# 600mA USB-Compatible Lithium Battery Charger CN3062

## **General Description:**

The CN3062 is a complete constant-current /constant voltage linear charger for single cell lithium rechargeable battery. The device contains an on-chip power MOSFET and eliminates the need for the external current sense resistor and blocking diode. Furthermore, the CN3062 is specifically designed to work within USB power specifications. Its low external component count makes CN3062 ideally suited for portable applications.

Thermal feedback regulates the charge current to limit the die temperature during high power operation or high ambient temperature. The regulation voltage is internally fixed at 4.2V, it can also be adjusted with an external resistor. The charge current can be programmed externally with a single resistor. When the input supply (wall adapter or USB supply) is removed, the CN3062 automatically enters a low power sleep mode, dropping the battery drain current to less than 3uA. Other features include under-voltage lockout, automatic recharge, battery temperature sensing and charging/termination indicator.

The CN3062 is available in a thermally enhanced 8-pin SOP package.

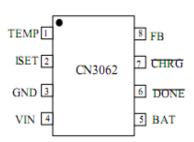

## **Applications:**

- Mobile Phones
- Digital Still Cameras
- MP4 Players
- Electronic Dictionary
- Portable Devices
- Variety Of Chargers

#### **Features:**

- Charges Single Cell Li-Ion Batteries Directly from USB Port or AC Adaptor
- Input Voltage Range From 4.35V to 6V
- On-chip Power MOSFET
- No external Blocking Diode or Current Sense Resistors Required
- Constant Charge Voltage 4.2V, and also can be adjustable by an external resistor
- Precharge Conditioning for Reviving Deeply Discharged Cells and Minimizing Heat Dissipation During Initial Stage of Charge
- Programmable Continuous Charge Current Up to 600mA
- Constant-Current/Constant-Voltage/Constant-Temp Operation with Thermal Regulation to Maximize Charge Rate Without Risk of Overheating
- Automatic Low-Power Sleep Mode When Input Supply Voltage is Removed
- Status Indication for LEDs or uP Interface
- C/10 Charge Termination
- Automatic Recharge
- Battery Temperature Sensing
- Available in SOP8 Package
- Pb-free Available

## **Pin Assignment**

# **Typical Application Circuit**

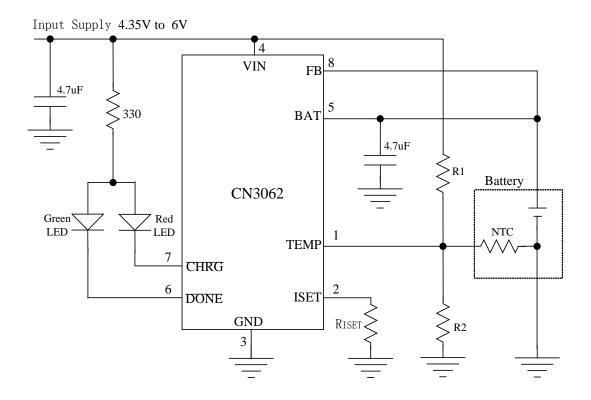

Figure 1 Typical Application Circuit(Constant Voltage Fixed at 4.2V)

