

Antenna Switch Module: BGSF1717MN26

Antenna Switch Module with integrated MIPI RFFE Interface, 2 GSMTX Ports for multi-mode GSM/EDGE, WCDMA or LTE Applications and Carrier Aggregation

Application Note AN384

About this document

Scope and purpose

This application note describes Infineon's Antenna Switch Module BGSF1717MN26 as main antenna switch module for multi-mode GSM/EDGE, WCDMA or LTE Applications and Carrier Aggregation applications.

1. This application notes gives an overview about main purpose of this SP7T Low Band + SP7T High Band Antenna Switch Module.
2. Multi-mode GSM/EDGE, WCDMA or LTE Applications and Carrier Aggregation are the primary application of this document.
3. The Printed Circuit Board (PCB) design as well as antenna matching network proposed in this note provides a customer oriented approach where a single ASM enables multi-mode GSM/EDGE, WCDMA or LTE and Carrier Aggregation applications
4. Key performance parameters include higher Isolation between input channels (~ 32 dB), integrated SAW Filter for LB and HB GSM Tx inputs, very low IL of the TX channels (0.5dB), integration of SP7T LB and SP7T HB in one module and an integrated MIPI RFFE Interface.

1 Introduction of BGSF1717MN26

For RF Front-End solutions that integrate new features such as downlink inter-band carrier aggregation to increase Downlink data rates, Antenna Switch Modules (ASMs) are facing new challenges. Two RF signals being transmitted in different frequency bands have to be routed from two different antennas – one dedicated for low frequency band and one for high frequency band - to the RF Transceiver at the same time. For this kind of application, the new switch which combines two SP7T ICs and the MIPI control interface, the so-called DP14T, have been introduced to the market.

The BGSF1717MN26 is a double Pole Fourteen Throw (DP14T / SP7T+SP7T) ASM optimized for wireless applications up to 2.7 GHz. It is a perfect solution for multi-mode handsets based on quad-band GSM, WCDMA, LTE and ideal for carrier aggregation solutions. TRX10 is designed to achieve ultra-high linearity. The ASM configuration is shown in the [Figure 2](#).

The module comes in a miniature TSNP package shown in the [Figure 1](#) and comprises of two high power SP7T switches with integrated MIPI RFFE interface and harmonic filters for GSM high and low band transmitter signal paths. The on-chip MIPI RFFE interface supports both 1.2 V and 1.8 V supply voltages. No external DC blocking capacitors are required in typical applications as long as no DC is applied to any RF port. The pin assignment can be found in the [Figure 3](#).

1.1 Main Features

- Suitable for multi-mode GSM / EDGE / C2K / WCDMA / LTE applications and carrier aggregation
- Operating from 0.1 to 2.7 GHz coverage
- Ultra-low insertion loss and harmonics generation
- Integrated GSM transmit filters
- 12 interchangeable, high-linearity WCDMA TRX ports
- Port TRX10 designed for ultra-high linearity

- 2 high-linearity GSM TX paths
- High port-to-port isolation
- Integrated MIPI RFFE interface
- No decoupling DC capacitors required, if no DC applied on RF lines
- Small form factor: 3.2 mm x 2.8 mm x 0.73 mm

2 Application

A typical application of BGSF1717MN26 ASM in a mobile phone is shown in the **Figure 4**. At the main antenna path of the RF Front-End the BGSF1717MN26 switches signals from the high band and low band antenna to the different transceiver IC input and outputs. For the diversity path different Infineon RF switches can be used e.g. BGS16MN14, BGS18MN14. Infineon offers also besides ASMs, general purpose RF Switches and a broad portfolio of **Low Noise Amplifiers** and Antenna Tuner Devices. All of Infineon Products concerning mobile phone applications can be found in our newest [Application Guide for RF & Protection Devices/ Mobile Communication](#).

