 1.50 44 July 12, 2017

# **Programming Considerations**

Care must be taken that data is not inadvertently written to the EEPROM. Protection can be enhanced by ensuring that the Write Enable bit is normally cleared to zero when not writing. Also the Bank Pointer could be normally cleared to zero as this would inhibit access to Bank 1 where the EEPROM control register exist. Although certainly not necessary, consideration might be given in the application program to the checking of the validity of new write data by a simple read back process. When writing data the WR bit must be set high immediately after the WREN bit has been set high, to ensure the write cycle executes correctly. The global interrupt bit EMI should also be cleared before a write cycle is executed and then re-enabled after the write cycle starts.

### **Programming Examples**

## Reading data from the EEPROM – polling method

```
MOV A, EEPROM ADRES ; user defined address
MOV EEA, A
                  ; setup memory pointer MP1
MOV A, 040H
MOV MP1, A
                   ; MP1 points to EEC register
MOV A, 01H
                   ; setup Bank Pointer
MOV BP, A
SET IAR1.1
                   ; set RDEN bit, enable read operations
                    ; start Read Cycle - set RD bit
SET IAR1.0
BACK:
SZ IAR1.0
                   ; check for read cycle end
JMP BACK
CLR IAR1
                    ; disable EEPROM read/write
CLR BP
MOV A, EED
                   ; move read data to register
MOV READ DATA, A
```

## Writing Data to the EEPROM – polling method

```
CLR EMI
MOV A, EEPROM ADRES ; user defined address
MOV EEA, A
MOV A, EEPROM DATA ; user defined data
MOV EED, A

                   ; setup memory pointer MP1
MOV MP1, A
                    ; MP1 points to EEC register
MOV A, 01H
                    ; setup Bank Pointer
MOV BP, A
SET TAR1.3
                    ; set WREN bit, enable write operations
SET IAR1.2
                     ; Start Write Cycle - set WR bit - executed immediately
                     ; after set WREN bit
SET EMI
BACK:
SZ IAR1.2
                    ; check for write cycle end
JMP BACK
CLR IAR1
                     ; disable EEPROM read/write
CLR BP
```

# **Oscillator**

Various oscillator options offer the user a wide range of functions according to their various application requirements. The flexible features of the oscillator functions ensure that the best optimisation can be achieved in terms of speed and power saving. Oscillator selections and operation are selected through a combination of configuration options and registers.

#### Oscillator Overview

In addition to being the source of the main system clock the oscillators also provide clock sources for the Watchdog Timer and Time Base Interrupts. External oscillators requiring some external components as well as fully integrated internal oscillators, requiring no external components, are provided to form a wide range of both fast and slow system oscillators. All oscillator options are selected through the configuration options. The higher frequency oscillators provide higher performance but carry with it the disadvantage of higher power requirements, while the opposite is of course true for the lower frequency oscillators. With the capability of dynamically switching between fast and slow system clock, the devices have the flexibility to optimize the performance/power ratio, a feature especially important in power sensitive portable applications.

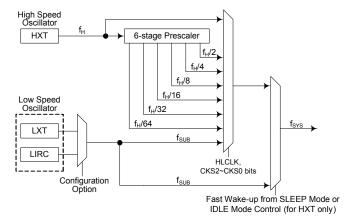

| Туре                       | Name | Freq.     | Pins      |
|----------------------------|------|-----------|-----------|
| External Crystal           | HXT  | 16MHz     | OSC1/OSC2 |
| External Low Speed Crystal | LXT  | 32.768kHz | XT1/XT2   |
| Internal Low Speed RC      | LIRC | 32kHz     | _         |

**Oscillator Types** 

## **System Clock Configurations**

There are three system oscillators, one high speed oscillator and two low speed oscillators. The high speed oscillator is the external crystal/ceramic oscillator – HXT. The low speed oscillators are the internal 32kHz oscillator – LIRC and the external 32.768kHz crystal oscillator. Selecting whether the low or high speed oscillator is used as the system oscillator is implemented using the HLCLK bit and CKS2~CKS0 bits in the SMOD register and as the system clock can be dynamically selected.

The actual source clock used for the low speed oscillator is chosen via a configuration option. The frequency of the slow speed or high speed system clock is also determined using the HLCLK bit and CKS2~CKS0 bits in the SMOD register. Note that two oscillator selections must be made namely one high speed and one low speed system oscillators. It is not possible to choose a no-oscillator selection for either the high or low speed oscillator.

**System Clock Configurations** 

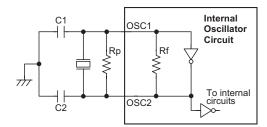

Rev. 1.50 46 July 12, 2017

## External Crystal/Ceramic Oscillator - HXT

The External Crystal/Ceramic System Oscillator is the high frequency oscillator. For most crystal oscillator configurations, the simple connection of a crystal across OSC1 and OSC2 will create the necessary phase shift and feedback for oscillation, without requiring external capacitors. However, for some crystal types and frequencies, to ensure oscillation, it may be necessary to add two small value capacitors, C1 and C2. Using a ceramic resonator will usually require two small value capacitors, C1 and C2, to be connected as shown for oscillation to occur. The values of C1 and C2 should be selected in consultation with the crystal or resonator manufacturers specification.

For oscillator stability and to minimise the effects of noise and crosstalk, it is important to ensure that the crystal and any associated resistors and capacitors along with inter connecting lines are all located as close to the MCU as possible.

Note: 1. Rp is normally not required. C1 and C2 are required.
2. Although not shown OSC1/OSC2 pins have a parasitic capacitance of around 7pF.

Crystal/Resonator Oscillator - HXT

| Crystal Oscillator C1 and C2 Values           |  |  |  |  |  |  |
|---|--|--|--|--|--|--|
| Crystal Frequency C1 C2                       |  |  |  |  |  |  |
| 16MHz 0pF 0pF                                 |  |  |  |  |  |  |
| Note: C1 and C2 values are for guidance only. |  |  |  |  |  |  |

**Crystal Recommended Capacitor Values** 

Rev. 1.50 47 July 12, 2017

## External 32.768kHz Crystal Oscillator - LXT

The External 32.768kHz Crystal System Oscillator is one of the low frequency oscillator choices, which is selected via configuration option. This clock source has a fixed frequency of 32.768kHz and requires a 32.768kHz crystal to be connected between pins XT1 and XT2. The external resistor and capacitor components connected to the 32.768kHz crystal are necessary to provide oscillation. For applications where precise frequencies are essential, these components may be required to provide frequency compensation due to different crystal manufacturing tolerances. During power-up there is a time delay associated with the LXT oscillator waiting for it to start-up.

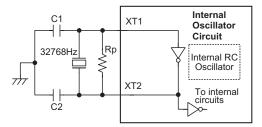

When the microcontroller enters the SLEEP or IDLE Mode, the system clock is switched off to stop microcontroller activity and to conserve power. However, in many microcontroller applications it may be necessary to keep the internal timers operational even when the microcontroller is in the SLEEP or IDLE Mode. To do this, another clock, independent of the system clock, must be provided.

However, for some crystals, to ensure oscillation and accurate frequency generation, it is necessary to add two small value external capacitors, C1 and C2. The exact values of C1 and C2 should be selected in consultation with the crystal or resonator manufacturer's specification. The external parallel feedback resistor, Rp, is required.

A configuration option determines if the XT1/XT2 pins are used for the LXT oscillator or as I/O pins.

- If the LXT oscillator is not used for any clock source, the XT1/XT2 pins can be used as normal I/O pins.
- If the LXT oscillator is used for any clock source, the 32.768kHz crystal should be connected to the XT1/XT2 pins.

For oscillator stability and to minimise the effects of noise and crosstalk, it is important to ensure that the crystal and any associated resistors and capacitors along with inter connecting lines are all located as close to the MCU as possible.

Note: 1. Rp, C1 and C2 are required.
2. Although not shown pins have a parasitic capacitance of around 7pF.

External LXT Oscillator - LXT

| LXT Oscillator C1 and C2 Values                |  |  |  |  |  |  |
|--|--|--|--|--|--|--|
| Crystal Frequency C1 C2                        |  |  |  |  |  |  |
| 32.768kHz 10pF 10pF                            |  |  |  |  |  |  |
| Note: 1 C1 and C2 values are for guidance only |  |  |  |  |  |  |

Note: 1. C1 and C2 values are for guidance only 2. Rp=5M~10MΩ is recommended.

32.768kHz Crystal Recommended Capacitor Values

Rev. 1.50 48 July 12, 2017

#### **LXT Oscillator Low Power Function**

The LXT oscillator can function in one of two modes, the Quick Start Mode and the Low Power Mode. The mode selection is executed using the LXTLP bit in the TBC register.

| LXTLP Bit | LXT Mode    |
|-----------|-------------|
| 0         | Quick Start |
| 1         | Low Power   |

After power on, the LXTLP bit will be automatically cleared to zero ensuring that the LXT oscillator is in the Quick Start operating mode. In the Quick Start Mode the LXT oscillator will power up and stabilise quickly. However, after the LXT oscillator has fully powered up it can be placed into the Low-power mode by setting the LXTLP bit high. The oscillator will continue to run but with reduced current consumption, as the higher current consumption is only required during the LXT oscillator start-up. In power sensitive applications, such as battery applications, where power consumption must be kept to a minimum, it is therefore recommended that the application program sets the LXTLP bit high about 2 seconds after power-on.

It should be noted that no matter what condition the LXTLP bit is set to, the LXT oscillator will always function normally, the only difference is that it will take more time to start up if in the Low-power mode.

### Internal 32kHz Oscillator - LIRC

The Internal 32kHz System Oscillator is the low frequency oscillator. It is a fully integrated RC oscillator with a typical frequency of 32kHz at 5V, requiring no external components for its implementation. Device trimming during the manufacturing process and the inclusion of internal frequency compensation circuits are used to ensure that the influence of the power supply voltage, temperature and process variations on the oscillation frequency are minimised. As a result, at a power supply of 5V and at a temperature of 25°C degrees, the fixed oscillation frequency of 32kHz will have a tolerance within 10%.

# **Supplementary Oscillator**

The low speed oscillator, in addition to providing a system clock source, is also used to provide a clock source to other device functions such as the Watchdog Timer and the Time Base Interrupts.

# **Operating Modes and System Clocks**

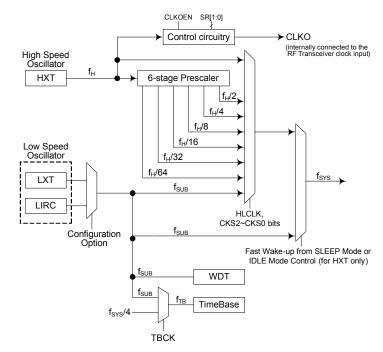

Present day applications require that their microcontrollers have high performance but often still demand that they consume as little power as possible, conflicting requirements that are especially true in battery powered portable applications. The fast clocks required for high performance will by their nature increase current consumption and of course vice-versa, lower speed clocks reduce current consumption. As Holtek has provided these devices with both high and low speed clock sources and the means to switch between them dynamically, the user can optimise the operation of their microcontroller to achieve the best performance/power ratio.

## **System Clocks**

The devices have many different clock sources for both the CPU and peripheral function operation. By providing the user with a wide range of clock options using configuration options and register programming, a clock system can be configured to obtain maximum application performance.

The main system clock can come from a high frequency  $f_H$  or low frequency  $f_{SUB}$  source and is selected using the HLCLK bit and CKS2~CKS0 bits in the SMOD register. The high speed system clock can be sourced from a HXT oscillator. The low speed system clock source can be sourced from the clock  $f_{SUB}$ . If  $f_{SUB}$  is selected, then it can be sourced from either the LIRC or LXT oscillator. The other choice, which is a divided version of the high speed system oscillator has a range of  $f_H/2~f_H/64$ . Note that when the system clock source  $f_{SYS}$  is switched to  $f_L$  from  $f_H$ , the high speed oscillation will stop to conserve the power. Thus there is no  $f_H~f_H/64$  for peripheral circuit to use.

The  $f_{SUB}$  clock is used to provide a substitute clock for the microcontroller just after a wake-up has occurred to enable faster wake-up times. Together with  $f_{SYS}/4$  it is also used as one of the clock sources for the Time Base interrupt function. The  $f_{SUB}$  clock is also used as a clock source for the Watchdog Timer, TMs or SIM functions.

**Operating Mode Clock Configurations** 

Note: When the system clock source  $f_{SYS}$  is switched to  $f_L$  from  $f_H$ , the high speed oscillation will stop to conserve the power. Thus there is no  $f_H \sim f_H/64$  for peripheral circuit to use.

Rev. 1.50 50 July 12, 2017

### **System Operation Modes**

There are six different modes of operation for the microcontroller, each one with its own special characteristics and which can be chosen according to the specific performance and power requirements of the application. There are two modes allowing normal operation of the microcontroller, the NORMAL Mode and SLOW Mode. The remaining four modes, the SLEEP0, SLEEP1, IDLE0 and IDLE1 Mode are used when the microcontroller CPU is switched off to conserve power.

| Operating Mode |     | Description                        |                  |  |  |  |  |  |
|----------------|-----|------------------------------------|------------------|--|--|--|--|--|
| Operating wode | CPU | f <sub>SYS</sub>                   | f <sub>SUB</sub> |  |  |  |  |  |
| NORMAL Mode    | On  | f <sub>H</sub> ∼f <sub>H</sub> /64 | On               |  |  |  |  |  |
| SLOW Mode      | On  | f <sub>SUB</sub>                   | On               |  |  |  |  |  |
| IDLE0 Mode     | Off | Off                                | On               |  |  |  |  |  |
| IDLE1 Mode     | Off | On                                 | On               |  |  |  |  |  |
| SLEEP0 Mode    | Off | Off                                | Off              |  |  |  |  |  |
| SLEEP1 Mode    | Off | Off                                | On               |  |  |  |  |  |

### **NORMAL Mode**

As the name suggests this is one of the main operating modes where the microcontroller has all of its functions operational and where the system clock is provided by one of the high speed oscillators. This mode operates allowing the microcontroller to operate normally with a clock source will come from the HXT high speed oscillator. The high speed oscillator will however first be divided by a ratio ranging from 1 to 64, the actual ratio being selected by the CKS2~LCKS0 and HLCLK bits in the SMOD register. Although a high speed oscillator is used, running the microcontroller at a divided clock ratio reduces the operating current.

### **SLOW Mode**

This is also a mode where the microcontroller operates normally although now with a slower speed clock source. The clock source used will be from the low speed oscillators, either the LXT or LIRC oscillators. Running the microcontroller in this mode allows it to run with much lower operating currents. In the SLOW Mode, the  $f_{\rm H}$  is off.

## **SLEEP0 Mode**

The SLEEP Mode is entered when a HALT instruction is executed and the IDLEN bit in the SMOD register is low. In the SLEEP0 mode the CPU will be stopped, and the f<sub>SUB</sub> clock will be stopped too, and the Watchdog Timer function is disabled. In this mode, the LVDEN is must set to 0. If the LVDEN is set to 1, it won't enter the SLEEP0 Mode.

## **SLEEP1 Mode**

The SLEEP Mode is entered when a HALT instruction is executed and the IDLEN bit in the SMOD register is low. In the SLEEP1 mode the CPU will be stopped. However, the  $f_{SUB}$  clock will continue to operate if the LVDEN is set to 1 or the Watchdog Timer function is enabled as its clock source is from the  $f_{SUB}$ .

#### **IDLE0 Mode**

The IDLE0 Mode is entered when a HALT instruction is executed and when the IDLEN bit in the SMOD register is high and the FSYSON bit in the CTRL0 register is low. In the IDLE0 Mode the system oscillator will be inhibited from driving the CPU but some peripheral functions will remain operational such as the Watchdog Timer, TMs and SIM. In the IDLE0 Mode, the system oscillator will be stopped. In the IDLE0 Mode the Watchdog Timer clock,  $f_{SUB}$ , will be on if the Watchdog Timer function is enabled.

### **IDLE1 Mode**

The IDLE1 Mode is entered when a HALT instruction is executed and when the IDLEN bit in the SMOD register is high and the FSYSON bit in the CTRL0 register is high. In the IDLE1 Mode the system oscillator will be inhibited from driving the CPU but may continue to provide a clock source to keep some peripheral functions operational such as the Watchdog Timer, TMs and SIM. In the IDLE1 Mode, the system oscillator will continue to run, and this system oscillator may be high speed or low speed system oscillator. In the IDLE1 Mode the Watchdog Timer clock, f<sub>SUB</sub>, will be on if the Watchdog Timer function is enabled.

## **Control Register**

A register, SMOD, together with the FSYSON bit in the CTRL0 register are used for overall control of the internal clocks within the devices.

# **SMOD Register**

| Bit  | 7    | 6    | 5    | 4     | 3   | 2   | 1     | 0     |
|------|------|------|------|-------|-----|-----|-------|-------|
| Name | CKS2 | CKS1 | CKS0 | FSTEN | LTO | HTO | IDLEN | HLCLK |
| R/W  | R/W  | R/W  | R/W  | R/W   | R   | R   | R/W   | R/W   |
| POR  | 1    | 1    | 0    | 0     | 0   | 1   | 1     | 0     |

Bit 7~5 **CKS2~CKS0:** The system clock selection when HLCLK is 0

000:  $f_{SUB}$  ( $f_{LIRC}$  or  $f_{LXT}$ )

001:  $f_{SUB}$  ( $f_{LIRC}$  or  $f_{LXT}$ )

010: f<sub>H</sub>/64 011: f<sub>H</sub>/32 100: f<sub>H</sub>/16 101: f<sub>H</sub>/8 110: f<sub>H</sub>/4 111: f<sub>H</sub>/2

These three bits are used to select which clock is used as the system clock source. In addition to the system clock source, which is the LIRC or LXT clock, a divided version of the high speed system oscillator can also be chosen as the system clock source.

Bit 4 **FSTEN:** Fast Wake-up Control (only for HXT)

0: Disable 1: Enable

This is the Fast Wake-up Control bit which determines if the  $f_{SUB}$  clock source is initially used after the devices wake up. When the bit is high, the  $f_{SUB}$  clock source can be used as a temporary system clock to provide a faster wake up time as the  $f_{SUB}$  clock is available.

Bit 3 LTO: Low speed system oscillator ready flag

0: Not ready 1: Ready

This is the low speed system oscillator ready flag which indicates when the low speed system oscillator is stable after power on reset or a wake-up has occurred. The flag will be low when in the SLEEPO Mode but after a wake-up has occurred, the flag will change to a high level after 1~2 clock cycles if the LIRC oscillator is used or 1024 clock cycles if the LXT oscillator is used.

Rev. 1.50 52 July 12, 2017

Bit 2 **HTO:** High speed system oscillator ready flag

0: Not ready 1: Ready

This is the high speed system oscillator ready flag which indicates when the high speed system oscillator is stable. This flag is cleared to 0 by hardware when the devices are powered on and then changes to a high level after the high speed system oscillator is stable. Therefore this flag will always be read as 1 by the application program after device power-on. The flag will be low when in the SLEEP or IDLE0 Mode but after a wake-up has occurred, the flag will change to a high level after 1024 clock cycles as the HXT oscillator is used.

Bit 1 **IDLEN:** IDLE Mode control

0: Disable 1: Enable

This is the IDLE Mode Control bit and determines what happens when the HALT instruction is executed. If this bit is high, when a HALT instruction is executed the devices will enter the IDLE Mode. In the IDLE1 Mode the CPU will stop running but the system clock will continue to keep the peripheral functions operational as the FSYSON bit is high. If FSYSON bit is low, the CPU and the system clock will all stop in IDLE0 mode. If the bit is low the devices will enter the SLEEP Mode when a HALT instruction is executed.

Bit 0 HLCLK: System clock selection

0:  $f_H/2 \sim f_H/64$  or  $f_{SUB}$ 

1: f<sub>H</sub>

This bit is used to select if the  $f_H$  clock or the  $f_H/2\sim f_H/64$  or  $f_{SUB}$  clock is used as the system clock. When the bit is high the  $f_H$  clock will be selected and if low the  $f_H/2\sim f_H/64$  or  $f_{SUB}$  clock will be selected. When system clock switches from the  $f_H$  clock to the  $f_{SUB}$  clock, the  $f_H$  clock will be automatically switched off to conserve power.

### **CTRL0** Register

| Bit  | 7      | 6 | 5 | 4 | 3 | 2    | 1   | 0   |
|------|--------|---|---|---|---|------|-----|-----|
| Name | FSYSON | _ | _ | _ | _ | LVRF | LRF | WRF |
| R/W  | R/W    | _ | _ | _ | _ | R/W  | R/W | R/W |
| POR  | 0      | _ | _ | _ | _ | Х    | 0   | 0   |

"x": unknown

Bit 7 **FSYSON:** f<sub>SYS</sub> Control in IDLE Mode

0: Disable 1: Enable

This is the Fast Wake-up Control bit which determines if the  $f_{SUB}$  clock source is initially used after the devices wake up.

Bit 6~3 Unimplemented, read as "0"

Bit 2 LVRF: LVR function reset flag

0: Not occurred 1: Occurred

This bit is set to 1 when a specific Low Voltage Reset situation occurs. This bit can only be cleared to 0 by the application program.

# BC66F840/BC66F850/BC66F860 2.4GHz Flash RF TX/RX MCU

Bit 1 LRF: LVR Control register software reset flag

0: Not occurred 1: Occurred

This bit is set to 1 if the LVRC register contains any non defined LVR voltage register values. This in effect acts like a software-reset function. This bit can only be cleared to 0 by the application program.

Bit 0 WRF: WDT Control register software reset flag

0: Not occurred1: Occurred

This bit is set to 1 by the WDT Control register software reset and cleared by the application program. Note that this bit can only be cleared to 0 by the application program.

The CLKO clock signal is derived from the external crystal oscillator and internally connected to the RF Transceiver clock input. It is recommended to enable the CLKO clock always when the RF transceiver is used.

### **CTRL1 Register**

| Bit  | 7 | 6 | 5 | 4      | 3 | 2 | 1   | 0   |
|------|---|---|---|--------|---|---|-----|-----|
| Name | _ | _ | _ | CLKOEN | _ | _ | SR1 | SR0 |
| R/W  | _ | _ | _ | R/W    | _ | _ | R/W | R/W |
| POR  | _ | _ | _ | 0      | _ | _ | 0   | 0   |

Bit 7~5 Unimplemented, read as "0"

Bit 4 CLKOEN: CLKO Output Enable Control

0: Disable 1: Enable

This bit is used to enable or disable the CLKO output signal which is internally connected to the RF transceiver clock input. It is recommended to enable the CLKO output when the RF transceiver is used even if the devices enter the power down mode.

Bit 3~2 Unimplemented, read as "0"

Bit 1~0 SR1~SR0: CLKO Output Slew Rate Control

| SR[1:0] | V <sub>CLKO</sub> =3V | V <sub>CLKO</sub> =5V |
|---------|-----------------------|-----------------------|
| 00      | 0.22V/ns              | 0.5V/ns               |
| 01      | 0.20V/ns              | 0.4V/ns               |
| 10      | 0.15V/ns              | 0.3V/ns               |
| 11      | 0.10V/ns              | 0.2V/ns               |

These bits are used to control the CLKO output slew rate.

Rev. 1.50 54 July 12, 2017

### Fast Wake-up

To minimise power consumption the devices can enter the SLEEP or IDLE0 Mode, where the system clock source to the devices will be stopped. However when the devices are woken up again, it can take a considerable time for the original system oscillator to restart, stabilise and allow normal operation to resume. To ensure the devices are up and running as fast as possible a Fast Wake-up function is provided, which allows  $f_{SUB}$ , namely the LIRC or LXT oscillator, to act as a temporary clock to first drive the system until the original system oscillator has stabilised. As the clock source for the Fast Wake-up function is  $f_{SUB}$ , the Fast Wake-up function is only available in the SLEEP1 and IDLE0 modes. When the devices are woken up from the SLEEP0 mode, the Fast Wake-up function has no effect because the  $f_{SUB}$  clock is stopped. The Fast Wake-up enable/disable function is controlled using the FSTEN bit in the SMOD register.

If the HXT oscillator is selected as the NORMAL Mode system clock and the Fast Wake-up function is enabled, then it will take one to two  $t_{SUB}$  clock cycles of the LIRC or LXT oscillator for the system to wake-up. The system will then initially run under the  $f_{SUB}$  clock source until 1024 HXT clock cycles have elapsed, at which point the HTO flag will switch high and the system will switch over to operating from the HXT oscillator.

If the LXT or LIRC oscillator is used as the system oscillator then it will take 1024 clock cycles of the LXT oscillator or 1~2 cycles of the LIRC oscillator to wake up the system from the SLEEP or IDLE0 Mode. The Fast Wake-up bit, FSTEN will have no effect in these cases.

| System Oscillator | FSTEN<br>Bit | Wake-up Time<br>(SLEEP0 Mode) | Wake-up Time Wake-up Time (SLEEP1 Mode) (IDLE0 Mode)  | Wake-up Time<br>(IDLE1 Mode) |
|-------------------|--------------|-------------------------------|---|------------------------------|
|                   | 0            | 1024 HXT cycles               | 1024 HXT cycles   | 1~2 HXT cycles               |
| нхт               | 1            | 1024 HXT cycles               | $1{\sim}2~f_{\text{SUB}}$ cycles (System runs first with $f_{\text{SUB}}$ for 1024 HXT cycles and then switches over to run with the HXT clock) | 1~2 HXT cycles               |
| LIRC              | Х            | 1~2 LIRC cycles               | 1~2 LIRC cycles   | 1~2 LIRC cycles              |
| LXT               | Х            | 1024 LXT cycles               | 1024 LXT cycles   | 1~2 LXT cycles               |

"x": don't care

### Wake-up Times

Note that if the Watchdog Timer is disabled, which means that the LIRC or LXT oscillator is off, then there will be no Fast Wake-up function available when the devices wake-up from the SLEEPO Mode.

Rev. 1.50 55 July 12, 2017

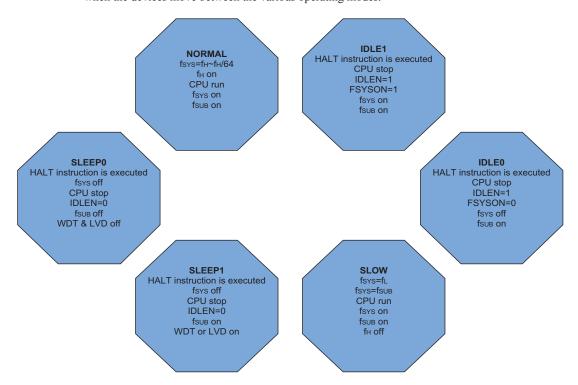

# **Operating Mode Switching**

The devices can switch between operating modes dynamically allowing the user to select the best performance/power ratio for the present task in hand. In this way microcontroller operations that do not require high performance can be executed using slower clocks thus requiring less operating current and prolonging battery life in portable applications.

In simple terms, Mode Switching between the NORMAL Mode and SLOW Mode is executed using the HLCLK bit and CKS2~CKS0 bits in the SMOD register while Mode Switching from the NORMAL/SLOW Modes to the SLEEP/IDLE Modes is executed via the HALT instruction. When a HALT instruction is executed, whether the devices enter the IDLE Mode or the SLEEP Mode is determined by the condition of the IDLEN bit in the SMOD register and FSYSON in the WDTC register.

When the HLCLK bit switches to a low level, which implies that clock source is switched from the high speed clock source,  $f_{\rm H}$ , to the clock source,  $f_{\rm H}/2\sim f_{\rm H}/64$  or  $f_{\rm L}$ . If the clock is from the  $f_{\rm L}$ , the high speed clock source will stop running to conserve power. When this happens it must be noted that the  $f_{\rm H}/16$  and  $f_{\rm H}/64$  internal clock sources will also stop running, which may affect the operation of other internal functions such as the TMs and the SIM. The accompanying flowchart shows what happens when the devices move between the various operating modes.

Rev. 1.50 56 July 12, 2017

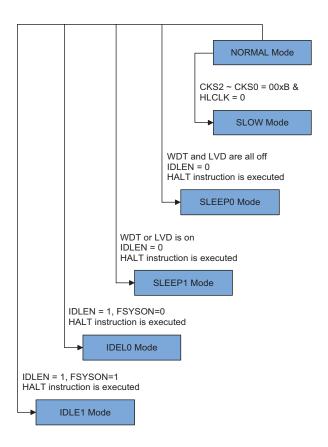

### **NORMAL Mode to SLOW Mode Switching**

When running in the NORMAL Mode, which uses the high speed system oscillator, and therefore consumes more power, the system clock can switch to run in the SLOW Mode by set the HLCLK bit to 0 and set the CKS2~CKS0 bits to 000B or 001B in the SMOD register. This will then use the low speed system oscillator which will consume less power. Users may decide to do this for certain operations which do not require high performance and can subsequently reduce power consumption.

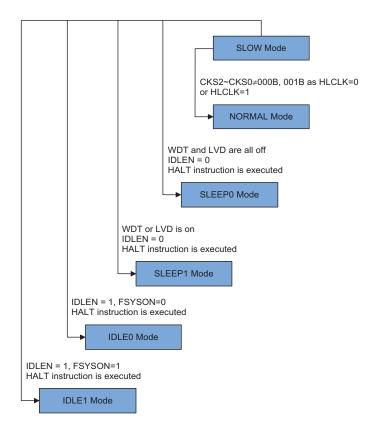

The SLOW Mode is sourced from the LIRC or LXT oscillator and therefore requires these oscillators to be stable before full mode switching occurs. This is monitored using the LTO bit in the SMOD register.

### **SLOW Mode to NORMAL Mode Switching**

In SLOW Mode the system uses the LIRC or LXT low speed system oscillator. To switch back to the NORMAL Mode, where the high speed system oscillator is used, the HLCLK bit should be set to 1 or HLCLK bit is 0 but CKS2~CKS0 is set to 010B, 011B, 100B, 101B, 110B or 111B. As a certain amount of time will be required for the high frequency clock to stabilise, the status of the HTO bit is checked. The amount of time required for high speed system oscillator stabilization depends upon which high speed system oscillator type is used.

## **Entering the SLEEP0 Mode**

There is only one way for the devices to enter the SLEEP0 Mode and that is to execute the HALT instruction in the application program with the IDLEN bit in SMOD register equal to 0 and the WDT and LVD both off. When this instruction is executed under the conditions described above, the following will occur:

- The system clock, WDT clock and Time Base clock will be stopped and the application program will stop at the HALT instruction.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and stopped.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag, PDF, will be set and the Watchdog time-out flag, TO, will be cleared.

Rev. 1.50 58 July 12, 2017

### **Entering the SLEEP1 Mode**

There is only one way for the devices to enter the SLEEP1 Mode and that is to execute the HALT instruction in the application program with the IDLEN bit in SMOD register equal to 0 and the WDT or LVD on. When this instruction is executed under the conditions described above, the following will occur:

- The system clock and Time Base clock will be stopped and the application program will stop at the HALT instruction, but the WDT or LVD will remain with the clock source coming from the f<sub>SUB</sub> clock.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting as the WDT function is enabled.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag, PDF, will be set and the Watchdog time-out flag, TO, will be cleared.

## **Entering the IDLE0 Mode**

There is only one way for the devices to enter the IDLE0 Mode and that is to execute the HALT instruction in the application program with the IDLEN bit in SMOD register equal to 1 and the FSYSON bit in the CTRL0 register equal to 0. When this instruction is executed under the conditions described above, the following will occur:

- The system clock will be stopped and the application program will stop at the HALT instruction, but the Time Base clock and f<sub>SUB</sub> clock will be on.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting as the WDT is enabled.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag, PDF, will be set and the Watchdog time-out flag, TO, will be cleared.

### **Entering the IDLE1 Mode**

There is only one way for the devices to enter the IDLE1 Mode and that is to execute the HALT instruction in the application program with the IDLEN bit in SMOD register equal to 1 and the FSYSON bit in the CTRL0 register equal to 1. When this instruction is executed under the conditions described above, the following will occur:

- The system clock, Time Base clock and f<sub>SUB</sub> clock will be on and the application program will stop at the HALT instruction.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting as the WDT is enabled.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag, PDF, will be set and the Watchdog time-out flag, TO, will be cleared.

## **Standby Current Considerations**

As the main reason for entering the SLEEP or IDLE Mode is to keep the current consumption of the devices to as low a value as possible, perhaps only in the order of several micro-amps except in the IDLE1 Mode, there are other considerations which must also be taken into account by the circuit designer if the power consumption is to be minimised. Special attention must be made to the I/O pins on the devices. All high-impedance input pins must be connected to either a fixed high or low level as any floating input pins could create internal oscillations and result in increased current consumption. This also applies to devices which have different package types, as there may be unbonbed pins. These must either be setup as outputs or if setup as inputs must have pull-high resistors connected.

Care must also be taken with the loads, which are connected to I/O pins, which are setup as outputs. These should be placed in a condition in which minimum current is drawn or connected only to external circuits that do not draw current, such as other CMOS inputs. Also note that additional standby current will also be required if the configuration options have enabled the LIRC oscillator.

In the IDLE1 Mode the system oscillator is on, if the system oscillator is from the high speed system oscillator, the additional standby current will also be perhaps in the order of several hundred micro-amps.

## Wake-up

After the system enters the SLEEP or IDLE Mode, it can be woken up from one of various sources listed as follows:

- · An external reset
- · An external falling edge on Port A
- · A system interrupt
- · A WDT overflow

If the system is woken up by an external reset, the devices will experience a full system reset, however, if the devices are woken up by a WDT overflow, a Watchdog Timer reset will be initiated. Although both of these wake-up methods will initiate a reset operation, the actual source of the wake-up can be determined by examining the TO and PDF flags. The PDF flag is cleared by a system power-up or executing the clear Watchdog Timer instructions and is set when executing the HALT instruction. The TO flag is set if a WDT time-out occurs, and causes a wake-up that only resets the Program Counter and Stack Pointer, the other flags remain in their original status.

Each pin on Port A can be setup using the PAWU register to permit a negative transition on the pin to wake-up the system. When a Port A pin wake-up occurs, the program will resume execution at the instruction following the HALT instruction. If the system is woken up by an interrupt, then two possible situations may occur. The first is where the related interrupt is disabled or the interrupt is enabled but the stack is full, in which case the program will resume execution at the instruction following the HALT instruction. In this situation, the interrupt which woke-up the devices will not be immediately serviced, but will rather be serviced later when the related interrupt is finally enabled or when a stack level becomes free. The other situation is where the related interrupt is enabled and the stack is not full, in which case the regular interrupt response takes place. If an interrupt request flag is set high before entering the SLEEP or IDLE Mode, the wake-up function of the related interrupt will be disabled.

Rev. 1.50 60 July 12, 2017

# **Programming Considerations**

The high speed and low speed oscillators both use the same SST counter. For example, if the system is woken up from the SLEEP0 Mode and both the HXT and LXT oscillators need to start-up from an off state. The LXT oscillator uses the SST counter after HXT oscillator has finished its SST period.

- If the devices are woken up from the SLEEPO Mode to the NORMAL Mode, the high speed
  system oscillator needs an SST period. The devices will execute first instruction after HTO
  is "1". At this time, the LXT oscillator may not be stable if f<sub>SUB</sub> is from LXT oscillator. The
  same situation occurs in the power-on state. The LXT oscillator is not ready yet when the first
  instruction is executed.
- If the devices are woken up from the SLEEP1 Mode to NORMAL Mode, and the system clock source is from the HXT oscillator and FSTEN is 1, the system clock can first be switched to the f<sub>SUB</sub> clock after wake up.
- There are peripheral functions, such as WDT and TMs, for which the f<sub>SYS</sub> is used. If the system clock source is switched from f<sub>H</sub> to f<sub>SUB</sub>, the clock source to the peripheral functions mentioned above will change accordingly.
- The on/off condition of f<sub>SUB</sub> depends upon whether the WDT or LVD function is enabled or disabled as the WDT clock source is selected from f<sub>SUB</sub>.

# **Watchdog Timer**

The Watchdog Timer is provided to prevent program malfunctions or sequences from jumping to unknown locations, due to certain uncontrollable external events such as electrical noise.

## **Watchdog Timer Clock Source**

The Watchdog Timer clock source is provided by the internal clock, f<sub>SUB</sub>. The f<sub>SUB</sub> clock can be sourced from either the LIRC or LXT oscillator selected by a configuration option. The LIRC internal oscillator has an approximate period of 32kHz at a supply voltage of 5V. However, it should be noted that this specified internal clock period can vary with V<sub>DD</sub>, temperature and process variations. The LXT oscillator us supplied by an external 32.768kHz crystal. The Watchdog Timer source clock is then subdivided by a ratio of 2<sup>8</sup> to 2<sup>18</sup> to give longer timeouts, the actual value being chosen using the WS2~WS0 bits in the WDTC register.

## **Watchdog Timer Control Register**

A single register, WDTC, controls the required timeout period as well as the enable/disable operation. This register together with several configuration options control the overall operation of the Watchdog Timer.

Rev. 1.50 61 July 12, 2017

### **WDTC Register**

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | WE4 | WE3 | WE2 | WE1 | WE0 | WS2 | WS1 | WS0 |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | 0   | 1   | 0   | 1   | 0   | 0   | 1   | 1   |

Bit 7~3 WE4~WE0: WDT Function Enable control

> 10101: Disabled 01010: Enable

Other Value: Reset MCU

If these bits are changed due to adverse environmental conditions, the microcontroller will be reset. The reset operation will be activated after 2~3 f<sub>SUB</sub> clock cycles and the WRF bit in the CTRL0 register will be set to 1

WS2~WS0: WDT Time-out period selection Bit 2~0

 $000: 2^8/f_S$  $001: 2^{10}/f_S$ 010:  $2^{12}/f_S$ 011:  $2^{14}/f_S$  $100: 2^{15}/f_S$ 101: 216/fs

110:  $2^{17}/f_S$ 111:  $2^{18}/f_S$ 

These three bits determine the division ratio of the Watchdog Timer source clock, which in turn determines the timeout period.