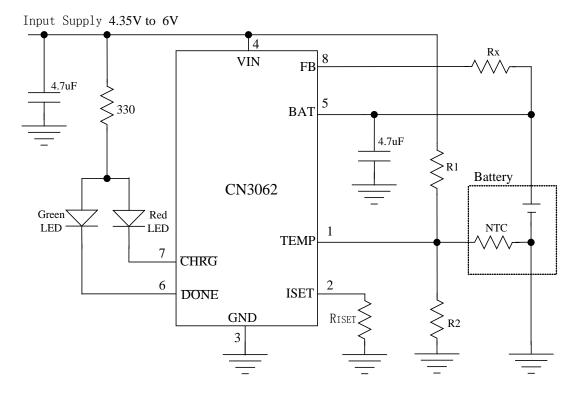

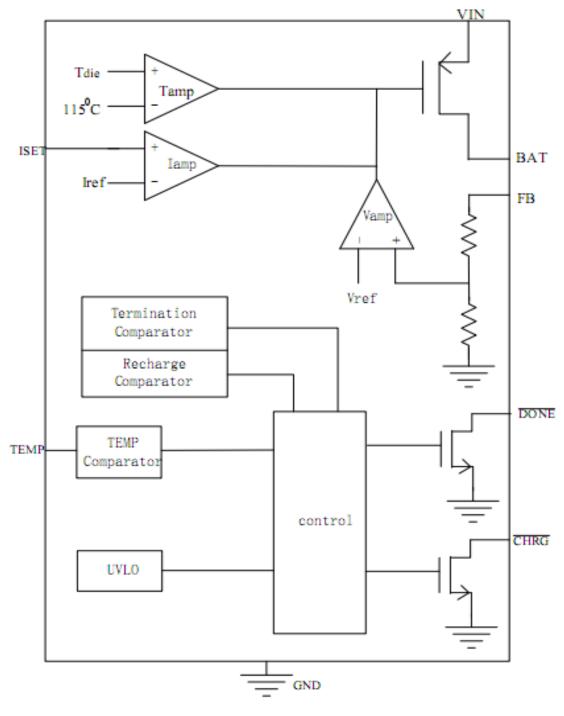

Figure 2 Application Circuit(Adjust Constant Voltage with Rx)

In Figure 2, the BAT pin's voltage in constant voltage mode is given by the following equation: Vbat =  $4.2+3.04\times10^{-6}\times Rx$ 

Where, Vbat's is in volt Rx's is in ohm

## **Pin Description**

Pin No.	Name	Function Description		
		Temperature Sense Input. Connecting TEMP pin to NTC thermistor's		
		output in Lithium ion battery pack. If TEMP pin's voltage is below 47% or		
	ТЕМР	above 84% of supply voltage $V_{IN}$ for more than 0.15S, this means that battery's		
1		temperature is too high or too low, charging is suspended. If TEMP's voltage		
		level is between 47% and 84% of supply voltage for more than 0.15S, battery		
		fault state is released, and charging will resume.		
		The temperature sense function can be disabled by grounding the TEMP pin.		
	ISET	Constant Charge Current Setting and Charge Current Monitor Pin. The		
		charge current is set by connecting a resistor R <sub>ISET</sub> from this pin to GND.		
		When in precharge mode, the ISET pin's voltage is regulated to 0.2V. When in		
2		constant charge current mode, the ISET pin's voltage is regulated to 2V.In all		
		modes during charging, the voltage on ISET pin can be used to measure the		
		charge current as follows:		
		$I_{CH} = (V_{ISET} / R_{ISET}) \times 900$		
3	GND	Ground Terminal.		
	VIN	Positive Input Supply Voltage. V <sub>IN</sub> is the power supply to the internal circuit.		
4		When $V_{IN}$ drops to within 40mv of the BAT pin voltage, CN3062 enters low		
		power sleep mode, dropping BAT pin's current to less than 3uA.		
	ВАТ	<b>Battery Connection Pin.</b> Connect the positive terminal of the battery to BAT		
5		pin. BAT pin draws less than 3uA current in chip disable mode or in sleep		
3		mode. BAT pin provides charge current to the battery and provides regulation		
		voltage of 4.2V.		
	DONE	Open-Drain Charge termination Status Output. In charge termination		
6		status, DONE is pulled low by an internal switch; Otherwise DONE pin is in		
		high impedance state.		
	CHRG	Open Drain Charge Status Output. When the battery is being charged, the		
7		CHRG pin is pulled low by an internal switch, otherwise CHRG pin is in high		
		impedance state.		
	FB	Battery Voltage Kevin Sense Input. This Pin can Kelvin sense the battery		
8		voltage; Also the regulation voltage in constant voltage mode can be adjusted		
		by connecting an external resistor between FB pin and BAT pin.		

# **Absolute Maximum Ratings**

All Terminal Voltage0.3V to 6.5V	Maximum Junction Temperature150°C
BAT Short-Circuit DurationContinuous	Operating Temperature−40°C to 85°C
Storage Temperature−65°C to 150°C	Lead Temperature(Soldering)300℃
Thermal Resistance (SOP8)TBD	

Stresses beyond those listed under 'Absolute Maximum Ratings' may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to Absolute Maximum Rating Conditions for extended periods may affect device reliability.

