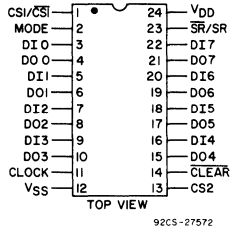
CDP1852, CDP1852C



CDP1852, CDP1852C
TERMINAL ASSIGNMENT

Byte-Wide Input/Output Port

Features:

- *Static silicon-gate CMOS circuitry*
- *Parallel 8-bit data register and buffer*
- *Handshaking via service request flip-flop*
- *Low quiescent and operating power*
- *Interfaces directly with CDP1800-series microprocessors*
- *Single voltage supply*
- *Full military temperature range (−55° C to +125° C)*

The RCA-CDP1852 and CDP1852C are parallel, 8-bit, mode-programmable input/output ports. They are compatible and will interface directly with CDP1800 series microprocessors. They are also useful as 8-bit address latches when used with the CDP1800 multiplexed address bus and as I/O ports in general-purpose applications.

The mode control is used to program the device as an input port (mode=0) or as an output port (mode=1). The $\overline{SR}$/SR output can be used as a signal to indicate when data is ready to be transferred. In the input mode, a peripheral device can strobe data into the CDP1852, and a microprocessor can read that data by device selection. In the output mode, a microprocessor strobes data into the CDP1852, and handshaking is established with a peripheral device when the CDP1852 is deselected.

In the input mode, data at the data-in terminals (D10-D17) is strobed into the port's 8-bit register by a high (1) level on the clock line. The negative high-to-low transition of the clock latches the data in the register and sets the service request output low ($\overline{SR}$/SR=0). When CS1/$\overline{CS1}$ and CS2 are high (CS1/$\overline{CS1}$ and CS2=1), the 3-state output drivers are enabled and data in the 8-bit register appear at the data-out terminals (D00-D07). When either CS1/$\overline{CS1}$ or CS2 goes low (CS1/$\overline{CS1}$ or CS2=0), the data-out terminals are tri-stated and the service request output returns high ($\overline{SR}$/SR=1).

In the output mode, the output drivers are enabled at all times. Data at the data-in terminals (D10-D17) is strobed into the 8-bit register when CS1/$\overline{CS1}$ is low (CS1/$\overline{CS1}$=0) and CS2 and the clock are high (1), and are present at the data-out terminals (D00-D07). The negative high-to-low transition of the clock latches the data in the register. The $\overline{SR}$/SR output goes high ($\overline{SR}$/SR=1) when the device is deselected (CS1/$\overline{CS1}$=1 or CS2=0) and returns low ($\overline{SR}$/SR=0) on the following trailing edge of the clock.

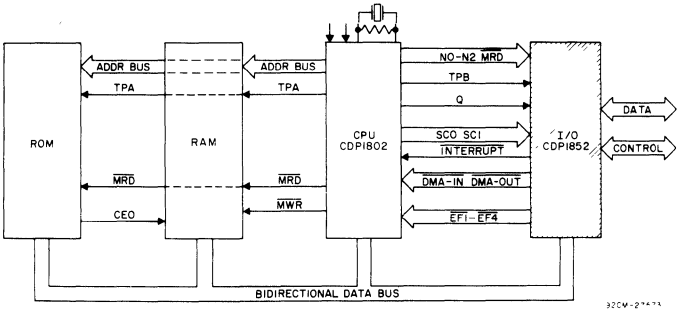


Fig. 1 - Typical CDP1802 microprocessor system.

File Number **1166**

CDP1852, CDP1852C

A $\overline{\text{CLEAR}}$ control is provided for resetting the port's register (D00-D07 = 0) and service request flip-flop (input mode: $\overline{\text{SR}}$/SR=1 and output mode: $\overline{\text{SR}}$/SR=0).

The CDP1852 is functionally identical to the CDP1852C. The CDP1852 has a recommended operating voltage range of 4 to 10.5 volts, and the CDP1852C has a recommended operating voltage range of 4 to 6.5 volts.

The CDP1852 and CDP1852C are supplied in 24-lead, hermetic, dual-in-line ceramic packages (D suffix), in 24-lead dual-in-line plastic packages (E suffix). The CDP1852C is also available in chip form (H suffix).

