Geode[™] CS5530A I/O Companion Multi-Function South Bridge

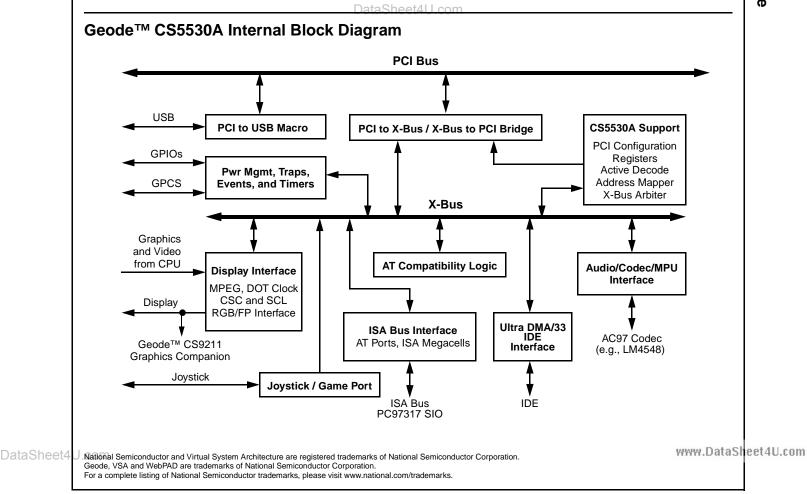

General Description

The CS5530A I/O companion is designed to work in conjunction with a GX-series processor (i.e., GX1, GXLV, GXm); all members of the National Semiconductor[®] GeodeTM family of products. Together, the Geode processor and CS5530A provide a system-level solution well suited for the high performance needs of a host of devices which include digital set-top boxes and thin client devices. Due to the low power consumption of the GX-series processors, this solution satisfies the needs of battery powered devices such as National's WebPADTM system, and thermal design is eased allowing for fanless system design.

The CS5530A I/O companion is a PCI-to-ISA bridge (South Bridge), ACPI-compliant chipset that provides AT/ISA style functionality. The device contains state-of-the-art power management that enables systems, especially battery powered systems, to significantly reduce power consumption.

Audio is supported through PCI bus master engines which connect to an AC97 compatible codec such as the National Semiconductor LM4548. If industry standard audio is required, a combination of hardware and software called Virtual System Architecture[®] (VSA[™]) technology is provided.

The Geode GX-series processors' graphics/video output is connected to the CS5530A. The CS5530A graphics/video support includes a PLL that generates the DOT clock for the GX-series processors (where the graphics controller is located), video acceleration hardware, gamma RAM plus three DACs for RGB output to CRT, and digital RGB that can be directly connected to TFT panels or NTSC/PAL encoders. The digital RGB output can also be connected to the National Semiconductor Geode CS9211 graphics companion (a flat panel display controller) for DSTN panel support.

Geode[™] CS5530A I/O Companion Multi-Function South Bridge

© 2001 National Semiconductor Corporation

et4U.com

Two bus mastering IDE controllers are included for support of up to four ATA-compliant devices. A two-port Universal Serial Bus (USB) provides high speed, Plug & Play expansion for a variety of consumer peripheral devices such as a keyboard, mouse, printer, and digital camera. If additional functions are required like real-time clock, floppy disk, PS2 keyboard, and PS2 mouse, a SuperI/O such as the National PC97317 can be easily connected to the CS5530A.

Features

General Features

- Designed for use with National's Geode GX-series processors
- 352 PBGA (Plastic Ball Grid Array) package
- 3.3V or 5.0V PCI bus compatible
- 5.0V tolerant on all inputs
- 3.3V core

PCI-to-ISA Bridge

- PCI 2.1 compliant
- Supports PCI initiator-to-ISA and ISA master-to-PCI cycle translations
- PCI master for audio I/O and IDE controllers
- Subtractive agent for unclaimed transactions
- PCI-to-ISA interrupt mapper/translator

AT Compatibility

- Two 8259A-equivalent interrupt controllers
- 8254-equivalent timer
- Two 8237-equivalent DMA controllers
- Boot ROM and keyboard chip select
- Extended ROM to 16 MB

