

CMOS Boost Converter - White LED Driver

Features

- Drives up to 5 White LEDs from 3V
- Power Efficiency up to 87%
- Low Quiescent Ground Current 0.1mA
- Adjustable Output Current (up to 30mA)
- High Frequency 1MHz Operation
- “Zero” current shutdown mode
- Operates down to 2V (from two AA batteries)
- Soft start power-up
- Open LED low power mode
- Automatic shutdown at 1.9V (UVLO)
- Thermal shutdown protection
- Thin SOT23 5-Lead (1mm max height)

Applications

- LCD Backlighting
- Cellular Phones
- Handheld Devices
- Digital Cameras

Ordering Information

Part Number	Package	Quantity per Reel	Package Marking
CAT4137TS	TSOT23-5	3000	LW
CAT4137TD	TSOT23-5 Green	3000	LX

Product Description

The CAT4137 is a DC/DC step-up converter that delivers a regulated output current. Operation at a constant switching frequency of 1MHz allows the device to be used with small value external ceramic capacitors and inductor.

The device drives a string of white LEDs connected in series and provides the regulated current to control the LEDs with inherent uniform brightness and matching. An external resistor R1 sets the output current and allows up to 30mA current to be supported over a wide range of input supply voltages from 2.2V to 5.5V, making the device ideal for battery-powered applications.

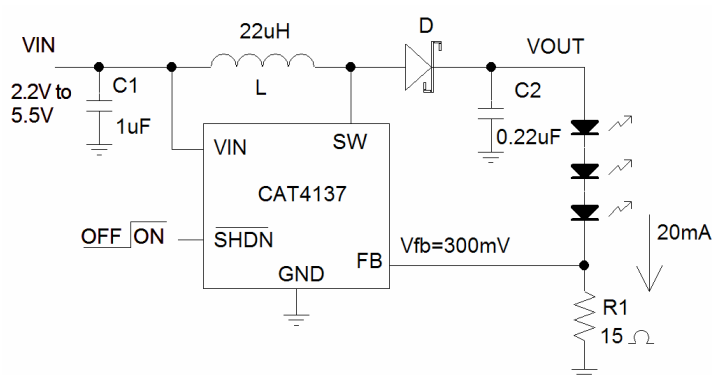

LED dimming can be done by using a DC voltage, a logic signal, or a pulse width modulation (PWM) signal. The shutdown control pin allows the device to be placed in power-down mode with “zero” quiescent current.

In addition to thermal protection and overload current limiting, the device also enters a very low power operating mode during “Open LED” fault conditions. The device is housed in a low profile (1mm max height) 5-lead thin SOT23 package for space critical applications.

Pin Configuration

Typical Application Circuit

L: Murata LQH32CN220
D: Central CMDSH2-3 (rated 30V)

ABSOLUTE MAXIMUM RATINGS

Parameter	Rating	Unit
VIN, FB voltage	-0.3 to +7	V
SHDN* voltage	-0.3 to +7	V
SW voltage	-0.3 to 40	V
Storage Temperature Range	-65 to +160	°C
Junction Temperature Range	-40 to +125	°C
Lead Temperature	300	°C

RECOMMENDED OPERATING CONDITIONS

Parameter	Range	Unit
VIN	2.2 to 5.5	V
SW pin voltage	0 to 24	V
Ambient Temperature Range	-40 to +85	°C
LED Bias Current	1 to 30	mA

ELECTRICAL OPERATING CHARACTERISTICS

VIN = 3.6V, ambient temperature of 25°C (over recommended operating conditions unless specified otherwise)

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
I _Q	Operating Current	V _{FB} = 0.3V V _{FB} = 0.4V (not switching)		0.4 0.1	1.5 0.3	mA

PIN DESCRIPTION

VIN is the supply input for the internal logic. The device is compatible with supply voltages down to 2.2V and up to 5.5V. A small bypass ceramic capacitor of 1 μ F is recommended between the VIN and GND pins near the device. The under-voltage lockout (UVLO) circuitry will place the device into an idle mode (not switching) whenever the supply falls below 1.9V.

SHDN* is the shutdown logic input. When the pin voltage is taken below 0.4V, the device immediately enters shutdown mode, drawing nearly zero current. At voltages greater than 1.5V, the device becomes fully enabled and operational.

GND is the ground reference pin. This pin should be connected directly to the ground plane on the PCB.

SW pin is the drain terminal of the internal low resistance power switch. The inductor and the Schottky diode anode should be connected to the SW pin. Traces going to the SW pin should be as short as possible with minimum loop area. This pin contains over-voltage circuitry which becomes active above 24V. In the event of an "Open-Led" fault condition, the device will enter a low power mode and the SW pin will be clamped to approximately 30V.

FB feedback pin is regulated at 0.3V. A resistor connected between the FB pin and ground sets the LED current according to the formula:

$$I_{LED} = 0.3V/R1$$

The lower LED cathode is connected to the FB pin.