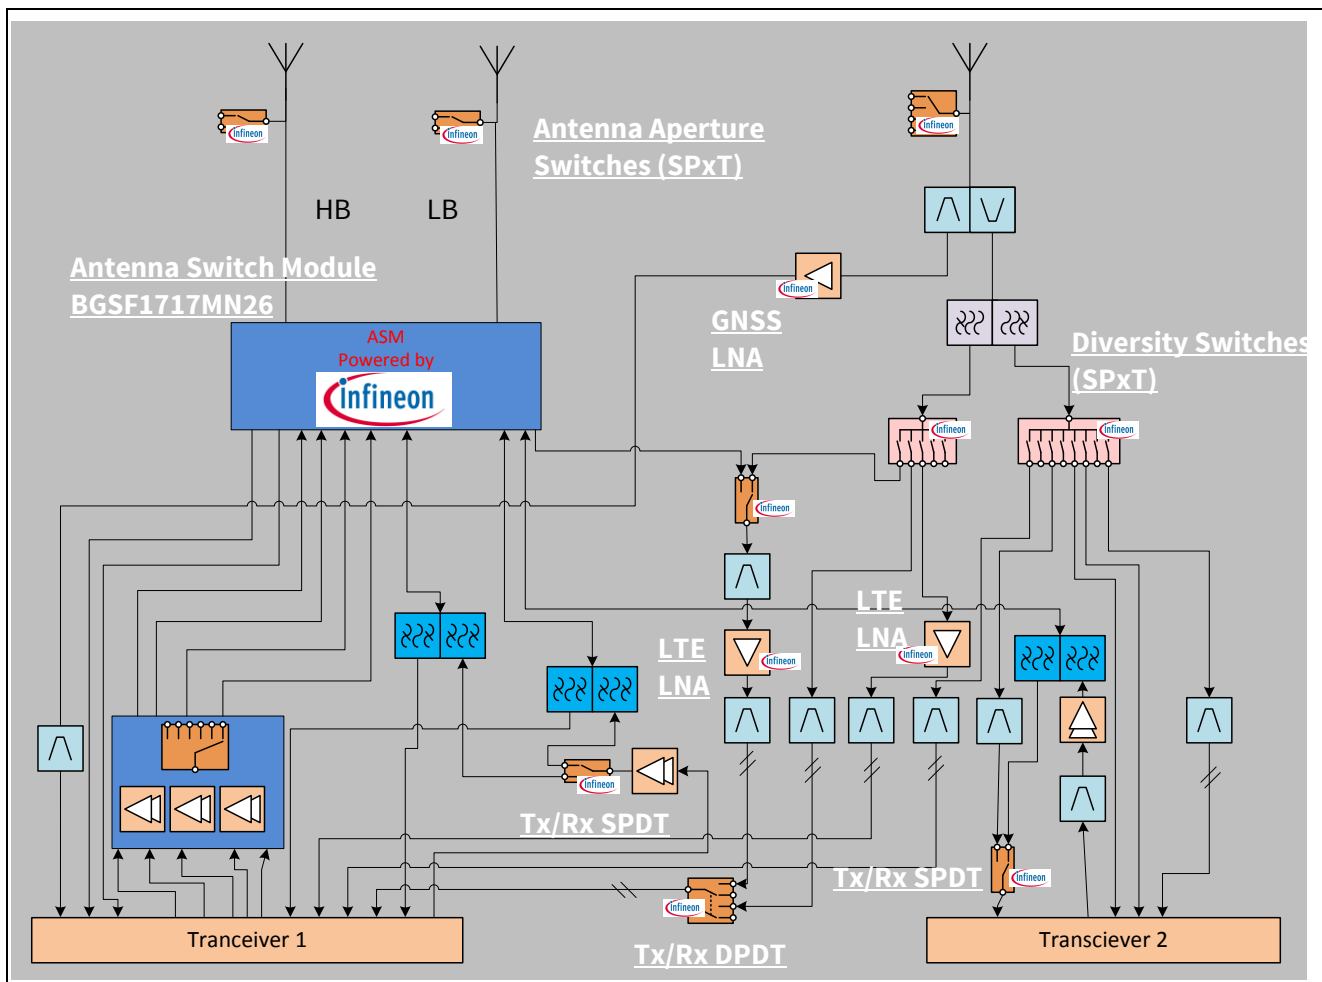

Figure 4 BGSF1717MN26 in mobile phone cellular frontend (typical discrete LTE-A feature set)

3 Application Circuit of BGSF1717MN26

In this chapter the evaluation board with application circuit including matching passive elements is presented. Afterwards, the deembedding process required for S-Parameter measurements is described.