Bus Mastering IDE Controllers

- Two controllers with support for up to four IDE devices
- Independent timing for master and slave devices for both channels
- PCI bus master burst reads and writes
- Ultra DMA/33 (ATA-4) support
- Multiword DMA support
- Programmed I/O (PIO) Modes 0-4 support

Power Management

- Intelligent system controller supports multiple power management standards:
 - Full ACPI and Legacy (APM) support
 - Directly manages all GX-series processors' power states (including automatic Suspend modulation for optimal performance/thermal balancing)
- I/O traps and idle timers for peripheral power management
- Up to eight GPIOs for system control:
 All eight are configurable as external wakeup events
- Dedicated inputs for keyboard and mouse wakeup events

XpressAUDIO

- Provides "back-end" hardware support via six buffered PCI bus masters
- AC97 codec interface:
 - Specification Revision 1.3, 2.0, and 2.1 compliant interface. Note that the codec (e.g., LM4548) must have SRC (sample rate conversion) support

Display Subsystem Extensions

- Complements the GX-series processors' graphics and video capabilities:
 - Three independent line buffers for accelerating video data streams
 - Handles asynchronous video and graphics data
- DataSheet4U.costreams concurrently from the processor
 - YUV to RGB conversion hardware
 - Arbitrary X & Y interpolative scaling
 - Color keying for graphics/video overlay
 - VDACs / Display interface:
 - Three integrated DACs
 - Gamma RAM:
 - Provides gamma correction for graphics data streams
 - Provides brightness/contrast correction for video data streams
 - Integrated DOT clock generator
 - Digital RGB interface drives TFT panels or standard NTSC/PAL encoders
 - Up to 1280x1024 @ 85 Hz

Universal Serial Bus

- Two independent USB interfaces:
 - Open Host Controller Interface (OpenHCI) specification compliant
 - Second generation proven core design

1.0 **Architecture Overview**

The Geode CS5530A can be described as providing the functional blocks shown in Figure 1-1.

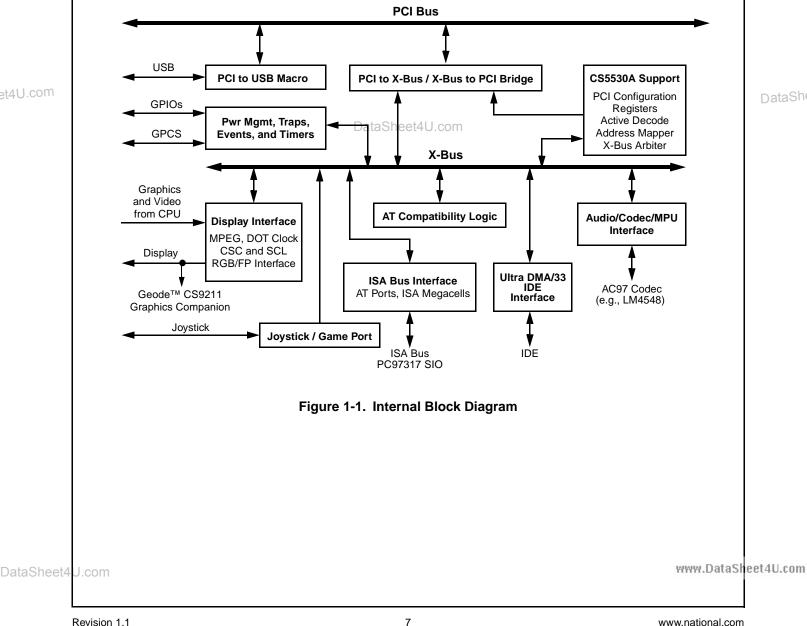

- PCI bus master/slave interface
- ISA bus interface
- AT compatibility logic
- **IDE** controllers
- Power management
 - GPIO interfaces
 - Traps, Events, Timers
- Joystick/Game Port interface
- Virtual audio support hardware
- Video display, which includes MPEG accelerator, RAMDAC, and video ports
- USB controller

For CPU interface connection refer to Figure 1-5 "Example System Block Diagram" on page 12.