### **CTRL0** Register

Rev. 1.50 62 July 12, 2017

## **Watchdog Timer Operation**

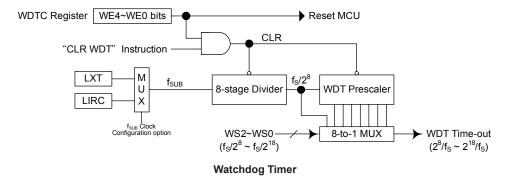

The Watchdog Timer operates by providing a device reset when its timer overflows. This means that in the application program and during normal operation the user has to strategically clear the Watchdog Timer before it overflows to prevent the Watchdog Timer from executing a reset. This is done using the clear watchdog instructions. If the program malfunctions for whatever reason, jumps to an unknown location, or enters an endless loop, these clear instructions will not be executed in the correct manner, in which case the Watchdog Timer will overflow and reset the device. With regard to the Watchdog Timer enable/disable function, there are five bits, WE4~WE0, in the WDTC register to offer the enable/disable control and reset control of the Watchdog Timer. The WDT function will be disabled when the WE4~WE0 bits are set to a value of 10101B while the WDT function will be enabled if the WE4~WE0 bits are equal to 01010B. If the WE4~WE0 bits are set to any other values, other than 01010B and 10101B, it will reset the device after 2~3 f<sub>SUB</sub> clock cycles. After power on these bits will have a value of 01010B.

| WDT Function Control        | WE4~WE0 Bits    | WDT Function |  |
|-----------------------------|-----------------|--------------|--|
|                             | 10101B          | Disable      |  |
| Application Program Enabled | 01010B          | Enable       |  |
|                             | Any other value | Reset MCU    |  |

Watchdog Timer Enable/Disable Control

Under normal program operation, a Watchdog Timer time-out will initialise a device reset and set the status bit TO. However, if the system is in the SLEEP or IDLE Mode, when a Watchdog Timer time-out occurs, the TO bit in the status register will be set and only the Program Counter and Stack Pointer will be reset. Three methods can be adopted to clear the contents of the Watchdog Timer. The first is a WDT reset, which means a certain value except 01010B and 10101B written into the WE4~WE0 bit filed, the second is using the Watchdog Timer software clear instructions and the third is via a HALT instruction.

There is only one method of using software instruction to clear the Watchdog Timer. That is to use the single "CLR WDT" instruction to clear the WDT.

# Reset and Initialisation

A reset function is a fundamental part of any microcontroller ensuring that the device can be set to some predetermined condition irrespective of outside parameters. The most important reset condition is after power is first applied to the microcontroller. In this case, internal circuitry will ensure that the microcontroller, after a short delay, will be in a well defined state and ready to execute the first program instruction. After this power-on reset, certain important internal registers will be set to defined states before the program commences. One of these registers is the Program Counter, which will be reset to zero forcing the microcontroller to begin program execution from the lowest Program Memory address.

In addition to the power-on reset, situations may arise where it is necessary to forcefully apply a reset condition when the microcontroller is running. One example of this is where after power has been applied and the microcontroller is already running, the RES line is forcefully pulled low. In such a case, known as a normal operation reset, some of the microcontroller registers remain unchanged allowing the microcontroller to precede with normal operation after the reset line is allowed to return high.

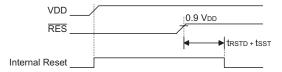

Another type of reset is when the Watchdog Timer overflows and resets the microcontroller. All types of reset operations result in different register conditions being setup. Another reset exists in the form of a Low Voltage Reset, LVR, where a full reset, similar to the RES reset is implemented in situations where the power supply voltage falls below a certain threshold.

### **Reset Functions**

There are five ways in which a microcontroller reset can occur, through events occurring both internally and externally:

### **Power-on Reset**

The most fundamental and unavoidable reset is the one that occurs after power is first applied to the microcontroller. As well as ensuring that the Program Memory begins execution from the first memory address, a power-on reset also ensures that certain other registers are preset to known conditions. All the I/O port and port control registers will power up in a high condition ensuring that all pins will be first set to inputs.

Note: t<sub>RSTD</sub> is power-on delay, typical time=50ms

Power-on Reset Timing Chart

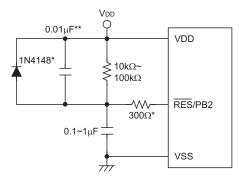

### **RES** Pin Reset

As the reset pin is shared with PB2, the reset function must be selected using a configuration option. Although the microcontroller has an internal RC reset function, if the VDD power supply rise time is not fast enough or does not stabilise quickly at power-on, the internal reset function may be incapable of providing proper reset operation. For this reason it is recommended that an external RC network is connected to the  $\overline{\text{RES}}$  pin, whose additional time delay will ensure that the  $\overline{\text{RES}}$  pin remains low for an extended period to allow the power supply to stabilise. During this time delay, normal operation of the microcontroller will be inhibited. After the  $\overline{\text{RES}}$  line reaches a certain voltage value, the reset delay time  $t_{\text{RSTD}}$  is invoked to provide an extra delay time after which the microcontroller will begin normal operation. The abbreviation SST in the figures stands for System

Rev. 1.50 64 July 12, 2017

Start-up Timer. For most applications a resistor connected between VDD and the  $\overline{RES}$  pin and a capacitor connected between VSS and the  $\overline{RES}$  pin will provide a suitable external reset circuit. Any wiring connected to the  $\overline{RES}$  pin should be kept as short as possible to minimise any stray noise interference. For applications that operate within an environment where more noise is present the Enhanced Reset Circuit shown is recommended.

Note: "\*" It is recommended that this component is added ESD protection.
"\*\*" It is recommended that this component is added in environments where power line noise is significant.

#### External RES Circuit

More information regarding external reset circuits is located in Application Note HA0075E on the Holtek website.

Pulling the RES Pin low using external hardware will also execute a device reset. In this case, as in the case of other resets, the Program Counter will reset to zero and program execution initiated from this point.

Note: t<sub>RSTD</sub> is power-on delay, typical time=16.7ms

# **RES** Reset Timing Chart

When the reset pin is driven low by external hardware, most of the microcontroller pins will be forced into a high impedance condition. However special attention must be made to the PA2/CX/AN2 as the pin will be forced into a logical output low condition when the reset pin is held low. For this reason it is recommended that the pin is not connected to low impedance source in the application circuit to eliminate the possibility of the low impedance being connected together. This situation only occurs when the reset pin is pulled low by external hardware and not during a power on or other reset type.

| Pin Name   | Pin Status     |
|------------|----------------|
| PA2/CX/AN2 | Output Low     |
| Other pins | High Impedance |

Reset Pin Forced Low - Pin Status

### Low Voltage Reset - LVR

The microcontroller contains a low voltage reset circuit in order to monitor the supply voltage of the device. The LVR function is always enabled with a specific LVR voltage,  $V_{LVR}$ . If the supply voltage of the device drops to within a range of  $0.9V \sim V_{LVR}$  such as might occur when changing the battery, the LVR will automatically reset the device internally and the LVRF bit in the CTRL0 register will also be set to 1. For a valid LVR signal, a low supply voltage, i.e., a voltage in the range between  $0.9V \sim V_{LVR}$  must exist for a time greater than that specified by  $t_{LVR}$  in the A.C. characteristics. If the low supply voltage state does not exceed this value, the LVR will ignore the low supply voltage and will not perform a reset function. The actual  $V_{LVR}$  value can be selected by the LVS bits in the LVRC register. If the LVS7~LVS0 bits have any other value, which may perhaps occur due to adverse environmental conditions such as noise, the LVR will reset the device after 2~3  $t_{SUB}$  clock cycles. When this happens, the LRF bit in the CTRL0 register will be set to 1. After power on the register will have the value of 01010101B. Note that the LVR function will be automatically disabled when the device enters the power down mode.

Note: t<sub>RSTD</sub> is power-on delay, typical time=16.7ms

### Low Voltage Reset Timing Chart

### · LVRC Register

| Bit  | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|

Bit 7 **FSYSON:** f<sub>SYS</sub> Control in IDLE Mode

Described elsewhere.

Bit 6~3 Unimplemented, read as "0"

Bit 2 LVRF: LVR function reset flag

0: Not occurred 1: occurred

This bit is set to 1 when a specific Low Voltage Reset situation condition occurs. This bit can only be cleared to 0 by the application program.

Bit 1 LRF: LVR Control register software reset flag

0: Not occurred 1: occurred

This bit is set to 1 if the LVRC register contains any non defined LVR voltage register values. This in effect acts like a software-reset function. This bit can only be cleared to

0 by the application program.

bit 0 WRF: WDT Control register software reset flag

Described elsewhere.

# **Watchdog Time-out Reset during Normal Operation**

The Watchdog time-out Reset during normal operation is the same as a hardware RES pin reset except that the Watchdog time-out flag TO will be set to "1".

Note: t<sub>RSTD</sub> is power-on delay, typical time=16.7ms

**WDT Time-out Reset during Normal Operation Timing Chart** 

## Watchdog Time-out Reset during SLEEP or IDLE Mode

The Watchdog time-out Reset during SLEEP or IDLE Mode is a little different from other kinds of reset. Most of the conditions remain unchanged except that the Program Counter and the Stack Pointer will be cleared to "0" and the TO flag will be set to "1". Refer to the A.C. Characteristics for  $t_{\text{SST}}$  details.

Note: The SST is 1024 clock cycles for HXT and LXT. The SST is 1~2 clock cycles for LIRC.

WDT Time-out Reset during SLEEP or IDLE Timing Chart

## **Reset Initial Conditions**

The different types of reset described affect the reset flags in different ways. These flags, known as PDF and TO are located in the status register and are controlled by various microcontroller operations, such as the SLEEP or IDLE Mode function or Watchdog Timer. The reset flags are shown in the table:

| то | PDF | RESET Conditions  |
|----|-----|---|
| 0  | 0   | Power-on Reset  |
| u  | u   | RES or LVR reset during NORMAL or SLOW Mode operation   |
| 1  | u   | WDT time-out reset during NORMAL or SLOW Mode operation |
| 1  | 1   | WDT time-out reset during IDLE or SLEEP Mode operation  |

Note: "u" stands for unchanged.

The following table indicates the way in which the various components of the microcontroller are affected after a power-on reset occurs.

| Item                | Condition After RESET                                       |
|---------------------|---|
| Program Counter     | Reset to zero   |
| Interrupts          | All interrupt will be disabled                              |
| WDT                 | Clear after reset, WDT begins counting                      |
| Timer/Event Counter | Timer Counter will be turned off                            |
| Input/Output Ports  | I/O ports will be setup as inputs and ANn as A/D input pins |
| Stack Pointer       | Stack Pointer will point to the top of the stack            |

The different kinds of resets all affect the internal registers of the microcontroller in different ways. To ensure reliable continuation of normal program execution after a reset occurs, it is important to know what condition the microcontroller is in after a particular reset occurs. The following table describes how each type of reset affects each of the microcontroller internal registers.

| Register | BC66F840 | BC66F850 | BC66F860 | Power-on Reset | RES or LVR Reset | WDT Time-out<br>(Normal Operation) | WDT Time-out<br>(HALT) |

"x" stands for "unknown"
"-" stands for unimplemented

# **Input/Output Ports**

Holtek microcontrollers offer considerable flexibility on their I/O ports. With the input or output designation of every pin fully under user program control, pull-high selections for all ports and wake-up selections on certain pins, the user is provided with an I/O structure to meet the needs of a wide range of application possibilities.

The devices provide bidirectional input/output lines labeled with port names such as PA and PB, etc. These I/O ports are mapped to the RAM Data Memory with specific addresses as shown in the Special Purpose Data Memory table. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, which means the inputs must be ready at the T2 rising edge of instruction "MOV A, [m]", where m denotes the port address. For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

### **I/O Resistor Lists**

# **Pull-high Resistors**

Many product applications require pull-high resistors for their switch inputs usually requiring the use of an external resistor. To eliminate the need for these external resistors, all I/O pins, when configured as an input have the capability of being connected to an internal pull-high resistor. These pull-high resistors are selected using registers PAPU~PFPU and are implemented using weak PMOS transistors.

### Port A Wake-up

The HALT instruction forces the microcontroller into the SLEEP or IDLE Mode which preserves power, a feature that is important for battery and other low-power applications. Various methods exist to wake-up the microcontroller, one of which is to change the logic condition on one of the Port A pins from high to low. This function is especially suitable for applications that can be woken up via external switches. Each pin on Port A can be selected individually to have this wake-up feature using the PAWU register.

### I/O Port Control Registers

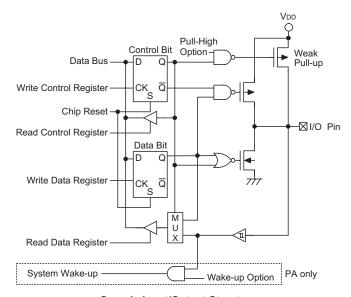

Each I/O port has its own control register known as PAC~PFC, to control the input/output configuration. With this control register, each CMOS output or input can be reconfigured dynamically under software control. Each pin of the I/O ports is directly mapped to a bit in its associated port control register. For the I/O pin to function as an input, the corresponding bit of the control register must be written as 1. This will then allow the logic state of the input pin to be directly read by instructions. When the corresponding bit of the control register is written as 0, the I/O pin will be setup as a CMOS output. If the pin is currently setup as an output, instructions can still be used to read the output register. However, it should be noted that the program will in fact only read the status of the output data latch and not the actual logic status of the output pin.

#### I/O Pin Structures

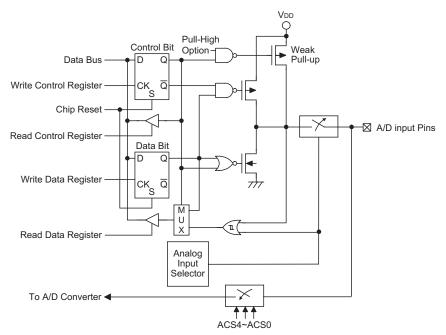

The accompanying diagrams illustrate the internal structures of some generic I/O pin types. As the exact logical construction of the I/O pin will differ from these drawings, they are supplied as a guide only to assist with the functional understanding of the I/O pins. The wide range of pin-shared structures does not permit all types to be shown.

**Generic Input/Output Structure** 

A/D Input/Output Structure

# **Programming Considerations**

Within the user program, one of the first things to consider is port initialisation. After a reset, all of the I/O data and port control registers will be set high. This means that all I/O pins will default to an input state, the level of which depends on the other connected circuitry and whether pull-high selections have been chosen. If the port control registers are then programmed to setup some pins as outputs, these output pins will have an initial high output value unless the associated port data registers are first programmed. Selecting which pins are inputs Within the user program, one of the first things to consider is port initialisation. After a reset, all of the I/O data and port control registers will be set high. This means that all I/O pins will default to an input state, the level of which depends on the other connected circuitry and whether pull-high selections have been chosen. If the port control registers, PAC and PBC, are then programmed to setup some pins as outputs, these output pins will have an initial high output value unless the associated port data registers, PA and PB, are first programmed. Selecting which pins are inputs and which are outputs can be achieved byte-wide by loading the correct values into the appropriate port control register or by programming individual bits in the port control register using the SET [m].i and CLR [m].i instructions. Note that when using these bit control instructions, a read-modify-write operation takes place. The microcontroller must first read in the data on the entire port, modify it to the required new bit values and then rewrite this data back to the output ports.

The power-on reset condition of the A/D converter control registers ensures that any A/D input pins – which are always shared with other I/O functions – will be setup as analog inputs after a reset. Although these pins will be configured as A/D inputs after a reset, the A/D converter will not be switched on. It is therefore important to note that if it is required to use these pins as I/O digital input pins or as other functions, the A/D converter control registers must be correctly programmed to remove the A/D function. Note also that as the A/D channel is enabled, any internal pull-high resistor connections will be removed.

Port A has the additional capability of providing wake-up functions. When the devices are in the SLEEP or IDLE Mode, various methods are available to wake the devices up. One of these is a high to low transition of any of the Port A pins. Single or multiple pins on Port A can be setup to have this function.

# **Timer Modules - TM**

One of the most fundamental functions in any microcontroller devices is the ability to control and measure time. To implement time related functions each device includes several Timer Modules, abbreviated to the name TM. The TMs are multi-purpose timing units and serve to provide operations such as Timer/Counter, Input Capture, Compare Match Output and Single Pulse Output as well as being the functional unit for the generation of PWM signals. Each of the TMs has either two individual interrupts. The addition of input and output pins for each TM ensures that users are provided with timing units with a wide and flexible range of features.

The common features of the different TM types are described here with more detailed information provided in the individual Compact, Standard and Enhanced TM sections.

#### Introduction

The devices contain up to four TMs with each TM having a reference name of TM0, TM1, TM2 and TM3. Each individual TM can be categorised as a certain type, namely Compact Type TM (CTM), Standard Type TM (STM) or Enhanced Type TM (ETM). Although similar in nature, the different TM types vary in their feature complexity. The common features to all of the Compact, Standard and Enhanced TMs will be described in this section and the detailed operation regarding each of the TM types will be described in separate sections. The main features and differences between the three types of TMs are summarised in the accompanying table.

| Function                     | СТМ            | STM            | ETM            |  |
|------------------------------|----------------|----------------|----------------|--|
| Timer/Counter                | V              | V              | √              |  |
| I/P Capture                  | _              | V              | <b>√</b>       |  |
| Compare Match Output         | V              | V              | √              |  |
| PWM Channels                 | 1              | 1              | 2              |  |
| Single Pulse Output          | _              | 1              | 2              |  |

| PWM Adjustment Period & Duty | Duty or Period | Duty or Period | Duty or Period |  |

**TM Function Summary** 

Each device in the series contains a specific number of either Compact Type, Standard Type and Enhanced Type TM units which are shown in the table together with their individual reference name, TM0~TM3.

| Device   | TM0        | TM1        | TM2        | TM3        |
|----------|------------|------------|------------|------------|
| BC66F840 | 16-bit CTM | _          | 16-bit STM | 16-bit ETM |
| BC66F850 | 16-bit CTM | 16-bit CTM | 16-bit STM | 16-bit ETM |
| BC66F860 | 16-bit CTM | 16-bit CTM | 16-bit STM | 16-bit ETM |

TM Name/Type Reference

# **TM Operation**

The three different types of TM offer a diverse range of functions, from simple timing operations to PWM signal generation. The key to understanding how the TM operates is to see it in terms of a free running counter whose value is then compared with the value of pre-programmed internal comparators. When the free running counter has the same value as the pre-programmed comparator, known as a compare match situation, a TM interrupt signal will be generated which can clear the counter and perhaps also change the condition of the TM output pin. The internal TM counter is driven by a user selectable clock source, which can be an internal clock or an external pin.

#### **TM Clock Source**

The clock source which drives the main counter in each TM can originate from various sources. The selection of the required clock source is implemented using the  $TnCK2\sim TnCK0$  bits in the TM control registers. The clock source can be a ratio of either the system clock  $f_{SYS}$  or the internal high clock  $f_{H}$ , the  $f_{SUB}$  clock source or the external TCKn pin. Note that setting these bits to the value 101 will select a reserved clock input, in effect disconnecting the TM clock source. The TCKn pin clock source is used to allow an external signal to drive the TM as an external clock source or for event counting.

### **TM Interrupts**

The Compact and Standard type TMs each have two internal interrupts, one for each of the internal comparator A or comparator P, which generate a TM interrupt when a compare match condition occurs. As the Enhanced type TM has three internal comparators and comparator A or comparator B or comparator P compare match functions, it consequently has three internal interrupts. When a TM interrupt is generated it can be used to clear the counter and also to change the state of the TM output pin.

#### **TM External Pins**

Each of the TMs, irrespective of what type, has one TM input pin, with the label TCKn. The TM input pin is essentially a clock source for the TM and is selected using the TnCK2~TnCK0 bits in the TMnC0 register. This external TM input pin allows an external clock source to drive the internal TM. This external TM input pin is shared with other functions but will be connected to the internal TM if selected using the TnCK2~TnCK0 bits. The TM input pin can be chosen to have either a rising or falling active edge.

The TMs each have one or more output pins with the label TPn. When the TM is in the Compare Match Output Mode, these pins can be controlled by the TM to switch to a high or low level or to toggle when a compare match situation occurs. The external TPn output pin is also the pin where the TM generates the PWM output waveform. As the TM output pins are pin-shared with other function, the TM output function must first be setup using registers. A single bit in one of the registers determines if its associated pin is to be used as an external TM output pin or if it is to have another function. The number of output pins for each TM type and device is different, the details are provided in the accompanying table.

| Device   | СТМ      | STM | ETM        | Register |
|----------|----------|-----|------------|----------|
| BC66F840 | TP0      | TP2 | TP3A, TP3B | TMPC     |

**TM Input/Output Pins** 

Rev. 1.50 78 July 12, 2017

# TM Input/Output Pin Control Registers

Selecting to have a TM input/output or whether to retain its other shared function is implemented using one register, with a single bit in each register corresponding to a TM input/output pin. Setting the bit high will setup the corresponding pin as a TM input/output, if reset to zero the pin will retain its original other function.

# **Programming Considerations**

The TM Counter Registers and the Capture/Compare CCRA and CCRB registers, being 16-bit, all have a low and high byte structure. The high bytes can be directly accessed, but as the low bytes can only be accessed via an internal 8-bit buffer, reading or writing to these register pairs must be carried out in a specific way. The important point to note is that data transfer to and from the 8-bit buffer and its related low byte only takes place when a write or read operation to its corresponding high byte is executed. As the CCRA and CCRB registers are implemented in the way shown in the following diagram and accessing these register pairs is carried out in a specific way described above, it is recommended to use the "MOV" instruction to access the CCRA and CCRB low byte registers, named TMxAL and TMxBL, using the following access procedures. Accessing the CCRA or CCRB low byte registers without following these access procedures will result in unpredictable values.

The following steps show the read and write procedures:

- · Writing Data to CCRB or CCRA
  - Write data to Low Byte TMxAL or TMxBL note that here data is only written to the 8-bit buffer.
  - Write data to High Byte TMxAH or TMxBH here data is written directly to the high byte registers and simultaneously data is latched from the 8-bit buffer to the Low Byte registers.
- · Reading Data from the Counter Registers and CCRB or CCRA
  - Read data from the High Byte TMxDH, TMxAH or TMxBH here data is read directly from the High Byte registers and simultaneously data is latched from the Low Byte register into the 8-bit buffer.
  - Read data from the Low Byte TMxDL, TMxAL or TMxBL this step reads data from the 8-bit buffer.

# Compact Type TM - CTM

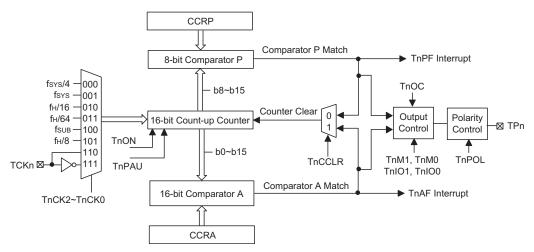

Although the simplest form of the three TM types, the Compact TM type still contains three operating modes, which are Compare Match Output, Timer/Event Counter and PWM Output modes. The Compact TM can also be controlled with an external input pin and can drive one external output pin.

| СТМ                   | Name       | TM No. | TM Input Pin | TM Output Pin |
|-----------------------|------------|--------|--------------|---------------|
| BC66F840              | 16-bit CTM | 0      | TCK0         | TP0           |
| BC66F850/<br>BC66F860 | 16-bit CTM | 0, 1   | TCK0, TCK1   | TP0, TP1      |

# **Compact TM Operation**

At its core is a 16-bit count-up counter which is driven by a user selectable internal or external clock source. There are also two internal comparators with the names, Comparator A and Comparator P. These comparators will compare the value in the counter with CCRP and CCRAregisters. The CCRP is 8-bit wide whose value is compared with the highest eight bits in the counter while the CCRA is 16-bit wide and therefore compares with all counter bits.

The only way of changing the value of the 16-bit counter using the application program, is to clear the counter by changing the TnON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a TM interrupt signal will also usually be generated. The Compact Type TM can operate in a number of different operational modes, can be driven by different clock sources including an input pin and can also control an output pin. All operating setup conditions are selected using relevant internal registers.

Compact Type TM Block Diagram (n=0 or 1)

Rev. 1.50 84 July 12, 2017

# **Compact Type TM Register Description**

Overall operation of the Compact TM is controlled using a series of registers. Aread only register pair exists to store the internal counter 16-bit value, while a read/write register pair exists to store the internal 16-bit CCRA value. There is also a read/write register used to store the internal 8-bit CCRP value. The remaining two registers are control registers which setup the different operating and control modes.

| Register |       | Bit   |       |       |       |       |       |        |  |  |  |

#### TMnC0 Register

| Bit  | 7     | 6     | 5     | 4     | 3    | 2 | 1 | 0 |
|------|-------|-------|-------|-------|------|---|---|---|
| Name | TnPAU | TnCK2 | TnCK1 | TnCK0 | TnON | _ | _ | _ |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W  | _ | _ | _ |
| POR  | 0     | 0     | 0     | 0     | 0    | _ | _ | _ |

Bit 7 TnPAU: TMn Counter Pause Control

0: Run 1: Pause

The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the TM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

Bit 6~4 TnCK2~TnCK0: Select TMn Counter clock

 $\begin{array}{c} 000: \, f_{SYS}/4 \\ 001: \, f_{SYS} \\ 010: \, f_{H}/16 \\ 011: \, f_{H}/64 \\ 100: \, f_{SUB} \\ 101: \, f_{H}/8 \end{array}$ 

110: TCKn rising edge clock 111: TCKn falling edge clock

These three bits are used to select the clock source for the TM. Selecting the Reserved clock input will effectively disable the internal counter. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source  $f_{SYS}$  is the system clock, while  $f_H$  and  $f_{SUB}$  are other internal clocks, the details of which can be found in the oscillator section.

Bit 3 TnON: TMn Counter On/Off Control

0: Off 1: On

This bit controls the overall on/off function of the TM. Setting the bit high enables the counter to run and clearing the bit disables the TM. Clearing this bit to zero will stop the counter from counting and turn off the TM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value.

If the TM is in the Compare Match Output Mode then the TM output pin will be reset to its initial condition, as specified by the TnOC bit, when the TnON bit changes from low to high.

Bit 2~0 Unimplemented, read as "0"

#### TMnC1 Register

| Bit  | 7    | 6    | 5     | 4     | 3    | 2     | 1     | 0      |
|------|------|------|-------|-------|------|-------|-------|--------|
| Name | TnM1 | TnM0 | TnIO1 | TnIO0 | TnOC | TnPOL | TnDPX | TnCCLR |
| R/W  | R/W  | R/W  | R/W   | R/W   | R/W  | R/W   | R/W   | R/W    |
| POR  | 0    | 0    | 0     | 0     | 0    | 0     | 0     | 0      |

Bit 7~6 **TnM1~TnM0:** Select TMn Operation Mode

00: Compare Match Output Mode

01: Undefined 10: PWM Mode

11: Timer/Counter Mode

These bits setup the required operating mode for the TM. To ensure reliable operation the TM should be switched off before any changes are made to the TnM1 and TnM0 bits. In the Timer/Counter Mode, the TM output pin control must be disabled.

Bit 5~4 TnIO1~TnIO0: Select TPn output function

Compare Match Output Mode

00: No change01: Output low10: Output high11: Toggle output

PWM Mode

00: PWM Output inactive state01: PWM Output active state

10: PWM output 11: Undefined Timer/Counter Mode

Unused

These two bits are used to determine how the TM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the TM is running.

In the Compare Match Output Mode, the TnIO1 and TnIO0 bits determine how the TM output pin changes state when a compare match occurs from the Comparator A. The TM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the bits are both zero, then no change will take place on the output. The initial value of the TM output pin should be setup using the TnOC bit in the TMnC1 register. Note that the output level requested by the TnIO1 and TnIO0 bits must be different from the initial value setup using the TnOC bit otherwise no change will occur on the TM output pin when a compare match occurs. After the TM output pin changes state, it can be reset to its initial level by changing the level of the TnON bit from low to high.

In the PWM Mode, the TnIO1 and TnIO0 bits determine how the TM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to change the values of the TnIO1 and TnIO0 bits only after the TMn has been switched off. Unpredictable PWM outputs will occur if the TnIO1 and TnIO0 bits are changed when the TM is running.

Bit 3 TnOC: TPn output control bit

Compare Match Output Mode

0: Initial low

1: Initial high

PWM Mode

0: Active low

1: Active high

This is the output control bit for the TM output pin. Its operation depends upon whether TM is being used in the Compare Match Output Mode or in the PWM Mode. It has no effect if the TM is in the Timer/Counter Mode. In the Compare Match Output Mode it determines the logic level of the TM output pin before a compare match occurs. In the PWM Mode it determines if the PWM signal is active high or active low.

Bit 2 TnPOL: TPn output Polarity control

0: Non-invert

1: Invert

This bit controls the polarity of the TPn output pin. When the bit is set high the TM output pin will be inverted and not inverted when the bit is zero. It has no effect if the TM is in the Timer/Counter Mode.

Bit 1 TnDPX: TMn PWM period/duty Control

0: CCRP - period; CCRA - duty

1: CCRP - duty; CCRA - period

This bit, determines which of the CCRA and CCRP registers are used for period and duty control of the PWM waveform.

Bit 0 TnCCLR: Select TMn Counter clear condition

0: TMn Comparator P match

1: TMn Comparator A match

This bit is used to select the method which clears the counter. Remember that the Compact TM contains two comparators, Comparator A and Comparator P, either of which can be selected to clear the internal counter. With the TnCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The TnCCLR bit is not used in the PWM Mode.

#### **TMnRP Register**

| Bit  | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| Name | TnRP7 | TnRP6 | TnRP5 | TnRP4 | TnRP3 | TnRP2 | TnRP1 | TnRP0 |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |
| POR  | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

Bit 7~0 TnRP7~TnRP0: TMn CCRP register bit 7~bit 0, compare with the TMn counter bit 15~bit 8

Comparator P Match Period

0: 65536 TMn clocks

1~255: (1~255)×256 TMn clocks

These eight bits are used to setup the value on the internal CCRP 8-bit register, which are then compared with the internal counter's highest eight bits. The result of this comparison can be selected to clear the internal counter if the TnCCLR bit is set to zero. Setting the TnCCLR bit to zero ensures that a compare match with the CCRP values will reset the internal counter. As the CCRP bits are only compared with the highest eight counter bits, the compare values exist in 256 clock cycle multiples. Clearing all eight bits to zero is in effect allowing the counter to overflow at its maximum value.

# **Compact Type TM Operation Modes**

The Compact Type TM can operate in one of three operating modes, Compare Match Output Mode, PWM Mode or Timer/Counter Mode. The operating mode is selected using the TnM1 and TnM0 bits in the TMnC1 register.

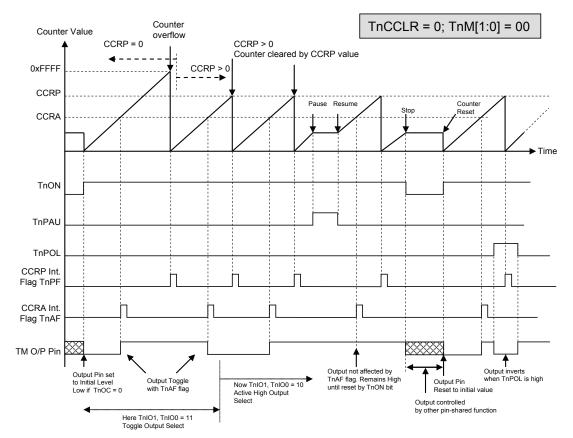

### **Compare Match Output Mode**

To select this mode, bits TnM1 and TnM0 in the TMnC1 register, should be set to 00B respectively. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the TnCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match occurs from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both TnAF and TnPF interrupt request flags for the Comparator A and Comparator P respectively, will both be generated.

If the TnCCLR bit in the TMnC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the TnAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when TnCCLR is high no TnPF interrupt request flag will be generated. If the CCRA bits are all zero, the counter will overflow when its reaches its maximum 16-bit, FFFF Hex, value, however here the TnAF interrupt request flag will not be generated.

As the name of the mode suggests, after a comparison is made, the TM output pin will change state. The TM output pin condition however only changes state when a TnAF interrupt request flag is generated after a compare match occurs from Comparator A. The TnPF interrupt request flag, generated from a compare match occurs from Comparator P, will have no effect on the TM output pin. The way in which the TM output pin changes state are determined by the condition of the TnIO1 and TnIO0 bits in the TMnC1 register. The TM output pin can be selected using the TnIO1 and TnIO0 bits to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A. The initial condition of the TM output pin, which is setup after the TnON bit changes from low to high, is setup using the TnOC bit. Note that if the TnIO1 and TnIO0 bits are zero then no pin change will take place.

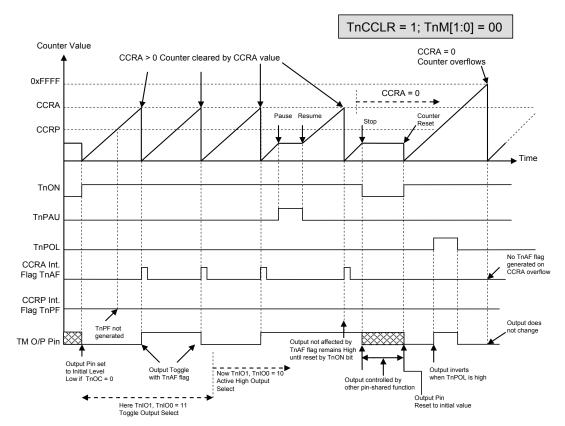

Compare Match Output Mode - TnCCLR=0

Note: 1. With TnCCLR=0, a Comparator P match will clear the counter

- 2. The TM output pin is controlled only by the TnAF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. n=0, 1

Rev. 1.50 90 July 12, 2017

# Compare Match Output Mode - TnCCLR=1

Note: 1. With TnCCLR=1, a Comparator A match will clear the counter

- 2. The TM output pin is controlled only by the TnAF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. The TnPF flag is not generated when TnCCLR=1
- 5. n=0, 1

#### **Timer/Counter Mode**

To select this mode, bits TnM1 and TnM0 in the TMnC1 register should be set to 11 respectively. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the TM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the TM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function.

# **PWM Output Mode**

To select this mode, bits TnM1 and TnM0 in the TMnC1 register should be set to 10 respectively. The PWM function within the TM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the TM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS values.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM mode, the TnCCLR bit has no effect on the PWM operation. Both of the CCRA and CCRP registers are used to generate the PWM waveform, one register is used to clear the internal counter and thus control the PWM waveform frequency, while the other one is used to control the duty cycle. Which register is used to control either frequency or duty cycle is determined using the TnDPX bit in the TMnC1 register. The PWM waveform frequency and duty cycle can therefore be controlled by the values in the CCRA and CCRP registers.

An interrupt flag, one for each of the CCRA and CCRP, will be generated when a compare match occurs from either Comparator A or Comparator P. The TnOC bit in the TMnC1 register is used to select the required polarity of the PWM waveform while the two TnIO1 and TnIO0 bits are used to enable the PWM output or to force the TM output pin to a fixed high or low level. The TnPOL bit is used to reverse the polarity of the PWM output waveform.

#### 16-bit CTM, PWM Mode, Edge-aligned Mode, TnDPX=0

| CCRP   | 1~255    | 0     |  |  |  |
|--------|----------|-------|--|--|--|
| Period | CCRP×256 | 65536 |  |  |  |
| Duty   | CCRA     |       |  |  |  |

If f<sub>SYS</sub>=16MHz, TM clock source is f<sub>SYS</sub>/4, CCRP=2 and CCRA=128

The CTM PWM output frequency= $(f_{SYS}/4)/(2\times256)=f_{SYS}/2048=7.8125$ kHz, duty= $128/(2\times256)=25\%$ .

If the Duty value defined by the CCRA register is equal to or greater than the Period value, then the PWM output duty is 100%.

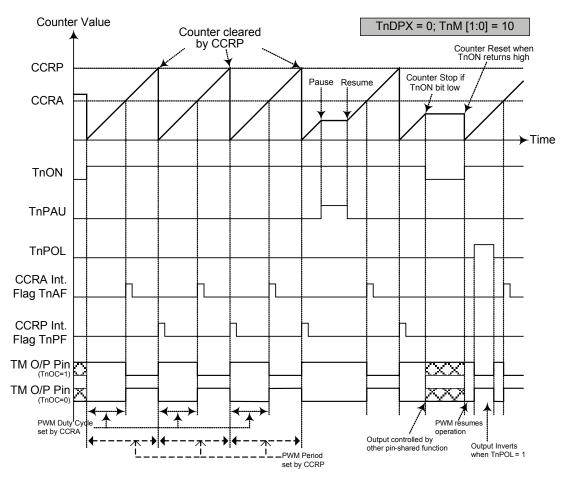

#### 16-bit CTM, PWM Mode, Edge-aligned Mode, TnDPX=1

| CCRP   | 1~255 0  |       |  |  |  |  |
|--------|----------|-------|--|--|--|--|
| Period | CCRA     |       |  |  |  |  |
| Duty   | CCRP×256 | 65536 |  |  |  |  |

The PWM output period is determined by the CCRA register value together with the TM clock while the PWM duty cycle is defined by the (CCRP×256) except when the CCRP value is equal to 0.