### **Detailed Description**

The CN3062 is a linear battery charger designed primarily for charging single cell lithium-ion batteries. Featuring an internal P-channel power MOSFET, the charger uses a constant-current/constant-voltage to charge the batteries. Continuous charge current can be programmed up to 600mA with an external resistor. No blocking diode or current sense resistor is required. The open-drain output CHRG and DONE indicates the charger's status. The internal thermal regulation circuit reduces the programmed charge current if the die temperature attempts to rise above a preset value of approximate 115°C. This feature protects the CN3062 from excessive temperature, and allows the user to push the limits of the power handling capability of a given circuit board without risk of damaging the CN3062 or the external components. Another benefit of adopting thermal regulation is that charge current can be set according to typical, not worst-case, ambient temperatures for a given application with the assurance that the charger will automatically reduce the current in worst-case conditions. The charge cycle begins when the voltage at the V<sub>IN</sub> pin rises above the UVLO level, a current set resistor is connected from the ISET pin to ground. The CHRG pin outputs a logic low to indicate that the charge cycle is ongoing. At the beginning of the charge cycle, if the voltage at FB pin is below 3V, the charger is in precharge mode to bring the cell voltage up to a safe level for charging. The charger goes into the fast charge constant current mode once the voltage on the FB pin rises above 3V. In constant current mode, the charge current is set by R<sub>ISET</sub>. When the battery approaches the regulation voltage, the charge current begins to decrease as the CN3062 enters the constant-voltage mode. When the current drops to charge termination threshold, the charge cycle is terminated, DONE is pulled low by an internal switch and CHRG pin assumes a high impedance state to indicate that the charge cycle is terminated. The charge termination threshold is 10% of the current in constant current mode. To restart the charge cycle, remove the input voltage and reapply it. The charge cycle can also be automatically restarted if the FB pin voltage falls below the recharge threshold. The on-chip reference voltage, error amplifier and the resistor divider provide regulation voltage with 1% accuracy which can meet the requirement of lithium-ion and lithium polymer batteries. When the input voltage is not present, the charger goes into a sleep mode, dropping battery drain current to less than 3uA. This greatly reduces the current drain on the battery and increases the standby time. The charging profile is shown in the following figure:

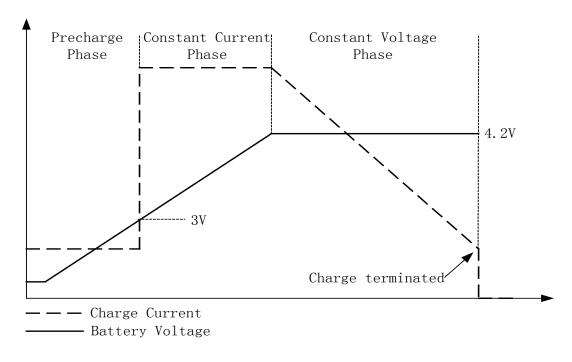

Figure 4 Charging Profile

## **Application Information**

#### **Undervoltage Lockout (UVLO)**

CN3062 has an internal undervoltage lockout circuit monitors the input voltage and keeps the charger in shutdown mode until  $V_{IN}$  rises above the undervoltage lockout voltage.

#### Sleep mode

There is an on-chip sleep comparator in CN3062. The comparator keeps the charger in sleep mode if  $V_{IN}$  falls below sleep mode threshold(VBAT+20mv). Once in sleep mode, the charger will not come out of sleep mode until  $V_{IN}$  rises 50mv above the battery voltage.

#### Precharge mode

At the beginning of a charge cycle, if the battery voltage is below 3V, the charger goes into precharge mode, and the charge current is 10% of fast charge current in constant current mode.