1.1 PCI BUS INTERFACE

The CS5530A provides a PCI bus interface that is both a slave for PCI cycles initiated by the CPU or other PCI master devices, and a non-preemptable master for DMA transfer cycles. The chip also is a standard PCI master for the IDE controllers and audio I/O logic. The CS5530A supports positive decode for configurable memory and I/O regions and implements a subtractive decode option for unclaimed PCI accesses. The CS5530A also generates address and data parity and performs parity checking. The CS5530A does not include the PCI bus arbiter, which is located in the processor.

Configuration registers are accessed through the PCI interface using the PCI Bus Type 1 configuration mechanism as described in the PCI 2.1 Specification.

Geode[™] CS5530A

et4U.com

Architecture Overview (Continued)

1.2 ISA BUS INTERFACE

The CS5530A provides an ISA bus interface for unclaimed memory and I/O cycles on PCI. The CS5530A is the default subtractive decoding agent and forwards all unclaimed memory and I/O cycles to the ISA interface; however, the CS5530A may be configured to ignore either I/O, memory, or all unclaimed cycles (subtractive decode disabled).

The CS5530A supports two modes on the ISA interface. The default mode, Limited ISA Mode, supports the full memory and I/O address range without ISA mastering. The address and data buses are multiplexed together, requiring an external latch to latch the lower 16 bits of address of the ISA cycle. The signal SA_LATCH is generated when the data on the SA/SD bus is a valid address. Additionally, the upper four address bits, SA[23:20], are multiplexed on GPIO[7:4].

The second mode, ISA Master Mode, supports ISA bus masters and requires no external circuitry. When the CS5530A is placed in ISA Master Mode, a large number of pins are redefined. In this mode, the CS5530A cannot support TFT flat panels or TV controllers since most of the signals used to support these functions have been redefined. This mode is required if ISA slots or ISA masters are used. ISA master cycles are only passed to the PCI bus if they access memory. I/O accesses are left to complete on the ISA bus.

For further information regarding mode selection and operational details refer to Section 3.5.2.2 "Limited ISA and ISA Master Modes" on page 90.

1.3 AT COMPATIBILITY LOGIC

The CS5530A integrates:

- Two 8237-equivalent DMA controllers with full 32-bit addressing
- Two 8259-equivalent interrupt controllers providing 13 individually programmable external interrupts
- An 8254-equivalent timer for refresh, timer, and speaker logic
- NMI control and generation for PCI system errors and all parity errors
- Support for standard AT keyboard controllers
- Positive decode for the AT I/O register space
- Reset control

1.3.1 DMA Controller

The CS5530A supports the industry standard DMA architecture using two 8237-compatible DMA controllers in cascaded configuration. CS5530A-supported DMA functions include:

- Standard seven-channel DMA support
- 32-bit address range support via high page registers
- IOCHRDY extended cycles for compatible timing transfers
- ISA bus master device support using cascade mode

1.3.2 Programmable Interval Timer

The CS5530A contains an 8254-equivalent programmable interval timer. This device has three timers, each with an input frequency of 1.193 MHz.

1.3.3 Programmable Interrupt Controller

The CS5530A contains two 8259-equivalent programmable interrupt controllers (PICs), with eight interrupt request lines each, for a total of 16 interrupts. The two controllers are cascaded internally, and two of the interrupt request inputs are connected to the internal circuitry. This allows a total of 13 externally available interrupt requests.

Each CS5530A IRQ signal can be individually selected as edge- or level-sensitive. The PCI interrupt signals are routed internally to the PICs IRQs.

1.4 IDE CONTROLLERS

The CS5530A integrates two PCI bus mastering, ATA-4 compatible IDE controllers. These controllers support Ultra DMA/33 (enabled in Microsoft Windows 95 and Windows NT by using a driver provided by National Semiconductor), Multiword DMA, and Programmed I/O (PIO) modes. Two devices are supported on each controller. The data-transfer speed for each device on each controller can be independently programmed. This allows high-speed IDE peripherals to coexist on the same channel as lower speed devices. Faster devices must be ATA-4 compatible.