Rev. 1.50 92 July 12, 2017

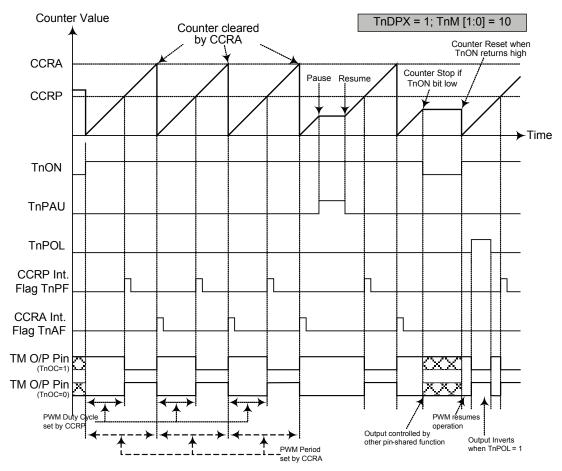

PWM Mode - TnDPX=0

Note: 1. Here TnDPX=0 - Counter cleared by CCRP

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues even when TnIO [1:0]=00 or 01
- 4. The TnCCLR bit has no influence on PWM operation
- 5. n=0, 1

PWM Mode - TnDPX=1

Note: 1. Here TnDPX=1 – Counter cleared by CCRA

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues even when TnIO [1:0]=00 or 01
- 4. The TnCCLR bit has no influence on PWM operation
- 5. n=0, 1

# Standard Type TM - STM

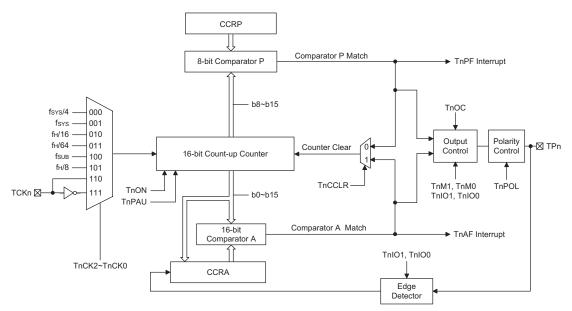

The Standard Type TM contains five operating modes, which are Compare Match Output, Timer/ Event Counter, Capture Input, Single Pulse Output and PWM Output modes. The Standard TM can also be controlled with an external input pin and can drive one external output pin.

| STM                              | Name       | TM No. | TM Input Pin | TM Output Pin |
|----------------------------------|------------|--------|--------------|---------------|
| BC66F840<br>BC66F850<br>BC66F860 | 16-bit STM | 2      | TCK2         | TP2           |

# **Standard TM Operation**

At its core is a 16-bit count-up counter which is driven by a user selectable internal or external clock source. There are also two internal comparators with the names, Comparator A and Comparator P. These comparators will compare the value in the counter with CCRP and CCRA registers. The CCRP comparator is 8-bit wide whose value is compared with the highest eight bits in the counter while the CCRA is 16-bit wide and therefore compares with all counter bits.

The only way of changing the value of the 16-bit counter using the application program, is to clear the counter by changing the TnON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a TM interrupt signal will also usually be generated. The Standard Type TM can operate in a number of different operational modes, can be driven by different clock sources including an input pin and can also control an output pin. All operating setup conditions are selected using relevant internal registers.

Standard Type TM Block Diagram (n=2)

# **Standard Type TM Register Description**

Overall operation of the Standard TM is controlled using a series of registers. A read only register pair exists to store the internal counter 16-bit value, while a read/write register pair exists to store the internal 16-bit CCRA value. There is also a read/write register used to store the internal 8-bit CCRP value. The remaining two registers are control registers which setup the different operating and control modes.

| Register | Bit   |       |       |       |       |       |       |        |  |  |  |

| R/W  | R/W   | R/W   | R/W   | R/W   | R/W  | _ | _ | _ |
| POR  | 0     | 0     | 0     | 0     | 0    | _ | _ | _ |

Bit 7 TnPAU: TMn Counter Pause Control

0: Run 1: Pause

The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the TM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

Bit 6~4 TnCK2~TnCK0: Select TMn Counter clock

 $\begin{array}{c} 000: \, f_{SYS}/4 \\ 001: \, f_{SYS} \\ 010: \, f_{H}/16 \\ 011: \, f_{H}/64 \\ 100: \, f_{SUB} \\ 101: \, f_{H}/8 \end{array}$ 

110: TCKn rising edge clock 111: TCKn falling edge clock

These three bits are used to select the clock source for the TM. Selecting the Reserved clock input will effectively disable the internal counter. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source  $f_{SYS}$  is the system clock, while  $f_H$  and  $f_{SUB}$  are other internal clocks, the details of which can be found in the oscillator section.

Bit 3 TnON: TMn Counter On/Off Control

0: Off 1: On

This bit controls the overall on/off function of the TM. Setting the bit high enables the counter to run and clearing the bit disables the TM. Clearing this bit to zero will stop the counter from counting and turn off the TM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value.

If the TM is in the Compare Match Output Mode then the TM output pin will be reset to its initial condition, as specified by the TnOC bit, when the TnON bit changes from low to high.

Bit 2~0 Unimplemented, read as "0"

#### TMnC1 Register

| Bit  | 7    | 6    | 5     | 4     | 3    | 2     | 1     | 0      |
|------|------|------|-------|-------|------|-------|-------|--------|
| Name | TnM1 | TnM0 | TnIO1 | TnIO0 | TnOC | TnPOL | TnDPX | TnCCLR |
| R/W  | R/W  | R/W  | R/W   | R/W   | R/W  | R/W   | R/W   | R/W    |
| POR  | 0    | 0    | 0     | 0     | 0    | 0     | 0     | 0      |

Bit 7~6 **TnM1~TnM0:** Select TMn Operation Mode

00: Compare Match Output Mode

01: Capture Input Mode

10: PWM Mode or Single Pulse Output Mode

11: Timer/Counter Mode

These bits setup the required operating mode for the TM. To ensure reliable operation the TM should be switched off before any changes are made to the TnM1 and TnM0 bits. In the Timer/Counter Mode, the TM output pin control must be disabled.

Bit 5~4 TnIO1~TnIO0: Select TPn output function

Compare Match Output Mode

00: No change

01: Output low

10: Output high

11: Toggle output

PWM Mode/Single Pulse Output Mode

00: PWM Output inactive state

01: PWM Output active state

10: PWM output

11: Single pulse output

Capture input Mode

00: Input capture at rising edge of TPn

01: Input capture at falling edge of TPn

01: Input capture at falling/rising edge of TPn

11: Input capture disabled

Timer/Counter Mode

Unused

These two bits are used to determine how the TM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the TM is running.

In the Compare Match Output Mode, the TnIO1 and TnIO0 bits determine how the TM output pin changes state when a compare match occurs from the Comparator A. The TM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the bits are both zero, then no change will take place on the output. The initial value of the TM output pin should be setup using the TnOC bit in the TMnC1 register. Note that the output level requested by the TnIO1 and TnIO0 bits must be different from the initial value setup using the TnOC bit otherwise no change will occur on the TM output pin when a compare match occurs. After the TM output pin changes state, it can be reset to its initial level by changing the level of the TnON bit from low to high.

In the PWM Mode, the TnIO1 and TnIO0 bits determine how the TM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to change the values of the TnIO1 and TnIO0 bits only after the TM has been switched off. Unpredictable PWM outputs will occur if the TnIO1 and TnIO0 bits are changed when the TM is running.

Rev. 1.50 98 July 12, 2017

Bit 3 **TnOC:** TPn output control bit

Compare Match Output Mode

0: Initial low

1: Initial high

PWM Mode/Single Pulse Output Mode

0: Active low

1: Active high

This is the output control bit for the TM output pin. Its operation depends upon whether TM is being used in the Compare Match Output Mode or in the PWM Mode/Single Pulse Output Mode. It has no effect if the TM is in the Timer/Counter Mode. In the Compare Match Output Mode it determines the logic level of the TM output pin before a compare match occurs. In the PWM Mode it determines if the PWM signal is active high or active low.

Bit 2 TnPOL: TPn output Polarity control

0: Non-invert

1. Invert

This bit controls the polarity of the TPn output pin. When the bit is set high the TM output pin will be inverted and not inverted when the bit is zero. It has no effect if the TM is in the Timer/Counter Mode.

Bit 1 TnDPX: TMn PWM period/duty Control

0: CCRP - period; CCRA - duty

1: CCRP - duty; CCRA - period

This bit, determines which of the CCRA and CCRP registers are used for period and duty control of the PWM waveform.

Bit 0 TnCCLR: Select TMn Counter clear condition

0: TMn Comparator P match

1: TMn Comparator A match

This bit is used to select the method which clears the counter. Remember that the Standard TM contains two comparators, Comparator A and Comparator P, either of which can be selected to clear the internal counter. With the TnCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The TnCCLR bit is not used in the PWM Mode, Single Pulse or Input Capture Mode.

#### **TMnRP Register**

| Bit  | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| Name | TnRP7 | TnRP6 | TnRP5 | TnRP4 | TnRP3 | TnRP2 | TnRP1 | TnRP0 |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |
| POR  | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

Bit 7~0 TnRP7~TnRP0: TMn CCRP register bit 7~bit 0, compare with the TMn counter bit 15~bit 8

Comparator P Match Period

0: 65536 TMn clocks

1~255: (1~255)×256 TMn clocks

These eight bits are used to setup the value on the internal CCRP 8-bit register, which are then compared with the internal counter's highest eight bits. The result of this comparison can be selected to clear the internal counter if the TnCCLR bit is set to zero. Setting the TnCCLR bit to zero ensures that a compare match with the CCRP values will reset the internal counter. As the CCRP bits are only compared with the highest eight counter bits, the compare values exist in 256 clock cycle multiples. Clearing all eight bits to zero is in effect allowing the counter to overflow at its maximum value.

# **Standard Type TM Operation Modes**

The Standard Type TM can operate in one of five operating modes, Compare Match Output Mode, PWM Mode, Single Pulse Output Mode, Capture Input Mode or Timer/Counter Mode. The operating mode is selected using the TnM1 and TnM0 bits in the TMnC1 register.

### **Compare Match Output Mode**

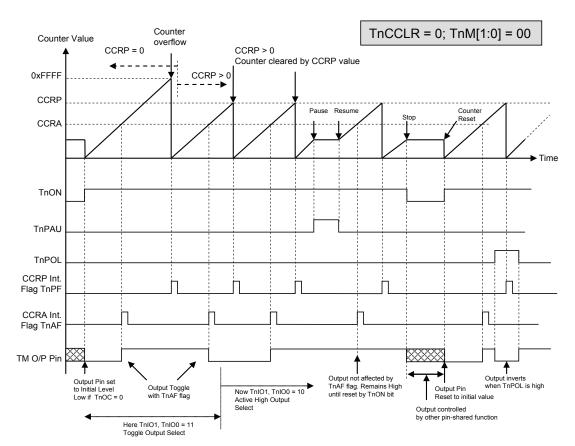

To select this mode, bits TnM1 and TnM0 in the TMnC1 register, should be set to 00 respectively. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the TnCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both TnAF and TnPF interrupt request flags for Comparator Aand Comparator P respectively, will both be generated.

If the TnCCLR bit in the TMnC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the TnAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when TnCCLR is high no TnPF interrupt request flag will be generated. In the Compare Match Output Mode, the CCRA can not be set to 0.

As the name of the mode suggests, after a comparison is made, the TM output pin, will change state. The TM output pin condition however only changes state when a TnAF interrupt request flag is generated after a compare match occurs from Comparator A. The TnPF interrupt request flag, generated from a compare match occurs from Comparator P, will have no effect on the TM output pin. The way in which the TM output pin changes state are determined by the condition of the TnIO1 and TnIO0 bits in the TMnC1 register. The TM output pin can be selected using the TnIO1 and TnIO0 bits to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A. The initial condition of the TM output pin, which is setup after the TnON bit changes from low to high, is setup using the TnOC bit. Note that if the TnIO1 and TnIO0 bits are zero then no pin change will take place.

Rev. 1.50 100 July 12, 2017

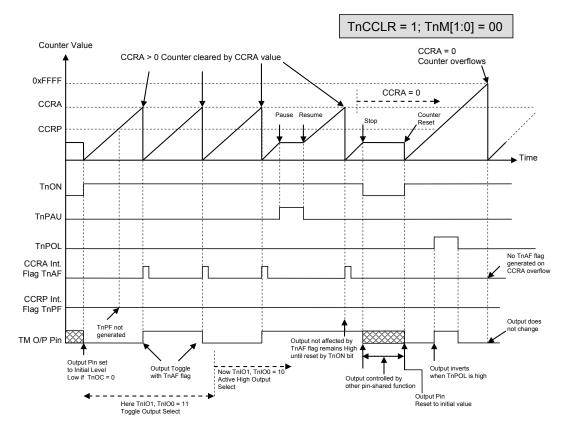

# Compare Match Output Mode - TnCCLR=0

Note: 1. With TnCCLR=0, A Comparator P match will clear the counter

- 2. The TM output pin is controlled only by the TnAF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. n=2

Compare Match Output Mode - TnCCLR=1

Note: 1. With TnCCLR=1, A Comparator A match will clear the counter

- 2. The TM output pin is controlled only by the TnAF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. A TnPF flag is not generated when TnCCLR=1
- 5. n=2

Rev. 1.50 July 12, 2017

#### **Timer/Counter Mode**

To select this mode, bits TnM1 and TnM0 in the TMnC1 register should be set to 11 respectively. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the TM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the TM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function.

### **PWM Output Mode**

To select this mode, bits TnM1 and TnM0 in the TMnC1 register should be set to 10 respectively. The PWM function within the TM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the TM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS values.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM mode, the TnCCLR bit has no effect on the PWM operation. Both of the CCRA and CCRP registers are used to generate the PWM waveform, one register is used to clear the internal counter and thus control the PWM waveform frequency, while the other one is used to control the duty cycle. Which register is used to control either frequency or duty cycle is determined using the TnDPX bit in the TMnC1 register. The PWM waveform frequency and duty cycle can therefore be controlled by the values in the CCRA and CCRP registers.

An interrupt flag, one for each of the CCRA and CCRP, will be generated when a compare match occurs from either Comparator A or Comparator P. The TnOC bit in the TMnC1 register is used to select the required polarity of the PWM waveform while the two TnIO1 and TnIO0 bits are used to enable the PWM output or to force the TM output pin to a fixed high or low level. The TnPOL bit is used to reverse the polarity of the PWM output waveform.

# 16-bit STM, PWM Mode, Edge-aligned Mode, TnDPX=0

| CCRP   | 1~255      | 0     |  |  |
|--------|------------|-------|--|--|
| Period | CCRP × 256 | 65536 |  |  |
| Duty   | CCRA       |       |  |  |

If f<sub>SYS</sub>=16MHz, TM clock source is f<sub>SYS</sub>/4, CCRP=2 and CCRA=128

The STM PWM output frequency= $(f_{SYS}/4)/(2\times256)=f_{SYS}/2048=7.8125$ kHz, duty= $128/(2\times256)=25\%$ .

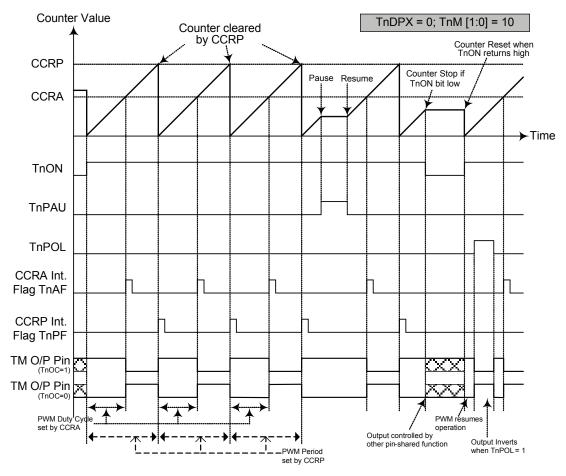

If the Duty value defined by the CCRA register is equal to or greater than the Period value, then the PWM output duty is 100%.

#### 16-bit STM, PWM Mode, Edge-aligned Mode, TnDPX=1

| CCRP   | 1~255      | 0     |  |
|--------|------------|-------|--|
| Period | CCRA       |       |  |
| Duty   | CCRP × 256 | 65536 |  |

The PWM output period is determined by the CCRA register value together with the TM clock while the PWM duty cycle is defined by the (CCRP×256) except when the CCRP value is equal to 0.

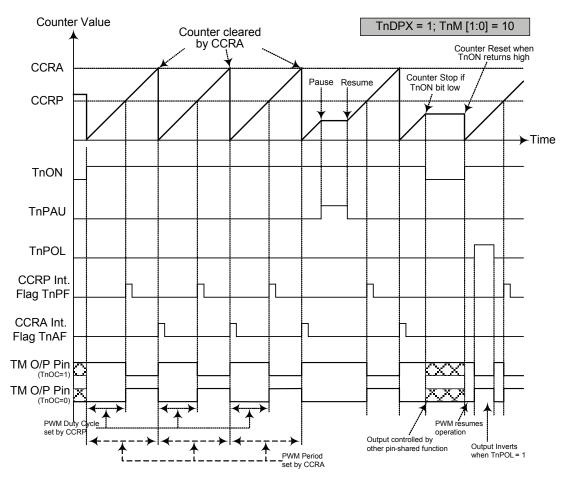

PWM Mode - TnDPX=0

Note: 1. Here TnDPX=0 -- Counter cleared by CCRP

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues running even when TnIO [1:0]=00 or 01
- 4. The TnCCLR bit has no influence on PWM operation
- 5. n=2

Rev. 1.50 July 12, 2017

PWM Mode - TnDPX=1

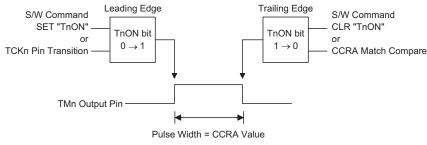

Note: 1. Here TnDPX=1 -- Counter cleared by CCRA

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues running even when TnIO [1:0]=00 or 01
- 4. The TnCCLR bit has no influence on PWM operation
- 5. n=2

# Single Pulse Mode

To select this mode, bits TnM1 and TnM0 in the TMnC1 register should be set to 10 respectively and also the TnIO1 and TnIO0 bits should be set to 11 respectively. The Single Pulse Output Mode, as the name suggests, will generate a single shot pulse on the TM output pin. The trigger for the pulse output leading edge is a low to high transition of the TnON bit, which can be implemented using the application program. However in the Single Pulse Mode, the TnON bit can also be made to automatically change from low to high using the external TCKn pin, which will in turn initiate the Single Pulse output. When the TnON bit transitions to a high level, the counter will start running and the pulse leading edge will be generated. The TnON bit should remain high when the pulse is in its active state. The generated pulse trailing edge will be generated when the TnON bit is cleared to zero, which can be implemented using the application program or when a compare match occurs from Comparator A.

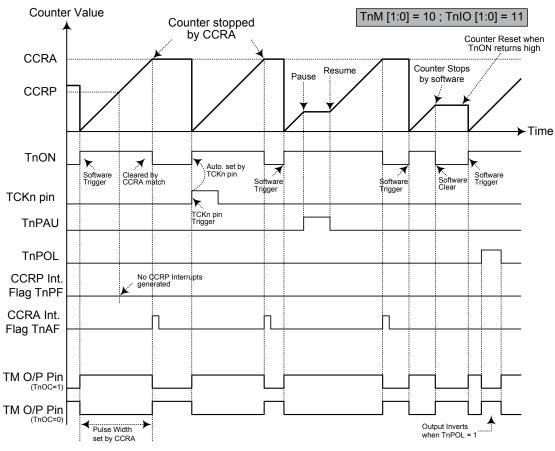

Single Pulse Generation

However a compare match from Comparator A will also automatically clear the TnON bit and thus generate the Single Pulse output trailing edge. In this way the CCRA value can be used to control the pulse width. A compare match from Comparator A will also generate a TM interrupt. The counter can only be reset back to zero when the TnON bit changes from low to high when the counter restarts. In the Single Pulse Mode CCRP is not used. The TnCCLR and TnDPX bits are not used in this Mode.

Rev. 1.50 106 July 12, 2017

Single Pulse Mode

Note: 1. Counter stopped by CCRA

- 2. CCRP is not used
- 3. The pulse triggered by the TCKn pin or by setting the TnON bit high
- 4. A TCKn pin active edge will automatically set the TnON bit high
- 5. In the Single Pulse Mode, TnIO [1:0] must be set to 11 and can not be changed
- 6. n=2

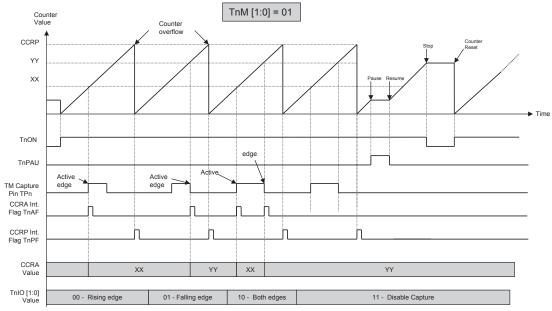

# **Capture Input Mode**

To select this mode bits TnM1 and TnM0 in the TMnC1 register should be set to 01 respectively. This mode enables external signals to capture and store the present value of the internal counter and can therefore be used for applications such as pulse width measurements. The external signal is supplied on the TPn pin, whose active edge can be either a rising edge, a falling edge or both rising and falling edges; the active edge transition type is selected using the TnIO1 and TnIO0 bits in the TMnC1 register. The counter is started when the TnON bit changes from low to high which is initiated using the application program.

When the required edge transition appears on the TPn pin, the present value in the counter will be latched into the CCRA registers and a TM interrupt generated. Irrespective of what events occur on the TPn pin the counter will continue to free run until the TnON bit changes from high to low. When a CCRP compare match occurs, the counter will reset back to zero; in this way the CCRP value can be used to control the maximum counter value. When a CCRP compare match occurs from Comparator P, a TM interrupt will also be generated. Counting the number of overflow interrupt signals from the CCRP can be a useful method in measuring long pulse widths. The TnIO1 and TnIO0 bits can select the active trigger edge on the TPn pin to be a rising edge, falling edge or both edge types. If the TnIO1 and TnIO0 bits are both set high, then no capture operation will take place irrespective of what happens on the TPn pin, however it must be noted that the counter will continue to run.

As the TPn pin is pin shared with other functions, care must be taken if the TM is in the Input Capture Mode. This is because if the pin is setup as an output, then any transitions on this pin may cause an input capture operation to be executed. The TnCCLR and TnDPX bits are not used in this Mode.

Capture Input Mode

Note: 1. TnM [1:0]=01 and active edge set by the TnIO [1:0] bits

- 2. A TM Capture input pin active edge transfers the counter value to CCRA
- 3. The TnCCLR bit is not used
- 4. No output function -- TnOC and TnPOL bits are not used
- 5. CCRP determines the counter value and the counter has a maximum count value when CCRP is equal to zero

6. n=2

# **Enhanced Type TM - ETM**

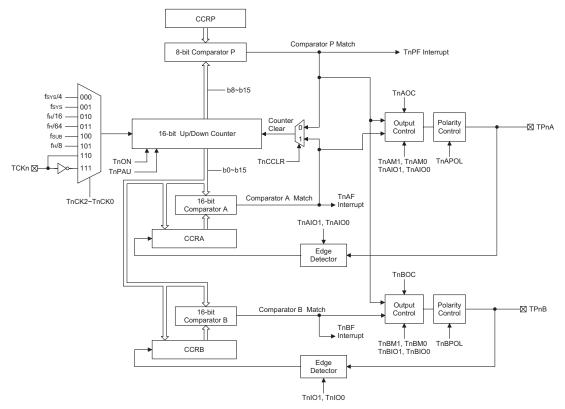

The Enhanced Type TM contains five operating modes, which are Compare Match Output, Timer/ Event Counter, Capture Input, Single Pulse Output and PWM Output modes. The Enhanced TM can also be controlled with an external input pin and can drive three or four external output pins.

| ETM                  | Name       | TM No. | TM Input Pin | TM Output Pin |
|----------------------|------------|--------|--------------|---------------|
| BC66F840<br>BC66F850 | 16-bit ETM | 3      | TCK3         | TP3           |
| BC66F860             |            |        |              |               |

#### **Enhanced TM Operation**

At its core is a 16-bit count-up/count-down counter which is driven by a user selectable internal or external clock source. There are three internal comparators with the names, Comparator A, Comparator B and Comparator P. These comparators will compare the value in the counter with the CCRA, CCRB and CCRP registers. The CCRP comparator is 8 bits wide whose value is compared with the highest 8 bits in the counter while CCRA and CCRB are 16 bits wide and therefore compared with all counter bits.

The only way of changing the value of the 16-bit counter using the application program, is to clear the counter by changing the TnON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a TM interrupt signal will also usually be generated. The Enhanced Type TM can operate in a number of different operational modes, can be driven by different clock sources including an input pin and can also control output pins. All operating setup conditions are selected using relevant internal registers.

Enhanced Type TM Block Diagram (n=3)

# **Enhanced Type TM Register Description**

Overall operation of the Enhanced TM is controlled using a series of registers. A read only register pair exists to store the internal counter 16-bit value, while two read/write register pairs exist to store the internal 16-bit CCRA and CCRB value. The remaining three registers are control registers which setup the different operating and control modes as well as the eight CCRP bits.

| Register |       |       |        | В      | it    |        |        |        |

Bit 7 TnPAU: TMn Counter Pause Control

0: Run 1: Pause

The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the TM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

Bit 6~4 TnCK2~TnCK0: Select TMn Counter clock

000: f<sub>SYS</sub>/4 001: f<sub>SYS</sub> 010: f<sub>H</sub>/16 011: f<sub>H</sub>/64 100: f<sub>SUB</sub> 101: f<sub>H</sub>/8

110: TCKn rising edge clock 111: TCKn falling edge clock

These three bits are used to select the clock source for the TM. Selecting the Reserved clock input will effectively disable the internal counter. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source  $f_{SYS}$  is the system clock, while  $f_H$  and  $f_{SUB}$  are other internal clocks, the details of which can be found in the oscillator section.

Bit 3 TnON: TMn Counter On/Off Control

0: Off 1: On

This bit controls the overall on/off function of the TM. Setting the bit high enables the counter to run while clearing the bit disables the TM. Clearing this bit to zero will stop the counter from counting and turn off the TM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value until the bit returns high again.

If the TM is in the Compare Match Output Mode, then the TM output pin will be reset to its initial condition, as specified by the TnOC bit, when the TnON bit changes from low to high.

Bit 7~2 Unimplemented, read as "0"

#### TMnC1 Register

Bit 7~6 TnAM1~TnAM0: Select TMn CCRA Operation Mode

00: Compare Match Output Mode

01: Capture Input Mode

10: PWM Mode or Single Pulse Output Mode

11: Timer/Counter Mode

These bits setup the required operating mode for the TM. To ensure reliable operation the TM should be switched off before any changes are made to the TnAM1 and TnAM0 bits. In the Timer/Counter Mode, the TM output pin control must be disabled.

Bit 5~4 TnAIO1~TnAIO0: Select TPnA output function

Compare Match Output Mode

00: No change

01: Output low

10: Output high

11: Toggle output

PWM Mode/Single Pulse Output Mode

00: PWM Output inactive state

01: PWM Output active state

10: PWM output

11: Single pulse output

Capture input Mode

00: Input capture at rising edge of TPnA

01: Input capture at falling edge of TPnA

01: Input capture at falling/rising edge of TPnA

11: Input capture disabled

Timer/Counter Mode

Unused

These two bits are used to determine how the TM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the TM is running.

In the Compare Match Output Mode, the TnAIO1 and TnAIO0 bits determine how the TM output pin changes state when a compare match occurs from the Comparator A. The TM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the bits are both zero, then no change will take place on the output. The initial value of the TM output pin should be setup using the TnAOC bit in the TMnC1 register. Note that the output level requested by the TnAIO1 and TnAIO0 bits must be different from the initial value setup using the TnAOC bit otherwise no change will occur on the TM output pin when a compare match occurs. After the TM output pin changes state, it can be reset to its initial level by changing the level of the TnON bit from low to high.

In the PWM Mode, the TnAIO1 and TnAIO0 bits determine how the TM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to change the values of the TnAIO1 and TnAIO0 bits only after the TM has been switched off. Unpredictable PWM outputs will occur if the TnAIO1 and TnAIO0 bits are changed when the TM is running.

# BC66F840/BC66F850/BC66F860 2.4GHz Flash RF TX/RX MCU

Bit 3 TnAOC: TPnA output control bit

Compare Match Output Mode

0: Initial low

1: Initial high

PWM Mode/Single Pulse Output Mode

0: Active low

1: Active high

This is the output control bit for the TM output pin. Its operation depends upon whether TM is being used in the Compare Match Output Mode or in the PWM Mode/ Single Pulse Output Mode. It has no effect if the TM is in the Timer/Counter Mode. In the Compare Match Output Mode it determines the logic level of the TM output pin before a compare match occurs. In the PWM Mode it determines if the PWM signal is active high or active low.

Bit 2 TnAPOL: TPnA output Polarity control

0: Non-invert

1: Invert

This bit controls the polarity of the TPnA output pin. When the bit is set high the TM output pin will be inverted and not inverted when the bit is zero. It has no effect if the TM is in the Timer/Counter Mode.

Bit 1 TnCDN: TMn Counter count up or down flag

0: Count Up

1: Count Down

Bit 0 TnCCLR: Select TMn Counter clear condition

0: TMn Comparator P match

1: TMn Comparator A match

This bit is used to select the method which clears the counter. Remember that the Enhanced TM contains three comparators, Comparator A, Comparator B and Comparator P, but only Comparator A or Comparator P can be selected to clear the internal counter. With the TnCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The TnCCLR bit is not used in the Single Pulse or Input Capture Mode.

| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |
| POR  | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

Bit 7~0 TnRP7~TnRP0: TMn CCRP register bit 7~bit 0, compare with the TMn counter bit

Comparator P Match Period

0: 65536 TMn clocks

1~255: (1~255)×256 TMn clocks

These eight bits are used to setup the value on the internal CCRP 8-bit register, which are then compared with the internal counter's highest eight bits. The result of this comparison can be selected to clear the internal counter if the TnCCLR bit is set to zero. Setting the TnCCLR bit to zero ensures that a compare match with the CCRP values will reset the internal counter. As the CCRP bits are only compared with the highest eight counter bits, the compare values exist in 256 clock cycle multiples. Clearing all eight bits to zero is in effect allowing the counter to overflow at its maximum value.

## **Enhanced Type TM Operation Modes**

The Enhanced Type TM can operate in one of five operating modes, Compare Match Output Mode, PWM Output Mode, Single Pulse Output Mode, Capture Input Mode or Timer/Counter Mode. The operating mode is selected using the TnAM1 and TnAM0 bits in the TMnC1, and the TnBM1 and TnBM0 bits in the TMnC2 register.

"√": permitted, "—": not permitted

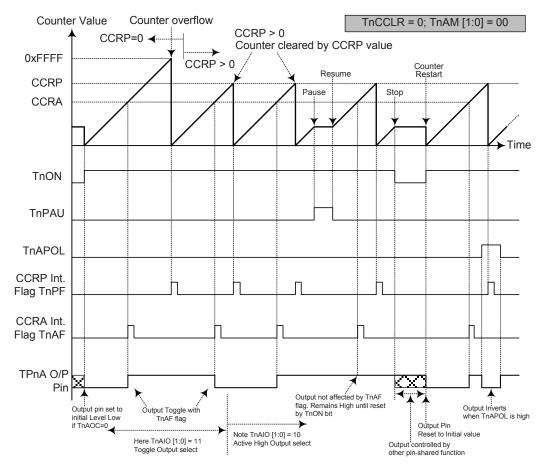

## **Compare Match Output Mode**

To select this mode, bits TnAM1, TnAM0 and TnBM1, TnBM0 in the TMnC1/TMnC2 registers should be all cleared to zero. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the TnCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match occurs from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both the TnAF and TnPF interrupt request flags for Comparator A and Comparator P respectively, will both be generated.

If the TnCCLR bit in the TMnC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the TnAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when TnCCLR is high no TnPF interrupt request flag will be generated.

As the name of the mode suggests, after a comparison is made, the TM output pin, will change state. The TM output pin condition however only changes state when a TnAF or TnBF interrupt request flag is generated after a compare match occurs from Comparator A or Comparator B. The TnPF interrupt request flag, generated from a compare match from Comparator P, will have no effect on the TM output pin. The way in which the TM output pin changes state is determined by the condition of the TnAIO1 and TnAIO0 bits in the TMnC1 register for ETM CCRA, and the TnBIO1 and TnBIO0 bits in the TMnC2 register for ETM CCRB. The TM output pin can be selected using the TnAIO1, TnAIO0 bits for the TPnA pin and TnBIO1, TnBIO0 bits for the TPnB pin to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A or a compare match occurs from Comparator B. The initial condition of the TM output pin, which is setup after the TnON bit changes from low to high, is setup using the TnAOC or TnBOC bit for TPnA or TPnB output pin. Note that if the TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits are zero then no pin change will take place.

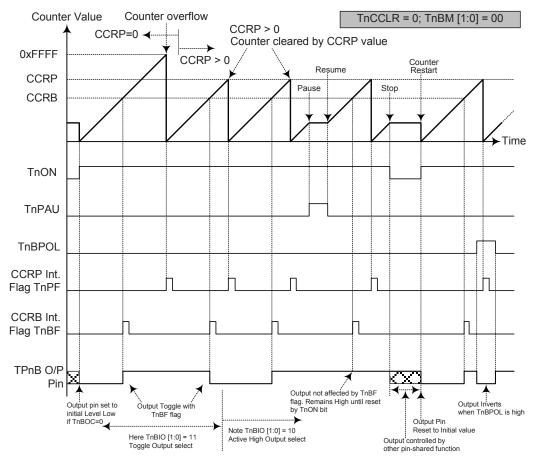

ETM CCRA Compare Match Output Mode - TnCCLR=0

Note: 1. With TnCCLR=0, a Comparator P match will clear the counter

- 2. The TPnA output pin is controlled only by the TnAF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. n=3

Rev. 1.50 118 July 12, 2017

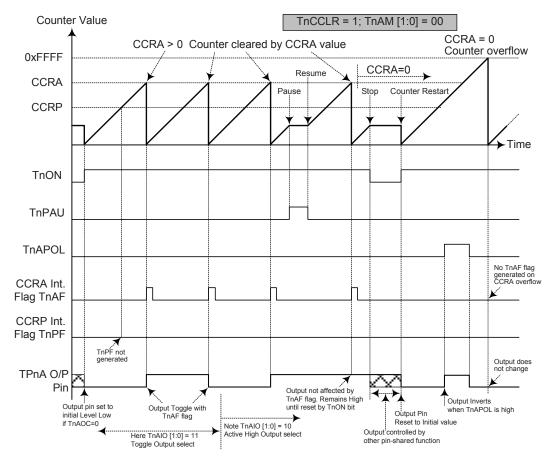

ETM CCRB Compare Match Output Mode - TnCCLR=0

Note: 1. With TnCCLR=0, a Comparator P match will clear the counter

- 2. The TPnB output pin is controlled only by the TnBF flag
- 3. The output pin is reset to its initial state by a TnON bit rising edge
- 4. n=3

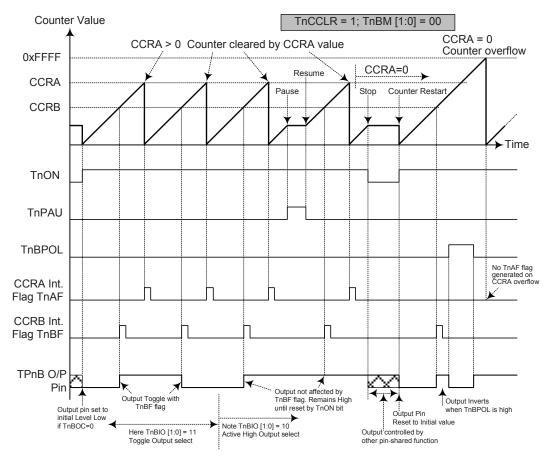

ETM CCRA Compare Match Output Mode - TnCCLR=1

Note: 1. With TnCCLR=1, a Comparator A match will clear the counter

- 2. The TPnA output pin is controlled only by the TnAF flag
- 3. The TPnA output pin is reset to its initial state by a TnON bit rising edge
- 4. The TnPF flag is not generated when TnCCLR=1
- 5. n=3

ETM CCRB Compare Match Output Mode - TnCCLR=1

Note: 1. With TnCCLR=1, a Comparator A match will clear the counter

- 2. The TPnB output pin is controlled only by the TnBF flag
- 3. The TPnB output pin is reset to its initial state by a TnON bit rising edge
- 4. The TnPF flag is not generated when TnCCLR=1
- 5. n=3

#### **Timer/Counter Mode**

To select this mode, bits TnAM1, TnAM0 and TnBM1, TnBM0 in the TMnC1 and TMnC2 register should all be set high. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the TM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the TM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function.