Device: BGSF1717MN26
Application: Antenna Switch Module
PCB Marking: BGSF1717MN26 v1.1
EVB Order No.: BGSF1717MN26 BOARD SP001136296

3.1 Application Board

The EVAluation Board (EVB) used for the RF measurements is shown in the [Figure 5](#). The EVB is designed so that every 50 Ohm signal lines have the same length. The layer stack-up of the PCB is presented in [Figure 6](#).

Figure 5 Layout of the application board

Figure 6 PCB cross section with layer stack-up

3.2 Deembedding

The device (BGSF1717MN26) is deembedded from influence of the application circuit and coaxial connectors by at first measuring a coaxial connector and a “half-board” micro strip line and then by loading this data in the fixture simulator of the network analyzer. In the **Figure 7** this deembedding concept is given. The deembedding of this RF device is performed in several steps explained in the next subchapters.

Figure 7 Deembedding concept with a “prepared” SMA connector and a “Half-Thru” board

3.2.1 Port Extension

In order to shift the reference plane of the network analyzer to the PCB signal line connect a SMA connector with a cut pin of the inner conductor to one port of the Vector Network Analyzer (VNA) and measure port extensions at this port.

Figure 8 shows such a “prepared” SMA connector with an outer pin cut with a wire cutter.

Figure 8 SMA connector with cut inner pin

After the measurement of the S21 of the half-thru board (given in [Figure 9](#)) with port extension turned on is completed, the s2p-data ought to be loaded in the fixture simulator. This measurement result includes the insertion loss and the phase shift of the one SMA connector and the transmission line to the chip. After all the port extension has to be deactivated.

Figure 9 “Half-Thru” deembedding board

3.2.2 Deembedding control process

Measure this full-thru PCB (given in the [Figure 10](#)) to verify your deembedding having the fixture simulator turned on for each port of the VNA, whereas port extension must be off. If the insertion loss is close to 0 dB and S11 reflection has a considerable value, further RF measurements can be done.

Figure 10 “Full-Thru” deembedding board

4 Small Signal Characteristics of BGSF1717MN26

The S-Parameters are measured at 25 °C with a VNA in an application circuit shown in **Figure 11**.

5 Non-Linear performance of BGSF1717MN26

Smart phones today can operate across several cellular bands covering GSM / EDGE / CDMA / UMTS / WCDMA / LTE/TD-SCDMA / TD-LTE / LTE-A. The design of the RF front-end part in modern cellular phones is becoming increasingly complex and demanding due to the increasing number of frequency bands and modes that the phone needs to support. One of the main components of the RF front-end is the antenna switch that selects which transmitter (TX)/receiver (RX) path can be connected to the antenna. The RF switch has to satisfy high linearity requirements. The following material describes some of the main challenges of antenna switches in mobile applications.

Modern smartphones are multi-mode devices that are capable of connecting to 2G, 3G and 4G networks. These networks often use different frequency bands. The smartphone's RF frontend must therefore include band-specific components. In order to appropriately route signals for a given mode and band of operation, a high-performance RF switch is an essential component of the front-end circuitry. The performance requirements of the RF switch are discussed in the following sections.

5.1 Intermodulation

Intermodulation Distortion (IMD2 and IMD3) is a parameter that describes the linearity of a device under multi-tone conditions. The intermodulation between different frequency components generates undesired output frequencies at the sum and difference frequencies of the input tones, and at multiples of those sum and difference frequencies. Some of these possible intermodulation scenarios are shown in the [Figure 28](#).

In this example, the transmitted (Tx) signal from the main antenna is coupled into the diversity antenna with high power. This signal (20 dBm) and a received jammer signal (-15 dBm) are entering the switch. Certain combinations of the TX and jammer frequencies are producing second- and third-order intermodulation products that fall into the desired reception band, and reduce the sensitivity of the receiver.

In [Table 18](#) and [Table 20](#) test conditions Band I and V and the linearity specifications for an undisturbed communication are given.