DataShe

DataSheet4J.com

Architecture Overview (Continued)

1.5 POWER MANAGEMENT

The CS5530A integrates advanced power management features including:

- · Idle timers for common system peripherals
- Address trap registers for programmable address ranges for I/O or memory accesses
- Up to eight programmable GPIOs
- Clock throttling with automatic speedup for the CPU clock
- Software CPU stop clock
- Save-to-Disk/RAM with peripheral shadow registers
- Dedicated serial bus to/from the GX-series processor providing CPU power management status

The CS5530A is an ACPI (Advanced Control and Power Interface) compliant chipset. An ACPI compliant system is one whose underlying BIOS, device drivers, chipset and peripherals conform to revision 1.0 or newer of the ACPI specification. The "Fixed Feature" and "General Purpose" registers are virtual. They are emulated by the SMI handling code rather than existing in physical hardware. To the ACPI compliant operating system, the SMI-base virtualization is transparent; however, to eliminate unnecessary latencies, the ACPI timer exists in physical hardware.

The CS5530A V-ACPI (Virtual ACPI) solution provides the bus mas following support: DataSheet4U.com

- CPU States C1, C2
- Sleep States S1, S2, S4, S4BIOS, S5
- Embedded Controller (Optional) SCI and SWI event inputs.
- General Purpose Events Fully programmable GPE0 Event Block registers.

1.5.1 GPIO Interface

Eight GPIO pins are provided for general usage in the system. GPIO[3:0] are dedicated pins and can be configured as inputs or outputs. GPIO[7:4] can be configured as the upper addresses of the ISA bus, SA[23:20]. All GPIOs can also be configured to generate an SMI on input edge transitions.

1.6 XPRESSAUDIO

XpressAUDIO in the CS5530A offers a combined hardware/software support solution to meet industry standard audio requirements. XpressAUDIO uses VSA technology along with additional hardware features to provide the necessary support for industry standard 16-bit stereo synthesis and OPL3 emulation.

The hardware portion of the XpressAUDIO subsystem can broadly be divided into two categories. Hardware for:

- Transporting streaming audio data to/from the system memory and an AC97 codec.
- VSA technology support.

1.6.1 AC97 Codec Interface

The CS5530A provides an AC97 Specification Revision 1.3, 2.0, and 2.1 compatible interface. Any AC97 codec which supports an independent input and output sample rate conversion interface (e.g., National Semiconductor LM4548) can be used with the CS5530A. This type of codec allows for a design which meets the requirements for PC97 and PC98-compliant audio as defined by Microsoft Corporation. Figure 1-2 shows the codec and CS5530A signal connections. For specifics on the serial interface, refer to the appropriate codec manufacturer's data sheet.

Low latency audio I/O is accomplished by a buffered PCI bus mastering controller.