MAXIMUM RATINGS, *Absolute-Maximum Values:*

DC SUPPLY-VOLTAGE RANGE, (V_{DD})
(Voltage referenced to V_{SS} Terminal
CDP1852 ..... −0.5 to +11 V
CDP1852C ..... −0.5 to +7 V
INPUT VOLTAGE RANGE, ALL INPUTS ..... −0.5 to V_{DD} + 0.5 V
DC INPUT CURRENT, ANY ONE INPUT ..... ±10 mA
POWER DISSIPATION PER PACKAGE (P_D).
For T_A = −40 to +60°C (PACKAGE TYPE E) ..... 500 mW
For T_A = +60 to +85°C (PACKAGE TYPE E) ..... Derate Linearly at 12 mW/°C to 200 mW
For T_A = −55 to +100°C (PACKAGE TYPE D) ..... 500 mW
For T_A = +100 to +125°C (PACKAGE TYPE D) ..... Derate Linearly at 12 mW/°C to 200 mW
DEVICE DISSIPATION PER OUTPUT TRANSISTOR
FOR T_A = FULL PACKAGE-TEMPERATURE RANGE (All Package Types) ..... 100 mW
OPERATING-TEMPERATURE RANGE (T_A):
PACKAGE TYPES D, H ..... −55 to +125°C
PACKAGE TYPE E ..... −40 to +85°C
STORAGE TEMPERATURE RANGE (T_{stg}) ..... −65 to +150°C
LEAD TEMPERATURE (DURING SOLDERING).
At distance 1/16 ± 1/32 inch (1.59 ± 0.79 mm) from case for 10 s max ..... +265°C

RECOMMENDED OPERATING CONDITIONS at T_A = Full Package Temperature Range. For maximum reliability, operating conditions should be selected so that operation is always within the following ranges:

INPUT PORT MODE 0 — TYPICAL OPERATION

General Operation

When the mode control is tied to VSS, the CDP1852 becomes an input port. In this mode, the peripheral device places data into the CDP1852 with a strobe pulse and the CDP1852 signals the microprocessor that data is ready to be transferred on the strobe's trailing edge via the $\overline{SR}$ output line. The CDP1802 then issues an input instruction that enables the CDP1852 to place the information from the peripheral device on the data bus to be entered into a memory location and the accumulator of the microprocessor.

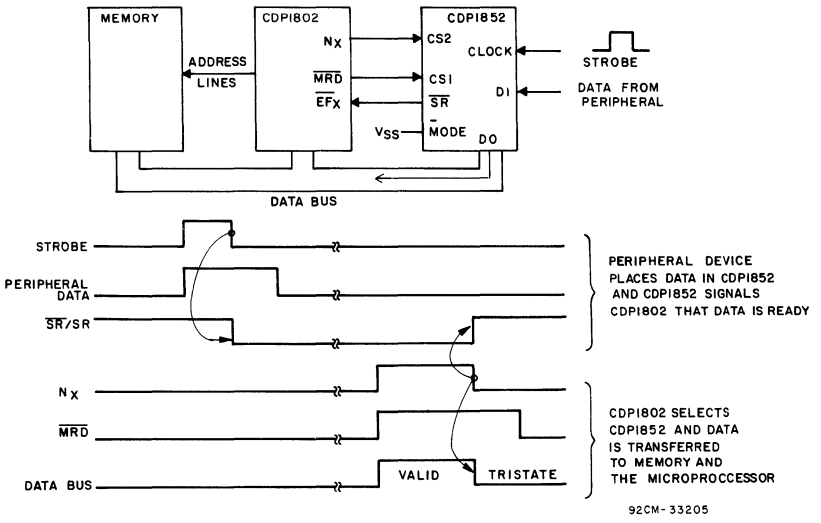
Fig. 4 - MODE 0 input port timing waveforms and truth tables.



92CM-33205

Fig. 5 - Input port mode 0 functional diagram and waveforms - typical operation.

Detailed Operation (See Fig. 5)

The STROBE from the peripheral device places DATA into the 8-bit register of the CDP1852 when it goes high and latches the DATA on its trailing edge. The $\overline{SR}$ output is set low on the strobe's trailing edge. This output is connected to a flag line of the CDP1802 microprocessor and software polling will determine that the flag line has gone low and peripheral data is ready to be transferred. The CDP1802 then issues an input instruction that places an N_x line high. With the $\overline{MRD}$ line also high, the CDP1852 is selected and its output drivers place the DATA from the peripheral device on the DATA BUS. When the CDP1802 selected the CDP1852, it also selected and addressed the memory via one of the 16 internal address registers selected by an internal "X" register. The data from the CDP1852 is therefore entered into the memory [Bus → M(R(X))]. The data is also transferred to the D register (accumulator) in the microprocessor (Bus → D). When the CDP1802's execute cycle is completed, the CDP1852 is deselected by the N_X line returning low and its data output pins are tri-stated. The $\overline{SR}$ output returns high.

*Typical values are for $T_A = 25°C$ and nominal V_{DD}

OUTPUT PORT MODE 1 — TYPICAL OPERATION

General Operation

Connecting the mode control to V_{DD} configures the CDP1852 as an output port. The output drivers are always on in this mode, so any data in the 8-bit register will be present at the data-out lines when the CDP1852 is selected. The N line and MRD connections between the CDP1852 and CDP1802 remain the same as in the input mode configuration, but now the clock input of the CDP1852 is tied to the TPB output of the CDP1802 and the SR output of the CDP1852 will be used to signal the peripheral device that valid data is present on its input lines. The microprocessor issues an output instruction, and data from the memory is strobed into the CDP1852 with the TPB pulse. When the CDP1852 is deselected, the SR output goes high to signal the peripheral device.