Pin #	Name	Function
1	SW	Switch pin. This is the drain of the internal power switch.
2	GND	Ground pin. Connect the pin to the ground plane.
3	FB	Feedback pin. Connect to the last LED cathode.
4	SHDN*	Shutdown pin (Logic Low). Set high to enable the driver.
5	VIN	Power Supply input.

DEVICE OPERATION

The CAT4137 is a fixed frequency (1MHz), low noise, inductive boost converter providing constant current to the load. A high voltage internal CMOS power switch is used to energize the external inductor. When the power switch is then turned off, the stored energy inductor is released into the load via the external Schottky diode.

The on/off duty cycle of the power switch is internally adjusted and controlled to maintain a constant regulated voltage of 0.3V across the external feedback resistor connected to the feedback pin (FB). The value of external resistor will accurately set the LED bias current accordingly ($0.3V/R1$).

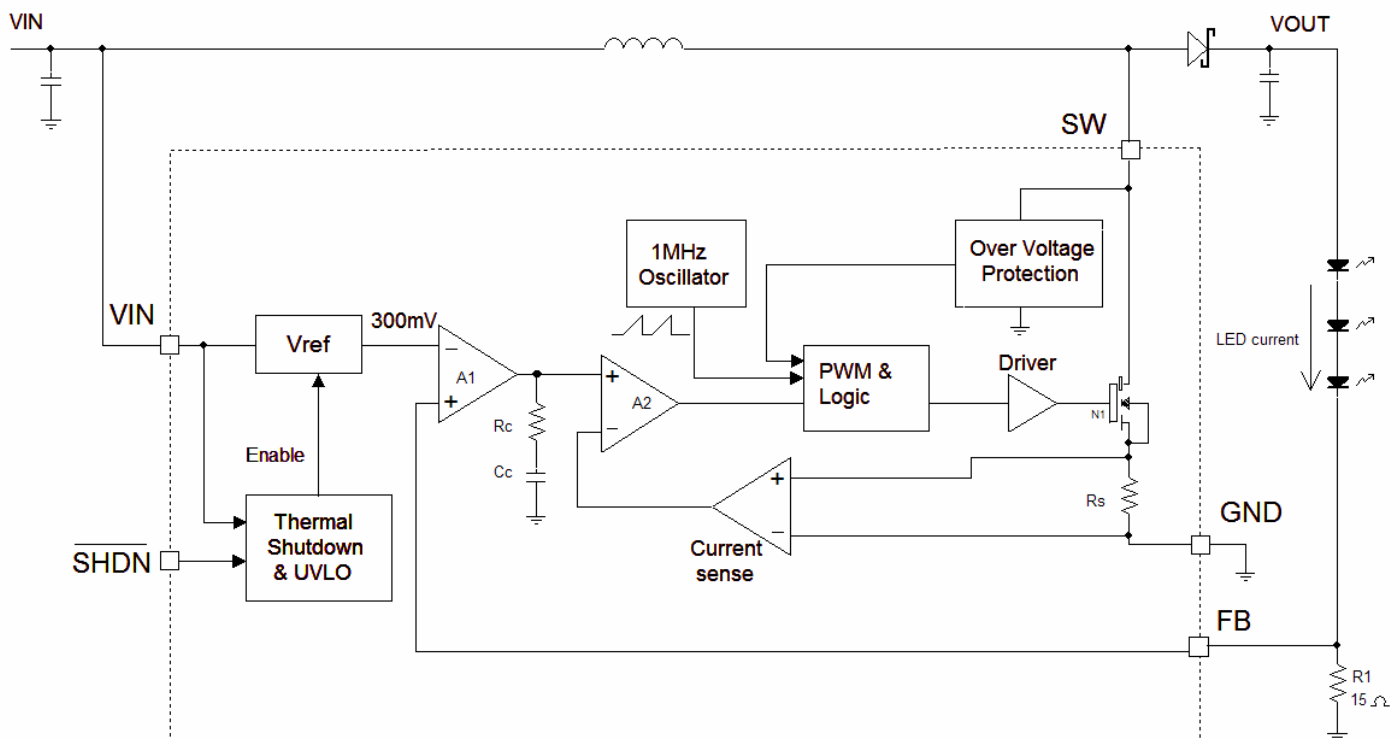

During the initial power-up stage, the duty cycle of the internal power switch is limited to prevent excessive in-rush currents and thereby provide a “soft-start” mode of operation.

While in normal operation, the device will comfortably deliver up to 30mA of bias current into a string of up to 5 white LEDs.

In the event of a “Open-Led” fault condition, where the feedback control loop becomes open, the output voltage will continue to increase. Once this voltage exceeds 24V, an internal protection circuit will become active and place the device into a very low power safe operating mode. In addition, an internal clamping circuit will limit the peak output voltage to 29V. If this fault condition is repaired, the device will automatically resume normal operation.

Thermal overload protection circuitry has been included to prevent the device from operating at unsafe junction temperatures above 150°C. In the event of a thermal overload condition the device will automatically shutdown and wait till the junction temperatures cools to 130°C before normal operation is resumed.