DataShe

Figure 1-2. AC97 Codec Signal Connections

SDATA_OUT

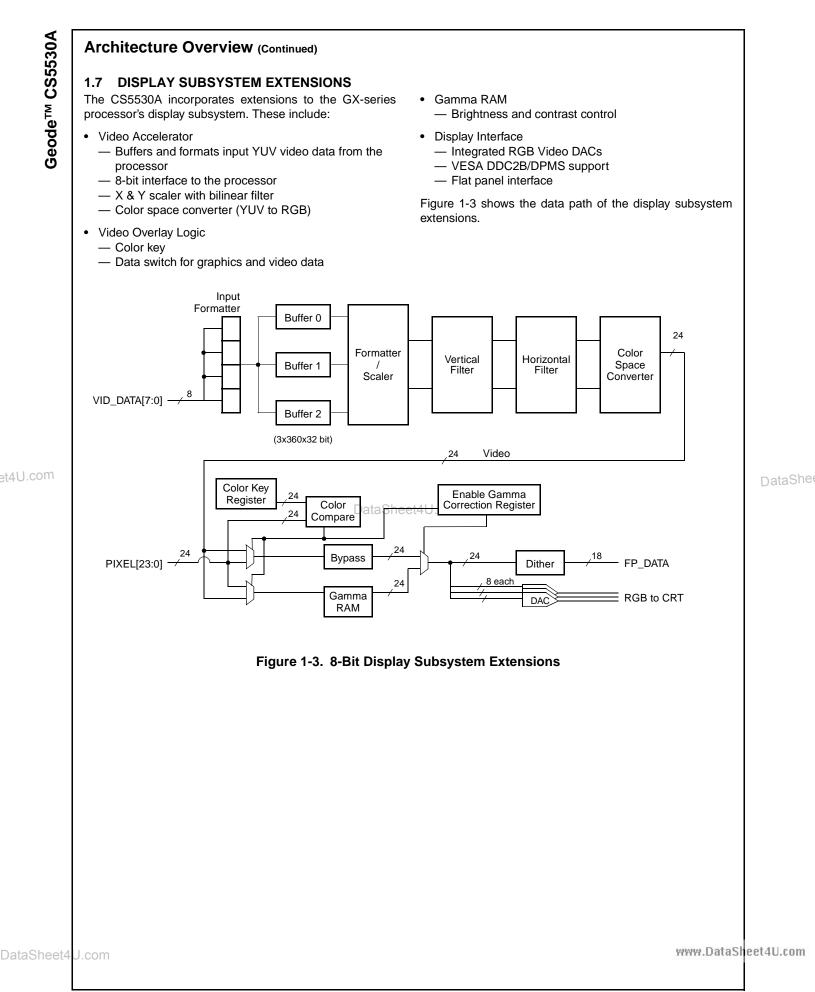

1.6.2 VSA Technology Support Hardware

SDAT_O

The CS5530A I/O companion incorporates the required hardware in order to support VSA technology for the capture and playback of audio using an external codec. This eliminates much of the hardware traditionally associated with industry standard audio functions.

XpressAUDIO software provides 16-bit compatible sound. This software is available to OEMs for incorporation into the system BIOS ROM.

et4U.com

Architecture Overview (Continued)

1.8 CLOCK GENERATION

In a CS5530A/GX-series processor based system, the CS5530A generates only the video DOT clock (DCLK) for the CPU and the ISA clock. All other clocks are generated by an external clock chip.

The ISACLK is created by dividing the PCICLK. For ISA compatibility, the ISACLK nominally runs at 8.33 MHz or less. The ISACLK dividers are programmed via F0 Index 50h[2:0].

DCLK is generated from the 14.31818 MHz input (CLK_14MHZ). A combination of a phase locked loop (PLL), linear feedback shift register (LFSR) and divisors are used to generate the desired frequencies for the DCLK. The divisors and LFSR are configurable through the F4BAR+Memory Offset 24h. For applications that do not use the GX-series processor's graphics subsystem, this is an available clock for general purpose use.

Figure 1-4 shows a block diagram for clock generation within the CS5530A.

1.9 UNIVERSAL SERIAL BUS

The CS5530A provides two complete, independent USB ports. Each port has a Data "--" and a Data "+" pin.

The USB controller is a compliant Open Host Controller Interface (OpenHCI). The OpenHCI specification provides a register-level description for a host controller, as well as a common industry hardware/software interface and drivers (see OpenHCI Specification, Revision 1.0, for description).

Architecture Overview (Continued)

1.10 PROCESSOR SUPPORT

The traditional south bridge functionality included in the CS5530A I/O companion chip has been designed to support the GX-series of processors. When combined with a GX-series processor, the CS5530A provides a bridge which supports a standard ISA bus and system ROM. As part of the video subsystem, the CS5530A provides MPEG video acceleration and a digital RGB interface, to allow direct connection to TFT LCD panels. This chip also inte-

grates a gamma RAM and three DACs, allowing for direct connection of a CRT monitor. Figure 1-5 shows a typical system block diagram.

For detailed information regarding processor signal connections refer to Section 3.1 "Processor Interface" on page 42.