## **PWM Output Mode**

To select this mode, the required bit pairs, TnAM1, TnAM0 and TnBM1, TnBM0 should be set to 10 respectively and also the TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits should be set to 10 respectively. The PWM function within the TM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the TM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS values.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM mode, the TnCCLR bit is used to determine in which way the PWM period is controlled. With the TnCCLR bit set high, the PWM period can be finely controlled using the CCRA registers. In this case the CCRB registers are used to set the PWM duty value (for TPnB output pins). The CCRP bits are not used and TPnA output pin is not used. The PWM output can only be generated on the TPnB output pins. With the TnCCLR bit cleared to zero, the PWM period is set using the eight CCRP bits, in multiples of 256. Now both CCRA and CCRB registers can be used to setup different duty cycle values to provide dual PWM outputs on their relative TPnA and TPnB pins.

The TnPWM1 and TnPWM0 bits determine the PWM alignment type, which can be either edge or centre type. In edge alignment, the leading edge of the PWM signals will all be generated concurrently when the counter is reset to zero. With all power currents switching on at the same time, this may give rise to problems in higher power applications. In centre alignment the centre of the PWM active signals will occur sequentially, thus reducing the level of simultaneous power switching currents.

Interrupt flags, one for each of the CCRA, CCRB and CCRP, will be generated when a compare match occurs from either the Comparator A, Comparator B or Comparator P. The TnAOC and TnBOC bits in the TMnC1 and TMnC2 register are used to select the required polarity of the PWM waveform while the two TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits pairs are used to enable the PWM output or to force the TM output pin to a fixed high or low level. The TnAPOL and TnBPOL bit are used to reverse the polarity of the PWM output waveform.

Rev. 1.50 122 July 12, 2017

#### ETM, PWM Mode, Edge-aligned Mode, TnCCLR=0

| CCRP   | 1     | 2     |  | 127     | 128     |  | 254     | 255     |  |  |
|--------|-------|-------|--|---------|---------|--|---------|---------|--|--|
| Period | 1×256 | 2×256 |  | 127×256 | 128×256 |  | 254×256 | 255×256 |  |  |
| A Duty |       | CCRA  |  |         |         |  |         |         |  |  |
| B Duty |       | CCRB  |  |         |         |  |         |         |  |  |

If  $f_{SYS}$ =16MHz, TM clock source select  $f_{SYS}$ /4, CCRP=2, CCRA=128 and CCRB=256,

The TP1A PWM output frequency= $(f_{SYS}/4)/(2\times256)=f_{SYS}/2048=7.8125$ kHz, duty=128/512=25%.

The TP1B PWM output frequency= $(f_{SYS}/4)/(2\times256)=f_{SYS}/2048=7.8125$ kHz, duty=256/512=50%.

If the Duty value defined by CCRA or CCRB register is equal to or greater than the Period value, then the PWM output duty is 100%.

- 4. CCRA controls the TPnB PWM period and CCRB controls the TPnB PWM duty
- 5. CCRP will generate an interrupt request when the counter decrements to its zero value
- 6. n=3

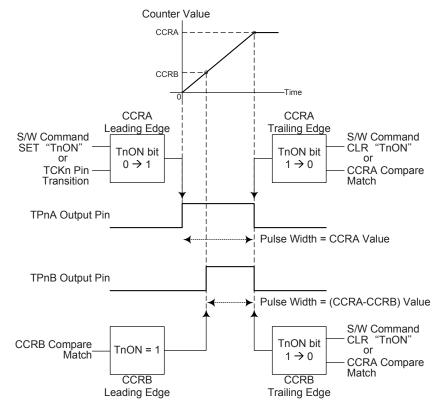

## Single Pulse Output Mode

To select this mode, the required bit pairs, TnAM1, TnAM0 and TnBM1, TnBM0 should be set to 10 respectively and also the corresponding TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits should be set to 11 respectively. The Single Pulse Output Mode, as the name suggests, will generate a single shot pulse on the TM output pin.

The trigger for the pulse TPnA output leading edge is a low to high transition of the TnON bit, which can be implemented using the application program. The trigger for the pulse TPnB output leading edge is a compare match from Comparator B, which can be implemented using the application program. However in the Single Pulse Mode, the TnON bit can also be made to automatically change from low to high using the external TCKn pin, which will in turn initiate the Single Pulse output of TPnA. When the TnON bit transitions to a high level, the counter will start running and the pulse leading edge of TPnA will be generated. The TnON bit should remain high when the pulse is in its active state. The generated pulse trailing edge of TPnA and TPnB will be generated when the TnON bit is cleared to zero, which can be implemented using the application program or when a compare match occurs from Comparator A.

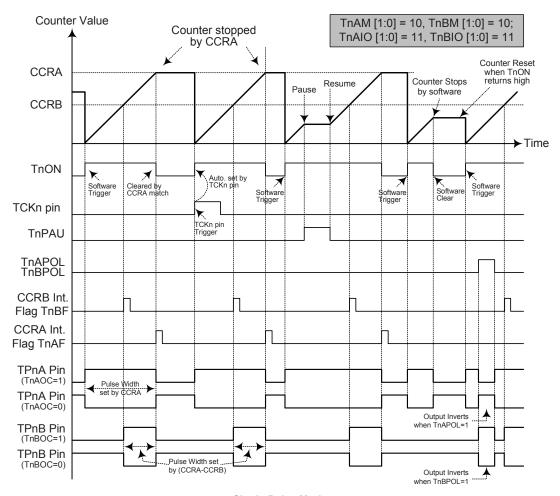

However a compare match from Comparator A will also automatically clear the TnON bit and thus generate the Single Pulse output trailing edge of TPnA and TPnB. In this way the CCRA value can be used to control the pulse width of TPnA. The CCRA-CCRB value can be used to control the pulse width of TPnB. A compare match from Comparator A and Comparator B will also generate TM interrupts. The counter can only be reset back to zero when the TnON bit changes from low to high when the counter restarts. In the Single Pulse Mode CCRP is not used. The TnCCLR bit is also not used.

Single Pulse Generation

Rev. 1.50 128 July 12, 2017

Single Pulse Mode

Note: 1. Counter stopped by CCRA

- 2. CCRP is not used
- 3. The pulse is triggered by the TCKn pin or by setting the TnON bit high
- 4. A TCKn pin active edge will automatically set by the TnON bit high
- $5.\ In\ the\ Single\ Pulse\ Mode,\ TnAIO\ [1:0]\ and\ TnBIO\ [1:0]\ must\ be\ set\ to\ ``11"\ and\ can\ not\ be\ changed$
- 6. n=3

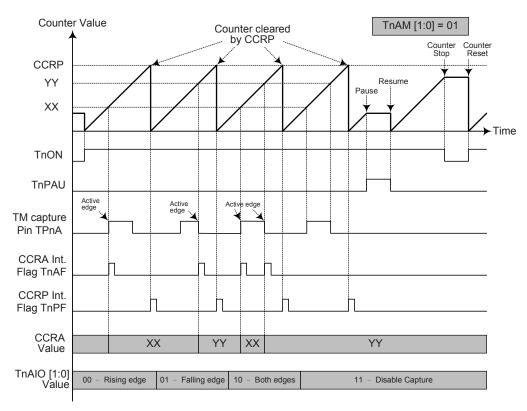

## **Capture Input Mode**

To select this mode bits TnAM1, TnAM0 and TnBM1, TnBM0 in the TMnC1 and TMnC2 registers should be set to 01 respectively. This mode enables external signals to capture and store the present value of the internal counter and can therefore be used for applications such as pulse width measurements. The external signal is supplied on the TPnA and TPnB pins, whose active edge can be either a rising edge, a falling edge or both rising and falling edges; the active edge transition type is selected using the TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits in the TMnC1 and TMnC2 registers. The counter is started when the TnON bit changes from low to high which is initiated using the application program.

When the required edge transition appears on the TPnA and TPnB pins the present value in the counter will be latched into the CCRA and CCRB registers and a TM interrupt generated. Irrespective of what events occur on the TPnA and TPnB pins the counter will continue to free run until the TnON bit changes from high to low. When a CCRP compare match occurs the counter will reset back to zero; in this way the CCRP value can be used to control the maximum counter value. When a CCRP compare match occurs from Comparator P, a TM interrupt will also be generated. Counting the number of overflow interrupt signals from the CCRP can be a useful method in measuring long pulse widths. The TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits can select the active trigger edge on the TPnA and TPnB pins to be a rising edge, falling edge or both edge types. If the TnAIO1, TnAIO0 and TnBIO1, TnBIO0 bits are both set high, then no capture operation will take place irrespective of what happens on the TPnA and TPnB pins, however it must be noted that the counter will continue to run.

As the TPnA and TPnB pins are pin shared with other functions, care must be taken if the TM is in the Capture Input Mode. This is because if the pin is setup as an output, then any transitions on this pin may cause an input capture operation to be executed. The TnCCLR, TnAOC, TnBOC, TnAPOL and TnBPOL bits are not used in this mode.

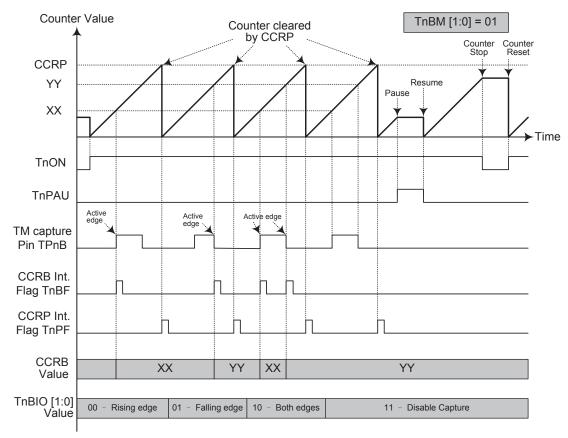

# **ETM CCRA Capture Input Mode**

Note: 1. TnAM [1:0]=01 and active edge set by the TnAIO [1:0] bits

- 2. The TM Capture input pin active edge transfers the counter value to CCRA
- 3. TnCCLR bit not used
- 4. No output function TnAOC and TnAPOL bits not used
- 5. CCRP determines the counter value and the counter has a maximum count value when CCRP is equal to zero
- 6. n=3

**ETM CCRB Capture Input Mode** 

Note: 1. TnBM [1:0]=01 and active edge set by the TnBIO [1:0] bits

- 2. The TM Capture input pin active edge transfers the counter value to CCRB
- 3. TnCCLR bit not used
- 4. No output function TnBOC and TnBPOL bits not used
- 5. CCRP determines the counter value and the counter has a maximum count value when CCRP is equal to zero
- 6. n=3

# **Analog to Digital Converter**

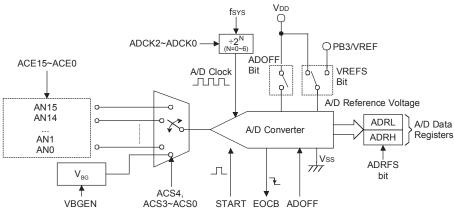

The need to interface to real world analog signals is a common requirement for many electronic systems. However, to properly process these signals by a microcontroller, they must first be converted into digital signals by A/D converters. By integrating the A/D conversion electronic circuitry into the microcontroller, the need for external components is reduced significantly with the corresponding follow-on benefits of lower costs and reduced component space requirements.

#### A/D Overview

The devices contain a multi-channel analog to digital converter which can directly interface to external analog signals, such as that from sensors or other control signals and convert these signals directly into either a 12-bit digital value.

| Part No.              | Input Channels | A/D Channel Select Bits | Input Pins |
|-----------------------|----------------|-------------------------|------------|
| BC66F840              | 8              | ACS4, ACS2~ACS0         | AN0~AN7    |
| BC66F850/<br>BC66F860 | 16             | ACS4~ACS0               | AN0~AN15   |

The accompanying block diagram shows the overall internal structure of the A/D converter, together with its associated registers.

A/D Converter Structure

# A/D Converter Register Description

Overall operation of the A/D converter is controlled using five registers. A read only register pair exists to store the ADC data 12-bit value. The remaining three registers are control registers which setup the operating and control function of the A/D converter.

A/D Converter Register List – BC66F850/BC66F860

## A/D Converter Data Registers - ADRL, ADRH

As the devices contain an internal 12-bit A/D converter, they require two data registers to store the converted value. These are a high byte register, known as ADRH, and a low byte register, known as ADRL. After the conversion process takes place, these registers can be directly read by the microcontroller to obtain the digitised conversion value. As only 12 bits of the 16-bit register space is utilised, the format in which the data is stored is controlled by the ADRFS bit in the ADCR0 register as shown in the accompanying table. D0~D11 are the A/D conversion result data bits. Any unused bits will be read as zero.

#### A/D Converter Control Registers - ADCR0, ADCR1, ACERL, ACERH

To control the function and operation of the A/D converter, up to four control registers known as ADCR0, ADCR1, ACERL and ACERH are provided. These 8-bit registers define functions such as the selection of which analog channel is connected to the internal A/D converter, the digitised data format, the A/D clock source as well as controlling the start function and monitoring the A/D converter end of conversion status. The ACS bit field in the ADCR0 register and ACS4 bit is the ADCR1 register define the ADC input channel number. As the devices contain only one actual analog to digital converter hardware circuit, each of the individual analog inputs must be routed to the converter. It is the function of the ACS4 and ACS bit field to determine which analog channel input pins or internal bandgap reference voltage is actually connected to the internal A/D converter.

The ACERL and ACERH control registers contain the ACE bit field which determines which pins on I/O ports are used as analog inputs for the A/D converter input and which pins are not to be used as the A/D converter input. Setting the corresponding bit high will select the A/D input function, clearing the bit to zero will select either the I/O or other pin-shared function. When the pin is selected to be an A/D input, its original function whether it is an I/O or other pin-shared function will be removed. In addition, any internal pull-high resistors connected to these pins will be automatically removed if the pin is selected to be an A/D input.

## ADCR0 Register - BC66F840

| Bit  | 7     | 6    | 5     | 4     | 3 | 2    | 1    | 0    |
|------|-------|------|-------|-------|---|------|------|------|
| Name | START | EOCB | ADOFF | ADRFS | _ | ACS2 | ACS1 | ACS0 |
| R/W  | R/W   | R    | R/W   | R/W   | _ | R/W  | R/W  | R/W  |
| POR  | 0     | 1    | 1     | 0     | _ | 0    | 0    | 0    |

Bit 7 START: Start the A/D conversion

 $0 \rightarrow 1 \rightarrow 0$ : start

0→1: Reset the A/D converter and set EOCB to "1"

This bit is used to initiate an A/D conversion process. The bit is normally low but if set high and then cleared low again, the A/D converter will initiate a conversion process. When the bit is set high the A/D converter will be reset.

Bit 6 **EOCB:** End of A/D conversion flag

0: A/D conversion ended

1: A/D conversion in progress

This read only flag is used to indicate when an A/D conversion process has completed. When the conversion process is running, the bit will be high.

Bit 5 ADOFF: A/D module on/off control bit

0: A/D module power on

1: A/D module power off

This bit controls the power to the A/D internal function. This bit should be cleared to zero to enable the A/D converter. If the bit is set high then the A/D converter will be switched off reducing the devices power consumption. As the A/D converter will consume a limited amount of power, even when not executing a conversion, this may be an important consideration in power sensitive battery powered applications.

Note: 1. It is recommended to set ADOFF=1 before entering IDLE/SLEEP Mode for saving power.

2. ADOFF=1 will power down the ADC module.

Bit 4 ADRFS: A/D Data Format control bit

0: ADC Data MSB is ADRH bit 7, LSB is ADRL bit 4

1: ADC Data MSB is ADRH bit 3, LSB is ADRL bit 0

This bit controls the format of the 12-bit converted A/D value in the two A/D data registers. Details are provided in the A/D data register section.

Bit 3 Unimplemented, read as "0"

Bit 2~0 ACS2~ACS0: Select A/D channel (when ACS4 is 0)

000: AN0 001: AN1 010: AN2 011: AN3 100: AN4 101: AN5 110: AN6 111: AN7

#### ADCR0 Register - BC66F850/BC66F860

| Bit  | 7     | 6    | 5     | 4     | 3    | 2    | 1    | 0    |

| Name | START | EOCB | ADOFF | ADRFS | ACS3 | ACS2 | ACS1 | ACS0 |
| R/W  | R/W   | R    | R/W   | R/W   | R/W  | R/W  | R/W  | R/W  |
| POR  | 0     | 1    | 1     | 0     | 0    | 0    | 0    | 0    |

Bit 7 START: Start the A/D conversion

 $0 \rightarrow 1 \rightarrow 0$ : start

0→1: Reset the A/D converter and set EOCB to "1"

This bit is used to initiate an A/D conversion process. The bit is normally low but if set high and then cleared low again, the A/D converter will initiate a conversion process. When the bit is set high the A/D converter will be reset.

Bit 6 EOCB: End of A/D conversion flag

0: A/D conversion ended

1: A/D conversion in progress

This read only flag is used to indicate when an A/D conversion process has completed. When the conversion process is running, the bit will be high.

Bit 5 ADOFF: A/D module on/off control bit

0: A/D module power on

1: A/D module power off

This bit controls the power to the A/D internal function. This bit should be cleared to zero to enable the A/D converter. If the bit is set high then the A/D converter will be switched off reducing the devices power consumption. As the A/D converter will consume a limited amount of power, even when not executing a conversion, this may be an important consideration in power sensitive battery powered applications.

Note: 1. It is recommended to set ADOFF=1 before entering IDLE/SLEEP Mode for saving power.

2. ADOFF=1 will power down the ADC module.

Bit 4 ADRFS: A/D Data Format control bit

0: ADC Data MSB is ADRH bit 7, LSB is ADRL bit 4

1: ADC Data MSB is ADRH bit 3, LSB is ADRL bit 0

This bit controls the format of the 12-bit converted A/D value in the two A/D data registers. Details are provided in the A/D data register section.

Bit 3~0 ACS3~ACS0: Select A/D channel (when ACS4 is 0)

0000: AN0

0001: AN1

0010: AN2

0011: AN3

0100: AN4

0101: AN5

0110: AN6

0111: AN7

1000: AN8

1001: AN9

1010: AN10

1011: AN11

1110: AN14

1111: AN15

## **ADCR1 Register**

| Bit  | 7    | 6     | 5 | 4     | 3 | 2     | 1     | 0     |
|------|------|-------|---|-------|---|-------|-------|-------|
| Name | ACS4 | VBGEN | _ | VREFS | _ | ADCK2 | ADCK1 | ADCK0 |
| R/W  | R/W  | R/W   | _ | R/W   | _ | R/W   | R/W   | R/W   |
| POR  | 0    | 0     | _ | 0     | _ | 0     | 0     | 0     |

Bit 7 ACS4: Select internal bandgap reference voltage as ADC input Control

0: Disable 1: Enable

This bit enables the internal bandgap reference voltage to be connected to the A/D converter. The VBGEN bit must first have been set to enable the bandgap circuit reference voltage to be used by the A/D converter. When the ACS4 bit is set high, the Bandgap reference voltage will be routed to the A/D converter and the other A/D input channels disconnected.

Bit 6 VBGEN: Internal Bandgap reference voltage Control

0: Disable 1: Enable

This bit controls the internal Bandgap circuit on/off function to the A/D converter. When the bit is set high the bandgap voltage can be used by the A/D converter. If the bandgap voltage is not used by the A/D converter and the LVR/LVD function is disabled then the bandgap reference circuit will be automatically switched off to conserve power. When the bandgap reference voltage is switched on for use by the A/D converter, a time  $t_{BG}$  should be allowed for the bandgap circuit to stabilise before implementing an A/D conversion.

Bit 5 Unimplemented, read as "0"

Bit 4 VREFS: Select ADC reference voltage

0: Internal ADC power

1: VREF pin

This bit is used to select the reference voltage for the A/D converter. If the bit is high, then the A/D converter reference voltage is supplied on the external VREF pin. If the pin is low, then the internal reference is used which is taken from the power supply pin VDD.

Bit 3 Unimplemented, read as "0"

Bit 2~0 ADCK2~ADCK0: Select ADC converter clock source

000: f<sub>SYS</sub> 001: f<sub>SYS</sub>/2 010: f<sub>SYS</sub>/4 011: f<sub>SYS</sub>/8 100: f<sub>SYS</sub>/16 101: f<sub>SYS</sub>/32 110: f<sub>SYS</sub>/64

111: Undefined, can not be used

These three bits are used to select the clock source for the A/D converter.

#### **ACERL Register**

0: Not A/D input 1: A/D input, AN9

Bit 0 ACE8: Define AN8 is A/D input or not

0: Not A/D input 1: A/D input, AN8

## A/D Operation

The START bit in the ADCR0 register is used to start and reset the A/D converter. When the microcontroller sets this bit from low to high and then low again, an analog to digital conversion cycle will be initiated. When the START bit is brought from low to high but not low again, the EOCB bit in the ADCR0 register will be set high and the analog to digital converter will be reset. It is the START bit that is used to control the overall start operation of the internal analog to digital converter.

The EOCB bit in the ADCR0 register is used to indicate when the analog to digital conversion process is complete. This bit will be automatically set to 0 by the microcontroller after a conversion cycle has ended. In addition, the corresponding A/D interrupt request flag will be set in the interrupt control register, and if the interrupts are enabled, an appropriate internal interrupt signal will be generated. This A/D internal interrupt signal will direct the program flow to the associated A/D internal interrupt address for processing. If the A/D internal interrupt is disabled, the microcontroller can be used to poll the EOCB bit in the ADCR0 register to check whether it has been cleared as an alternative method of detecting the end of an A/D conversion cycle.

The clock source for the A/D converter, which originates from the system clock  $f_{SYS}$ , can be chosen to be either  $f_{SYS}$  or a subdivided version of  $f_{SYS}$ . The division ratio value is determined by the ADCK2 $\sim$ ADCK0 bits in the ADCR1 register.

Although the A/D clock source is determined by the system clock f<sub>SYS</sub>, and by bits ADCK2~ADCK0, there are some limitations on the A/D clock source speed range that can be selected. As the recommended range of permissible A/D clock period, t<sub>ADCK</sub>, is from 0.5µs to 10µs, care must be taken for selected system clock frequencies. For example, if the system clock operates at a frequency of 4MHz, the ADCK2~ADCK0 bits should not be set to 000B or 110B. Doing so will give A/D clock periods that are less than the minimum A/D clock period or greater than the maximum A/D clock period which may result in inaccurate A/D conversion values. Refer to the following table for examples, where values marked with an asterisk \* show where, depending upon the devices, special care must be taken, as the values may be less than the specified minimum A/D Clock Period.

| fsys  | A/D Clock Period (tadck)                    |   |  |   |  |  |  |                                   |  |  |

A/D Clock Period Examples

Rev. 1.50 141 July 12, 2017

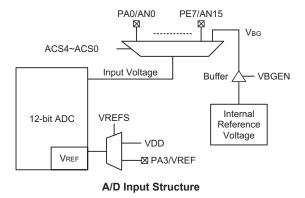

Controlling the power on/off function of the A/D converter circuitry is implemented using the ADOFF bit in the ADCR0 register. This bit must be zero to power on the A/D converter. When the ADOFF bit is cleared to zero to power on the A/D converter internal circuitry a certain delay, as indicated in the timing diagram, must be allowed before an A/D conversion is initiated. Even if no pins are selected for use as A/D inputs by clearing the ACE15~ACE0 bits in the ACERL and ACERH registers, if the ADOFF bit is zero then some power will still be consumed. In power conscious applications it is therefore recommended that the ADOFF is set high to reduce power consumption when the A/D converter function is not being used.

The reference voltage supply to the A/D Converter can be supplied from either the positive power supply pin, VDD, or from an external reference sources supplied on pin VREF. The desired selection is made using the VREFS bit. As the VREF pin is pin-shared with other functions, when the VREFS bit is set high, the VREF pin function will be selected and the other pin functions will be disabled automatically.

## A/D Input Pins

All of the A/D analog input pins are pin-shared with the I/O pins as well as other functions. The ACE7~ACE0 bits in the ACERL register together with the ACE15~ACE8 bits in the ACERH register for BC66F850 and BC66F860 devices determine whether the input pins are setup as A/D converter analog inputs or whether they have other functions. If the ACE15~ACE0 bits for its corresponding pin is set high then the pin will be setup to be an A/D converter input and the original pin functions disabled. In this way, pins can be changed under program control to change their function between A/D inputs and other functions. All pull-high resistors, which are setup through register programming, will be automatically disconnected if the pins are setup as A/D inputs. Note that it is not necessary to first setup the A/D pin as an input in the port control register to enable the A/D input as when the ACE15~ACE0 bits enable an A/D input, the status of the port control register will be overridden.

The A/D converter has its own reference voltage pin VREF however the reference voltage can also be supplied from the power supply pin, a choice which is made through the VREFS bit in the ADCR1 register. The analog input values must not be allowed to exceed the value of  $V_{\text{REF}}$ .

Rev. 1.50 142 July 12, 2017

• Step 7

## **Summary of A/D Conversion Steps**

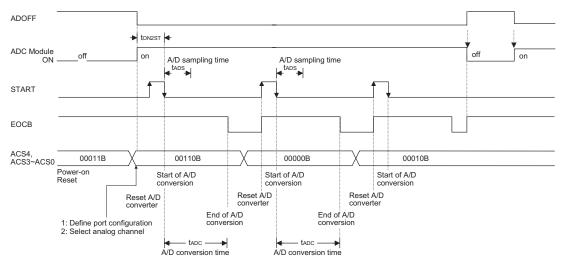

The following summarises the individual steps that should be executed in order to implement an A/D conversion process.

- Step 1
   Select the required A/D conversion clock by correctly programming bits ADCK2~ADCK0 in the ADCR1 register.
- Step 2
   Enable the A/D by clearing the ADOFF bit in the ADCR0 register to zero.
- Step 3
   Select which channel is to be connected to the internal A/D converter by correctly programming the ACS4 and ACS3~ACS0 bits which are also contained in the ADCR1 and ADCR0 registers.
- Step 4
   Select which pins are to be used as A/D inputs and configure them by correctly programming the ACE15~ACE0 bits in the ACERL and ACERH registers.
- Step 5
   If the interrupts are to be used, the interrupt control registers must be correctly configured to ensure the A/D converter interrupt function is active. The master interrupt control bit, EMI, and the A/D converter interrupt bit, ADE, must both be set to high to do this.
- Step 6
   The analog to digital conversion process can now be initialised by setting the START bit in the ADCR0 register from low to high and then to low again. Note that this bit should have been originally cleared to 0.
  - To check when the analog to digital conversion process is complete, the EOCB bit in the ADCR0 register can be polled. The conversion process is complete when this bit goes low. When this occurs, the A/D data registers ADRL and ADRH can be read to obtain the conversion value. As an alternative method if the interrupts are enabled and the stack is not full, the program can wait for an A/D interrupt to occur.

Note: When checking for the end of the conversion process, if the method of polling the EOCB bit in the ADCR0 register is used, the interrupt enable step above can be omitted.

The accompanying diagram shows graphically the various stages involved in an analog to digital conversion process and its associated timing. After an A/D conversion process has been initiated by the application program, the microcontroller internal hardware will begin to carry out the conversion, during which time the program can continue with other functions. The time taken for the A/D conversion is 16 t<sub>ADCK</sub> where t<sub>ADCK</sub> is equal to the A/D clock period.

A/D Conversion Timing

## **Programming Considerations**

During microcontroller operates where the A/D converter is not being used, the A/D internal circuitry can be switched off to reduce power consumption, by setting bit ADOFF high in the ADCR0 register. When this happens, the internal A/D converter circuits will not consume power irrespective of what analog voltage is applied to their input lines. If the A/D converter input lines are used as normal I/Os, then care must be taken as if the input voltage is not at a valid logic level, then this may lead to some increase in power consumption.

The power-on reset condition of the A/D converter control registers will ensure that the shared function pins are setup as A/D converter inputs. If any of the A/D converter input pins are to be used for other functions, then the A/D converter control register bits must be properly setup to disable the A/D input configuration.

## A/D Transfer Function

As the devices contain a 12-bit A/D converter, its full-scale converted digitised value is equal to FFFH. Since the full-scale analog input value is equal to the  $V_{DD}$  or  $V_{REF}$  voltage, this gives a single bit analog input value of  $V_{DD}$  or  $V_{REF}$  divided by 4096.

1 LSB= 
$$(V_{DD} \text{ or } V_{REF}) \div 4096$$

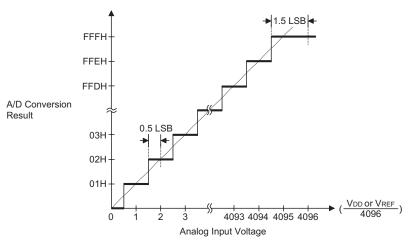

The A/D Converter input voltage value can be calculated using the following equation:

A/D input voltage = A/D output digital value 
$$\times$$
 (V<sub>DD</sub> or V<sub>REF</sub>) $\div$ 4096

The diagram shows the ideal transfer function between the analog input value and the digitised output value for the A/D converter. Except for the digitised zero value, the subsequent digitised values will change at a point 0.5 LSB below where they would change without the offset, and the last full scale digitised value will change at a point 1.5 LSB below the  $V_{\rm DD}$  or  $V_{\rm REF}$  level.

Ideal A/D Transfer Function

## A/D Programming Examples

The following two programming examples illustrate how to setup and implement an A/D conversion. In the first example, the method of polling the EOCB bit in the ADCR0 register is used to detect when the conversion cycle is complete, whereas in the second example, the A/D interrupt is used to determine when the conversion is complete.

### Example 1: using an EOCB polling method to detect the end of conversion

```
clr ADE
                      ; disable ADC interrupt
mov a,03H
mov ADCR1,a
                      ; select f_{\text{SYS}}/8 as A/D clock and switch off the internal Bandgap
                      ; reference voltage
clr ADOFF
                      ; setup ACERL to configure pins ANO~AN3
mov a,0Fh
mov ACERL, a
mov a,00h
mov ADCR0, a
                      ; enable and connect ANO channel to A/D converter
start conversion:
clr START
                      ; high pulse on start bit to initiate conversion
set START
                      ; reset A/D
clr START
                      ; start A/D
polling EOC:
sz EOCB
                      ; poll the ADCRO register EOCB bit to detect end of A/D conversion
jmp polling EOC
                     ; continue polling
mov a,ADRL
                     ; read low byte conversion result value
mov ADRL buffer,a
                   ; save result to user defined register
mov a, ADRH
                     ; read high byte conversion result value
mov ADRH buffer,a
                    ; save result to user defined register
jmp start conversion ; start next a/d conversion
```

### Example 2: using the interrupt method to detect the end of conversion

```
clr ADE
                       ; disable ADC interrupt
mov a,03H
                  ; select f_{\mbox{\scriptsize SYS}}/8 as A/D clock and switch off the internal Bandgap
mov ADCR1,a
                        ; reference voltage
clr ADOFF
mov a,0Fh
                       ; setup ACERL to configure pins ANO~AN3
mov ACERL, a
mov a,00h
mov ADCRO, a
               ; enable and connect ANO channel to A/D converter
Start conversion:
                       ; high pulse on START bit to initiate conversion
clr START
set START
                      ; reset A/D
clr START
                      ; start A/D
clr ADF
                       ; clear ADC interrupt request flag
                      ; enable ADC interrupt
set ADE
set EMI
                      ; enable global interrupt
                       ; ADC interrupt service routine
ADC ISR:
mov acc stack,a
                      ; save ACC to user defined memory
mov a,STATUS
mov status stack,a ; save STATUS to user defined memory
                      ; read low byte conversion result value
mov a, ADRL
mov adrl_buffer,a ; save result to user defined register mov a,ADRH ; read high byte conversion result value mov adrh_buffer,a ; save result to user defined register
EXIT INT ISR:
mov a, status stack
mov STATUS,a ; restore STATUS from user defined memory mov a,acc_stack ; restore ACC from user defined memory
reti
```

# **Comparators**

An analog comparator is contained within these devices. These functions offer flexibility via their register controlled features such as power-down, polarity select, hysteresis etc. In sharing their pins with normal I/O pins the comparators do not waste precious I/O pins if there functions are otherwise unused.

## **Comparator Operation**

The devices contain a comparator function which is used to compare two analog voltages and provide an output based on their difference. Full control over the internal comparators is provided via the control register CPC assigned to the comparator. The comparator output is recorded via a bit in the control register, but can also be transferred out onto a shared I/O pin. Additional comparator functions include, output polarity, hysteresis functions and power down control.

Any pull-high resistors connected to the shared comparator input pins will be automatically disconnected when the comparator is enabled. As the comparator inputs approach their switching level, some spurious output signals may be generated on the comparator output due to the slow rising or falling nature of the input signals. This can be minimised by selecting the hysteresis function will apply a small amount of positive feedback to the comparator. Ideally the comparator should switch at the point where the positive and negative inputs signals are at the same voltage level, however, unavoidable input offsets introduce some uncertainties here. The hysteresis function, if enabled, also increases the switching offset value.

## Comparator Interrupt

The comparator possesses its own interrupt function. When the comparator output changes state, its relevant interrupt flag will be set, and if the corresponding interrupt enable bit is set, then a jump to its relevant interrupt vector will be executed. Note that it is the changing state of the COUT bit and not the output pin which generates an interrupt. If the microcontroller is in the SLEEP or IDLE Mode and the Comparator is enabled, then if the external input lines cause the Comparator output to change state, the resulting generated interrupt flag will also generate a wake-up. If it is required to disable a wake-up from occurring, then the interrupt flag should be first set high before entering the SLEEP or IDLE Mode.

## **Programming Considerations**

If the comparator is enabled, it will remain active when the microcontroller enters the SLEEP or IDLE Mode, however as it will consume a certain amount of power, the user may wish to consider disabling it before the SLEEP or IDLE Mode is entered.

As comparator pins are shared with normal I/O pins the I/O registers for these pins will be read as zero (port control register is "1") or read as port data register value (port control register is "0") if the comparator function is enabled.

#### **CPC Register**

| Bit  | 7    | 6   | 5    | 4    | 3   | 2 | 1 | 0     |
|------|------|-----|------|------|-----|---|---|-------|
| Name | CSEL | CEN | CPOL | COUT | cos | _ | _ | CHYEN |
| R/W  | R/W  | R/W | R/W  | R/W  | R/W | _ | _ | R/W   |
| POR  | 1    | 0   | 0    | 0    | 0   | _ | _ | 1     |

Bit 7 CSEL: Select Comparator pins or I/O pins

0: I/O pin select

1: Comparator pin select

This is the Comparator pin or I/O pin select bit. If the bit is high the comparator will be selected and the two comparator input pins will be enabled. As a result, these two pins will lose their I/O pin functions. Any pull-high configuration options associated with the comparator shared pins will also be automatically disconnected.

Bit 6 CEN: Comparator On/Off control

0: Off

1: On

This is the Comparator on/off control bit. If the bit is zero the comparator will be switched off and no power consumed even if analog voltages are applied to its inputs. For power sensitive applications this bit should be cleared to zero if the comparator is not used or before the device enters the SLEEP or IDLE mode.

Bit 5 **CPOL**: Comparator output polarity

0: Output not inverted

1: Output inverted

This is the comparator polarity bit. If the bit is zero then the COUT bit will reflect the non-inverted output condition of the comparator. If the bit is high the comparator COUT bit will be inverted.

Bit 4 **COUT:** Comparator output bit

CPOL=0

0: C+ < C-

1: C+>C-

CPOL=1

0: C+ > C-

1: C+ < C-

This bit stores the comparator output bit. The polarity of the bit is determined by the voltages on the comparator inputs and by the condition of the CPOL bit.

Bit 3 **COS**: Output path select

0: CX pin

1: Internal use

This is the comparator output path select control bit. If the bit is set to "0" and the CSEL bit is "1" the comparator output is connected to an external CX pin. If the bit is set to "1" or the CSEL bit is "0" the comparator output signal is only used internally by the device allowing the shared comparator output pin to retain its normal I/O operation.

Bit 2~1 Unimplemented, read as "0"

Bit 0 **CHYEN:** Hysteresis Control

0: Off

1: On

This is the hysteresis control bit and if set high will apply a limited amount of hysteresis to the comparator, as specified in the Comparator Electrical Characteristics table. The positive feedback induced by hysteresis reduces the effect of spurious switching near the comparator threshold.

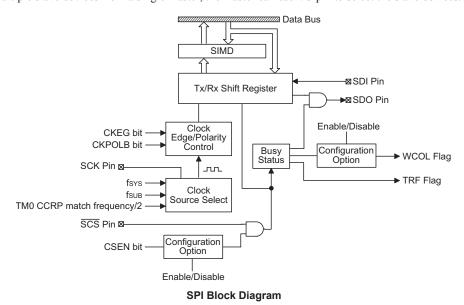

# Serial Interface Module - SIM

These devices contain a Serial Interface Module, which includes both the four line SPI interface and the two line I<sup>2</sup>C interface types, to allow an easy method of communication with external peripheral hardware. Having relatively simple communication protocols, these serial interface types allow the microcontroller to interface to external SPI or I<sup>2</sup>C based hardware such as sensors, Flash or EEPROM memory, etc. The SIM interface pins are pin-shared with other I/O pins therefore the SIM interface function must first be selected using a configuration option. As both interface types share the same pins and registers, the choice of whether the SPI or I<sup>2</sup>C type is used is made using the SIM operating mode control bits, named SIM2~SIM0, in the SIMC0 register. These pull-high resistors of the SIM pin-shared I/O pins are selected using pull-high control registers and also if the SIM function is enabled.

#### **SPI Interface**

The SPI interface is often used to communicate with external peripheral devices such as sensors, Flash or EEPROM memory devices etc. Originally developed by Motorola, the four line SPI interface is a synchronous serial data interface that has a relatively simple communication protocol simplifying the programming requirements when communicating with external hardware devices.

The communication is full duplex and operates as a slave/master type, where the devices can be either master or slave. Although the SPI interface specification can control multiple slave devices from a single master, these devices provided only one  $\overline{SCS}$  pin. If the master needs to control multiple slave devices from a single master, the master can use I/O pin to select the slave devices.