#### **Battery Voltage Kelvin Detection**

There is a battery voltage Kelvin detection of input pin (FB). This pin connects with error amplifier of constant charge though precise resistor divider network on chip. FB pin can be connected to battery's positive electrode directly, and this way can avoid the influence of parasitic resistor for charge between positive electrode and BAT pin. The existence of these parasitic resistors would prolong the charging time or come to constant charging state earlier, or even under-charge of battery. But these problems can be solved by FB pin. If vacant FB pin, CN3062 would always in precharge state, and charging current is 10% of constant current.

#### Adjusting the regulation voltage in constant voltage mode

The regulation voltage in constant voltage mode can be adjusted by an external resistor connecting between FB pin and BAT pin as shown in Figure 5:

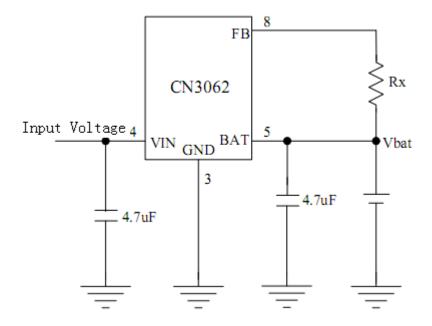

Figure 5 Adjusting Regulation Voltage in Constant Voltage Mode

In Figure 5, the regulation voltage in constant voltage mode will be given by the following equation:

Vbat = 
$$4.2+3.04\times10^{-6}\times Rx$$

Where,

Vbat is in volt Rx is in ohm

#### **Programming Charge Current**

The formula for the battery charge current in constant current mode is:

$$I_{CH} = 1800V / R_{ISET}$$

Where:

I<sub>CH</sub> is the charge current in ampere

 $R_{\mbox{\scriptsize ISET}}$  is the total resistance from the ISET pin to ground in ohm

For example, if 500mA charge current is required, calculate:

$$R_{ISET} = 1800V/0.5A = 3.6k \Omega$$

For best stability over temperature and time, 1% metal film resistors are recommended. If the charger is in constant-temperature or constant voltage mode, the charge current can be monitored by measuring the ISET pin voltage, and the charge current is calculated as the following equation:

$$I_{CH} = (V_{ISET} / R_{ISET}) \times 900$$

#### **USB** and Wall Adapter Power

Although the CN3062 allows charging from a USB port, a wall adapter can also be used to charge Li-Ion/Li-polymer batteries. Figure 6 shows an example of how to combine wall adapter and USB power inputs. A P-channel MOSFET, M1, is used to prevent back conducting into the USB port when a wall adapter is present and Schottky diode, D1, is used to prevent USB power loss through the  $1k\,\Omega$  pull-down resistor.

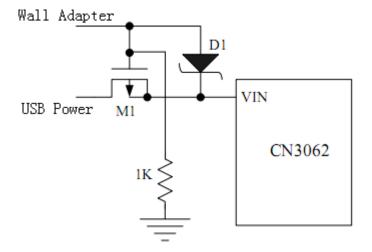

Figure 6 Combining Wall Adapter and USB Power

#### **Battery Temperature Sense**

To prevent the damage caused by the very high or very low temperature done to the battery pack, the CN3062 continuously senses battery pack temperature by measuring the voltage at TEMP pin determined by the voltage divider circuit and the battery's internal NTC thermistor as shown in Figure 1.

The CN3062 compares the voltage at TEMP pin ( $V_{TEMP}$ ) against its internal  $V_{LOW}$  and  $V_{HIGH}$  thresholds to determine if charging is allowed. In CN3062,  $V_{LOW}$  is fixed at (47%  $\times$  VIN), while  $V_{HIGH}$  is fixed at (84%  $\times$  VIN). If  $V_{TEMP} < V_{LOW}$  or  $V_{TEMP} > V_{HIGH}$  for 0.15 seconds, it indicates that the battery temperature is too high or too low and the charge cycle is suspended. When  $V_{TEMP}$  is between  $V_{LOW}$  and  $V_{HIGH}$  for more than 0.15 seconds, the charge cycle resumes.

The battery temperature sense function can be disabled by connecting TEMP pin to GND.