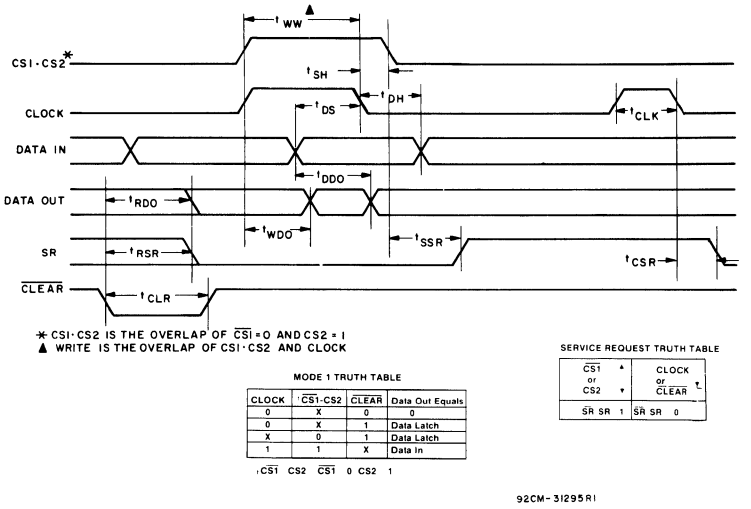

Fig 6 - MODE 1 output port timing waveforms and truth tables

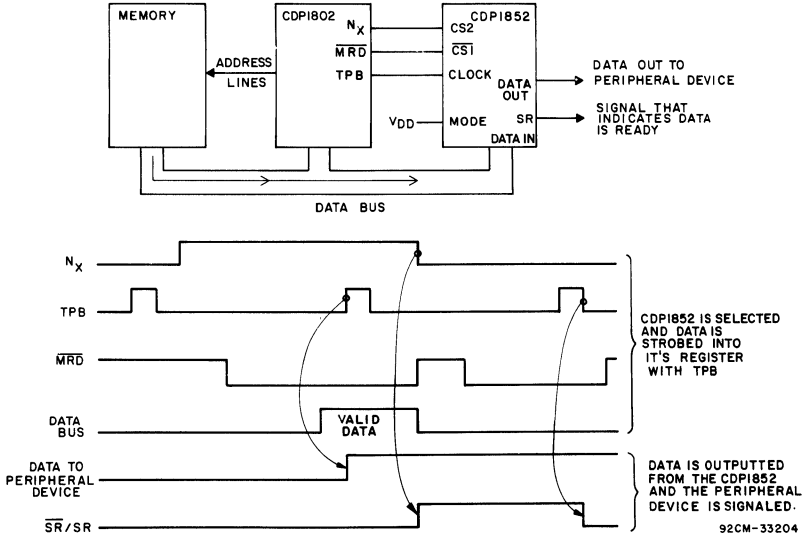

Fig. 7 - Output port mode 1 functional diagram and waveforms - typical operation

Detailed Operation (See Fig 7)

The CDP1802 issues an output instruction The N_x line goes high and the MRD line goes low. The memory is accessed M(R(X)) → BUS and places data on the DATA BUS This data are strobed into the 8-bit register of the CDP1852 when TPB goes high and latched on the TPB's trailing edge. The valid data thus appears on the CDP1852 output lines. When the CDP1802 output instruction cycle is complete, the N_x line goes low and the SR output goes high SR will remain high until the trailing edge of the next TPB pulse, when it will return low.

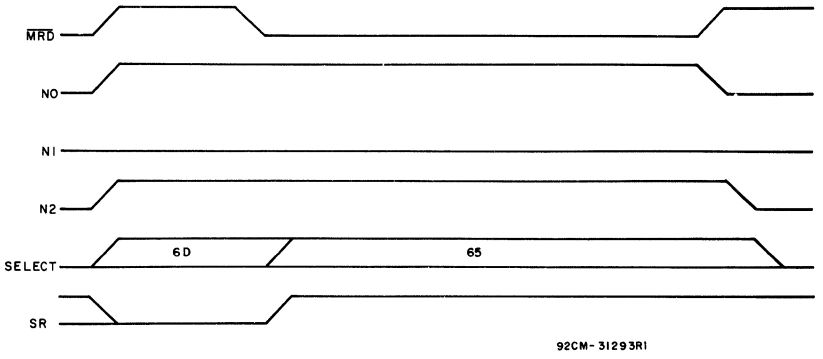

Fig. 8 - Execution of a "65" output instruction showing momentary selection of input port "D".

Application Information

In a CDP1800 series microprocessor-based system where MRD is used to distinguish between INP and OUT instructions, an INP instruction is assumed to occur at the beginning of every I/O cycle because MRD starts high Therefore, at the start of an OUT instruction, which uses the same 3-bit N code as that used for selection of an input port, the input device is selected for a short time (see Fig. 8). This condition forces SR low and sets the internal SR latch (see Fig. 3). In a small system with unique N codes for inputs and outputs, this situation does not arise. Using the CDP1853 N-bit decoder or equivalent logic to decode the N lines after TPA prevents dual selection in larger systems (see Fig. 9 and Fig. 10).