## **SPI Interface Operation**

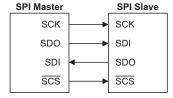

The SPI interface is a full duplex synchronous serial data link. It is a four line interface with pin names SDI, SDO, SCK and  $\overline{SCS}$ . Pins SDI and SDO are the Serial Data Input and Serial Data Output lines, SCK is the Serial Clock line and  $\overline{SCS}$  is the Slave Select line. As the SPI interface pins are pin-shared with normal I/O pins and with the I²C function pins, the SPI interface must first be enabled by selecting the SIM enable configuration option and setting the correct bits in the SIMCO and SIMC2 registers. After the SPI configuration option has been configured it can also be additionally disabled or enabled using the SIMEN bit in the SIMCO register. Communication between devices connected to the SPI interface is carried out in a slave/master mode with all data transfer initiations being implemented by the master. The Master also controls the clock signal. As the devices only contain a single  $\overline{SCS}$  pin only one slave device can be utilized. The  $\overline{SCS}$  pin is controlled by software, set CSEN bit to 1 to enable  $\overline{SCS}$  pin function, set CSEN bit to 0 the  $\overline{SCS}$  pin will be floating state.

The SPI function in these devices offer the following features:

- · Full duplex synchronous data transfer
- · Both Master and Slave modes
- · LSB first or MSB first data transmission modes
- · Transmission complete flag
- · Rising or falling active clock edge
- · WCOL and CSEN bit enabled or disable select

The status of the SPI interface pins is determined by a number of factors such as whether the devices are in the master or slave mode and upon the condition of certain control bits such as CSEN and SIMEN.

There are several configuration options associated with the SPI interface. One of these is to enable the SIM function which selects the SIM pins rather than normal I/O pins. Note that if the configuration option does not select the SIM function then the SIMEN bit in the SIMC0 register will have no effect. Another two SPI configuration options determine if the CSEN and WCOL bits are to be used.

**SPI Master/Slave Connection** 

# **SPI Registers**

There are three internal registers which control the overall operation of the SPI interface. These are the SIMD data register and two registers SIMC0 and SIMC2. Note that the SIMC1 register is only used by the I<sup>2</sup>C interface.

| Register |      |      |        | В     | it    |       |       |     |
|----------|------|------|--------|-------|-------|-------|-------|-----|
| Name     | 7    | 6    | 5      | 4     | 3     | 2     | 1     | 0   |
| SIMC0    | SIM2 | SIM1 | SIM0   | PCKEN | PCKP1 | PCKP0 | SIMEN | _   |
| SIMD     | D7   | D6   | D5     | D4    | D3    | D2    | D1    | D0  |
| SIMC2    | D7   | D6   | CKPOLB | CKEG  | MLS   | CSEN  | WCOL  | TRF |

**SIM Registers List** 

### SIMD Register

The SIMD register is used to store the data being transmitted and received. The same register is used by both the SPI and I<sup>2</sup>C functions. Before the devices write data to the SPI bus, the actual data to be transmitted must be placed in the SIMD register. After the data is received from the SPI bus, the devices can read it from the SIMD register. Any transmission or reception of data from the SPI bus must be made via the SIMD register.

#### SIMD Register

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | D7  | D6  | D5  | D4  | D3  | D2  | D1  | D0  |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | х   | Х   | Х   | Х   | Х   | Х   | х   | х   |

"x": unknown

There are also two control registers for the SPI interface, SIMC0 and SIMC2. Note that the SIMC2 register also has the name SIMA which is used by the I<sup>2</sup>C function. The SIMC1 register is not used by the SPI function, only by the I<sup>2</sup>C function. Register SIMC0 is used to control the enable/disable function and to set the data transmission clock frequency. Although not connected with the SPI function, the SIMC0 register is also used to control the Peripheral Clock Prescaler. Register SIMC2 is used for other control functions such as LSB/MSB selection, write collision flag etc.

### SIMC0 Register

| Bit  | 7    | 6    | 5    | 4     | 3     | 2     | 1     | 0 |
|------|------|------|------|-------|-------|-------|-------|---|
| Name | SIM2 | SIM1 | SIM0 | PCKEN | PCKP1 | PCKP0 | SIMEN | _ |
| R/W  | R/W  | R/W  | R/W  | R/W   | R/W   | R/W   | R/W   | _ |
| POR  | 1    | 1    | 1    | 0     | 0     | 0     | 0     | _ |

Bit 7~5 SIM2, SIM1, SIM0: SIM Operating Mode Control

000: SPI master mode; SPI clock is f<sub>SYS</sub>/4 001: SPI master mode; SPI clock is f<sub>SYS</sub>/16 010: SPI master mode; SPI clock is f<sub>SYS</sub>/64 011: SPI master mode; SPI clock is f<sub>SUB</sub>

100: SPI master mode; SPI clock is TM0 CCRP match frequency/2

101: SPI slave mode 110: I<sup>2</sup>C slave mode 111: Unused mode

These bits setup the overall operating mode of the SIM function. As well as selecting if the I<sup>2</sup>C or SPI function, they are used to control the SPI Master/Slave selection and the SPI Master clock frequency. The SPI clock is a function of the system clock but can also be chosen to be sourced from the TM0. If the SPI Slave Mode is selected then the clock will be supplied by an external Master device.

Bit 4 **PCKEN:** PCK Output Pin Control

0: Disable 1: Enable

Bit 3~2 **PCKP1, PCKP0**: Select PCK output pin frenquency

00: f<sub>SYS</sub> 01: f<sub>SYS</sub>/4 10: f<sub>SYS</sub>/8

11: TM0 CCRP match frequency/2

Bit 1 SIMEN: SIM Control

0: Disable 1: Enable

The bit is the overall on/off control for the SIM interface. When the SIMEN bit is cleared to zero to disable the SIM interface, the SDI, SDO, SCK and SCS, or SDA and SCL lines will be in a floating condition and the SIM operating current will be reduced to a minimum value. When the bit is high the SIM interface is enabled. The SIM configuration option must have first enabled the SIM interface for this bit to be effective. If the SIM is configured to operate as an SPI interface via the SIM2~SIM0 bits, the contents of the SPI control registers will remain at the previous settings when the SIMEN bit changes from low to high and should therefore be first initialised by the application program. If the SIM is configured to operate as an I²C interface via the SIM2~SIM0 bits and the SIMEN bit changes from low to high, the contents of the I²C control bits such as HTX and TXAK will remain at the previous settings and should therefore be first initialised by the application program while the relevant I²C flags such as HCF, HAAS, HBB, SRW and RXAK will be set to their default states.

Bit 0 Unimplemented, read as "0"

#### SIMC2 Register

| Bit  | 7   | 6   | 5      | 4    | 3   | 2    | 1    | 0   |
|------|-----|-----|--------|------|-----|------|------|-----|
| Name | D7  | D6  | CKPOLB | CKEG | MLS | CSEN | WCOL | TRF |
| R/W  | R/W | R/W | R/W    | R/W  | R/W | R/W  | R/W  | R/W |
| POR  | 0   | 0   | 0      | 0    | 0   | 0    | 0    | 0   |

#### Bit 7~6 Undefined bit

This bit can be read or written by the user software program.

Bit 5 **CKPOLB:** Determines the base condition of the clock line

0: The SCK line will be high when the clock is inactive

1: The SCK line will be low when the clock is inactive

The CKPOLB bit determines the base condition of the clock line, if the bit is high, then the SCK line will be low when the clock is inactive. When the CKPOLB bit is low, then the SCK line will be high when the clock is inactive.

Bit 4 CKEG: Determines SPI SCK active clock edge type

CKPOLB=0

0: SCK is high base level and data capture at SCK rising edge

1: SCK is high base level and data capture at SCK falling edge

CKPOLB=1

0: SCK is low base level and data capture at SCK falling edge

1: SCK is low base level and data capture at SCK rising edge

The CKEG and CKPOLB bits are used to setup the way that the clock signal outputs and inputs data on the SPI bus. These two bits must be configured before data transfer is executed otherwise an erroneous clock edge may be generated. The CKPOLB bit determines the base condition of the clock line, if the bit is high, then the SCK line will be low when the clock is inactive. When the CKPOLB bit is low, then the SCK line will be high when the clock is inactive. The CKEG bit determines active clock edge type which depends upon the condition of CKPOLB bit.

Bit 3 MLS: SPI Data shift order

0: LSB

1: MSB

This is the data shift select bit and is used to select how the data is transferred, either MSB or LSB first. Setting the bit high will select MSB first and low for LSB first.

### Bit 2 CSEN: SPI SCS pin Control

0: Disable

1: Enable

The CSEN bit is used as an enable/disable for the  $\overline{SCS}$  pin. If this bit is low, then the  $\overline{SCS}$  pin will be disabled and placed into a floating condition. If the bit is high the  $\overline{SCS}$  pin will be enabled and used as a select pin.

Note that using the CSEN bit can be disabled or enabled via configuration option.

# Bit 1 WCOL: SPI Write Collision flag

0: No collision

1: Collision

The WCOL flag is used to detect if a data collision has occurred. If this bit is high it means that data has been attempted to be written to the SIMD register during a data transfer operation. This writing operation will be ignored if data is being transferred. The bit can be cleared by the application program.

Note that using the WCOL bit can be disabled or enabled via configuration option.

Bit 0 TRF: SPI Transmit/Receive Complete flag

0: Data is being transferred

1: SPI data transmission is completed

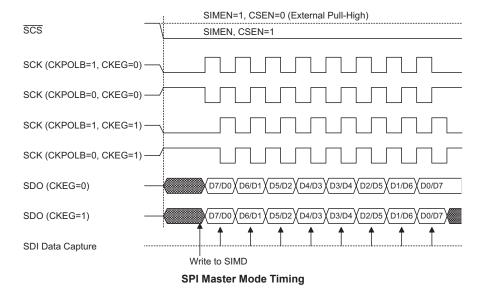

The TRF bit is the Transmit/Receive Complete flag and is set "1" automatically when an SPI data transmission is completed, but must set to "0" by the application program. It can be used to generate an interrupt.

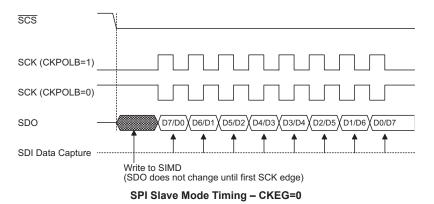

### **SPI Communication**

After the SPI interface is enabled by setting the SIMEN bit high, then in the Master Mode, when data is written to the SIMD register, transmission/reception will begin simultaneously. When the data transfer is complete, the TRF flag will be set automatically, but must be cleared using the application program. In the Slave Mode, when the clock signal from the master has been received, any data in the SIMD register will be transmitted and any data on the SDI pin will be shifted into the SIMD register.

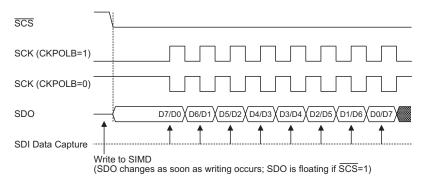

The master should output an  $\overline{SCS}$  signal to enable the slave device before a clock signal is provided. The slave data to be transferred should be well prepared at the appropriate moment relative to the  $\overline{SCS}$  signal depending upon the configurations of the CKPOLB bit and CKEG bit. The accompanying timing diagram shows the relationship between the slave data and  $\overline{SCS}$  signal for various configurations of the CKPOLB and CKEG bits. The SPI will continue to function even in the IDLE Mode.

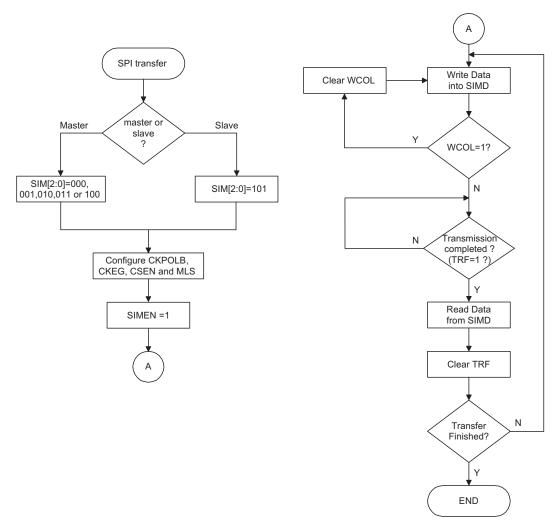

Rev. 1.50 154 July 12, 2017

Note: For SPI slave mode, if SIMEN=1 and CSEN=0, SPI is always enabled and ignores the SCS level.

# SPI Slave Mode Timing - CKEG=1

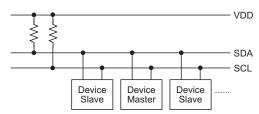

**SPI Transfer Control Flowchart** 

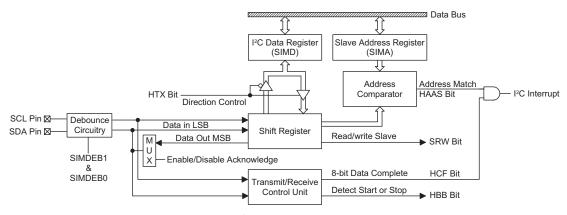

### I<sup>2</sup>C Interface

The I<sup>2</sup>C interface is used to communicate with external peripheral devices such as sensors, EEPROM memory etc. Originally developed by Philips, it is a two line low speed serial interface for synchronous serial data transfer. The advantage of only two lines for communication, relatively simple communication protocol and the ability to accommodate multiple devices on the same bus has made it an extremely popular interface type for many applications.

I<sup>2</sup>C Master Slave Bus Connection

I<sup>2</sup>C Block Diagram

## I<sup>2</sup>C Interface Operation

The I<sup>2</sup>C serial interface is a two line interface, a serial data line, SDA, and serial clock line, SCL. As many devices may be connected together on the same bus, their outputs are both open drain types. For this reason it is necessary that external pull-high resistors are connected to these outputs. Note that no chip select line exists, as each device on the I<sup>2</sup>C bus is identified by a unique address which will be transmitted and received on the I<sup>2</sup>C bus.

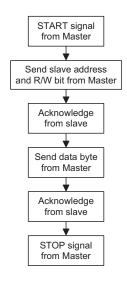

When two devices communicate with each other on the bidirectional I<sup>2</sup>C bus, one is known as the master device and one as the slave device. Both master and slave can transmit and receive data. However, it is the master device that has overall control of the bus. For these devices, which only operates in slave mode, there are two methods of transferring data on the I<sup>2</sup>C bus, the slave transmit mode and the slave receive mode.

There are several configuration options associated with the  $I^2C$  interface. One of these is to enable the function which selects the SIM pins rather than normal I/O pins. Note that if the configuration option does not select the SIM function then the SIMEN bit in the SIMC0 register will have no effect. A configuration option determines the debounce time of the  $I^2C$  interface. This uses the system clock to in effect add a debounce time to the external clock to reduce the possibility of glitches on the clock line causing erroneous operation. The debounce time, if selected, can be chosen to be either 2 or 4 system clocks. To achieve the required  $I^2C$  data transfer speed, there exists a relationship between the system clock,  $f_{SYS}$ , and the  $I^2C$  debounce time. For either the  $I^2C$  Standard or Fast mode operation, users must take care of the selected system clock frequency and the configured debounce time to match the criterion shown in the following table.

| I <sup>2</sup> C Debounce Time Selection | I <sup>2</sup> C Standard Mode (100kHz) | I <sup>2</sup> C Fast Mode (400kHz) |
|--|---|-------------------------------------|
| No debounce                              | $f_{SYS} > 2MHz$                        | f <sub>SYS</sub> > 5MHz             |
| 2 system clock debounce                  | f <sub>SYS</sub> > 4MHz                 | f <sub>SYS</sub> > 10MHz            |
| 4 system clock debounce                  | f <sub>SYS</sub> > 8MHz                 | f <sub>SYS</sub> > 20MHz            |

I<sup>2</sup>C Minimum f<sub>SYS</sub> Frequency

# I<sup>2</sup>C Registers

There are three control registers associated with the I<sup>2</sup>C bus, SIMC0, SIMC1 and SIMA and one data register, SIMD. The SIMD register, which is shown in the above SPI section, is used to store the data being transmitted and received on the I<sup>2</sup>C bus. Before the microcontroller writes data to the I<sup>2</sup>C bus, the actual data to be transmitted must be placed in the SIMD register. After the data is received from the I<sup>2</sup>C bus, the microcontroller can read it from the SIMD register. Any transmission or reception of data from the I<sup>2</sup>C bus must be made via the SIMD register.

Note that the SIMA register also has the name SIMC2 which is used by the SPI function. Bit SIMEN and bits SIM2 $\sim$ SIM0 in register SIMC0 are used by the I<sup>2</sup>C interface.

| Register |         |        |         | В       | it      |         |         |         |

I<sup>2</sup>C Registers List

### SIMC0 Register

| Bit  | 7    | 6    | 5    | 4     | 3     | 2     | 1     | 0 |
|------|------|------|------|-------|-------|-------|-------|---|
| Name | SIM2 | SIM1 | SIM0 | PCKEN | PCKP1 | PCKP0 | SIMEN | _ |
| R/W  | R/W  | R/W  | R/W  | R/W   | R/W   | R/W   | R/W   | _ |
| POR  | 1    | 1    | 1    | 0     | 0     | 0     | 0     | _ |

Bit 7~5 SIM2, SIM1, SIM0: SIM Operating Mode Control

000: SPI master mode; SPI clock is f<sub>SYS</sub>/4 001: SPI master mode; SPI clock is f<sub>SYS</sub>/16 010: SPI master mode; SPI clock is f<sub>SYS</sub>/64 011: SPI master mode; SPI clock is f<sub>SUB</sub>

100: SPI master mode; SPI clock is TM0 CCRP match frequency/2

101: SPI slave mode 110: I<sup>2</sup>C slave mode 111: Unused mode

These bits setup the overall operating mode of the SIM function. As well as selecting if the I<sup>2</sup>C or SPI function, they are used to control the SPI Master/Slave selection and the SPI Master clock frequency. The SPI clock is a function of the system clock but can also be chosen to be sourced from the TM0. If the SPI Slave Mode is selected then the clock will be supplied by an external Master device.

Bit 4 **PCKEN:** PCK Output Pin Control

0: Disable 1: Enable

Bit 3~2 **PCKP1, PCKP0**: Select PCK output pin frenquency

00: f<sub>SYS</sub> 01: f<sub>SYS</sub>/4 10: f<sub>SYS</sub>/8

11: TM0 CCRP match frequency/2

Bit 1 SIMEN: SIM Control

0: Disable 1: Enable

The bit is the overall on/off control for the SIM interface. When the SIMEN bit is cleared to zero to disable the SIM interface, the SDI, SDO, SCK and SCS, or SDA and SCL lines will be in a floating condition and the SIM operating current will be reduced to a minimum value. When the bit is high the SIM interface is enabled. The SIM configuration option must have first enabled the SIM interface for this bit to be effective. If the SIM is configured to operate as an SPI interface via the SIM2~SIM0 bits, the contents of the SPI control registers will remain at the previous settings when the SIMEN bit changes from low to high and should therefore be first initialised by the application program. If the SIM is configured to operate as an I²C interface via the SIM2~SIM0 bits and the SIMEN bit changes from low to high, the contents of the I²C control bits such as HTX and TXAK will remain at the previous settings and should therefore be first initialised by the application program while the relevant I²C flags such as HCF, HAAS, HBB, SRW and RXAK will be set to their default states.

Bit 0 Unimplemented, read as "0"

#### SIMC1 Register

| Bit  | 7   | 6    | 5   | 4   | 3    | 2   | 1     | 0    |
|------|-----|------|-----|-----|------|-----|-------|------|
| Name | HCF | HAAS | HBB | HTX | TXAK | SRW | IAMWU | RXAK |
| R/W  | R   | R    | R   | R/W | R/W  | R   | R/W   | R    |
| POR  | 1   | 0    | 0   | 0   | 0    | 0   | 0     | 1    |

Bit 7 HCF: I<sup>2</sup>C Bus data transfer completion flag

0: Data is being transferred

1: Completion of an 8-bit data transfer

The HCF flag is the data transfer flag. This flag will be zero when data is being transferred. Upon completion of an 8-bit data transfer the flag will go high and an interrupt will be generated.

Bit 6 **HAAS:** I<sup>2</sup>C Bus address match flag

0: Not address match 1: Address match

The HAAS flag is the address match flag. This flag is used to determine if the slave device address is the same as the master transmit address. If the addresses match then this bit will be high, if there is no match then the flag will be low.

Bit 5 **HBB:** I<sup>2</sup>C Bus busy flag

0: I<sup>2</sup>C Bus is not busy

1: I<sup>2</sup>C Bus is busy

The HBB flag is the I<sup>2</sup>C busy flag. This flag will be "1" when the I<sup>2</sup>C bus is busy which will occur when a START signal is detected. The flag will be set to "0" when the bus is free which will occur when a STOP signal is detected.

Bit 4 HTX: Select I<sup>2</sup>C slave device is transmitter or receiver

0: Slave device is the receiver

1: Slave device is the transmitter

Bit 3 TXAK: I<sup>2</sup>C Bus transmit acknowledge flag

0: Slave send acknowledge flag

1: Slave do not send acknowledge flag

The TXAK bit is the transmit acknowledge flag. After the slave device receipt of 8-bits of data, this bit will be transmitted to the bus on the 9th clock from the slave device. The slave device must always set TXAK bit to "0" before further data is received.

Bit 2 SRW: I<sup>2</sup>C Slave Read/Write flag

0: Slave device should be in receive mode

1: Slave device should be in transmit mode

The SRW flag is the I<sup>2</sup>C Slave Read/Write flag. This flag determines whether the master device wishes to transmit or receive data from the I<sup>2</sup>C bus. When the transmitted address and slave address is match, that is when the HAAS flag is set high, the slave device will check the SRW flag to determine whether it should be in transmit mode or receive mode. If the SRW flag is high, the master is requesting to read data from the bus, so the slave device should be in transmit mode. When the SRW flag is zero, the master will write data to the bus, therefore the slave device should be in receive mode to read this data.

Bit 1 IAMWU: I<sup>2</sup>C Address Match Wake-up Control

0: Disable

1: Enable – must be cleared by the application program after wake-up

This bit should be set to 1 to enable the I<sup>2</sup>C address match wake up from the SLEEP or IDLE Mode. If the IAMWU bit has been set before entering either the SLEEP or IDLE mode to enable the I<sup>2</sup>C address match wake up, then this bit must be cleared by the application program after wake-up to ensure correction device operation.

# BC66F840/BC66F850/BC66F860 2.4GHz Flash RF TX/RX MCU

Bit 0 **RXAK:** I<sup>2</sup>C Bus Receive acknowledge flag

0: Slave receive acknowledge flag

1: Slave does not receive acknowledge flag

The RXAK flag is the receiver acknowledge flag. When the RXAK flag is "0", it means that a acknowledge signal has been received at the 9th clock, after 8 bits of data have been transmitted. When the slave device in the transmit mode, the slave device checks the RXAK flag to determine if the master receiver wishes to receive the next byte. The slave transmitter will therefore continue sending out data until the RXAK flag is "1". When this occurs, the slave transmitter will release the SDA line to allow the master to send a STOP signal to release the I<sup>2</sup>C Bus.

The SIMD register is used to store the data being transmitted and received. The same register is used by both the SPI and I<sup>2</sup>C functions. Before the devices write data to the SPI bus, the actual data to be transmitted must be placed in the SIMD register. After the data is received from the SPI bus, the devices can read it from the SIMD register. Any transmission or reception of data from the SPI bus must be made via the SIMD register.

## **SIMD Register**

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | D7  | D6  | D5  | D4  | D3  | D2  | D1  | D0  |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | Х   | Х   | Х   | х   | х   | Х   | Х   | Х   |

"x": unknown

#### **SIMA Register**

| Bit  | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0 |
|------|-------|-------|-------|-------|-------|-------|-------|---|
| Name | IICA6 | IICA5 | IICA4 | IICA3 | IICA2 | IICA1 | IICA0 | _ |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | _ |
| POR  | х     | Х     | Х     | х     | Х     | х     | х     | _ |

"x": unknown

Bit 7~1 **IICA6~IICA0:** I<sup>2</sup>C slave address

IICA6~IICA0 is the I2C slave address bit 6~bit 0

The SIMA register is also used by the SPI interface but has the name SIMC2. The SIMA register is the location where the 7-bit slave address of the slave device is stored. Bits 7~1 of the SIMA register define the device slave address. Bit 0 is not defined.

When a master device, which is connected to the I<sup>2</sup>C bus, sends out an address, which matches the slave address in the SIMA register, the slave device will be selected. Note that the SIMA register is the same register address as SIMC2 which is used by the SPI interface.

Bit 0 Unimplemented, read as "0"

This bit can be read or written by user software program.

Rev. 1.50 160 July 12, 2017

### I<sup>2</sup>C Bus Communication

Communication on the I<sup>2</sup>C bus requires four separate steps, a START signal, a slave device address transmission, a data transmission and finally a STOP signal. When a START signal is placed on the I<sup>2</sup>C bus, all devices on the bus will receive this signal and be notified of the imminent arrival of data on the bus. The first seven bits of the data will be the slave address with the first bit being the MSB. If the address of the slave device matches that of the transmitted address, the HAAS bit in the SIMC1 register will be set and an I<sup>2</sup>C interrupt will be generated. After entering the interrupt service routine, the slave device must first check the condition of the HAAS bit to determine whether the interrupt source originates from an address match or from the completion of an 8-bit data transfer. During a data transfer, note that after the 7-bit slave address has been transmitted, the following bit, which is the 8th bit, is the read/write bit whose value will be placed in the SRW bit. This bit will be checked by the slave device to determine whether to go into transmit or receive mode. Before any transfer of data to or from the I<sup>2</sup>C bus, the microcontroller must initialise the bus, the following are steps to achieve this:

#### Step 1

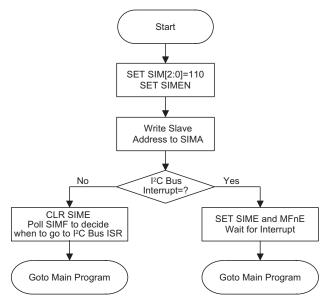

Set the SIM2~SIM0 and SIMEN bits in the SIMC0 register to 1 to enable the I<sup>2</sup>C bus.

### Step 2

Write the slave address of the devices to the I2C bus address register SIMA.

#### Step 3

Set the SIME and SIM Multi-Function interrupt enable bit of the interrupt control register to enable the SIM interrupt and Multi-function interrupt.

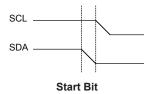

I<sup>2</sup>C Bus Initialisation Flow Chart

## I2C Bus Start Signal

The START signal can only be generated by the master device connected to the I<sup>2</sup>C bus and not by the slave device. This START signal will be detected by all devices connected to the I<sup>2</sup>C bus. When detected, this indicates that the I<sup>2</sup>C bus is busy and therefore the HBB bit will be set. A START condition occurs when a high to low transition on the SDA line takes place when the SCL line remains high.

#### **Slave Address**

The transmission of a START signal by the master will be detected by all devices on the I<sup>2</sup>C bus. To determine which slave device the master wishes to communicate with, the address of the slave device will be sent out immediately following the START signal. All slave devices, after receiving this 7-bit address data, will compare it with their own 7-bit slave address. If the address sent out by the master matches the internal address of the microcontroller slave device, then an internal I<sup>2</sup>C bus interrupt signal will be generated. The next bit following the address, which is the 8th bit, defines the read/write status and will be saved to the SRW bit of the SIMC1 register. The slave device will then transmit an acknowledge bit, which is a low level, as the 9th bit. The slave device will also set the status flag HAAS when the addresses match.

As an I<sup>2</sup>C bus interrupt can come from two sources, when the program enters the interrupt subroutine, the HAAS bit should be examined to see whether the interrupt source has come from a matching slave address or from the completion of a data byte transfer. When a slave address is matched, the device must be placed in either the transmit mode and then write data to the SIMD register, or in the receive mode where it must implement a dummy read from the SIMD register to release the SCL line.

#### I<sup>2</sup>C Bus Read/Write Signal

The SRW bit in the SIMC1 register defines whether the slave device wishes to read data from the I<sup>2</sup>C bus or write data to the I<sup>2</sup>C bus. The slave device should examine this bit to determine if it is to be a transmitter or a receiver. If the SRW flag is 1, then this indicates that the master device wishes to read data from the I<sup>2</sup>C bus, therefore the slave device must be setup to send data to the I<sup>2</sup>C bus as a transmitter. If the SRW flag is 0, then this indicates that the master wishes to send data to the I<sup>2</sup>C bus, therefore the slave device must be setup to read data from the I<sup>2</sup>C bus as a receiver.

### I<sup>2</sup>C Bus Slave Address Acknowledge Signal

After the master has transmitted a calling address, any slave device on the I<sup>2</sup>C bus, whose own internal address matches the calling address, must generate an acknowledge signal. The acknowledge signal will inform the master that a slave device has accepted its calling address. If no acknowledge signal is received by the master then a STOP signal must be transmitted by the master to end the communication. When the HAAS flag is high, the addresses have matched and the slave device must check the SRW flag to determine if it is to be a transmitter or a receiver. If the SRW flag is high, the slave device should be setup to be a transmitter so the HTX bit in the SIMC1 register should be set to 1. If the SRW flag is low, then the microcontroller slave device should be setup as a receiver and the HTX bit in the SIMC1 register should be set to 0.

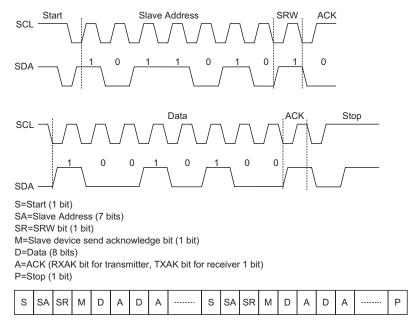

Rev. 1.50 162 July 12, 2017

# I<sup>2</sup>C Bus Data and Acknowledge Signal

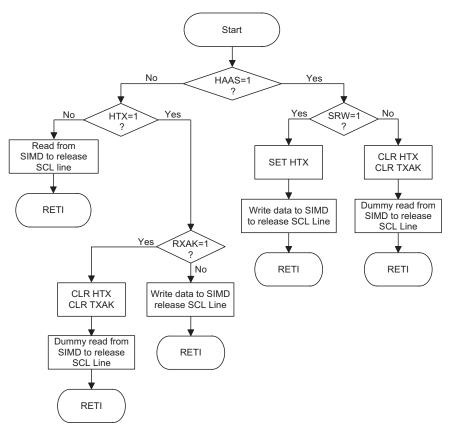

The transmitted data is 8-bits wide and is transmitted after the slave device has acknowledged receipt of its slave address. The order of serial bit transmission is the MSB first and the LSB last. After receipt of 8-bits of data, the receiver must transmit an acknowledge signal, level 0, before it can receive the next data byte. If the slave transmitter does not receive an acknowledge bit signal from the master receiver, then the slave transmitter will release the SDA line to allow the master to send a STOP signal to release the I<sup>2</sup>C Bus. The corresponding data will be stored in the SIMD register. If setup as a transmitter, the slave device must first write the data to be transmitted into the SIMD register. If setup as a receiver, the slave device must read the transmitted data from the SIMD register.

When the slave receiver receives the data byte, it must generate an acknowledge bit, known as TXAK, on the 9th clock. The slave device, which is setup as a transmitter will check the RXAK bit in the SIMC1 register to determine if it is to send another data byte, if not then it will release the SDA line and await the receipt of a STOP signal from the master.

**Note:** \*When a slave address is matched, the devices must be placed in either the transmit mode and then write data to the SIMD register, or in the receive mode where it must implement a dummy read from the SIMD register to release the SCL line.

I<sup>2</sup>C Communication Timing Diagram

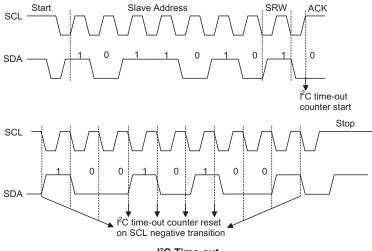

I2C Bus ISR Flow Chart

# I<sup>2</sup>C Time-out Control

In order to reduce the I<sup>2</sup>C lockup problem due to reception of erroneous clock sources, a time-out function is provided. If the clock source connected to the I<sup>2</sup>C bus is not received for a while, then the I<sup>2</sup>C circuitry and registers will be reset after a certain time-out period. The time-out counter starts to count on an I<sup>2</sup>C bus "START" & "address match" condition, and is cleared by an SCL falling edge. Before the next SCL falling edge arrives, if the time elapsed is greater than the time-out period specified by the I2CTOC register, then a time-out condition will occur. The time-out function will stop when an I<sup>2</sup>C "STOP" condition occurs.

Rev. 1.50 164 July 12, 2017

I<sup>2</sup>C Time-out

When an I<sup>2</sup>C time-out counter overflow occurs, the counter will stop and the I2CTOEN bit will be cleared to zero and the I2CTF bit will be set high to indicate that a time-out condition has occurred. The time-out condition will also generate an interrupt which uses the I<sup>2</sup>C interrupt vector. When an I<sup>2</sup>C time-out occurs, the I<sup>2</sup>C internal circuitry will be reset and the registers will be reset into the following condition:

| Register          | After I <sup>2</sup> C Time-out |
|-------------------|---------------------------------|
| SIMD, SIMA, SIMC0 | No change                       |
| SIMC1             | Reset to POR condition          |

I<sup>2</sup>C Registers after Time-out

The I2CTOF flag can be cleared by the application program. There are 64 time-out period selections which can be selected using the I2CTOS bits in the I2CTOC register. The time-out duration is calculated by the formula:  $((1\sim64)\times(32/f_{SUB}))$ . This gives a time-out period which ranges from about 1ms to 64ms.

# **I2CTOC** Register

| Bit  | 7       | 6      | 5       | 4       | 3       | 2       | 1       | 0       |

 $I^2C$  Time-out clock source is  $f_{SUB}/32$ 

I<sup>2</sup>C Time-out time is given by: (I2CTOS [5:0] +1)×(32/ $f_{SUB}$ )

# **Peripheral Clock Output**

The Peripheral Clock Output allows the devices to supply external hardware with a clock signal synchronised to the microcontroller clock.

# **Peripheral Clock Operation**

As the peripheral clock output pin, PCK, is shared with I/O line, the required pin function is chosen via PCKEN in the SIMC0 register. The Peripheral Clock function is controlled using the SIMC0 register. The clock source for the Peripheral Clock Output can originate from either the TM0 CCRP match frequency/2 or a divided ratio of the internal f<sub>SYS</sub> clock. The PCKEN bit in the SIMC0 register is the overall on/off control, setting PCKEN bit to 1 enables the Peripheral Clock and setting PCKEN bit to 0 disables it. The required division ratio of the system clock is selected using the PCKP1 and PCKP0 bits in the same register. If the devices enter the SLEEP Mode, this will disable the Peripheral Clock output.

### SIMC0 Register

| Bit  | 7    | 6    | 5    | 4     | 3     | 2     | 1     | 0 |

Bit 7~5 SIM2, SIM1, SIM0: SIM Operating Mode Control

000: SPI master mode; SPI clock is  $f_{SYS}/4$  001: SPI master mode; SPI clock is  $f_{SYS}/16$  010: SPI master mode; SPI clock is  $f_{SYS}/64$  011: SPI master mode; SPI clock is  $f_{SUB}$ 

100: SPI master mode; SPI clock is TM0 CCRP match frequency/2

101: SPI slave mode 110: I<sup>2</sup>C slave mode 111: Unused mode

These bits setup the overall operating mode of the SIM function. As well as selecting if the I<sup>2</sup>C or SPI function, they are used to control the SPI Master/Slave selection and the SPI Master clock frequency. The SPI clock is a function of the system clock but can also be chosen to be sourced from the TM0. If the SPI Slave Mode is selected then the clock will be supplied by an external Master device.

Bit 4 **PCKEN:** PCK Output Pin Control

0: Disable 1: Enable

Bit 3~2 **PCKP1**, **PCKP0**: Select PCK output pin frenquency

00: f<sub>SYS</sub> 01: f<sub>SYS</sub>/4 10: f<sub>SYS</sub>/8

11: TM0 CCRP match frequency/2

Rev. 1.50 166 July 12, 2017

Bit 1 SIMEN: SIM Control

0: Disable 1: Enable

The bit is the overall on/off control for the SIM interface. When the SIMEN bit is cleared to zero to disable the SIM interface, the SDI, SDO, SCK and \$\overline{SCS}\$, or SDA and SCL lines will be in a floating condition and the SIM operating current will be reduced to a minimum value. When the bit is high the SIM interface is enabled. The SIM configuration option must have first enabled the SIM interface for this bit to be effective. If the SIM is configured to operate as an SPI interface via the SIM2~SIM0 bits, the contents of the SPI control registers will remain at the previous settings when the SIMEN bit changes from low to high and should therefore be first initialised by the application program. If the SIM is configured to operate as an I²C interface via the SIM2~SIM0 bits and the SIMEN bit changes from low to high, the contents of the I²C control bits such as HTX and TXAK will remain at the previous settings and should therefore be first initialised by the application program while the relevant I²C flags such as HCF, HAAS, HBB, SRW and RXAK will be set to their default states.

Bit 0 Unimplemented, read as "0"

# Serial Interface - SPIA

The devices contain an independent SPI function. It is important not to confuse this independent SPI function with the additional one contained within the combined SIM function, which is described in another section of this datasheet. This independent SPI function will carry the name SPIA to distinguish it from the other one in the SIM.