BLOCK DIAGRAM

APPLICATION INFORMATION

External Component Selection

Capacitors

The CAT4137 only requires small ceramic capacitors of 1 μ F on the input and 0.22 μ F on the output. Under normal condition, a 1 μ F input capacitor is sufficient. For applications with higher output power, a larger input capacitor of 2.2 μ F or 4.7 μ F may be appropriate. X5R and X7R capacitor types are ideal due to their stability across temperature range.

Inductor

A 22 μ H inductor is recommended for most of the CAT4137 applications. In cases where the efficiency is critical, inductances with lower series resistance are preferred. Several inductor types from various vendors can be used. Figure 1 shows how different inductor types affect the efficiency across the load range.

Figure 1. Efficiency for various inductors

Schottky Diode

The current rating of the Schottky diode must exceed the peak current flowing through it. The Schottky diode performance is rated in terms of its forward voltage at a given current. In order to achieve the best efficiency, this forward voltage should be as low as possible. The response time is also critical since the driver is operating at 1MHz. Central Semiconductor Schottky CMDSH2-3 (200mA rated) or the CMDSH-3 (100mA rated) are recommended for most applications.

LED Current Setting

The LED current is set by the external resistor between the feedback pin (FB) and ground. The formula below gives the relationship between the resistor and the current:

$$R1 = 0.3V/LED \text{ current}$$

LED current (mA)	R1 (Ω)
5	60
10	30
15	20
20	15
25	12
30	10

Table 1. Resistor R1 and LED current

Dimming Control

There are several methods available to control the LED brightness.

1. PWM signal on the SHDN* pin

LED brightness dimming can be done by applying a PWM signal to the SHDN* input. The LED current is repetitively turned on and off, so that the average current is proportional to the duty cycle. A 100% duty cycle, with SHDN* always high, corresponds to the LEDs at nominal current. Figures 2 and 3 show 1kHz and 4kHz signals with a 50% duty cycle applied to the SHDN* pin. The PWM frequency range is from 100Hz to 10kHz. The recommended PWM frequency range is from 100Hz to 4kHz.

Switching waveforms PWM on SHDN*

Figure 2. PWM at 1kHz

Figure 3. PWM at 4kHz

2. Filtered PWM signal

A filtered PWM signal can be used as a variable DC voltage that can be used to control the LED current. Figure 4 shows the PWM control circuitry connected to the CAT4137 FB pin. The PWM signal has a voltage swing of 0V to 2.5V. The LED current can be dimmed within a range from 0 to 22mA. The PWM signal frequency can vary from very low frequency up to 100kHz.

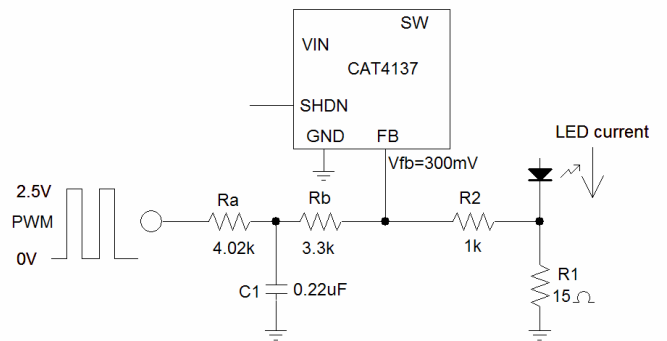

Figure 4. Circuit for filtered PWM signal

A PWM signal at 0V DC, or a 0% duty cycle, results in a max LED current of about 22mA. A PWM signal with a 100% duty cycle results in an LED current of 0mA.

LED Current vs. Duty Cycle

Open LED Protection

In the event of an “Open LED” fault condition, the CAT4137 will continue to boost the output voltage with maximum power until the output voltage reaches approximately 24V. Once the output exceeds this level, internal circuitry immediately places the device into a very low power mode where the total input power consumed is less than 10mW.

In low power mode, the input supply current will typically drop to 2mA. An internal clamping circuit will limit the subsequent output voltage to approximately 29V. This operating mode eliminates the need for any external protection zener diode. This protection scheme also fully protects the device against any malfunction in the external Schottky diode (open-circuit).

Open LED Protection

Open LED Power-up Waveforms

Open LED Supply Current vs. VIN

Board Layout

The CAT4137 is a high-frequency switching regulator. Traces carrying high-frequency switching current have to be carefully layout on the board in order to minimize EMI, ripple and noise in general. The thicker lines shown on Figure 4 indicate the switching current path. All these traces have to be short and wide enough to minimize the parasitic inductance and resistance. The loop shown on Figure 4 corresponds to the current path when the CAT4137 internal switch is closed. On Figure 5 is shown the current loop when the CAT4137 switch is

open. Both loop areas should be as small as possible.

Capacitor C1 has to be placed as close as possible to the VIN pin and GND. The capacitor C2 has to be connected separately to the top LED anode. A ground plane under the CAT4137 allows for direct connection of the capacitors to ground. The resistor R1 must be connected directly to the GND pin of the CAT4137 and not shared with the switching current loops and any other components.