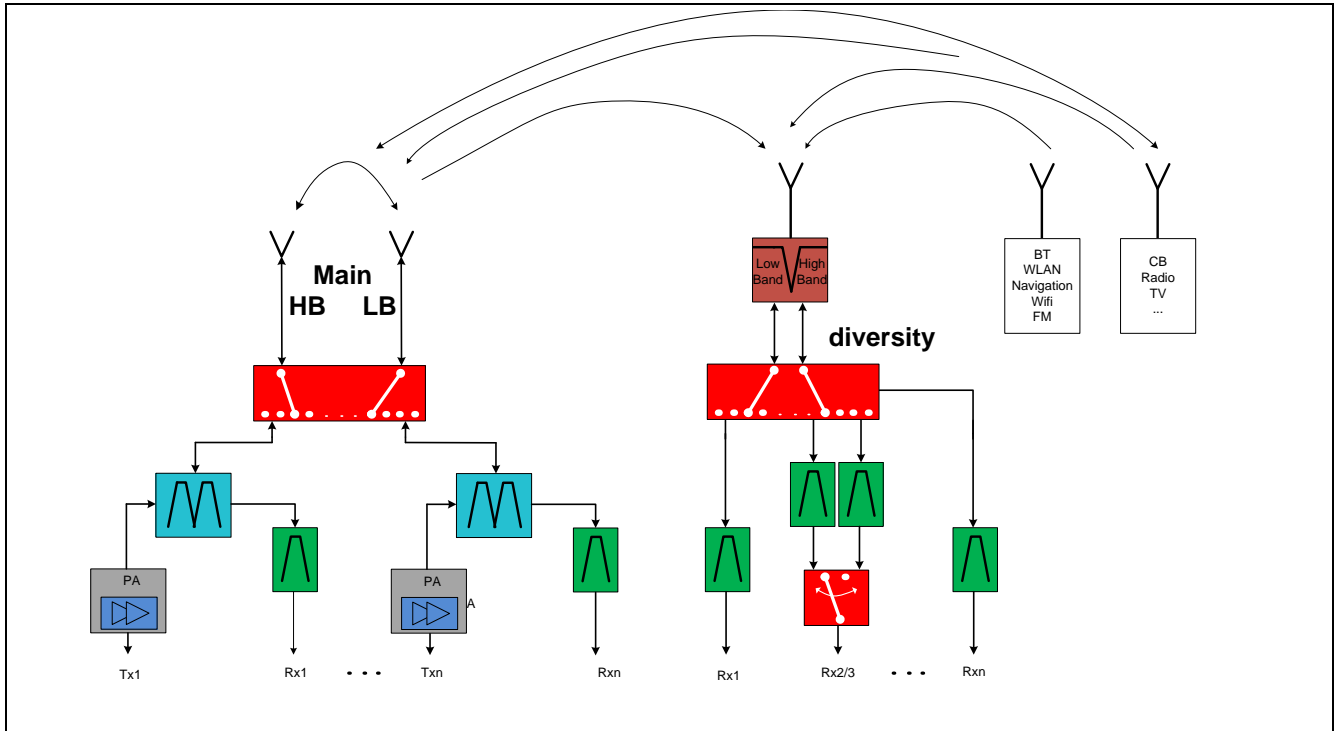

Figure 28 Block diagram of RF Switch intermodulation

5.1.1 Intermodulation Measurement Setup

Figure 29 Intermodulation Measurement Test Setup

The test setup for the IMD measurements has to provide a very high isolation between RX and TX signals. As an example the test set-up for the high band is shown in the **Figure 29**. In practice, a laboratory-graded duplexer with an isolation of 80 dB is used. In the **Figure 30** and **Figure 31** the results for IMD measurements in Band I and V are given. For each distortion scenario there is a minimum and a maximum value given. This variation is caused by a phase shifter connected between the switch and the duplexer. In the test set-up a phase shifter represents a not ideal matching of the switch to a 50 Ohm load.