#### Selecting R1 and R2

The values of R1 and R2 in the application circuit can be determined according to the assumed temperature monitor range and thermistor's values. The Follows is an example:

Assume temperature monitor range is  $T_L \sim T_H$  ( $T_L < T_H =$ ; the thermistor in battery has negative temperature coefficient (NTC),  $R_{TL}$  is thermistor's resistance at  $T_L$ ,  $R_{TH}$  is the resistance at  $T_H$ , so  $R_{TL} > R_{TH}$ , then at temperature  $T_L$ , the voltage at TEMP pin is:

$$V_{TEMPL} = \frac{R2||R|_{TL}}{R1+R2||R|_{TL}} \times VIN$$

At temperature T<sub>H</sub>, the voltage at TEMP pin is:

$$V_{TEMPH} = \frac{R2||RTH}{R1 + R2||RTH} \times VIN$$

We know,  $V_{TEMPL} = V_{HIGH} = k_2 \times VIN (k_2=0.84)$ 

$$V_{TEMPH} = V_{LOW} = k_1 \times VIN (k_1 = 0.47)$$

Then we can have:

$$R1 = \frac{R_{TL}R_{TH}(k_2 - k_1)}{(R_{TL} - R_{TH})k_1k_2}$$

$$R2 = \frac{R_{TL}R_{TH}(k_2 - k_1)}{R_{TL}(k_1 - k_1k_2) - R_{TH}(k_2 - k_1k_2)}$$

Likewise, for positive temperature coefficient thermistor in battery, we have  $R_{TH} > R_{TL}$  and we can calculate:

$$R1 = \frac{R_{TL}R_{TH}(k_2 - k_1)}{(R_{TH} - R_{TL})k_1k_2}$$

$$R2 = \frac{R_{TL}R_{TH}(k_2 - k_1)}{R_{TH}(k_1 - k_1k_2) - R_{TL}(k_2 - k_1k_2)}$$

We can conclude that temperature monitor range is independent of power supply voltage VIN and it only depends on R1, R2,  $R_{TL}$  and  $R_{TH}$ : The values of  $R_{TH}$  and  $R_{TL}$ can be found in related battery handbook or deduced from testing data.

In actual application, if only one terminal temperature is concerned(normally protecting overheating), there is no need to use R2 but R1. In this case it becomes very simple to calculate R1.

#### Recharge

After a charge cycle has terminated, if the battery voltage drops below the recharge threshold voltage, a new charge cycle will begin automatically.

#### Constant-Current/Constant-Voltage/Constant-Temperature

The CN3062 use a unique architecture to charge a battery in a constant-current, constant-voltage, constant temperature fashion as shown in Figure 3. Amplifiers Iamp, Vamp, and Tamp are used in three separate feedback loops to force the charger into constant-current, constant-voltage, or constant-temperature mode, respectively. In constant current mode the charge current delivered to the battery equal to  $1800 \text{V/R}_{\text{ISET}}$ . If the power dissipation of the CN3062 results in the junction temperature approaching  $115\,^{\circ}\text{C}$ , the amplifier Tamp will begin decreasing the charge current to limit the die temperature to approximately  $115\,^{\circ}\text{C}$ . As the battery voltage rises, the CN3062 either returns to constant-current mode or it enters constant voltage mode straight from constant-temperature mode.

#### **Open-Drain Status Outputs**

The CN3062 have 2 open-drain status outputs: CHRG and DONE. CHRG is pulled low when the charger is in charging status, otherwise CHRG becomes high impedance. DONE is pulled low if the charger is in charge termination status, otherwise DONE becomes high impedance.

When the battery is not present, the charger charges the output capacitor to the regulation voltage quickly, then the BAT pin's voltage decays slowly to recharge threshold because of low leakage current at BAT pin, which results in a 100mv ripple waveform at BAT pin, in the meantime,  $\overline{\text{CHRG}}$  pin outputs a pulse to indicate that the battery's absence. The pulse's frequency is around 10Hz when a 4.7uF output capacitor is used.

The open drain status output that is not used should be tied to ground.

The following table lists the two indicator status and its corresponding charging state. It is supposed that red LED is connected to  $\overline{\text{CHRG}}$  pin and green LED is connected to  $\overline{\text{DONE}}$  pin.