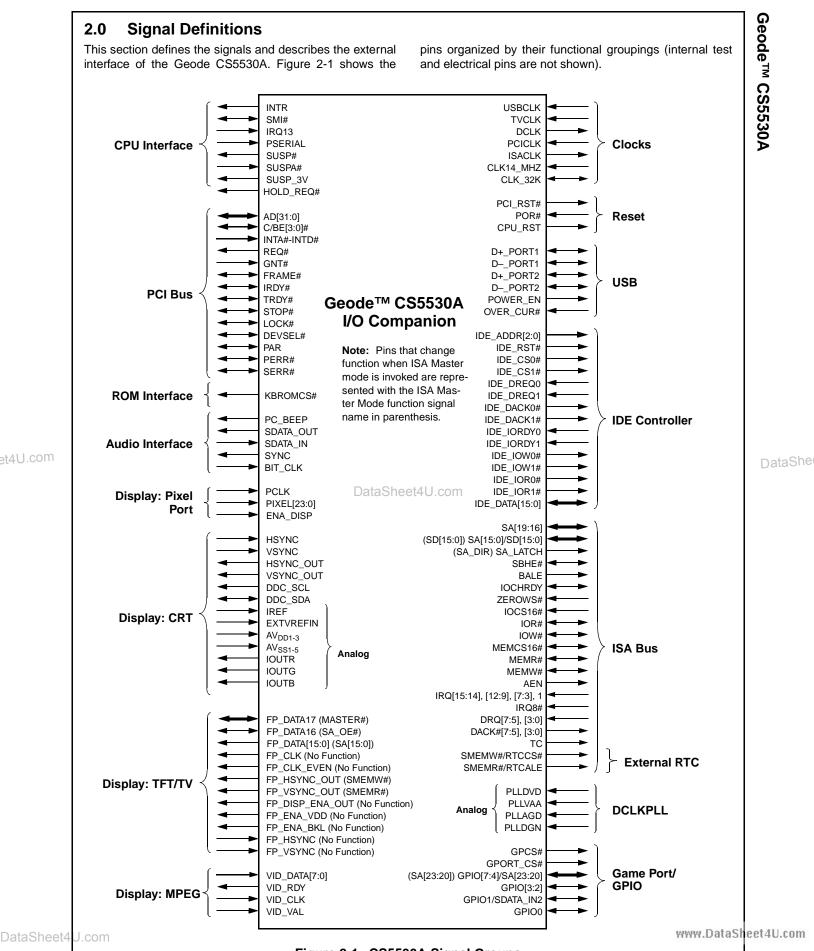

Figure 2-1. CS5530A Signal Groups

2.1 PIN ASSIGNMENTS

The tables in this section use several common abbreviations. Table 2-1 lists the mnemonics and their meanings.

Figure 2-2 shows the pin assignment for the CS5530A with Tables 2-2 and 2-3 listing the pin assignments sorted by pin number and alphabetically by signal name, respectively.

In Section 2.2 "Signal Descriptions" on page 23 a description of each signal within its associated functional group is provided.

In the signal definitions, references to F0-F4, F1BAR, F2BAR, F3BAR, F4BAR, and PCIUSB are made. These terms relate to designated register spaces. Refer to Table 4-1 "PCI Configuration Address Register (0CF8h)" on page 141 for details regarding these register spaces and their access mechanisms.

Mnemonic	Definition
I	Input pin ¹
I/O	Bidirectional pin ^{1,2}
0	Output pin ^{1, 2}
OD	Open-drain output structure that allows multiple devices to share the pin in a wired-OR configuration
PU	Pull-up resistor
SMT	Schmitt Trigger
V _{DD} (PWR)	Power pin
V _{SS} (GND)	Ground pin
#	The "#" symbol at the end of a signal name indicates that the active, or asserted state occurs when the signal is at a low voltage level. When "#" is not present after the signal name, the signal is asserted when at a high volt- age level.

Table 2-1. Pin Type Definitions

1. All buffers are 5 volt tolerant.

2. All digital bidirectional and output pins can be TRI-STATE signals unless a weak pull-up is enabled.

2.2 SIGNAL DESCRIPTIONS

2.2.1 Reset Interface

Signal Name	Pin No.	Pin Type	Description
PCI_RST#	C14	0	PCI Reset
			PCI_RST# resets the PCI bus and is asserted while POR# is asserted, and for approximately 9 ms following the deassertion of POR#.
POR#	K24	I	Power On Reset
			POR# is the system reset signal generated from the power supply to indi- cate that the system should be reset.
CPU_RST	K25	0	CPU Reset
			CPU_RST resets the CPU and is asserted while POR# is asserted, and for approximately 9 ms following the deassertion of POR#. CLK_14MHZ is used to generate this signal.