This SPIA interface is often used to communicate with external peripheral devices such as sensors, Flash or EEPROM memory devices, etc. Originally developed by Motorola, the four-line SPI interface is a synchronous serial data interface that has a relatively simple communication protocol simplifying the programming requirements when communicating with external hardware devices.

The communication is full duplex and operates as a slave/master type, where the devices can be either master or slave. Although the SPIA interface specification can control multiple slave devices from a single master, these devices are provided only one SCSA line. If the master needs to control multiple slave devices from a single master, the master can use I/O pins to select the slave devices.

## **SPIA Interface Operation**

The SPIA interface is a full duplex synchronous serial data link. It is a four line interface with pin names SDIA, SDOA, SCKA and  $\overline{\text{SCSA}}$ . Signals SDIA and SDOA are the Serial Data Input and Serial Data Output lines, SCKA is the Serial Clock line and  $\overline{\text{SCSA}}$  is the Slave Select line. As the SPIA interface lines are pin-shared with other functions, the SPIA interface lines must first be enabled by selecting the SPIA interface enable configuration option and setting the correct bits in the SPIAC0 and SPIAC1 registers. After the SPIA enable configuration option has been configured, the SPIA interface function can also be additionally disabled or enabled using the SPIAEN bit in the SPIAC0 register. Communication between devices connected to the SPIA interface is carried out in a slave/master mode with all data transfer initiations being implemented by the master. The master also controls the clock/signal. As the devices only contain a single  $\overline{\text{SCSA}}$  pin only one slave device can be utilised.

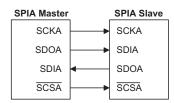

The  $\overline{SCSA}$  line is controlled by the application program, set the SACSEN bit to "1" to enable the  $\overline{SCSA}$  line function and clear the SACSEN bit to "0" to place the  $\overline{SCSA}$  pin into other pin-shared functions.

The SPIA Serial Interface function includes the following features:

- · Full duplex synchronous data transfer
- · Both Master and Slave modes
- · LSB first or MSB first data transmission modes
- · Transmission complete flag
- · Rising or falling active clock edge
- · SAWCOL and SACSEN bit enabled or disable select

The status of the SPIA interface lines is determined by a number of factors such as whether the devices are in the master or slave mode and upon the condition of certain control bits such as SACSEN and SPIAEN.

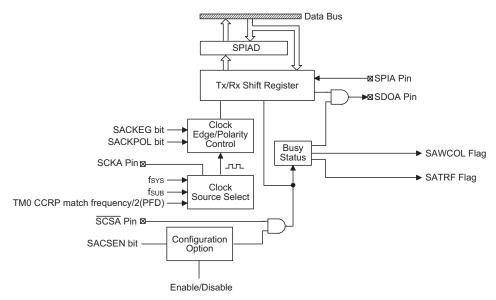

There are several configuration options associated with the SPIA interface. One of these is to enable the SPIA function which selects the SPIA lines rather than normal I/O pins. Note that if the configuration option does not select the SPIA function then the SPIAEN bit in the SPIACO register will have no effect. Another two SPIA configuration options determine if the SACSEN and SAWCOL bits are to be used.

**SPIA Master/Slave Connection** 

Rev. 1.50 168 July 12, 2017

**SPIA Block Diagram** 

# **SPIA Registers**

There are three internal registers which control the overall operation of the SPIA interface. These are the SPIAD data register and two registers SPIAC0 and SPIAC1.

| Register |        | Bit    |         |        |       |        |        |       |  |  |
|----------|--------|--------|---------|--------|-------|--------|--------|-------|--|--|
| Name     | 7      | 6      | 5       | 4      | 3     | 2      | 1      | 0     |  |  |
| SPIAC0   | SASPI2 | SASPI1 | SASPI0  | _      | _     | _      | SPIAEN | _     |  |  |
| SPIAC1   | _      | _      | SACKPOL | SACKEG | SAMLS | SACSEN | SAWCOL | SATRF |  |  |
| SPIAD    | D7     | D6     | D5      | D4     | D3    | D2     | D1     | D0    |  |  |

**SPIA Registers List** 

The SPIAD register is used to store the data being transmitted and received. Before the devices write data to the SPIA bus, the actual data to be transmitted must be placed in the SPIAD register. After the data is received from the SPIA bus, the devices can read it from the SPIAD register. Any transmission or reception of data from the SPIA bus must be made via the SPIAD register.

### **SPIAD Register**

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | D7  | D6  | D5  | D4  | D3  | D2  | D1  | D0  |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | ×   | ×   | ×   | ×   | ×   | ×   | ×   | ×   |

"x" unknown

There are also two control registers for the SPIA interface, SPIAC0 and SPIAC1. Register SPIAC0 is used to control the enable or disable function and to set the data transmission clock frequency. Register SPIAC1 is used for other control functions such as LSB/MSB selection, write collision flag, etc.

### **SPIAC0** Register

| Bit  | 7      | 6      | 5      | 4 | 3 | 2 | 1      | 0 |
|------|--------|--------|--------|---|---|---|--------|---|
| Name | SASPI2 | SASPI1 | SASPI0 | _ | _ | _ | SPIAEN | _ |
| R/W  | R/W    | R/W    | R/W    | _ | _ | _ | R/W    | _ |
| POR  | 1      | 1      | 1      | _ | _ |   | 0      | _ |

Bit 7~5 SASPI2~SASPI0: SPIA Master/Slave Clock Select

000: SPIA master, f<sub>SYS</sub>/4 001: SPIA master, f<sub>SYS</sub>/16 010: SPIA master, f<sub>SYS</sub>/64 011: SPIA master, f<sub>SUB</sub>

100: SPIA master, TM0 CCRP match frequency/2 (PFD)

101: SPIA slave 11x: Reserved

Bit 4~2 Unimplemented, read as "0"

Bit 1 SPIAEN: SPIA enable or disable

0: Disable 1: Enable

The bit is the overall on/off control for the SPIA interface. When the SPIAEN bit is cleared to zero to disable the SPIA interface, the SDIA, SDOA, SCKA and SCSA lines will lose their SPI function and the SPIA operating current will be reduced to a minimum value. When the bit is high, the SPIA interface is enabled.

Bit 0 Unimplemented, read as "0"

#### **SPIAC1** Register

| Bit  | 7 | 6 | 5       | 4      | 3     | 2      | 1      | 0     |
|------|---|---|---------|--------|-------|--------|--------|-------|
| Name | _ | _ | SACKPOL | SACKEG | SAMLS | SACSEN | SAWCOL | SATRF |
| R/W  | _ | _ | R/W     | R/W    | R/W   | R/W    | R/W    | R/W   |
| POR  | _ | _ | 0       | 0      | 0     | 0      | 0      | 0     |

Bit 7~6 Unimplemented, read as "0"

Bit 5 SACKPOL: Determines the base condition of the clock line

0: SCKA line will be high when the clock is inactive

1: SCKA line will be low when the clock is inactive

The SACKPOL bit determines the base condition of the clock line, if the bit is high, then the SCKA line will be low when the clock is inactive. When the SACKPOL bit is low, then the SCKA line will be high when the clock is inactive.

Bit 4 SACKEG: Determines the SPIA SCKA active clock edge type SACKPOL=0:

0: SCKA has high base level with data capture on SCKA rising edge

1: SCKA has high base level with data capture on SCKA falling edge SACKPOL=1:

0: SCKA has low base level with data capture on SCKA falling edge

1: SCKA has low base level with data capture on SCKA rising edge

The SACKEG and SACKPOL bits are used to setup the way that the clock signal outputs and inputs data on the SPIA bus. These two bits must be configured before a data transfer is executed otherwise an erroneous clock edge may be generated. The SACKPOL bit determines the base condition of the clock line, if the bit is high, then the SCKA line will be low when the clock is inactive. When the SACKPOL bit is low, then the SCKA line will be high when the clock is inactive. The SACKEG bit determines active clock edge type which depends upon the condition of the SACKPOL bit.

Bit 3 SAMLS: data shift order

0: the LSB of data is transmitted first

1: the MSB of data is transmitted first

Bit 2 SACSEN: SPIA SCSA pin Control

0: Disable

1: Enable

The SACSEN bit is used as an enable/disable for the  $\overline{SCSA}$  pin. If this bit is low, then the  $\overline{SCSA}$  pin function will be disabled and used as an I/O function. If the bit is high the  $\overline{SCSA}$  pin will be enabled and used as a select pin. Note that using the SACSEN bit can be disabled or enabled via a configuration option.

# Bit 1 SAWCOL: SPIA Write Collision flag

0: Collision free

1: Collision detected

The SAWCOL flag is used to detect if a data collision has occurred. If this bit is high it means that data has been attempted to be written to the SPIAD register during a data transfer operation. This writing operation will be ignored if data is being transferred. The bit can be cleared by the application program. Note that using the SAWCOL bit can be disabled or enabled via a configuration option.

Bit 0 SATRF: SPIA Transmit/Receive Complete flag

0: Data is being transferred

1: SPIA data transmission is completed

The SATRF bit is the Transmit/Receive Complete flag and is set to "1" automatically when an SPIA data transmission is completed, but must cleared to "0" by the application program. It can be used to generate an interrupt.

## **SPIA Communication**

After the SPIA interface is enabled by setting the SPIAEN bit high, then in the Master Mode, when data is written to the SPIAD register, transmission/reception will begin simultaneously. When the data transfer is complete, the SATRF flag will be set automatically, but must be cleared using the application program. In the Slave Mode, when the clock signal from the master has been received, any data in the SPIAD register will be transmitted and any data on the SDIA pin will be shifted into the SPIAD registers.

The master should output a  $\overline{SCSA}$  signal to enable the slave device before a clock signal is provided. The slave data to be transferred should be well prepared at the appropriate moment relative to the  $\overline{SCSA}$  signal depending upon the configurations of the SACKPOL bit and SACKEG bit. The accompanying timing diagram shows the relationship between the slave data and  $\overline{SCSA}$  signal for various configurations of the SACKPOL and SACKEG bits.

The SPIA will continue to function even in the IDLE Mode.

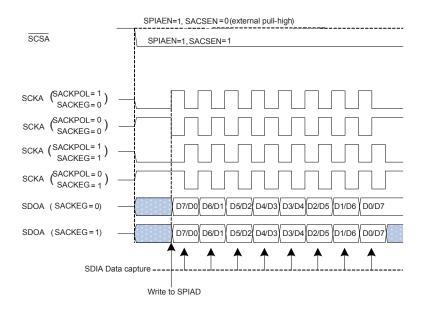

#### SPIA Bus Enable/Disable

To enable the SPIA bus, set SACSEN=1 and SCSA=0, then wait for data to be written into the SPIAD (TXRX buffer) register. For the Master Mode, after data has been written to the SPIAD (TXRX buffer) register, then transmission or reception will start automatically. When all the data has been transferred the SATRF bit should be set. For the Slave Mode, when clock pulses are received on SCKA, data in the TXRX buffer will be shifted out or data on SDIA will be shifted in.

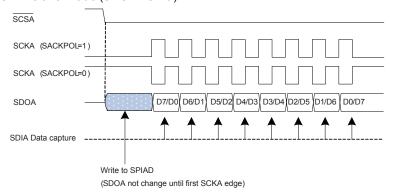

To disable the SPIA bus the SCKA, SDIA, SDOA and SCSA lines will become I/O pins or other pin-shared functions.

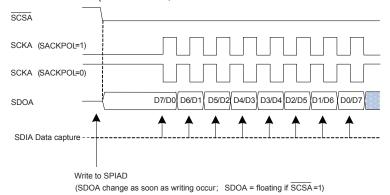

#### SPIA master mode

## SPIA slave mode (SACKEG=0)

# SPIA slave mode (SACKEG=1)

Note: For SPIA slave mode, if SPIAEN=1 and SACSEN=0, SPIA is always enabled and ignore the  $\overline{SCSA}$  level.

# **SPIA Master/Slave Mode Timing Diagram**

# **SPIA Operation**

All communication is carried out using the 4-line interface for either Master or Slave Mode.

The SACSEN bit in the SPIAC1 register controls the overall function of the SPIA interface. Setting this bit high will enable the SPIA interface by allowing the  $\overline{\text{SCSA}}$  line to be active, which can then be used to control the SPIA interface. If the SACSEN bit is low, the SPIA interface will be disabled and the  $\overline{\text{SCSA}}$  line will be an I/O pin or other pin-shared functions and can therefore not be used for control of the SPIA interface. If the SACSEN bit and the SPIAEN bit in the SPIAC0 register are set high, this will place the SDIA line in a floating condition and the SDOA line high. If in Master Mode the SCKA line will be either high or low depending upon the clock polarity selection bit SACKPOL in the SPIAC1 register. If in Slave Mode the SCKA line will be in a floating condition. If SPIAEN is low then the bus will be disabled and  $\overline{\text{SCSA}}$ , SDIA, SDOA and SCKA lines will all become I/O pins or other pin-shared functions. In the Master Mode the Master will always generate the clock signal. The clock and data transmission will be initiated after data has been written into the SPIAD register. In the Slave Mode, the clock signal will be received from an external master device for both data transmission and reception. The following sequences show the order to be followed for data transfer in both Master and Slave Mode:

#### **Master Mode**

- Step 1
   Select the clock source and Master mode using the SASPI2~SASPI0 bits in the SPIAC0 control register
- Step 2
   Setup the SACSEN bit and setup the SAMLS bit to choose if the data is MSB or LSB shifted first, this must be same as the Slave device.
- Step 3
   Setup the SPIAEN bit in the SPIAC0 control register to enable the SPIA interface.
- For write operations: write the data to the SPIAD register, which will actually place the data into the TXRX buffer. Then use the SCKA and SCSA lines to output the data. After this go to step 5. For read operations: the data transferred in on the SDIA line will be stored in the TXRX buffer until all the data has been received at which point it will be latched into the SPIAD register.
- Step 5
   Check the SAWCOL bit if set high then a collision error has occurred so return to step 4. If equal to zero then go to the following step.
- Step 6
   Check the SATRF bit or wait for a SPIA serial bus interrupt.
- Step 7
  Read data from the SPIAD register.
- Step 8 Clear SATRF.
- Step 9
  Go to step 4.

#### **Slave Mode**

• Step 1

Select the SPI Slave mode using the SASPI2~SASPI0 bits in the SPIAC0 control register

Step 2

Setup the SACSEN bit and setup the SAMLS bit to choose if the data is MSB or LSB shifted first, this setting must be the same with the Master device.

• Step 3

Setup the SPIAEN bit in the SPIAC0 control register to enable the SPIA interface.

• Step 4

For write operations: write the data to the SPIAD register, which will actually place the data into the TXRX buffer. Then wait for the master clock SCKA and  $\overline{\text{SCSA}}$  signal. After this, go to step 5. For read operations: the data transferred in on the SDIA line will be stored in the TXRX buffer until all the data has been received at which point it will be latched into the SPIAD register.

Sten 5

Check the SAWCOL bit if set high then a collision error has occurred so return to step 4. If equal to zero then go to the following step.

Step 6

Check the SATRF bit or wait for a SPIA serial bus interrupt.

Step 7

Read data from the SPIAD register.

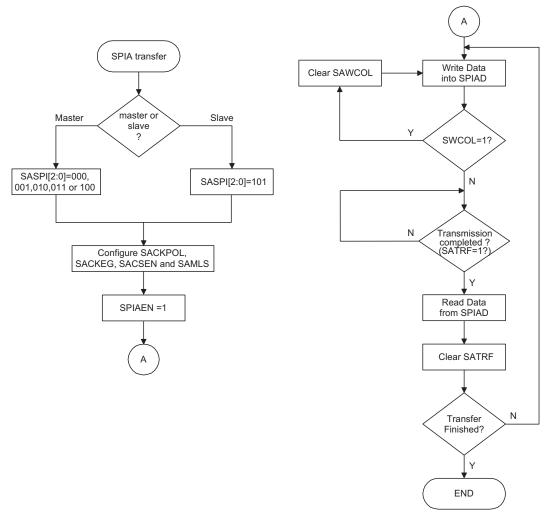

• Step 8

Clear SATRF.

• Step 9

Go to step 4.

**SPIA Transfer Control Flowchart** 

# **Error Detection**

The SAWCOL bit in the SPIAC1 register is provided to indicate errors during data transfer. The bit is set by the SPIA serial Interface but must be cleared by the application program. This bit indicates a data collision has occurred which happens if a write to the SPIAD register takes place during a data transfer operation and will prevent the write operation from continuing.

# Interrupts

Interrupts are an important part of any microcontroller system. When an external event or an internal function such as a Timer Module or an A/D converter requires microcontroller attention, their corresponding interrupt will enforce a temporary suspension of the main program allowing the microcontroller to direct attention to their respective needs. The devices contain several external interrupt and internal interrupts functions. The external interrupts are generated by the action of the external INT0 and INT1 pins while the internal interrupts are generated by various internal functions such as the TMs, Time Base, LVD and the A/D converter, etc.

# **Interrupt Registers**

Overall interrupt control, which basically means the setting of request flags when certain microcontroller conditions occur and the setting of interrupt enable bits by the application program, is controlled by a series of registers, located in the Special Purpose Data Memory, as shown in the accompanying table. The number of registers depends upon the devices chosen but fall into three categories. The first is the INTC0~INTC2 registers which setup the primary interrupts, the second is the MFI0~MFI4 registers which setup the Multi-function interrupts. Finally there is an INTEG register to setup the external interrupt trigger edge type.

Each register contains a number of enable bits to enable or disable individual registers as well as interrupt flags to indicate the presence of an interrupt request. The naming convention of these follows a specific pattern. First is listed an abbreviated interrupt type, then the (optional) number of that interrupt followed by either an "E" for enable/disable bit or "F" for request flag.

| Function       | Enable Bit | Request Flag | Notes    |
|----------------|------------|--------------|----------|
| Global         | EMI        | _            | _        |
| INTn Pins      | INTnE      | INTnF        | n=0 or 1 |
| Comparator     | CPE        | CPF          | _        |
| Multi-function | MFnE       | MFnF         | n=0~4    |
| A/D converter  | ADE        | ADF          | _        |
| Time Base      | TBnE       | TBnF         | n=0 or 1 |
| LVD            | LVE        | LVF          | _        |
| EEPROM         | DEE        | DEF          | _        |

# **Interrupt Operation**

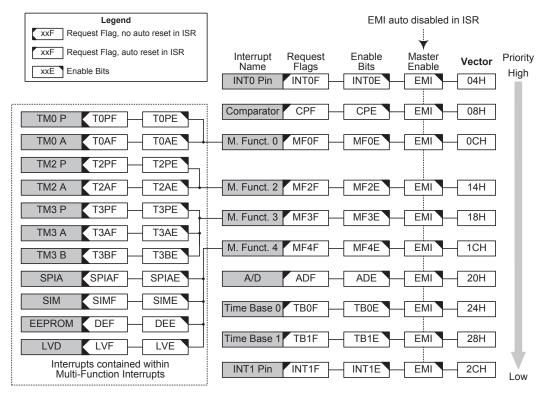

When the conditions for an interrupt event occur, such as a TM Comparator P or Comparator A match or A/D conversion completion etc, the relevant interrupt request flag will be set. Whether the request flag actually generates a program jump to the relevant interrupt vector is determined by the condition of the interrupt enable bit. If the enable bit is set high then the program will jump to its relevant vector; if the enable bit is zero then although the interrupt request flag is set an actual interrupt will not be generated and the program will not jump to the relevant interrupt vector. The global interrupt enable bit, if cleared to zero, will disable all interrupts.

When an interrupt is generated, the Program Counter, which stores the address of the next instruction to be executed, will be transferred onto the stack. The Program Counter will then be loaded with a new address which will be the value of the corresponding interrupt vector. The microcontroller will then fetch its next instruction from this interrupt vector. The instruction at this vector will usually be a JMP which will jump to another section of program which is known as the interrupt service routine. Here is located the code to control the appropriate interrupt. The interrupt service routine must be terminated with a RETI, which retrieves the original Program Counter address from the stack and allows the microcontroller to continue with normal execution at the point where the interrupt occurred.

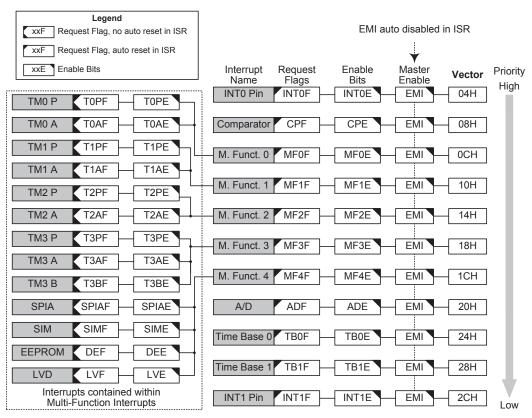

The various interrupt enable bits, together with their associated request flags, are shown in the accompanying diagrams with their order of priority. Some interrupt sources have their own individual vector while others share the same Multi-function Interrupt vector. Once an interrupt subroutine is serviced, all the other interrupts will be blocked, as the global interrupt enable bit, EMI bit will be cleared automatically. This will prevent any further interrupt nesting from occurring. However, if other interrupt requests occur during this interval, although the interrupt will not be immediately serviced, the request flag will still be recorded.

If an interrupt requires immediate servicing while the program is already in another interrupt service routine, the EMI bit should be set after entering the routine, to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the Stack Pointer is decremented. If immediate service is desired, the stack must be prevented from becoming full. In case of simultaneous requests, the accompanying diagram shows the priority that is applied. All of the interrupt request flags when set will wake-up the devices if it is in SLEEP or IDLE Mode, however to prevent a wake-up from occurring the corresponding flag should be set before the devices are in SLEEP or IDLE Mode.

### Interrupt Structure - BC66F840

Interrupt Structure - BC66F850/BC66F860

Rev. 1.50 186 July 12, 2017

### **External Interrupt**

The external interrupts are controlled by signal transitions on the INT0~INT1 pins. An external interrupt request will take place when the external interrupt request flags, INT0F~INT1F, are set, which will occur when a transition, whose type is chosen by the edge select bits, appears on the external interrupt pins. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and respective external interrupt enable bit, INT0E~INT1E, must first be set. Additionally the correct interrupt edge type must be selected using the INTEG register to enable the external interrupt function and to choose the trigger edge type. As the external interrupt pins are pin-shared with I/O pins, they can only be configured as external interrupt pins if their external interrupt enable bit in the corresponding interrupt register has been set. The pin must also be setup as an input by setting the corresponding bit in the port control register. When the interrupt is enabled, the stack is not full and the correct transition type appears on the external interrupt pin, a subroutine call to the external interrupt vector, will take place. When the interrupt is serviced, the external interrupt request flags, INT0F~INT1F, will be automatically reset and the EMI bit will be automatically cleared to disable other interrupts. Note that any pull-high resistor selections on the external interrupt pins will remain valid even if the pin is used as an external interrupt input.

The INTEG register is used to select the type of active edge that will trigger the external interrupt. A choice of either rising or falling or both edge types can be chosen to trigger an external interrupt. Note that the INTEG register can also be used to disable the external interrupt function. The INT1 pin is internally connected to the 2.4GHz RF Transceiver interrupt output. The correct interrupt edge type must be selected using the INTEG register to ensure the correct interrupt operation.

## **Comparator Interrupt**

The comparator interrupt is controlled by the internal comparator. A comparator interrupt request will take place when the comparator interrupt request flag, CPF, is set, a situation that will occur when the comparator output changes state. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and comparator interrupt enable bit, CPE, must first be set. When the interrupt is enabled, the stack is not full and the comparator inputs generate a comparator output transition, a subroutine call to the comparator interrupt vector, will take place. When the interrupt is serviced, the comparator interrupt request flag, will be automatically reset and the EMI bit will be automatically cleared to disable other interrupts.

### **Multi-function Interrupt**

Within these devices there are up to five Multi-function interrupts. Unlike the other independent interrupts, these interrupts have no independent source, but rather are formed from other existing interrupt sources, namely the TM, LVD, EEPROM, SIM and SPIA interrupts.

A Multi-function interrupt request will take place when any of the Multi-function interrupt request flags, MFnF are set. The Multi-function interrupt flags will be set when any of their included functions generate an interrupt request flag. To allow the program to branch to its respective interrupt vector address, when the Multi-function interrupt is enabled and the stack is not full, and either one of the interrupts contained within each of Multi-function interrupt occurs, a subroutine call to one of the Multi-function interrupt vectors will take place. When the interrupt is serviced, the related Multi-Function request flag, will be automatically reset and the EMI bit will be automatically cleared to disable other interrupts.

However, it must be noted that, although the Multi-function Interrupt flags will be automatically reset when the interrupt is serviced, the request flags from the original source of the Multi-function interrupts, namely the TM, LVD, EEPROM, SIM and SPIA interrupts, will not be automatically reset and must be manually reset by the application program.

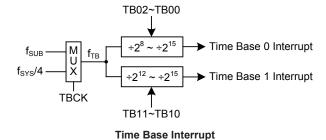

# A/D Converter Interrupt

The A/D Converter Interrupt is controlled by the termination of an A/D conversion process. An A/D Converter Interrupt request will take place when the A/D Converter Interrupt request flag, ADF, is set, which occurs when the A/D conversion process finishes. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and A/D Interrupt enable bit, ADE, must first be set. When the interrupt is enabled, the stack is not full and the A/D conversion process has ended, a subroutine call to the A/D Converter Interrupt vector, will take place. When the interrupt is serviced, the A/D Converter Interrupt flag, ADF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

# **Time Base Interrupt**

The function of the Time Base Interrupts is to provide regular time signal in the form of an internal interrupt. They are controlled by the overflow signals from their respective timer functions. When these happens their respective interrupt request flags, TB0F or TB1F will be set. To allow the program to branch to their respective interrupt vector addresses, the global interrupt enable bit, EMI and Time Base enable bits, TB0E or TB1E, must first be set. When the interrupt is enabled, the stack is not full and the Time Base overflows, a subroutine call to their respective vector locations will take place. When the interrupt is serviced, the respective interrupt request flag, TB0F or TB1F, will be automatically reset and the EMI bit will be cleared to disable other interrupts.

The purpose of the Time Base Interrupt is to provide an interrupt signal at fixed time periods. Their clock sources originate from the internal clock source  $f_{TB}$ . This  $f_{TB}$  input clock passes through a divider, the division ratio of which is selected by programming the appropriate bits in the TBC register to obtain longer interrupt periods whose value ranges. The clock source that generates  $f_{TB}$ , which in turn controls the Time Base interrupt period, can originate from several different sources, as shown in the System Operating Mode section.

Bit 2~0 **TB02~TB00:** Select Time Base 0 Time-out Period

 $\begin{array}{c} 000:\ 256/f_{TB} \\ 001:\ 512/f_{TB} \\ 010:\ 1024/f_{TB} \\ 011:\ 2048/f_{TB} \\ 100:\ 4096/f_{TB} \\ 101:\ 8192/f_{TB} \\ 110:\ 16384/f_{TB} \\ 111:\ 32768/f_{TB} \end{array}$ 

# **EEPROM Interrupt**

The EEPROM Interrupt, is contained within the Multi-function Interrupt. An EEPROM Interrupt request will take place when the EEPROM Interrupt request flag, DEF, is set, which occurs when an EEPROM Write cycle ends. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, EEPROM Interrupt enable bit, DEE, and associated Multi-function interrupt enable bit, must first be set. When the interrupt is enabled, the stack is not full and an EEPROM Write cycle ends, a subroutine call to the respective Multi-function Interrupt vector, will take place. When the EEPROM Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the DEF flag will not be automatically cleared, it has to be cleared by the application program.

## LVD Interrupt

The Low Voltage Detector Interrupt is contained within the Multi-function Interrupt. An LVD Interrupt request will take place when the LVD Interrupt request flag, LVF, is set, which occurs when the Low Voltage Detector function detects a low power supply voltage. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, Low Voltage Interrupt enable bit, LVE, and associated Multi-function interrupt enable bit, must first be set. When the interrupt is enabled, the stack is not full and a low voltage condition occurs, a subroutine call to the Multi-function Interrupt vector, will take place. When the Low Voltage Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the LVF flag will not be automatically cleared, it has to be cleared by the application program.

## Serial Interface Module Interrupt

The Serial Interface Module Interrupt, also known as the SIM interrupt, is contained within the Multi-function Interrupt. A SIM Interrupt request will take place when the SIM Interrupt request flag, SIMF, is set, which occurs when a byte of data has been received or transmitted by the SIM interface. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and the Serial Interface Interrupt enable bit, SIME, and Multi-function interrupt enable bits, must first be set. When the interrupt is enabled, the stack is not full and a byte of data has been transmitted or received by the SIM interface, a subroutine call to the respective Multi-function Interrupt vector, will take place. When the Serial Interface Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the SIMF flag will not be automatically cleared, it has to be cleared by the application program.

Rev. 1.50 190 July 12, 2017

# **SPIA Interface Interrupt**

The SPIA Interface Interrupt is contained within the Multi-function Interrupt. A SPIA Interrupt request will take place when the SPIA Interrupt request flag, SPIAF, is set, which occurs when a byte of data has been received or transmitted by the SPIA interface. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and the SPIA Interface Interrupt enable bit, SPIAE, and Multi-function interrupt enable bits, must first be set. When the interrupt is enabled, the stack is not full and a byte of data has been transmitted or received by the SPIA interface, a subroutine call to the respective Multi-function Interrupt vector, will take place. When the SPIA Interface Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the SPIAF flag will not be automatically cleared, it has to be cleared by the application program.

# **TM Interrupt**

The Compact and Standard Type TMs have two interrupts each while the Enhanced Type TM has three interrupts. All of the TM interrupts are contained within the Multi-function Interrupts. For each of the Compact and Standard Type TMs there are two interrupt request flags TnPF and TnAF and two enable bits TnPE and TnAE. For the Enhanced Type TM there are three interrupt request flags TnPF, TnAF and TnBF and three enable bits TnPE, TnAE and TnBE. A TM interrupt request will take place when any of the TM request flags are set, a situation which occurs when a TM comparator P, A or B match situation happens.

To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, respective TM Interrupt enable bit, and relevant Multi-function Interrupt enable bit, MFnE, must first be set. When the interrupt is enabled, the stack is not full and a TM comparator match situation occurs, a subroutine call to the relevant Multi-function Interrupt vector locations, will take place. When the TM interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the related MFnF flag will be automatically cleared. As the TM interrupt request flags will not be automatically cleared, they have to be cleared by the application program.

#### **Interrupt Wake-up Function**

Each of the interrupt functions has the capability of waking up the microcontroller when in the SLEEP or IDLE Mode. A wake-up is generated when an interrupt request flag changes from low to high and is independent of whether the interrupt is enabled or not. Therefore, even though the devices are in the SLEEP or IDLE Mode and its system oscillator stopped, situations such as external edge transitions on the external interrupt pins, a low power supply voltage or comparator output change may cause their respective interrupt flag to be set high and consequently generate an interrupt. Care must therefore be taken if spurious wake-up situations are to be avoided. If an interrupt wake-up function is to be disabled then the corresponding interrupt request flag should be set high before the devices enter the SLEEP or IDLE Mode. The interrupt enable bits have no effect on the interrupt wake-up function.

# **Programming Considerations**

By disabling the relevant interrupt enable bits, a requested interrupt can be prevented from being serviced, however, once an interrupt request flag is set, it will remain in this condition in the interrupt register until the corresponding interrupt is serviced or until the request flag is cleared by the application program.

Where a certain interrupt is contained within a Multi-function interrupt, then when the interrupt service routine is executed, as only the Multi-function interrupt request flags, MFnF, will be automatically cleared, the individual request flag for the function needs to be cleared by the application program.

It is recommended that programs do not use the CALL instruction within the interrupt service subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately. If only one stack is left and the interrupt is not well controlled, the original control sequence will be damaged once a CALL subroutine is executed in the interrupt subroutine.

Every interrupt has the capability of waking up the microcontroller when it is in SLEEP or IDLE Mode, the wake up being generated when the interrupt request flag changes from low to high. If it is required to prevent a certain interrupt from waking up the microcontroller then its respective request flag should be first set high before enter SLEEP or IDLE Mode.

As only the Program Counter is pushed onto the stack, then when the interrupt is serviced, if the contents of the accumulator, status register or other registers are altered by the interrupt service program, their contents should be saved to the memory at the beginning of the interrupt service routine.

To return from an interrupt subroutine, either a RET or RETI instruction may be executed. The RETI instruction in addition to executing a return to the main program also automatically sets the EMI bit high to allow further interrupts. The RET instruction however only executes a return to the main program leaving the EMI bit in its present zero state and therefore disabling the execution of further interrupts.

Rev. 1.50 192 July 12, 2017

# Low Voltage Detector - LVD

Each device has a Low Voltage Detector function, also known as LVD. This enabled the devices to monitor the power supply voltage,  $V_{DD}$ , and provide a warning signal should it fall below a certain level. This function may be especially useful in battery applications where the supply voltage will gradually reduce as the battery ages, as it allows an early warning battery low signal to be generated. The Low Voltage Detector also has the capability of generating an interrupt signal.

## **LVD Register**

The Low Voltage Detector function is controlled using a single register with the name LVDC. Three bits in this register, VLVD2 $\sim$ VLVD0, are used to select one of eight fixed voltages below which a low voltage condition will be determined. A low voltage condition is indicated when the LVDO bit is set. If the LVDO bit is low, this indicates that the  $V_{DD}$  voltage is above the preset low voltage value. The LVDEN bit is used to control the overall on/off function of the low voltage detector. Setting the bit high will enable the low voltage detector. Clearing the bit to zero will switch off the internal low voltage detector circuits. As the low voltage detector will consume a certain amount of power, it may be desirable to switch off the circuit when not in use, an important consideration in power sensitive battery powered applications.

### **LVDC** Register

| Bit  | 7 | 6 | 5    | 4     | 3 | 2     | 1     | 0     |
|------|---|---|------|-------|---|-------|-------|-------|
| Name | _ | _ | LVDO | LVDEN | _ | VLVD2 | VLVD1 | VLVD0 |
| R/W  | _ | _ | R    | R/W   | _ | R/W   | R/W   | R/W   |
| POR  | _ | _ | 0    | 0     | _ | 0     | 0     | 0     |

Bit 7~6 Unimplemented, read as "0"

Bit 5 LVDO: LVD Output Flag

0: No Low Voltage Detect

1: Low Voltage Detect

Bit 4 LVDEN: Low Voltage Detector control

0: Disable 1: Enable

Bit 3 Unimplemented, read as "0"

Bit 2~0 VLVD2~VLVD0: Select LVD Voltage

000: 2.0V

001: 2.2V

010: 2.4V

011: 2.7V

100: 3.0V

101: 3.3V

110: 3.6V

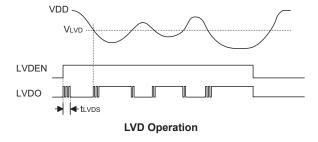

111: 4.0V

# **LVD Operation**

The Low Voltage Detector function operates by comparing the power supply voltage,  $V_{DD}$ , with a pre-specified voltage level stored in the LVDC register. This has a range of between 2.0V and 4.0V. When the power supply voltage,  $V_{DD}$ , falls below this pre-determined value, the LVDO bit will be set high indicating a low power supply voltage condition. The Low Voltage Detector function is supplied by a reference voltage which will be automatically enabled. When the devices are powered down the low voltage detector will remain active if the LVDEN bit is high. After enabling the Low Voltage Detector, a time delay  $t_{\rm LVDS}$  should be allowed for the circuitry to stabilise before reading the LVDO bit. Note also that as the  $V_{\rm DD}$  voltage may rise and fall rather slowly, at the voltage nears that of  $V_{\rm LVD}$ , there may be multiple bit LVDO transitions.

The Low Voltage Detector also has its own interrupt which is contained within one of the Multifunction interrupts, providing an alternative means of low voltage detection, in addition to polling the LVDO bit. The interrupt will only be generated after a delay of  $t_{\rm LVD}$  after the LVDO bit has been set high by a low voltage condition. When the devices are powered down the Low Voltage Detector will remain active if the LVDEN bit is high. In this case, the LVF interrupt request flag will be set, causing an interrupt to be generated if  $V_{\rm DD}$  falls below the preset LVD voltage. This will cause the devices to wake-up from the SLEEP or IDLE Mode, however if the Low Voltage Detector wake up function is not required then the LVF flag should be first set high before the devices enter the SLEEP or IDLE Mode.

Rev. 1.50 194 July 12, 2017

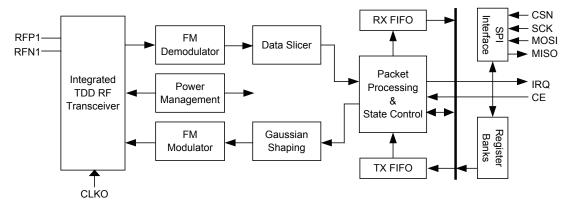

# **RF Transceiver**

The RF transceiver operates in the world wide ISM frequency band of 2400~2483.5MHz. Burst mode transmission and up to 2Mbps air data rate make them suitable for applications requiring ultra low power consumption. It operates as either a transmitter or a receiver in the Time Division Duplex mode, abbreviated as TDD.

The RF channel frequency determines the center of the channel used by the transceiver. The frequency is set by configuring the RF\_CH register in register bank 0 according to the following formula: F0=2400 + RF\_CH (MHz). The resolution of the RF channel frequency is 1MHz.