CHRG pin	DONE pin	State Description	
Low(the red LED on)	High(the green LED off)	Charging	
High(the red LED off)	Low(the green LED on)	Charge termination	
Pulse signal	Pulse signal	Battery not connected	
High(the red LED off)	High(the green LED off)	<ul> <li>There are three possible state:</li> <li>the voltage at the V<sub>IN</sub> pin below the UVLO level or</li> <li>the voltage at the V<sub>IN</sub> pin below V<sub>BAT</sub> or</li> <li>abnormal battery's temp</li> </ul>	

#### V<sub>IN</sub> Bypass Capacitor C<sub>IN</sub>

Many types of capacitors can be used for input bypassing,  $C_{IN}$  is typically a 4.7uF capacitor. For the consideration of the bypass capacitor, please refer to the Application Note AN102 from our website www.consonance-elec.com

#### **Stability**

Typically a 4.7uF capacitor from BAT pin to GND is required to stabilize the feedback loop.

In constant current mode, the stability is also affected by the impedance at the ISET pin . With no additional capacitance on the ISET pin, the loop is stable with current set resistors values as high as  $50 \, \mathrm{K} \, \Omega$ . However, additional capacitance on ISET pin reduces the maximum allowed current set resistor. The pole frequency at ISET pin should be kept above 200KHz. Therefore, if ISET pin is loaded with a capacitance C, the following equation should be used to calculate the maximum resistance value for  $R_{ISET}$ :

$$R_{ISET} < 1 / (6.28 \times 2 \times 10^5 \times C)$$

In order to measure average charge current or isolate capacitive load from ISET pin, a simple RC filter can be used on ISET pin as shown in Figure 7.

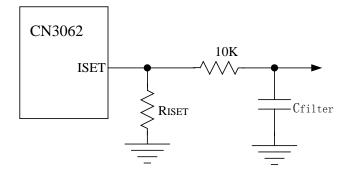

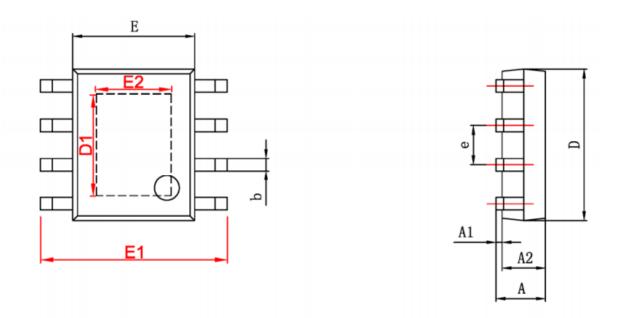

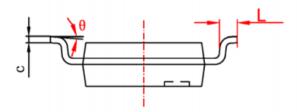

Figure 7 Isolating Capacitive Load on ISET Pin

#### **Board Layout Considerations**

- 1. R<sub>ISET</sub> at ISET pin should be as close to CN3062 as possible, also the parasitic capacitance at ISET pin should be kept as small as possible.
- 2. The capacitance at VIN pin and BAT pin should be as close to CN3062 as possible.
- 3. During charging, CN3062's temperature may be high, the NTC thermistor should be placed far enough to CN3062 so that the thermistor can reflect the battery's temperature correctly.
- 4. It is very important to use a good thermal PC board layout to maximize charging current. The thermal path for the heat generated by the IC is from the die to the copper lead frame through the package lead(especially the ground lead) to the PC board copper, the PC board copper is the heat sink. The footprint copper pads should be as wide as possible and expand out to larger copper areas to spread and dissipate the heat to the surrounding ambient. Feedthrough vias to inner or backside copper layers are also useful in improving the overall thermal performance of the charger. Other heat sources on the board, not related to the charger, must also be considered when designing a PC board layout because they will affect overall temperature rise and the maximum charge current. The ability to deliver maximum charge current under all conditions require that the exposed metal pad on the back side of the CN3062 package be soldered to the PC board ground. Failure to make the thermal contact between the exposed pad on the backside of the package and the copper board will result in larger thermal resistance.