2.2.2 Clock Interface

Signal Name	Pin No.	Pin Type	Description
PCICLK	J26	I	PCI Clock
		(SMT)	The PCI clock is used to drive most circuitry of the CS5530A.
TVCLK	B2	I	Television Clock The TVCLK is an input from a digital NTSC/PAL converter which is option- ally re-driven back out onto the DCLK signal under software program con- trol. This is only used if interfacing to a compatible digital NTSC/PAL encoder device.
DCLK	A10	0	DOT Clock
			DOT clock is generated by the CS5530A and typically connects to the pro- cessor to create the clock used by the graphics subsystem. The minimum frequency of DCLK is 10 MHz and the maximum is 200 MHz. However, when DCLK is used as the graphics subsystem clock, the Geode processor determines the maximum DCLK frequency.
ISACLK	AD6	0	ISA Bus Clock
			ISACLK is derived from PCICLK and is typically programmed for approxi- mately 8 MHz. F0 Index 50h[2:0] are used to program the ISA clock divisor.
CLK_14MHZ	P24	I	14.31818 MHz Clock
		(SMT)	This clock is used to generate CPU_RST to the Geode processor. DOT clock (DCLK) is also derived from this clock.
USBCLK	W1	I	USBCLK
		(SMT)	This input is used as the clock source for the USB. In this mode, a 48 MHz clock source input is required.
CLK_32K	AE3	I/O	32 KHz Clock
			CLK_32K is a 32.768 KHz clock used to generate reset signals, as well as to maintain power management functionality. It should be active when power is applied to the CS5530A.
			CLK_32K can be an input or an output. As an output CLK_32K is internally derived from CLK_14MHZ. F0 Index 44h[5:4] are used to program this pin.

Revision 1.1

Signal Definitions (Continued) 2.2.3 **CPU** Interface Pin Pin Signal Name Type No. Description 0 INTR P26 **CPU Interrupt Request** Strap INTR is the level output from the integrated 8259 PICs and is asserted if an Option unmasked interrupt request (IRQ_n) is sampled active. Pin Т **Strap Option Select Pin** Pin P26 is a strap option select pin. It is used to select whether the CS5530A operates in Limited ISA or ISA Master mode. ISA Limited Mode—Strap pin P26 low through a 10-kohm resistor. ISA Master Mode—Strap pin P26 high through a 10-kohm resistor. System Management Interrupt SMI# P25 I/O SMI# is a level-sensitive interrupt to the CPU that can be configured to assert on a number of different system events. After an SMI# assertion, System Management Mode (SMM) is entered, and program execution begins at the base of SMM address space. Once asserted, SMI# remains active until all SMI sources are cleared. IRQ13 R23 T IRQ13 IRQ13 is an input from the processor indicating that a floating point error was detected and that INTR should be asserted. PSERIAL L26 **Power Management Serial Interface** Т PSERIAL is the unidirectional serial data link between the GX-series processor and the CS5530A. An 8-bit serial data packet carries status on power management events within the CPU. Data is clocked synchronous to the PCICLK input clock. 0 SUSP# K26 **CPU Suspend** SUSP# asserted requests that the CPU enters Suspend mode and the CPU asserts SUSPA# after completion. The SUSP# pin is deasserted if SUSP# has gone active and any Speedup or Resume event has occurred, including

cessor to stabilize.

95h) expires.