A transmitter and a receiver must be programmed with the same RF channel frequency to be able to communicate with each other. The output power of the transceiver is set by the RF\_PWR bits in the RF\_SETUP register. Demodulation is implemented with the embedded data slicer and bit recovery logic. The air data rate can be programmed to be 250Kbps, 1Mbps or 2Mbps by configuring the RF\_DR\_HIGH and RF\_DR\_LOW registers. A transmitter and a receiver must be programmed with the same setting.

### **RF Transceiver State Control**

The RF transceiver block includes an integrated a state machine that controls the state transition between different modes. When the auto acknowledge feature is disabled, the state transition will be fully controlled by the MCU.

- SPI register: PWR UP, PRIM RX, EN AA, NO ACK, ARC, ARD
- System information: Time out, ACK received, ARD elapsed, ARC\_CNT, TX FIFO empty, ACK packet transmitted, Packet received

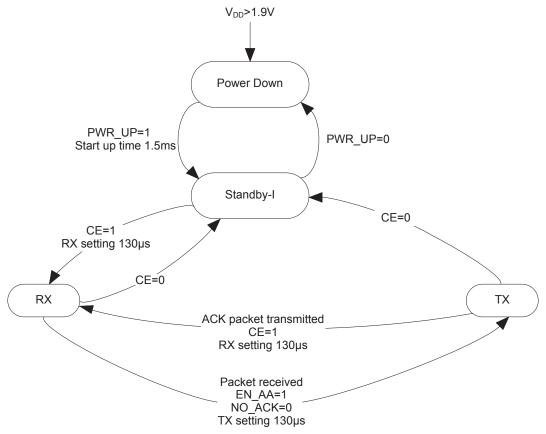

# • Primary Transmission State Control – PTX, PRIM\_RX=0

**Primary Transmission State Diagram** 

#### • Primary Reception State Control - PRX, PRIM RX=1

**Primary Reception State Diagram** 

### **Power Down Mode**

The Power down mode of the RF Transceiver is entered by setting the PWR\_UP bit in the CONFIG register to low. In the power down mode the transceiver block is in the sleep mode where it has minimal current consumption. However, the SPI interface is still active in this mode and all register values can be configured by the SPI interface.

The MCU and RF Transceiver are powered down independently of each other. The method of powering down the MCU is covered in the previous MCU section of the datasheet. The RF Transceiver must be powered down before the MCU is powered down. This is implemented by first clearing the PWR\_UP bit in the CONFIG register to disable the RF Transceiver circuitry and then pulling the  $\overline{SCSA}$  line to high to disable the RF SPI interface circuitry. After the RF transceiver is completely powered down, the MCU can be powered down to minimise the power consumption.

### Standby-I Mode

By setting the PWR\_UP bit in the CONFIG register to 1 and de-asserting the CE signal to a low state, the devices enter the Standby-I mode. The Standby-I mode is used to minimise the average current consumption and also to maintain a shorter start-up time. In this mode, the clock is still active. When the CE signal is set to a low state, the transceiver will return to the Standby-I mode regardless of whether it is in the TX or RX mode.

Rev. 1.50 198 July 12, 2017

#### Standby-II Mode

In the Standby-II mode more RF Transceiver circuitry is active than in the Standby-I mode and therefore more current is consumed. The transceiver will enter the Standby-II mode from the TX mode when the CE signal is set to a high state and the TX FIFO is empty. If a new data packet is uploaded into the TX FIFO, the devices will automatically return to the TX mode and the packet will be transmitted.

#### **TX Mode**

# • Primary Transmit Device - PTX, PRIM\_RX=0

The TX mode is an active mode where the PTX device transmits a data packet. To enter this mode from power down mode, the PTX device must set the PWR\_UP bit to high, the PRIM\_RX bit to low, a payload in the TX FIFO and generate a high pulse on the CE line for more than 15µs.

The PTX device stays in the TX mode until it finishes transmitting the current packet and then enters the Standby-II mode. If the CE signal is in a low state, it will return to Standby-I mode. If the CE signal is in a high state, the next action will be determined by the status of the TX FIFO. If the TX FIFO is not empty, the PTX device will enter the TX mode and then transmit the next packet. If the TX FIFO is empty, the PTX device will remain in the Standby-II mode. It is important to note that it never remains in the TX mode for more than 4ms during a transmit operation.

If the auto retransmit is enabled by setting the EN\_AA bit to 1 and an auto acknowledge is required by setting the NO\_ACK bit to 0, the PTX device will enter the TX mode from the Standby-I mode when the ARD has elapsed and the number of retry is less than the ARC.

The PTX device will enter the RX mode from the TX mode only when the EN\_AA bit is set to 1 and the NO\_ACK bit is cleared to 0 to receive the acknowledge packet.

#### **RX Mode**

### • Primary Receive Device – PRX, PRIM RX=1

The RX mode is an active mode where the transceiver is configured as a receiver. To enter this RX mode from the Standby-I mode, the PRX device must set the PWR\_UP bit to high, the PRIM\_RX bit to high and the CE signal to high. In this mode the receiver demodulates the signals from the RF channel, constantly presenting the demodulated data to the packet processing engine. The packet processing engine continuously searches for a valid packet. If a valid packet is found by a matching address and a valid CRC, the packet payload is presented to a vacant slot in the RX FIFO. If the RX FIFO is full, the received packet will be discarded.

The PRX device remains in the RX mode until the MCU configures it to enter the Standby-I mode or Power Down mode. In the RX mode a carrier detection signal, CD, is made available. The CD signal is set high when an RF signal is detected on the receiving frequency channel. The internal CD signal is filtered before being written into the CD register. The RF signal must be present for at least 128µs before the CD signal is set high.

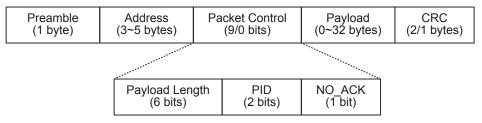

The PRX device will enter the TX mode from the RX mode only when the EN\_AA bit is set to 1 and the NO\_ACK bit is cleared to 0 in the received packet to transmit an acknowledge packet with a pending payload in the TX FIFO.

# **RF Transceiver Packet Processing**

#### **Packet Format**

The complete packet includes a preamble,  $3\sim5$  address bytes, a packet control field,  $0\sim32$  payload bytes and a CRC field.

**Packet Format** 

#### **Preamble**

The preamble is a bit sequence used to detect the "0" and "1" levels in the receiver. The preamble is one byte long whose value is either 01010101 or 10101010. If the first bit in the address is 1, the preamble is automatically set to 10101010 while if the first bit is 0, the preamble is automatically set to 01010101. This is done to ensure there are enough transitions in the preamble to stabilise the receiver.

#### **Address**

This field is the address for the receiver. An address ensures that the packet is detected by the target receiver. The address field can be configured to be 3, 4 or 5 bytes long by the AW register. The PRX device can open up to six data pipes to support up to six PTX devices with specific addresses. All six PTX device addresses are searched simultaneously. In the PRX device, the data pipes are enabled with the corresponding control bits in the EN\_RXADDR register. The default status is that only data pipe 0 and pipe 1 are enabled. Each data pipe address can be configured in the RX\_ADDR\_PX registers. Each pipe can have up to a 5 byte configurable address. Data pipe 0 has a unique 5-byte address. Data pipes 1~5 share the 4 most significant address bytes. The least significant byte must be unique for all 6 pipes.

To ensure that the ACK packet from the PRX is transmitted to the correct PTX, the PRX takes the data pipe address where it received the packet and uses it as the TX address when transmitting the ACK packet.

On the PRX device the RX\_ADDR\_Pn defined as the pipe address must be unique. On the PTX device the TX\_ADDR must be the same as the RX\_ADDR\_P0 on the PTX, and as the pipe address for the designated pipe on the PRX. No other data pipe can receive data until a complete packet is received by a data pipe that has detected its address. When multiple PTX devices are transmitting to a PRX, the ARD can be used to skew the auto retransmission so that they only block each other once.

Rev. 1.50 200 July 12, 2017

#### **Packet Control**

When the Dynamic Payload Length function is enabled, the packet control field contains a 6-bit payload length field, a 2-bit Packet Identity, PID, field and a 1-bit NO ACK flag.

### · Payload Length

The payload length field is used to define the payload length and only used if the Dynamic Payload Length function is enabled.

#### • PID

The 2-bit PID field is used to detect whether the received packet is new or retransmitted. The PID prevents the PRX device from presenting the same payload more than once to the MCU. The PID field is incremented at the TX side for each new packet received through the SPI interface. The PID and CRC fields are used by the PRX device to determine whether a packet is old or new. When several data packets are lost on the link, the PID fields may become equal to the last received PID. If a packet has the same PID as the previous packet, the transceiver compares the CRC sums from both packets. If the CRC sums are also the same, the last received packet will be considered a copy of the previously received packet and be discarded.

#### · NO ACK

The NO\_ACK flag is used only when the auto acknowledgement feature is used. Setting the flag high informs the receiver that the packet is not to be auto acknowledged. The PTX device can set the NO\_ACK flag bit in the Packet Control Field with the command: W\_TX\_PAYLOAD\_NOACK. However, the function must first be enabled in the FEATURE register by setting the EN\_DYN\_ACK bit. When the auto acknowledgement function is used, the PTX will directly enter to the Standby-I mode after the packet is transmitted and the PRX device does not transmit an ACK packet when it receives the PTX transmitted packet.

## **Payload**

The payload field is used to define the contents of the packet. It can be from 0 to 32 bytes wide and transmitted on-air as it is uploaded (unmodified) to the device. The transceiver provides two alternatives for handling payload lengths, static and dynamic payload length. The static payload length of the six data pipes can be individually set.

The default alternative is static payload length. With static payload length all packets between a transmitter and a receiver have the same length. The static payload length is set by the RX\_PW\_Pn registers. The payload length on the transmitter side is set by the number of bytes clocked into the TX\_FIFO and must equal to the value in the RX\_PW\_Pn register on the receiver side. Each pipe has its own payload length.

The Dynamic Payload Length, DPL, is an alternative to the static payload length. The DPL enables the transmitter to send packets with variable payload lengths to the receiver. This means that for a system with different payload lengths it is not necessary to scale the packet length to the longest payload.

With the DPL feature the transceiver can decode the payload length of the received packet automatically instead of using the RX\_PW\_Pn registers. The MCU can read the length of the received payload using the command: R\_RX\_PL\_WID. In order to enable the DPL function, the EN\_DPL bit in the FEATURE register must be set. In the RX mode the DYNPD register has to be properly configured. A PTX device must set the DPL\_P0 bit in the DYNPD register to transmit to a PRX with the DPL function being enabled.

#### **CRC**

The CRC is the error detection mechanism in the packet. The number of bytes in the CRC is set by the CRCO bit in the CONFIG register. It may be either 1 or 2 bytes and is calculated over the address, Packet Control Field and Payload. The polynomial for a1-byte CRC is  $X^8 + X^2 + X + 1$  with an initial value of 0xFFH. The polynomial for a 2-byte CRC is  $X^{16} + X^{12} + X^5 + 1$  with an initial value of 0xFFFH. No packet is accepted by the receiver side if the CRC fails.

### **Packet Handling**

The transceiver circuitry uses burst mode for payload transmission and reception.

The transmitter fetches the payload from the TX FIFO, automatically assembles it into a packet and transmits the packet in a very short burst period with a 1Mbps or 2Mbps air data rate. After a transmission, if the PTX packet has the NO\_ACK flag set, the transceiver sets the TX\_DS bit and gives an active low interrupt pulse on the IRQ line sent to the MCU. If the PTX is an ACK packet, the PTX needs to receive an ACK from the PRX and then assert the TX\_DS IRQ.

The receiver automatically validates and disassembles the received packet. If there is a valid packet within the new payload, it will write the payload into the RX FIFO, set the RX\_DR bit and give an active low interrupt pulse on the IRQ line sent to the MCU.

When the auto acknowledge function is enabled by setting the EN\_AA bit to 1, the PTX device will automatically wait for an acknowledge packet after transmission and re-transmit the original packet after the ARD delay until an acknowledge packet is received or the number of re-transmission exceeds a threshold defined by the ARC field. If the number of re-transmissions exceeds a threshold defined by the ARC field, the transceiver will set the MAX\_RT bit and give an active low interrupt pulse on the IRQ line sent to the MCU. Two packet loss counters, ARC\_CNT and PLOS\_CNT, are incremented by one each time a packet is lost. The ARC\_CNT counter counts the number of retransmissions for the current transaction. The PLOS\_CNT counter counts the total number of retransmissions since the last channel change. The ARC\_CNT counter is reset by initiating a new transaction while the PLOS\_CNT counter is reset by writing a value to the RF\_CH register to change a RF channel. It is possible to use the information in the OBSERVE\_TX register to make an overall assessment of the channel quality.

The PTX device will retransmit if its RX FIFO is full but the received ACK frame has a payload. As an alternative for the PTX device to auto retransmit it is possible to manually set the transceiver to retransmit a packet a number of times. This is done using the REUSE\_TX\_PL command. When the auto acknowledge function is enabled, the PRX device will automatically check the NO\_ACK field in the received packet, and if the NO\_ACK bit is 0, it will automatically send an acknowledge packet to the PTX device. If the EN\_ACK\_PAY bit is set, the acknowledge packet can also be regarded as a pending payload in the TX FIFO.

Rev. 1.50 202 July 12, 2017

#### **RF Transceiver Data and Control Interface**

#### TX/RX FIFO

The data FIFOs are used to store the payload that is to be transmitted in the TX FIFO or is received in the RX FIFO and ready to be clocked out. The FIFO is accessible in both the PTX mode and PRX modes. There is a three level 32 byte FIFO for both the TX and RX, supporting both the acknowledge mode or no acknowledge mode with up to six data pipes.

- TX three levels, 32 bytes FIFO
- RX three levels, 32 bytes FIFO

Both the TX and RX FIFOs have a controller and are accessible through the SPI interface using dedicated SPI commands. A TX FIFO in PRX can store the payload for ACK packets for three different PTX devices. If the TX FIFO contains more than one payload for a pipe, the different payloads are handled using the first-in first-out principle. The TX FIFO in a PRX device is blocked if all pending payloads are addressed to pipes where the link to the PTX device is lost. In this case, the MCU can flush the TX FIFO using the FLUSH\_TX command.

The RX FIFO in the PRX device may contain a payload from up to three different PTX devices. A TX FIFO in the PTX devices can have up to three payloads stored. The TX FIFO can be written to by three commands, W\_TX\_PAYLOAD and W\_TX\_PAYLOAD\_NO\_ACK in the PTX mode and W\_ACK\_PAYLOAD in the PRX mode. All three commands give access to the TX\_PLD register. The RX FIFO can be read by the command R\_RX\_PAYLOAD in both PTX and PRX modes. This command gives access to the RX\_PLD register. The payload in the TX FIFO in a PTX device is NOT removed if the MAX\_RT IRQ is asserted.

In the FIFO\_STATUS register it is possible to know whether the TX and RX FIFO are full or empty. The TX\_REUSE bit is also available in the FIFO\_STATUS register. The TX\_REUSE bit is set by the SPI command, REUSE\_TX\_PL, and is reset by the SPI command, W\_TX\_PAYLOAD or FLUSH TX.

#### Interrupt

In the RF transceiver circuitry there is an active low interrupt line, IRQ, which is activated when the TX\_DS IRQ, RX\_DR IRQ or MAX\_RT IRQ bit is set to high by the state machine in the STATUS register. The IRQ line is internally connected to the MCU external interrupt input. The detailed MCU external interrupt configurations are described in the preceding section in this datasheet. The IRQ line is reset when the MCU writes a '1' into the IRQ source bit in the STATUS register. The IRQ mask control bit in the CONFIG register is used to select which IRQ source is allowed to assert the IRQ line. By setting one of the MASK bits high, the corresponding IRQ source will be disabled. By default all IRQ sources are enabled. The 3-bit pipe information in the STATUS register is updated when the IRQ line changes state from high to low. If the STATUS register is read during a high to low transition of an IRQ line, the pipe information is not available.

#### **SPI Interface**

The SPI commands are shown in the following table. Every new command must be started by a high to low transition on the CSN line. In parallel to the SPI command byte applied on the MOSI line, the STATUS register bit, Sn, is serially shifted out on the MISO line. The RF Transceiver SPI interface is internally connected to the MCU SPIA interface. The detailed MCU SPIA interface operations are described in the corresponding SPIA interface section in this datasheet.

The serial shifting SPI commands are in the following format:

- · Command byte: one byte command word from MSB to LSB
- Data read operation: The data byte is shifted out from the least significant byte to the most significant byte and MSB first in each byte for all registers in all register banks.
- Data write operation: The data byte is shifted in from the most significant byte to the least significant byte and MSB in each byte first for register 0 to register 8 in register bank 1. For other registers in all banks the data byte is shifted in from the least significant byte to the most significant byte.

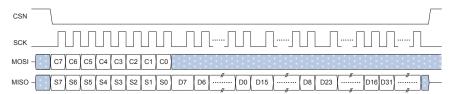

| Command name   | Command byte (Cn) | Data bytes<br>(Dn)        | Operation  |

The TX payload reuse is active until W_TX_PAYLOAD or FLUSH TX is executed. The TX payload reuse must not be activated or deactivated during package transmission. |

Rev. 1.50 204 July 12, 2017

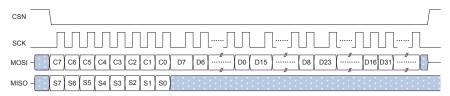

| Command name           | Command byte (Cn) | Data bytes<br>(Dn)        | Operation   |
|------------------------|-------------------|---------------------------|---|
| ACTIVATE               | 0101 0000         | 1                         | This write command followed by data 0x73 activates the following features:  • R_RX_PL_WID  • W_ACK_PAYLOAD  • W_TX_PAYLOAD_NOACK  A new ACTIVATE command with the same data deactivates them again. This is executable in power down or standby modes only. The features registers named as R_RX_PL_WID, W_ACK_PAYLOAD, and W_TX_PAYLOAD_NOACK are initially in a deactivated state; a write operation has no effect, a read operation only results in zeros on MISO. To activate these registers, use the ACTIVATE command followed by data 0x73. Then they can be accessed just like any other registers. Using the same command and data will deactivate the registers again.  This write command followed by data 0x53 toggles the register bank and the current register bank number can be read out from the STATUS register bit 7. |
| R_RX_PL_WID            | 0110 0000         |                           | Read RX-payload width for the top R_RX_PAYLOAD in the RX FIFO   |
| W_ACK_<br>PAYLOAD      | 1010 1PPP         | 1 to 32<br>LSB byte first | Write ACK Payload: 1~32 bytes, used in the RX mode Write Payload to be transmitted together with ACK packet on PIPE "PPP" where the "PPP" ranges from 000 to 101. Maximum three ACK packet payloads can be pending. Payloads with the same PPP are handled using first-in- first-out principle. A write operation to the ACK payload implemented in the register bank 0 always starts at byte 0.  |
| W_TX_PAYLOAD_<br>NOACK | 1011 0000         | 1 to 32<br>LSB byte first | Used in TX mode and implemented in the register bank 0 Disables AUTOACK on this specific packet.  |

Bit 2 ERX\_P2: Data Pipe 2 enable control

0: Disable1: Enable

Bit 1 ERX\_P1: Data Pipe 1 enable control

0: Disable 1: Enable

Bit 0 **ERX P0:** Data Pipe 0 enable control

0: Disable 1: Enable

# • Address 03H - SETUP\_AW Register

This register is used to specify the data pipe address field width.

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | _   | _   | _   | _   | _   | _   | AW1 | AW0 |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | 0   | 0   | 0   | 0   | 0   | 0   | 1   | 1   |

Bit 7~2 Reserved bits, only data "000000" allowed.

Bit 1~0 AW1~AW0: Data pipe Address Field Width

00: Illegal, can not be used.

01: 3 bytes 10: 4 bytes 11: 5 bytes

The field is used to specify the data pipe address field width which is the same for all data pipes.

# • Address 04H - SETUP\_RETR Register

This register is used to set the number and delay of the automatic retransmission.

| Bit  | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|
| Name | ARD3 | ARD2 | ARD1 | ARD0 | ARC3 | ARC2 | ARC1 | ARC0 |
| R/W  |
| POR  | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 1    |

Bit 7~4 ARD3~ARD0: Automatic Retransmission Delay selection

0000: (1×250)  $\mu s$ 

0001: (2×250) μs

0010: (3×250) μs

1110: (15×250) μs

1111: (16×250) μs

The Automatic Retransmission Delay is defined as the time from the end of the current transmission to the start of the next transmission.

Bit 3~0 ARC3~ARC0: Automatic Retransmission Number

0000: No retransmission when automatic acknowledgement failed.

0001: 1 retransmission when automatic acknowledgement failed.

0010: 2 retransmissions when automatic acknowledgement failed.

:

1110: 14 retransmissions when automatic acknowledgement failed.

1111: 15 retransmissions when automatic acknowledgement failed.

# • Address 05H - RF\_CH Register

This register is used to select the RF channel.

| Bit  | 7   | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
|------|-----|--------|--------|--------|--------|--------|--------|--------|
| Name | _   | RF_CH6 | RF_CH5 | RF_CH4 | RF_CH3 | RF_CH2 | RF_CH1 | RF_CH0 |
| R/W  | R/W | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    |
| POR  | 0   | 0      | 0      | 0      | 0      | 0      | 1      | 0      |

Bit 7 Reserved bits, only data "0" allowed.

Bit 6~0 RF CH6~RF CH0: RF Channel selection

0000000~1111111: RF channel 0~RF channel 127

# • Address 06H - RF\_SETUP Register

This register is used to configure the RF output power and data rate.

| Bit  | 7   | 6   | 5         | 4        | 3          | 2       | 1       | 0         |
|------|-----|-----|-----------|----------|------------|---------|---------|-----------|
| Name | _   | _   | RF_DR_LOW | PLL_LOCK | RF_DR_HIGH | RF_PWR1 | RF_PWR0 | LNA_HCURR |
| R/W  | R/W | R/W | R/W       | R/W      | R/W        | R/W     | R/W     | R/W       |
| POR  | 0   | 0   | 0         | 0        | 1          | 1       | 1       | 1         |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5 **RF\_DR\_LOW:** Air Data Rate select bit

This bit is used to select the air data rate together with the RF\_DR\_HIGH bit. Refer to RF\_DR\_HIGH bit definition for more details.

Bit 4 PLL\_LOCK: PLL Signal Lock control

0: No effect

1: PLL signal is locked

This bit is used to lock the PLL signal and only available in the test mode.

Bit 3 **RF\_DR\_HIGH:** Air Data Rate select bit

[RF\_DR\_LOW, RF\_DR\_HIGH]=Air Data Rate

00: 1Mbps

01: 2Mbps

10: 250Kbps

11: 2Mbps

Bit 2~1 **RF\_PWR1~RF\_PWR0:** RF TX Output Power selection

00: -26dBm

01: -14dBm

10: -6dBm

11: -1dBm

Note: The Optimisation Register 4 is located at address 04H in the RF Bank 1.

Bit 0 LNA HCURR: LNA Gain selection

0: Low gain

1: High gain

### • Address 07H - STATUS Register

This register is used to store the status during the RF data transfer. When the SPI command is committed to the RF Transceiver on the MOSI line, the content of the STATUS register will be serially shifted out from the RF Transceiver on the MISO line.

| Bit  | 7     | 6     | 5     | 4      | 3        | 2        | 1        | 0       |
|------|-------|-------|-------|--------|----------|----------|----------|---------|
| Name | RBANK | RX_DR | TX_DS | MAX_RT | RX_P_NO2 | RX_P_NO1 | RX_P_NO0 | TX_FULL |
| R/W  | R     | R/W   | R/W   | R/W    | R        | R        | R        | R       |
| POR  | 0     | 0     | 0     | 0      | 1        | 1        | 1        | 0       |

Bit 7 **RBANK:** Register Bank Status

0: Register bank 0

1: Register bank 1

Bit 6 **RX\_DR:** RX FIFO Data Received Status

0: No data is received in RX FIFO

1: New data has been received in RX FIFO

This bit is set to 1 by hardware and cleared to 0 by writing a "1" into it. When a new data packet is received in the RX FIFO, this bit will be asserted.

Bit 5 TX DS: TX FIFO Data Sent Status

0: No data is transmitted from TX FIFO

1: New data has been transmitted from TX FIFO

This bit is set to 1 by hardware and cleared to 0 by writing a "1" into it. When a new data packet is transmitted from the TX FIFO, this bit will be asserted. If the AUTO\_ACK function is enabled, this bit will be set to 1 after the ACK is received.

#### Bit 4 MAX RT: Maximum TX retransmission Status

0: TX re-transmission number does not reach to the maximum retransmission number

1: TX re-transmission number has reached to the maximum retransmission number.

This bit is set to 1 by hardware and cleared to 0 by writing a "1" into it. When the TX re-transmission number has reached to the maximum retransmission number, this bit will be asserted. If the MAX\_RT bit is set to 1, it must be cleared to 0 by application program to enable further data communication.

### Bit 3~1 **RX\_P\_NO2~RX\_P\_NO0:** Data pipe number in RX FIFO

000~101: Data pipe 0~Data pipe 5.

110: Not used

111: RX FIFO empty

This field is used to indicate the data pipe number for the available payload in the RX FIFO. When this field is "111", it means that the RX FIFO is empty.

### Bit 0 TX\_FULL: TX FIFO full flag

0: TX FIFO is not full

1: TX FIFO is full

This bit is set and cleared by hardware. When the TX FIFO is full, this bit will be asserted. If this bit is 0, it means that the TX FIFO is not full yet and still has available locations to be used.

### Address 08H – OBSERVE\_TX Register

This register includes two read-only counters and is used to indicate the status during the TX data transmission.

| Bit  | 7         | 6         | 5         | 4         | 3        | 2        | 1        | 0        |
|------|-----------|-----------|-----------|-----------|----------|----------|----------|----------|
| Name | PLOS_CNT3 | PLOS_CNT2 | PLOS_CNT1 | PLOS_CNT0 | ARC_CNT3 | ARC_CNT2 | ARC_CNT1 | ARC_CNT0 |
| R/W  | R         | R         | R         | R         | R        | R        | R        | R        |
| POR  | 0         | 0         | 0         | 0         | 0        | 0        | 0        | 0        |

# Bit 7~4 PLOS\_CNT3~PLOS\_CNT0: TX lost data packet number

0000~1111: 0 TX lost data packet~15 TX lost data packets

This field is used to count the total lost data packets during the TX data transmission. The PLOS\_CNT value will be incremented by one each time a TX data packet is lost and retransmitted. When the counter value is equal to "1111", it will stop counting and remain the maximum value of 1111 instead of counter overflow until a reset condition occurs. This counter will be reset by a write operation to the RF\_CH register.

# Bit 3~0 ARC\_CNT3~ARC\_CNT0: Automatic Retransmission number

This field is used to count the retransmitted data packets during the TX data transmission. The ARC\_CNT value will be incremented by one each time a TX data packet is lost and retransmitted. This counter will be reset when a new TX data starts to be transmitted.

# • Address 09H - CD Register

This register is used to indicate the carrier detect status.

| Bit  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0  |
|------|---|---|---|---|---|---|---|----|
| Name | _ | _ | _ | _ | _ | _ | _ | CD |
| R/W  | _ | _ | _ | _ | _ | _ | _ | R  |
| POR  | _ | _ | _ | _ | _ | _ | _ | 0  |

Bit 7~1 Unimplemented, read as "0"

Bit 0 **CD:** Carrier Detect status

0: No carrier is detected

1: Carrier has been detected

# • Address 0AH - RX\_ADDR\_P0 Register

This register is used to specify the data pipe 0 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P0<br>[39:32] | RX_ADDR_P0<br>[31:24] | RX_ADDR_P0<br>[23:16] | RX_ADDR_P0<br>[15:8] | RX_ADDR_P0<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | E7                    | E7                    | E7                    | E7                   | E7                  |

## Bit 39~0 **RX\_ADDR\_P0:** Data pipe0 receive address

This field is used to define the data pipe 0 receive address. The address field width can be up to 5 bytes which is specified in the SETUP\_AW register. This address field configuration is carried out in a specific way from the least significant byte to the most significant byte.

# • Address 0BH - RX\_ADDR\_P1 Register

This register is used to specify the data pipe 1 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P1<br>[39:32] | RX_ADDR_P1<br>[31:24] | RX_ADDR_P1<br>[23:16] | RX_ADDR_P1<br>[15:8] | RX_ADDR_P1<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | C2                    | C2                    | C2                    | C2                   | C2                  |

### Bit 39~0 **RX\_ADDR\_P1:** Data pipe1 receive address

This field is used to define the data pipe 1 receive address. The address field width can be up to 5 bytes which is specified in the SETUP\_AW register. This address field configuration is carried out in a specific way from the least significant byte to the most significant byte.

#### • Address 0CH - RX ADDR P2 Register

This register is used to specify the data pipe 2 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P1<br>[39:32] | RX_ADDR_P1<br>[31:24] | RX_ADDR_P1<br>[23:16] | RX_ADDR_P1<br>[15:8] | RX_ADDR_P2<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | C2                    | C2                    | C2                    | C2                   | C3                  |

Bit 39~8 **RX\_ADDR\_P1 [39:8]:** Data pipe1 receive address bit 39~bit 8

Bit 7~0 **RX\_ADDR\_P2 [7:0]:** Data pipe 2 receive address bit 7~bit 0

This field is used to define the data pipe 2 receive address. Note that only bit 7~bit 0 of the address field can be configured and other 32MSBs from bit 39 to bit 8 must be the same as the data pipe 1 address.

### • Address 0DH - RX ADDR P3 Register

This register is used to specify the data pipe 3 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P1<br>[39:32] | RX_ADDR_P1<br>[31:24] | RX_ADDR_P1<br>[23:16] | RX_ADDR_P1<br>[15:8] | RX_ADDR_P3<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | C2                    | C2                    | C2                    | C2                   | C4                  |

Bit 39~8 **RX\_ADDR\_P1 [39:8]:** Data pipe1 receive address bit 39~bit 8

Bit 7~0 **RX\_ADDR\_P3** [7:0]: Data pipe 3 receive address bit 7~bit 0

This field is used to define the data pipe 3 receive address. Note that only bit 7~bit 0 of the address field can be configured and other 32MSBs from bit 39 to bit 8 must be the same as the data pipe 1 address.

Rev. 1.50 214 July 12, 2017

### Address 0EH – RX\_ADDR\_P4 Register

This register is used to specify the data pipe 4 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P1<br>[39:32] | RX_ADDR_P1<br>[31:24] | RX_ADDR_P1<br>[23:16] | RX_ADDR_P1<br>[15:8] | RX_ADDR_P4<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | C2                    | C2                    | C2                    | C2                   | C5                  |

Bit 39~8 **RX ADDR P1 [39:8]:** Data pipe1 receive address bit 39~bit 8

Bit 7~0 **RX\_ADDR\_P4** [7:0]: Data pipe 4 receive address bit 7~bit 0

This field is used to define the data pipe 4 receive address. Note that only bit 7~bit 0 of the address field can be configured and other 32MSBs from bit 39 to bit 8 must be the same as the data pipe 1 address.

### Address 0FH – RX\_ADDR\_P5 Register

This register is used to specify the data pipe 5 RX address.

| Byte | 4                     | 3                     | 2                     | 1                    | 0                   |
|------|-----------------------|-----------------------|-----------------------|----------------------|---------------------|
| Name | RX_ADDR_P1<br>[39:32] | RX_ADDR_P1<br>[31:24] | RX_ADDR_P1<br>[23:16] | RX_ADDR_P1<br>[15:8] | RX_ADDR_P5<br>[7:0] |
| R/W  | R/W                   | R/W                   | R/W                   | R/W                  | R/W                 |
| POR  | C2                    | C2                    | C2                    | C2                   | C6                  |

Bit 39~8 **RX\_ADDR\_P1 [39:8]:** Data pipe1 receive address bit 39~bit 8

Bit 7~0 **RX\_ADDR\_P5 [7:0]:** Data pipe 5 receive address bit 7~bit 0

This field is used to define the data pipe 5 receive address. Note that only bit 7~bit 0 of the address field can be configured and other 32MSBs from bit 39 to bit 8 must be the same as the data pipe 1 address.

### • Address 10H - TX\_ADDR Register

This register is used to specify the TX address.

| Byte | 4 3             |                 | 2               | 1              | 0             |  |
|------|-----------------|-----------------|-----------------|----------------|---------------|--|
| Name | TX_ADDR [39:32] | TX_ADDR [31:24] | TX_ADDR [23:16] | TX_ADDR [15:8] | TX_ADDR [7:0] |  |
| R/W  | R/W             | R/W             | R/W             | R/W            | R/W           |  |
| POR  | E7              | E7              | E7              | E7             | E7            |  |

Bit 39~0 **TX\_ADDR:** TX Transmit address

This field is only used for the PTX device to define the TX transmit address. The address field can be up to 5 bytes which is specified in the SETUP\_AW register. This address field configuration is carried out in a specific way from the least significant byte to the most significant byte. It is recommended to specify the same address for both RX\_ADDR\_P0 and TX\_ADDR address field to properly handle the automatic acknowledgement function.

# • Address 11H - RX\_PW\_P0 Register

This register is used to specify the data pipe 0 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P05 | RX_PW_<br>P04 | RX_PW_<br>P03 | RX_PW_<br>P02 | RX_PW_<br>P01 | RX_PW_<br>P00 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 RX\_PW\_P0 [5:0]: Data Pipe 0 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

:

32: 32 bytes

Others: Can not be used

### • Address 12H - RX\_PW\_P1 Register

This register is used to specify the data pipe 1 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P15 | RX_PW_<br>P14 | RX_PW_<br>P13 | RX_PW_<br>P12 | RX_PW_<br>P11 | RX_PW_<br>P10 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 **RX\_PW\_P1 [5:0]:** Data Pipe 1 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

.

32: 32 bytes

Others: Can not be used

# • Address 13H - RX\_PW\_P2 Register

This register is used to specify the data pipe 2 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P25 | RX_PW_<br>P24 | RX_PW_<br>P23 | RX_PW_<br>P22 | RX_PW_<br>P21 | RX_PW_<br>P20 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 **RX\_PW\_P2 [5:0]:** Data Pipe 2 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

:

32: 32 bytes

Others: Can not be used

### • Address 14H - RX\_PW\_P3 Register

This register is used to specify the data pipe 3 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P35 | RX_PW_<br>P34 | RX_PW_<br>P33 | RX_PW_<br>P32 | RX_PW_<br>P31 | RX_PW_<br>P30 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 **RX\_PW\_P3 [5:0]:** Data Pipe 3 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

:

32: 32 bytes

Others: Can not be used.

#### • Address 15H - RX\_PW\_P4 Register

This register is used to specify the data pipe 4 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P45 | RX_PW_<br>P44 | RX_PW_<br>P43 | RX_PW_<br>P42 | RX_PW_<br>P41 | RX_PW_<br>P40 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 **RX\_PW\_P4 [5**:0]: Data Pipe 4 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

:

32: 32 bytes

Others: Can not be used.

#### • Address 16H - RX PW P5 Register

This register is used to specify the data pipe 5 RX payload byte number.

| Bit  | 7   | 6   | 5             | 4             | 3             | 2             | 1             | 0             |
|------|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|
| Name | _   | _   | RX_PW_<br>P55 | RX_PW_<br>P54 | RX_PW_<br>P53 | RX_PW_<br>P52 | RX_PW_<br>P51 | RX_PW_<br>P50 |
| R/W  | R/W | R/W | R/W           | R/W           | R/W           | R/W           | R/W           | R/W           |
| POR  | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5~0 **RX\_PW\_P5 [5:0]:** Data Pipe 5 RX payload byte number

0: Not used

1: 1 byte

2: 2 bytes

:

32: 32 bytes

Others: Can not be used.

### • Address 17H - FIFO\_STATUS Register

This register is used to indicate the FIFO status during the data transfer.

| Bit  | 7   | 6        | 5       | 4        | 3   | 2   | 1       | 0        |
|------|-----|----------|---------|----------|-----|-----|---------|----------|
| Name | _   | TX_REUSE | TX_FULL | TX_EMPTY | _   | _   | RX_FULL | RX_EMPTY |
| R/W  | R/W | R        | R       | R        | R/W | R/W | R       | R        |
| POR  | 0   | 0        | 0       | 0        | 0   | 0   | 0       | 1        |

Bit 7 Reserved bits, only data "0" allowed.

Bit 6 TX\_REUSE: Last Transmitted Data Packet Reuse status

0: Last transmitted data packet is not reused1: Last transmitted data packet is reused

This bit is used to indicate whether the last TX data packet is repeatedly transmitted or not. If the CE line is kept in a high state, the last data packet will be repeatedly retransmitted. This bit is set to 1 by the SPI command, REUSE\_TX\_PL, and cleared to 0 by the SPI command, W\_TX\_PAYLOAD or FLUSH\_TX.

Bit 5 TX\_FULL: TX FIFO Full Flag

0: TX FIFO is not full 1: TX FIFO is full

This bit is used to indicate whether the TX FIFO is full or not.

Bit 4 TX EMPTY: TX FIFO Empty Flag

0: TX FIFO is not empty 1: TX FIFO is empty

This bit is used to indicate whether the TX FIFO is empty or not.

Bit 3~2 Reserved bits, only data "00" allowed.

Bit 1 RX FULL: RX FIFO Full Flag

0: RX FIFO is not full
1: RX FIFO is full

This bit is used to indicate whether the RX FIFO is full or not.

Bit 0 **RX\_EMPTY:** RX FIFO Empty Flag

0: RX FIFO is not empty 1: RX FIFO is empty

This bit is used to indicate whether the RX FIFO is empty or not.