5.1.2 Intermodulation Measurement conditions for Band I

Table 18 Test conditions and specifications of IMD measurements

Band 1					
	TX		Interferer		IMD product
Test case	F _{IN} (MHz)	P _{IN} (dBm) CW	F _{IN} (MHz)	P _{IN} (dBm) CW	F _{IMD} (MHz)
IMD3	1950	20	1760	-15	2140
IMD2 low			190		
IMD2 high			4090		

5.1.3 Intermodulation Measurement Results for Band I

5.2 Harmonic Distortion

Harmonic distortion is another important parameter for the characterization of an RF switch. RF switches have to withstand high RF levels, up to 36 dBm. This high RF power at the input of a switch generates harmonics of the waveform that is present. These harmonics (2nd and 3rd) can interfere with other reception bands or can cause distortion in other RF applications (GPS, WLAN) within the mobile phone.

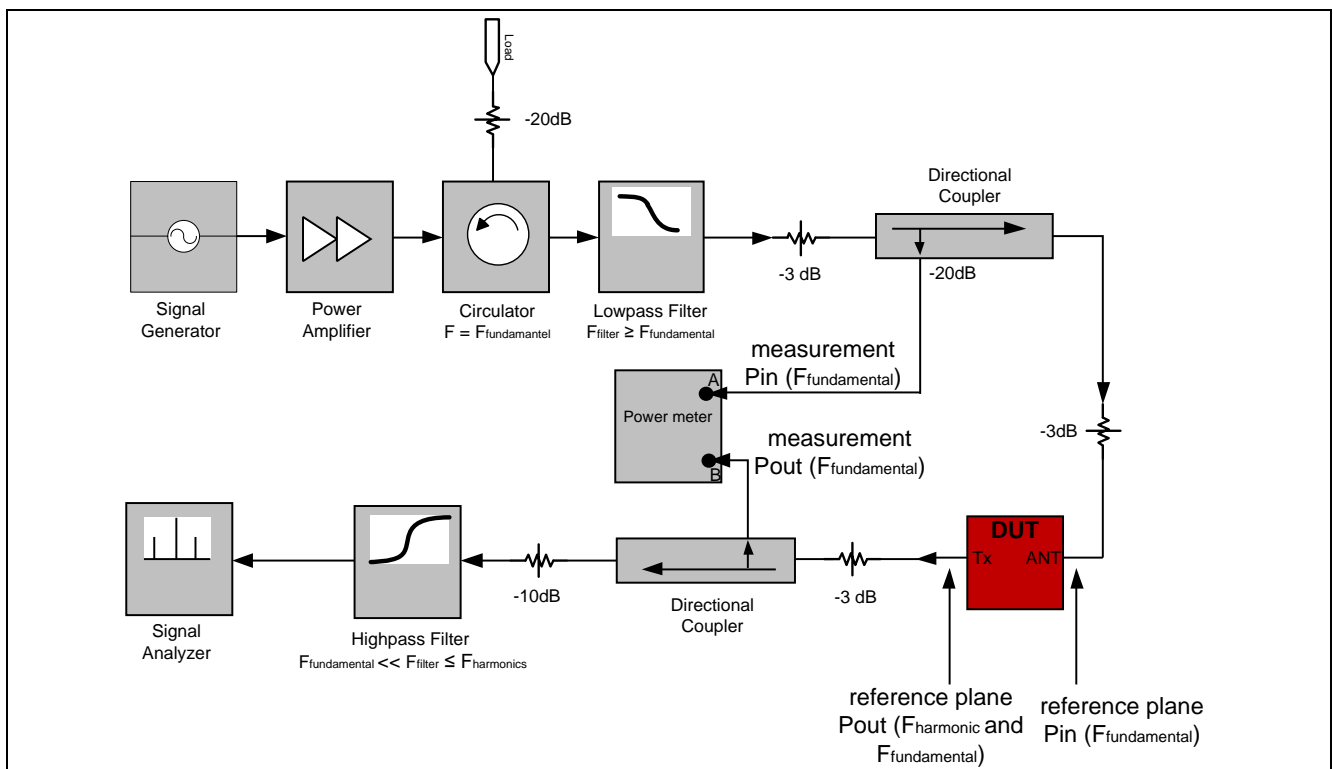

Figure 32 Harmonic Generation Measurement setup

5.2.1 Harmonic Generation Measurement conditions

Table 22 Harmonic Generation measurement Conditions

Tx		Harmonic Products	
F_{IN} (MHz)	P_{IN} (dBm), 50% DC	F_{H2} (MHz)	F_{H3} (MHz)
824	20...36 TX LB port	1648	2472
	20...27 TRX LB ports		
1800	20...36 TX HB port	3600	3600
	20...27 TRX HB ports		