#### • Address 1CH - DYNPD Register

This register is used to control the individual data pipe dynamic payload length function.

| Bit  | 7   | 6   | 5      | 4      | 3      | 2      | 1      | 0      |
|------|-----|-----|--------|--------|--------|--------|--------|--------|
| Name | _   | _   | DPL_P5 | DPL_P4 | DPL_P3 | DPL_P2 | DPL_P1 | DPL_P0 |
| R/W  | R/W | R/W | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    |
| POR  | 0   | 0   | 0      | 0      | 0      | 0      | 0      | 0      |

Bit 7~6 Reserved bits, only data "00" allowed.

Bit 5 **DPL\_P5:** Data Pipe 5 Dynamic Payload Length function enable control

0: Disable 1: Enable

This bit is used to control the data pipe5 dynamic payload length function. It is only available when the EN\_DPL and ENAA\_P5 bits are both set to 1.

Bit 4 DPL\_P4: Data Pipe 4 Dynamic Payload Length function enable control

0: Disable

1: Enable

This bit is used to control the data pipe4 dynamic payload length function. It is only available when the EN\_DPL and ENAA\_P4 bits are both set to 1.

Bit 3 **DPL\_P3:** Data Pipe 3 Dynamic Payload Length function enable control

0: Disable

1: Enable

This bit is used to control the data pipe3 dynamic payload length function. It is only available when the EN\_DPL and ENAA\_P3 bits are both set to 1.

Bit 2 **DPL\_P2:** Data Pipe 2 Dynamic Payload Length function enable control

0: Disable

1: Enable

This bit is used to control the data pipe2 dynamic payload length function. It is only available when the EN DPL and ENAA P2 bits are both set to 1.

Bit 1 **DPL\_P1:** Data Pipe 1 Dynamic Payload Length function enable control

0: Disable

1: Enable

This bit is used to control the data pipe1 dynamic payload length function. It is only available when the EN DPL and ENAA P1 bits are both set to 1.

Bit 0 **DPL\_P0:** Data Pipe 0 Dynamic Payload Length function enable control

0: Disable

1: Enable

This bit is used to control the data pipe0 dynamic payload length function. It is only available when the EN\_DPL and ENAA\_P0 bits are both set to 1.

#### • Address 1DH - FEATURE Register

This register is used to control several main features of the RF transceiver.

| Bit  | 7   | 6   | 5   | 4   | 3   | 2      | 1          | 0          |
|------|-----|-----|-----|-----|-----|--------|------------|------------|
| Name | _   | _   | _   | _   | _   | EN_DPL | EN_ACK_PAY | EN_DNY_ACK |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W    | R/W        | R/W        |
| POR  | 0   | 0   | 0   | 0   | 0   | 0      | 0          | 0          |

Bit 7~3 Reserved bits, only data "00000" allowed.

Bit 2 EN\_DPL: RF Transceiver Dynamic Payload Length Function control

0: Disable 1: Enable

This bit is used to control the RF Transceiver dynamic payload length function. If the EN\_DPL bit is set to 1 and the corresponding ENAA\_Pn bit is also set to 1, the dynamic payload length function of the relevant data pipe n will be available.

Bit 1 EN\_ACK\_PAY: RF Transceiver Payload with Acknowledgement control

0: Disable 1: Enable

Bit 0 EN\_DNY\_ACK: RF Transceiver "W\_TX\_PAYLOAD\_NOACK" Command control

0: Disable the command1: Enable the command

#### Register Bank 1

It is recommended that no access is executed on reserved or non defined registers. Otherwise, this may result in unpredictable conditions.

#### • Address 00H - Optimisation Register 0

| Bit  | 31 | 31 30 |                      | 1 | 0 |  |  |
|------|----|-------|----------------------|---|---|--|--|
| Name |    |       | Optimisation_Value_0 |   |   |  |  |
| R/W  |    | W     |                      |   |   |  |  |
| POR  |    |       | 0x0000_0000          |   |   |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value of 0x858A C01C into this register.

#### • Address 01H - Optimisation Register 1

| Bit  | 31 | 31 30                |  | 1 | 0 |  |  |  |
|------|----|----------------------|--|---|---|--|--|--|
| Name |    | Optimisation_Value_1 |  |   |   |  |  |  |
| R/W  |    | W                    |  |   |   |  |  |  |
| POR  |    | 0x0000_0000          |  |   |   |  |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value of 0x1103 C960 into this register.

#### • Address 02H - Optimisation Register 2

| Bit  | 31 | 31 30 |                      | 1 | 0 |  |  |
|------|----|-------|----------------------|---|---|--|--|
| Name |    |       | Optimisation_Value_2 |   |   |  |  |
| R/W  |    | W     |                      |   |   |  |  |
| POR  |    |       | 0x0000_0000          |   |   |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value of  $0x0000\,0004$  into this register.

Rev. 1.50 220 July 12, 2017

### • Address 03H - Optimisation Register 3

| Bit  | 31 | 30 |                      | 1 | 0 |  |  |
|------|----|----|----------------------|---|---|--|--|
| Name |    |    | Optimisation_Value_3 |   |   |  |  |
| R/W  |    | W  |                      |   |   |  |  |
| POR  |    |    | 0x0300_1200          |   |   |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value of  $0x0000\,0004$  into this register.

#### · Address 04H - Optimisation Register 4

| Bit  | 31 | 31 30 |                      | 1 | 0 |  |  |
|------|----|-------|----------------------|---|---|--|--|
| Name |    |       | Optimisation_Value_4 |   |   |  |  |
| R/W  |    | W     |                      |   |   |  |  |
| POR  |    |       | 0x0000_0000          |   |   |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value into this register for different operating modes.

• For 1Mbps and 2Mbps: 0x437D\_5D5F

• For 250kbps: 0x437D\_6D5F

For single carrier mode:

• For 1Mbps and 2Mbps: 0xC37D\_5D5D

• For 250kbps: 0xC37D\_6D5D

### • Address 05H - Optimisation Register 5

| Bit  | 31 | 30 | 1                    | 0 |  |  |  |  |
|------|----|----|----------------------|---|--|--|--|--|
| Name |    |    | Optimisation_Value_5 |   |  |  |  |  |
| R/W  |    | W  |                      |   |  |  |  |  |
| POR  |    |    | 0x0000_0000          |   |  |  |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value into this register for different data rates.

For 250kbps data rate: 0x7410\_6C9F
For 1Mbps data rate: 0x1412\_6C9F
For 2Mbps data rate: 0x7411\_4C9F

### • Address 06H – Optimisation Register 6

| Bit  | 31 | 30                   |  | 1 | 0 |  |  |
|------|----|----------------------|--|---|---|--|--|
| Name |    | Optimisation Value 6 |  |   |   |  |  |
| R/W  |    | W                    |  |   |   |  |  |
| POR  |    | 0x0000_0000          |  |   |   |  |  |

This register is used to optimise the performance of the RF Transceiver by writing a specific value into this register.

• For 1Mbps: 0x0007 C022

• For 250kbps and 2Mbps: 0x0007 C002

### • Address 07H - Status Register 1

| Bit  | 31               | 30 |   | 8     | 7             | 6 |  | 1 | 0 |
|------|------------------|----|---|-------|---------------|---|--|---|---|
| Name | me Reserved bits |    |   | RBANK | Reserved bits |   |  |   |   |
| R/W  | W                |    |   | R     | W             |   |  |   |   |
| POR  |                  | (  | ) |       | 0             | 0 |  |   |   |

This register is reserved except for bit 7, RBANK. It is recommended the reserved bits are not accessed to prevent unpredictable results.

Bit 7 **RBANK:** Register Bank Status

0: Register bank 0 1: Register bank 1

#### • Address 08H - Chip ID Register

| Bit  | 31 | 30          |  | 1 | 0 |  |
|------|----|-------------|--|---|---|--|
| Name |    | ID_Value    |  |   |   |  |
| R/W  |    | R           |  |   |   |  |
| POR  |    | 0x0000_0000 |  |   |   |  |

This register is a read-only register and is used to store the chip ID code.

#### • Address 0CH - Initialization Register

| Bit  | 31 | 30                   |  | 1 | 0 |  |
|------|----|----------------------|--|---|---|--|
| Name |    | Initialisation_Value |  |   |   |  |
| R/W  |    | W                    |  |   |   |  |
| POR  |    | 0x0000_0000          |  |   |   |  |

This register is used to initialise the RF Transceiver PLL Lock time by writing a specific value of 0x0573\_1200 into this register.

#### • Address 0DH - New Feature Register

| Bit  | 31 | 30                |  | 1 | 0 |  |
|------|----|-------------------|--|---|---|--|
| Name |    | New_Feature_Value |  |   |   |  |
| R/W  |    | W                 |  |   |   |  |
| POR  |    | 0x0000_0000       |  |   |   |  |

This register is used to configure the RF Transceiver features by writing a specific value into this register.

• For 1Mbps and 2Mbps: 0x0080\_B434

• For 250kbps: 0x0080 B436

#### • Address 0EH - RAMP Register

| Bit  | 87                         | 86         | 86 |  | 0 |  |  |
|------|----------------------------|------------|----|--|---|--|--|
| Name |                            | RAMP_Value |    |  |   |  |  |
| R/W  |                            | W          |    |  |   |  |  |
| POR  | 0хии_ииии_ ииии_ииии_ ииии |            |    |  |   |  |  |

This register is used to optimise the RF Transmitter output spectrum rate curve by writing a specific value of 0xCF EFBE F7DF 7CF3 CF20 8104 into this register.

Rev. 1.50 222 July 12, 2017

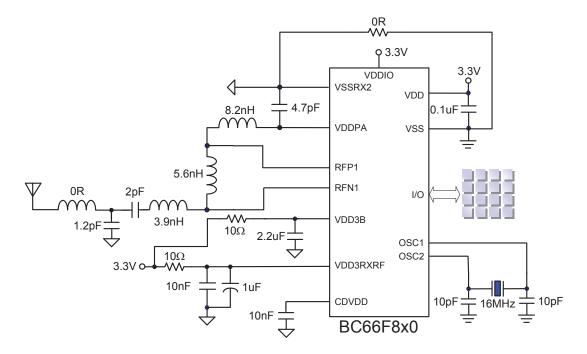

# **Configuration Options**

Configuration options refer to certain options within the MCU that are programmed into the devices during the programming process. During the development process, these options are selected using the HT-IDE software development tools. As these options are programmed into the devices using the hardware programming tools, once they are selected they cannot be changed later using the application program. All options must be defined for proper system function, the details of which are shown in the table.

| No.   | Options  |
|-------|--|
| Osci  | llator Options   |
| 1     | Supplementary Oscillator Selection – f <sub>SUB</sub> : LXT or LIRC                          |
| I/O P | in-Shared Options  |
| 2     | Reset pin function: RES or I/O   |
| 3     | VDDIO pin function: VDDIO or I/O   |
| SIM/S | SPIA Interface Options   |
| 4     | SIM Function: Enable or Disable  |
| 5     | SPIA Function: Enable or Disable   |
| 6     | SPI/SPIA – CSEN bit: Enable or Disable   |
| 7     | SPI/SPIA – WCOL bit: Enable or Disable   |
| 8     | I²C Debounce Time Selection: No debounce, 2 system clock debounce or 4 system clock debounce |

# **Application Circuits**

Rev. 1.50 224 July 12, 2017

#### Instruction Set

#### Introduction

Central to the successful operation of any microcontroller is its instruction set, which is a set of program instruction codes that directs the microcontroller to perform certain operations. In the case of Holtek microcontroller, a comprehensive and flexible set of over 60 instructions is provided to enable programmers to implement their application with the minimum of programming overheads.

For easier understanding of the various instruction codes, they have been subdivided into several functional groupings.

### **Instruction Timing**

Most instructions are implemented within one instruction cycle. The exceptions to this are branch, call, or table read instructions where two instruction cycles are required. One instruction cycle is equal to 4 system clock cycles, therefore in the case of an 8MHz system oscillator, most instructions would be implemented within 0.5µs and branch or call instructions would be implemented within 1µs. Although instructions which require one more cycle to implement are generally limited to the JMP, CALL, RET, RETI and table read instructions, it is important to realize that any other instructions which involve manipulation of the Program Counter Low register or PCL will also take one more cycle to implement. As instructions which change the contents of the PCL will imply a direct jump to that new address, one more cycle will be required. Examples of such instructions would be "CLR PCL" or "MOV PCL, A". For the case of skip instructions, it must be noted that if the result of the comparison involves a skip operation then this will also take one more cycle, if no skip is involved then only one cycle is required.

### **Moving and Transferring Data**

The transfer of data within the microcontroller program is one of the most frequently used operations. Making use of three kinds of MOV instructions, data can be transferred from registers to the Accumulator and vice-versa as well as being able to move specific immediate data directly into the Accumulator. One of the most important data transfer applications is to receive data from the input ports and transfer data to the output ports.

#### **Arithmetic Operations**

The ability to perform certain arithmetic operations and data manipulation is a necessary feature of most microcontroller applications. Within the Holtek microcontroller instruction set are a range of add and subtract instruction mnemonics to enable the necessary arithmetic to be carried out. Care must be taken to ensure correct handling of carry and borrow data when results exceed 255 for addition and less than 0 for subtraction. The increment and decrement instructions INC, INCA, DEC and DECA provide a simple means of increasing or decreasing by a value of one of the values in the destination specified.

### **Logical and Rotate Operation**

The standard logical operations such as AND, OR, XOR and CPL all have their own instruction within the Holtek microcontroller instruction set. As with the case of most instructions involving data manipulation, data must pass through the Accumulator which may involve additional programming steps. In all logical data operations, the zero flag may be set if the result of the operation is zero. Another form of logical data manipulation comes from the rotate instructions such as RR, RL, RRC and RLC which provide a simple means of rotating one bit right or left. Different rotate instructions exist depending on program requirements. Rotate instructions are useful for serial port programming applications where data can be rotated from an internal register into the Carry bit from where it can be examined and the necessary serial bit set high or low. Another application which rotate data operations are used is to implement multiplication and division calculations.

#### **Branches and Control Transfer**

Program branching takes the form of either jumps to specified locations using the JMP instruction or to a subroutine using the CALL instruction. They differ in the sense that in the case of a subroutine call, the program must return to the instruction immediately when the subroutine has been carried out. This is done by placing a return instruction "RET" in the subroutine which will cause the program to jump back to the address right after the CALL instruction. In the case of a JMP instruction, the program simply jumps to the desired location. There is no requirement to jump back to the original jumping off point as in the case of the CALL instruction. One special and extremely useful set of branch instructions are the conditional branches. Here a decision is first made regarding the condition of a certain data memory or individual bits. Depending upon the conditions, the program will continue with the next instruction or skip over it and jump to the following instruction. These instructions are the key to decision making and branching within the program perhaps determined by the condition of certain input switches or by the condition of internal data bits.

#### **Bit Operations**

The ability to provide single bit operations on Data Memory is an extremely flexible feature of all Holtek microcontrollers. This feature is especially useful for output port bit programming where individual bits or port pins can be directly set high or low using either the "SET [m].i" or "CLR [m].i" instructions respectively. The feature removes the need for programmers to first read the 8-bit output port, manipulate the input data to ensure that other bits are not changed and then output the port with the correct new data. This read-modify-write process is taken care of automatically when these bit operation instructions are used.

#### **Table Read Operations**

Data storage is normally implemented by using registers. However, when working with large amounts of fixed data, the volume involved often makes it inconvenient to store the fixed data in the Data Memory. To overcome this problem, Holtek microcontrollers allow an area of Program Memory to be setup as a table where data can be directly stored. A set of easy to use instructions provides the means by which this fixed data can be referenced and retrieved from the Program Memory.

#### Other Operations

In addition to the above functional instructions, a range of other instructions also exist such as the "HALT" instruction for Power-down operations and instructions to control the operation of the Watchdog Timer for reliable program operations under extreme electric or electromagnetic environments. For their relevant operations, refer to the functional related sections.

Rev. 1.50 226 July 12, 2017

# **Instruction Set Summary**

The following table depicts a summary of the instruction set categorised according to function and can be consulted as a basic instruction reference using the following listed conventions.

#### **Table Conventions**

x: Bits immediate data

m: Data Memory address

A: Accumulator

i: 0~7 number of bits

addr: Program memory address

| Mnemonic         | Description   | Cycles            | Flag Affected |
|------------------|---|-------------------|---------------|
| Arithmetic       |   |                   |               |
| ADD A,[m]        | Add Data Memory to ACC  | 1                 | Z, C, AC, OV  |
| ADDM A,[m]       | Add ACC to Data Memory  | 1 <sup>Note</sup> | Z, C, AC, OV  |
| ADD A,x          | Add immediate data to ACC                                       | 1                 | Z, C, AC, OV  |
| ADC A,[m]        | Add Data Memory to ACC with Carry                               | 1                 | Z, C, AC, OV  |
| ADCM A,[m]       | Add ACC to Data memory with Carry                               | 1 <sup>Note</sup> | Z, C, AC, OV  |
| SUB A,x          | Subtract immediate data from the ACC                            | 1                 | Z, C, AC, OV  |
| SUB A,[m]        | Subtract Data Memory from ACC                                   | 1                 | Z, C, AC, OV  |
| SUBM A,[m]       | Subtract Data Memory from ACC with result in Data Memory        | 1 <sup>Note</sup> | Z, C, AC, OV  |
| SBC A,[m]        | Subtract Data Memory from ACC with Carry                        | 1                 | Z, C, AC, OV  |
| SBCM A,[m]       | Subtract Data Memory from ACC with Carry, result in Data Memory | 1 <sup>Note</sup> | Z, C, AC, OV  |
| DAA [m]          | Decimal adjust ACC for Addition with result in Data Memory      | 1 <sup>Note</sup> | С             |
| Logic Operation  |   |                   |               |
| AND A,[m]        | Logical AND Data Memory to ACC                                  | 1                 | Z             |
| OR A,[m]         | Logical OR Data Memory to ACC                                   | 1                 | Z             |
| XOR A,[m]        | Logical XOR Data Memory to ACC                                  | 1                 | Z             |
| ANDM A,[m]       | Logical AND ACC to Data Memory                                  | 1 <sup>Note</sup> | Z             |
| ORM A,[m]        | Logical OR ACC to Data Memory                                   | 1 <sup>Note</sup> | Z             |
| XORM A,[m]       | Logical XOR ACC to Data Memory                                  | 1 <sup>Note</sup> | Z             |
| AND A,x          | Logical AND immediate Data to ACC                               | 1                 | Z             |
| OR A,x           | Logical OR immediate Data to ACC                                | 1                 | Z             |
| XOR A,x          | Logical XOR immediate Data to ACC                               | 1                 | Z             |
| CPL [m]          | Complement Data Memory  | 1 <sup>Note</sup> | Z             |
| CPLA [m]         | Complement Data Memory with result in ACC                       | 1                 | Z             |
| Increment & Deci | rement  |                   |               |
| INCA [m]         | Increment Data Memory with result in ACC                        | 1                 | Z             |
| INC [m]          | Increment Data Memory   | 1 <sup>Note</sup> | Z             |
| DECA [m]         | Decrement Data Memory with result in ACC                        | 1                 | Z             |
| DEC [m]          | Decrement Data Memory   | 1 <sup>Note</sup> | Z             |
| Rotate           |   |                   |               |
| RRA [m]          | Rotate Data Memory right with result in ACC                     | 1                 | None          |
| RR [m]           | Rotate Data Memory right  | 1 <sup>Note</sup> | None          |
| RRCA [m]         | Rotate Data Memory right through Carry with result in ACC       | 1                 | С             |
| RRC [m]          | Rotate Data Memory right through Carry                          | 1 <sup>Note</sup> | С             |
| RLA [m]          | Rotate Data Memory left with result in ACC                      | 1                 | None          |
| RL [m]           | Rotate Data Memory left   | 1 <sup>Note</sup> | None          |
| RLCA [m]         | Rotate Data Memory left through Carry with result in ACC        | 1                 | С             |
| RLC [m]          | Rotate Data Memory left through Carry                           | 1 <sup>Note</sup> | С             |

| Mnemonic      | Description  | Cycles            | Flag Affected |
|---------------|--|-------------------|---------------|
| Data Move     |  |                   |               |
| MOV A,[m]     | Move Data Memory to ACC                                  | 1                 | None          |
| MOV [m],A     | Move ACC to Data Memory                                  | 1 <sup>Note</sup> | None          |
| MOV A,x       | Move immediate data to ACC                               | 1                 | None          |
| Bit Operation |  |                   |               |
| CLR [m].i     | Clear bit of Data Memory                                 | 1 <sup>Note</sup> | None          |
| SET [m].i     | Set bit of Data Memory                                   | 1 <sup>Note</sup> | None          |
| Branch        |  |                   |               |
| JMP addr      | Jump unconditionally                                     | 2                 | None          |
| SZ [m]        | Skip if Data Memory is zero                              | 1 <sup>Note</sup> | None          |
| SZA [m]       | Skip if Data Memory is zero with data movement to ACC    | 1 <sup>Note</sup> | None          |
| SZ [m].i      | Skip if bit i of Data Memory is zero                     | 1 <sup>Note</sup> | None          |
| SNZ [m].i     | Skip if bit i of Data Memory is not zero                 | 1 <sup>Note</sup> | None          |
| SIZ [m]       | Skip if increment Data Memory is zero                    | 1 <sup>Note</sup> | None          |
| SDZ [m]       | Skip if decrement Data Memory is zero                    | 1 <sup>Note</sup> | None          |
| SIZA [m]      | Skip if increment Data Memory is zero with result in ACC | 1 <sup>Note</sup> | None          |
| SDZA [m]      | Skip if decrement Data Memory is zero with result in ACC | 1 <sup>Note</sup> | None          |
| CALL addr     | Subroutine call  | 2                 | None          |
| RET           | Return from subroutine                                   | 2                 | None          |
| RET A,x       | Return from subroutine and load immediate data to ACC    | 2                 | None          |
| RETI          | Return from interrupt                                    | 2                 | None          |
| Table Read    |  |                   |               |
| TABRD [m]     | Read table to TBLH and Data Memory                       | 2 <sup>Note</sup> | None          |
| TABRDL [m]    | Read table (last page) to TBLH and Data Memory           | 2 <sup>Note</sup> | None          |
| Miscellaneous |  |                   |               |
| NOP           | No operation   | 1                 | None          |
| CLR [m]       | Clear Data Memory  | 1 <sup>Note</sup> | None          |
| SET [m]       | Set Data Memory  | 1 <sup>Note</sup> | None          |
| CLR WDT       | Clear Watchdog Timer                                     | 1                 | TO, PDF       |
| CLR WDT1      | Pre-clear Watchdog Timer                                 | 1                 | TO, PDF       |
| CLR WDT2      | Pre-clear Watchdog Timer                                 | 1                 | TO, PDF       |
| SWAP [m]      | Swap nibbles of Data Memory                              | 1 <sup>Note</sup> | None          |
| SWAPA [m]     | Swap nibbles of Data Memory with result in ACC           | 1                 | None          |
| HALT          | Enter power down mode                                    | 1                 | TO, PDF       |

**Note:** 1. For skip instructions, if the result of the comparison involves a skip then two cycles are required, if no skip takes place only one cycle is required.

- 2. Any instruction which changes the contents of the PCL will also require 2 cycles for execution.
- 3. For the "CLR WDT1" and "CLR WDT2" instructions the TO and PDF flags may be affected by the execution status. The TO and PDF flags are cleared after both "CLR WDT1" and "CLR WDT2" instructions are consecutively executed. Otherwise the TO and PDF flags remain unchanged.

Rev. 1.50 228 July 12, 2017

### **Instruction Definition**

ADC A,[m] Add Data Memory to ACC with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + [m] + C$ 

Affected flag(s) OV, Z, AC, C

ADCM A,[m] Add ACC to Data Memory with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the specified Data Memory.

Operation  $[m] \leftarrow ACC + [m] + C$ 

Affected flag(s) OV, Z, AC, C

ADD A,[m] Add Data Memory to ACC

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + [m]$ Affected flag(s) OV, Z, AC, C

**ADD A,x** Add immediate data to ACC

Description The contents of the Accumulator and the specified immediate data are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + x$ Affected flag(s) OV, Z, AC, C

**ADDM A,[m]** Add ACC to Data Memory

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the specified Data Memory.

 $\label{eq:continuous} \begin{array}{ll} \text{Operation} & & [m] \leftarrow ACC + [m] \\ \text{Affected flag(s)} & & \text{OV, Z, AC, C} \end{array}$ 

AND A,[m] Logical AND Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical AND

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "AND" [m]$ 

Affected flag(s) Z

**AND A,x** Logical AND immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bit wise logical AND

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC$  "AND" x

Affected flag(s) Z

**ANDM A,[m]** Logical AND ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical AND

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "AND" [m]$ 

CALL addr Subroutine call

Description Unconditionally calls a subroutine at the specified address. The Program Counter then

increments by 1 to obtain the address of the next instruction which is then pushed onto the stack. The specified address is then loaded and the program continues execution from this new address. As this instruction requires an additional operation, it is a two cycle instruction.

Operation Stack  $\leftarrow$  Program Counter + 1

Program Counter ← addr

Affected flag(s) None

**CLR [m]** Clear Data Memory

Description Each bit of the specified Data Memory is cleared to 0.

Operation  $[m] \leftarrow 00H$ Affected flag(s) None

**CLR [m].i** Clear bit of Data Memory

Description Bit i of the specified Data Memory is cleared to 0.

Operation [m].i  $\leftarrow$  0 Affected flag(s) None

**CLR WDT** Clear Watchdog Timer

Description The TO, PDF flags and the WDT are all cleared.

Operation WDT cleared

 $TO \leftarrow 0$ <br/>PDF \leftleftharpoonup 0

Affected flag(s) TO, PDF

**CLR WDT1** Pre-clear Watchdog Timer

Description The TO, PDF flags and the WDT are all cleared. Note that this instruction works in

conjunction with CLR WDT2 and must be executed alternately with CLR WDT2 to have effect. Repetitively executing this instruction without alternately executing CLR WDT2 will

have no effect.

Operation WDT cleared

 $\begin{aligned} & TO \leftarrow 0 \\ & PDF \leftarrow 0 \end{aligned}$ 

TDF ← 0

Affected flag(s) TO, PDF

**CLR WDT2** Pre-clear Watchdog Timer

Description The TO, PDF flags and the WDT are all cleared. Note that this instruction works in conjunction

with CLR WDT1 and must be executed alternately with CLR WDT1 to have effect.

Repetitively executing this instruction without alternately executing CLR WDT1 will have no

effect.

Operation WDT cleared

 $TO \leftarrow 0$ <br/>PDF \leftleftharpoonup 0

Affected flag(s) TO, PDF

**CPL [m]** Complement Data Memory

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa.

Operation  $[m] \leftarrow \overline{[m]}$ 

**CPLA [m]** Complement Data Memory with result in ACC

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa. The complemented result is stored in

the Accumulator and the contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow \overline{[m]}$ 

Affected flag(s) Z

**DAA [m]** Decimal-Adjust ACC for addition with result in Data Memory

Description Convert the contents of the Accumulator value to a BCD (Binary Coded Decimal) value

resulting from the previous addition of two BCD variables. If the low nibble is greater than 9 or if AC flag is set, then a value of 6 will be added to the low nibble. Otherwise the low nibble remains unchanged. If the high nibble is greater than 9 or if the C flag is set, then a value of 6 will be added to the high nibble. Essentially, the decimal conversion is performed by adding 00H, 06H, 60H or 66H depending on the Accumulator and flag conditions. Only the C flag may be affected by this instruction which indicates that if the original BCD sum is greater than

100, it allows multiple precision decimal addition.

Operation  $[m] \leftarrow ACC + 00H \text{ or}$ 

 $[m] \leftarrow ACC + 06H \text{ or}$   $[m] \leftarrow ACC + 60H \text{ or}$  $[m] \leftarrow ACC + 66H$ 

Affected flag(s) C

**DEC [m]** Decrement Data Memory

Description Data in the specified Data Memory is decremented by 1.

Operation  $[m] \leftarrow [m] - 1$ 

Affected flag(s) Z

DECA [m] Decrement Data Memory with result in ACC

Description Data in the specified Data Memory is decremented by 1. The result is stored in the

Accumulator. The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] - 1$ 

Affected flag(s) Z

**HALT** Enter power down mode

Description This instruction stops the program execution and turns off the system clock. The contents of

the Data Memory and registers are retained. The WDT and prescaler are cleared. The power

down flag PDF is set and the WDT time-out flag TO is cleared.

Operation  $TO \leftarrow 0$ 

 $PDF \leftarrow 1$ 

Affected flag(s) TO, PDF

**INC [m]** Increment Data Memory

Description Data in the specified Data Memory is incremented by 1.

Operation  $[m] \leftarrow [m] + 1$ 

Affected flag(s) Z

**INCA [m]** Increment Data Memory with result in ACC

Description Data in the specified Data Memory is incremented by 1. The result is stored in the Accumulator.

The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] + 1$ 

JMP addr Jump unconditionally

Description The contents of the Program Counter are replaced with the specified address. Program

execution then continues from this new address. As this requires the insertion of a dummy

instruction while the new address is loaded, it is a two cycle instruction.

Operation Program Counter ← addr

Affected flag(s) None

MOV A,[m] Move Data Memory to ACC

Description The contents of the specified Data Memory are copied to the Accumulator.

 $\begin{array}{ll} \text{Operation} & \text{ACC} \leftarrow [m] \\ \text{Affected flag(s)} & \text{None} \end{array}$ 

**MOV A,x** Move immediate data to ACC

Description The immediate data specified is loaded into the Accumulator.

Operation  $ACC \leftarrow x$ Affected flag(s) None

**MOV [m],A** Move ACC to Data Memory

Description The contents of the Accumulator are copied to the specified Data Memory.

Operation  $[m] \leftarrow ACC$ Affected flag(s) None

**NOP** No operation

Description No operation is performed. Execution continues with the next instruction.

Operation No operation
Affected flag(s) None

OR A,[m] Logical OR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise

logical OR operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "OR" [m]$ 

Affected flag(s) Z

**OR A,x** Logical OR immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bitwise logical OR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "OR" x$ 

Affected flag(s) Z

**ORM A,[m]** Logical OR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical OR

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "OR" [m]$ 

Affected flag(s) Z

**RET** Return from subroutine

Description The Program Counter is restored from the stack. Program execution continues at the restored

address.

Operation Program Counter ← Stack

Affected flag(s) None

**RET A,x** Return from subroutine and load immediate data to ACC

Description The Program Counter is restored from the stack and the Accumulator loaded with the specified

immediate data. Program execution continues at the restored address.

Operation Program Counter ← Stack

 $ACC \leftarrow x$ 

Affected flag(s) None

**RETI** Return from interrupt

Description The Program Counter is restored from the stack and the interrupts are re-enabled by setting the

EMI bit. EMI is the master interrupt global enable bit. If an interrupt was pending when the RETI instruction is executed, the pending Interrupt routine will be processed before returning

to the main program.

Operation Program Counter ← Stack

 $EMI \leftarrow 1$ 

Affected flag(s) None

**RL [m]** Rotate Data Memory left

Description The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow [m].7$ 

Affected flag(s) None

**RLA [m]** Rotate Data Memory left with result in ACC

Description The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0.

The rotated result is stored in the Accumulator and the contents of the Data Memory remain

unchanged.

Operation ACC.(i+1)  $\leftarrow$  [m].i; (i=0 $\sim$ 6)

 $ACC.0 \leftarrow [m].7$ 

Affected flag(s) None

**RLC [m]** Rotate Data Memory left through Carry

Description The contents of the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7

replaces the Carry bit and the original carry flag is rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow C$ 

 $C \leftarrow [m].7$ 

Affected flag(s) C

RLCA [m] Rotate Data Memory left through Carry with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 replaces the

Carry bit and the original carry flag is rotated into the bit 0. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation ACC.(i+1)  $\leftarrow$  [m].i; (i=0 $\sim$ 6)

 $ACC.0 \leftarrow C$ 

 $C \leftarrow [m].7$ 

Affected flag(s) C

**RR [m]** Rotate Data Memory right

Description The contents of the specified Data Memory are rotated right by 1 bit with bit 0 rotated into bit 7.

Operation  $[m].i \leftarrow [m].(i+1); (i=0\sim6)$ 

 $[m].7 \leftarrow [m].0$ 

Affected flag(s) None

**RRA [m]** Rotate Data Memory right with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated right by 1 bit with bit 0

rotated into bit 7. The rotated result is stored in the Accumulator and the contents of the

Data Memory remain unchanged.

Operation ACC.i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $ACC.7 \leftarrow [m].0$ 

Affected flag(s) None

**RRC [m]** Rotate Data Memory right through Carry

Description The contents of the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0

replaces the Carry bit and the original carry flag is rotated into bit 7.

Operation  $[m].i \leftarrow [m].(i+1); (i=0\sim6)$ 

 $[m].7 \leftarrow C$ 

 $C \leftarrow [m].0$ 

Affected flag(s) C

**RRCA [m]** Rotate Data Memory right through Carry with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0 replaces

the Carry bit and the original carry flag is rotated into bit 7. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation ACC.i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $ACC.7 \leftarrow C$ 

 $C \leftarrow [m].0$ 

Affected flag(s) C

SBC A,[m] Subtract Data Memory from ACC with Carry

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - [m] - C$ 

Affected flag(s) OV, Z, AC, C

**SBCM A,[m]** Subtract Data Memory from ACC with Carry and result in Data Memory

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $[m] \leftarrow ACC - [m] - C$ 

Affected flag(s) OV, Z, AC, C

**SDZ [m]** Skip if decrement Data Memory is 0

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0 the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] - 1$ 

Skip if [m]=0

Affected flag(s) None

Rev. 1.50 234 July 12, 2017

**SDZA [m]** Skip if decrement Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy

instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0,

the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] - 1$ 

Skip if ACC=0

Affected flag(s) None

**SET [m]** Set Data Memory

Description Each bit of the specified Data Memory is set to 1.

Operation  $[m] \leftarrow FFH$ Affected flag(s) None

**SET [m].i** Set bit of Data Memory

Description Bit i of the specified Data Memory is set to 1.

 $\begin{array}{ll} \text{Operation} & \quad [m].i \leftarrow 1 \\ \text{Affected flag(s)} & \quad \text{None} \end{array}$ 

**SIZ [m]** Skip if increment Data Memory is 0

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] + 1$ 

Skip if [m]=0

Affected flag(s) None

Skip if increment Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy

instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not

0 the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] + 1$ 

Skip if ACC=0

Affected flag(s) None

**SNZ [m].i** Skip if bit i of Data Memory is not 0

Description If bit i of the specified Data Memory is not 0, the following instruction is skipped. As this

requires the insertion of a dummy instruction while the next instruction is fetched, it is a two

cycle instruction. If the result is 0 the program proceeds with the following instruction.

Operation Skip if  $[m].i \neq 0$ 

Affected flag(s) None

**SUB A,[m]** Subtract Data Memory from ACC

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - [m]$ 

Affected flag(s) OV, Z, AC, C

**SUBM A,[m]** Subtract Data Memory from ACC with result in Data Memory

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

Operation  $[m] \leftarrow ACC - [m]$ Affected flag(s) OV, Z, AC, C

**SUB A,x** Subtract immediate data from ACC

Description The immediate data specified by the code is subtracted from the contents of the Accumulator.

The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - x$ Affected flag(s) OV, Z, AC, C

**SWAP [m]** Swap nibbles of Data Memory

Description The low-order and high-order nibbles of the specified Data Memory are interchanged.

Operation  $[m].3\sim[m].0 \leftrightarrow [m].7\sim[m].4$ 

Affected flag(s) None

**SWAPA [m]** Swap nibbles of Data Memory with result in ACC

Description The low-order and high-order nibbles of the specified Data Memory are interchanged. The

result is stored in the Accumulator. The contents of the Data Memory remain unchanged.

Operation  $ACC.3 \sim ACC.0 \leftarrow [m].7 \sim [m].4$ 

 $ACC.7 \sim ACC.4 \leftarrow [m].3 \sim [m].0$ 

Affected flag(s) None

**SZ [m]** Skip if Data Memory is 0

Description If the contents of the specified Data Memory is 0, the following instruction is skipped. As this

requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds with the following instruction.

Operation Skip if [m]=0

Affected flag(s) None

**SZA [m]** Skip if Data Memory is 0 with data movement to ACC

Description The contents of the specified Data Memory are copied to the Accumulator. If the value is zero,

the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the

program proceeds with the following instruction.

Operation  $ACC \leftarrow [m]$ 

Skip if [m]=0

Affected flag(s) None

**SZ [m].i** Skip if bit i of Data Memory is 0

Description If bit i of the specified Data Memory is 0, the following instruction is skipped. As this requires

the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle

instruction. If the result is not 0, the program proceeds with the following instruction.

Operation Skip if [m].i=0

Affected flag(s) None

Rev. 1.50 236 July 12, 2017

**TABRD [m]** Read table (current page) to TBLH and Data Memory

Description The low byte of the program code (current page) addressed by the table pointer (TBLP) is

moved to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow \text{program code (low byte)}$ 

TBLH ← program code (high byte)

Affected flag(s) None

**TABRDL [m]** Read table (last page) to TBLH and Data Memory

Description The low byte of the program code (last page) addressed by the table pointer (TBLP) is moved

to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow \text{program code (low byte)}$ 

TBLH ← program code (high byte)

Affected flag(s) None

XOR A,[m] Logical XOR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical XOR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z

**XORM A,[m]** Logical XOR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical XOR

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z

**XOR A,x** Logical XOR immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bitwise logical XOR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "XOR" x$