The result for the harmonic generation at 824 MHz and 1800 MHz is shown in the [Figure 33](#) and [Figure 35](#). The input power (P_{IN}) is plotted on the X-Axis, and the generated harmonic amplitude is given in **dBm** on the Y-Axis.

5.2.2 Harmonic Generation Measurement Results of Low Band inputs

Figure 33 Measurements of Harmonic power over Carrier power of Low-Band inputs to LB Antenna

Figure 34 Harmonic power measurements of high linear LB input TRX10 over the Band 17 carrier

In **Figure 34** the generated harmonic power of a very high linear input TX10 is shown measured at the operating frequency of Band 17 FDD (710 MHz). The spacing between the carrier frequency and the generated harmonic at the maximum operated power sets up **to 98 dBc for H2 and 133 dBc for H3**. This is an outstanding performance among other competitors.

5.2.3 Harmonic Generation Measurement Results of High Band inputs

Figure 35 Measurements of Harmonic power over Carrier power of High-Band inputs to HB Antenna

6 Switching time

Table 23 Switching time values

Parameter	Symbol	Values			Unit	Note / Test Conditions
		Min.	Typ.	Max.		
Switching Time						
On/Off	$t_{on/off}$	-	1	-	μs	10% ON to 90% ON; 90% OFF to 10% OFF
Boost Converter Settling Time	t_{BC}	-	-	25	μs	After power down mode

For a “switching time” measurement a signal generator and a digital oscilloscope is used. A 100 MHz continuous sine signal with 0 dBm signal level was switched to all LB and HB inputs one after another. The output of the switch connected from one side either to HB Antenna or to LB Antenna and from the other side to a digital oscilloscope. Typical time required to raise the signal power from 10% ON Mode up to 90 % ON of the Signal Level lies by 1 μs . In the **Figure 36** the switching time of the TX_LB input is shown. Maximum time required between switch power-up till being able to switch to desired RF-path is 25 μs .

Figure 36 Switching time measurements of the TX_LB input to the LB Antenna

7 Appendix: Switch Controller Unit

The BGSF1717MN26 is controlled via MIPI interface and Infineon offers a MIPI-Controller unit to ease the evaluation of its BGSF1717MN26 on application board. The unit is very simple to use with a few buttons to select the right device and different states. This section helps as a short user guide for the controller unit shown in **Figure 37**. The controller unit requires a DC supply of 5.5V with a current capability of ~50mA.

Figure 37 Switch Controller Unit Board

7.1 Operating Guide

Please observe the following steps to use the controller unit:

1. Connect evaluation board and control unit via controller cable
2. Connect control unit to power supply
3. Press P1 and P3 simultaneously until desired switch type is displayed
 - “77” for BGSF1717MN26
4. Press P1 or P3 to enable active mode “PU” is displayed
5. Press P1 or P3 to alter switch state
 - IS ... Isolation Mode (all channels off)
 - PD ... Power Down Mode (low current consumption)
 - PU ... Power Up Mode (active mode)
 - T1 – TC and LB, HB ... TRX1 – TRX12 and TX LB and TXHB are enabled

7.2 Display Settings of the Controller Unit

Table 24 Setting Display of Active RF Path, Power UP, Power Down and Isolation State

LED Display	State of BGSF1717MN26
T1	TRX1
T2	TRX2
T3	TRX3
T4	TRX4
T5	TRX5
T6	TRX6
T7	TRX7
T8	TRX8
T9	TRX9
TA	TRX10
TB	TRX11
TC	TRX12
LB	TX LB
HB	TX LB
IS	Isolation State
PU	Power Up State
PD	Power Down State