HALT instruction.

expiration of the Suspend Modulation ON timer, which is loaded from F0 Index 95h. If the SUSP#/SUSPA# handshake is configured as a system 3 Volt Suspend, the deassertion of SUSP# is delayed by an interval programmed in F0 Index BCh[7:4] to allow the system clock chip and the pro-

The SUSP#/SUSPA# handshake occurs as a result of a write to the Suspend Notebook Command Register (F0 Index AFh), or expiration of the Suspend Modulation OFF timer (loaded from F0 Index 94h) when Suspend Modulation is enabled. Suspend Modulation is enabled via F0 Index 96h[0]. If SUSPA# is asserted as a result of a HALT instruction, SUSP# does not deassert when the Suspend Modulation ON timer (loaded from F0 Index

SUSPA# is a level input from the processor. When asserted it indicates the CPU is in Suspend mode as a result of SUSP# assertion or execution of a

SUSPA#

L25

T

CPU Suspend Acknowledge

2.2.3 CPU Interface (Continued)

Signal Name	Pin No.	Pin Type	Description
SUSP_3V	L24	I/O	Suspend 3 Volt Active
			SUSP_3V can be connected to the output enable (OE) of a clock synthesis or buffer chip to stop the clocks to the system. SUSP_3V is asserted after the SUSP#/SUSPA# handshake that follows a write to the Suspend Note- book Command Register (F0 Index AFh) with bit 0 set in the Clock Stop Control Register (F0 Index BCh).
			As an input, SUSP_3V is sampled during power-on-reset to determine the inactive state. This allows the system designer to match the active state of SUSP_3V to the inactive state for a clock driver output enabled with a pull-up/down 10-kohm resistor. If pulled down, SUSP_3V is active high. If pulled up, SUSP_3V is active low.

2.2.4 PCI Interface

Signal Name	Pin No.	Pin Type	Description					
AD[31:0]	Refer	I/O	PCI Address/Data					
	to Table 2-3		AD[31:0] is a physical address during the first clock of a PCI transaction; it is the data during subsequent clocks.					
			When the CS5530A is a PCI master, AD[31:0] are outputs during the address and write data phases, and are inputs during the read data phase a transaction. Data Sheet4U.com When the CS5530A is a PCI slave, AD[31:0] are inputs during the addre and write data phases, and are outputs during the read data phase of a transaction.					
C/BE[3:0]#	D26,	I/O	PCI Bus Command and Byte Enables					
	A24, B21, B18		During the address phase of a PCI transaction, C/BE[3:0]# define the bus command. During the data phase of a transaction, C/BE[3:0]# are the data byte enables.					
			C/BE[3:0]# are outputs when the CS5530A is a PCI master and inputs when it is a PCI slave.					
INTA#,	A14,	Ι	PCI Interrupt Pins					
INTB#, INTC#, INTD#	D15, C15, B14		The CS5530A provides inputs for the optional "level-sensitive" PCI interrupts (also known in industry terms as PIRQx#). These interrupts may be mapped to IRQs of the internal 8259s using PCI Interrupt Steering Registers 1 and 2 (F0 Index 5Ch and 5Dh).					
			The USB controller uses INTA# as its output signal. Refer to PCIUSB Index 3Dh.					
REQ#	J25	0	PCI Bus Request					
			The CS5530A asserts REQ# in response to a DMA request or ISA master request to gain ownership of the PCI bus. The REQ# and GNT# signals are used to arbitrate for the PCI bus.					
			REQ# should connect to the REQ0# of the GX-series processor and func- tion as the highest-priority PCI master.					

DataSheet4U.com

et4U.com

www.DataSheet4U.com

.2.4 PCI Interfa	ace (Continu	su)	
Signal Name	Pin No.	Pin Type	Description
GNT#	D24		PCI Bus Grant
		l	GNT# is asserted by an arbiter that indicates to the CS5530A that access to the PCI bus has been granted.
			GNT# should connect to GNT0# of the GX-series processor and function as the highest-priority PCI master.
HOLD_REQ#	H26	0	PCI Bus Hold Request
	Strap Option	I	This pin's function as HOLD_REQ# is no longer applicable.
	Pin		Strap Option Select Pin
		l	Pin H26 is a strap option select pin. It allows selection of which address bits are used as the IDSEL.
		l	Strap pin H26 low: IDSEL = AD28 (Chipset Register Space) and AD29 (USB Register Space)
		l	Strap pin H26 high: IDSEL = AD26 (Chipset Register Space) and AD27 (USB Register Space)
FRAME#	C23	I/O	PCI Cycle Frame
		l	FRAME# is asserted to indicate the start and duration of a transaction. It is deasserted on the final data phase.
		I	FRAME# is an input when the CS5530A is a PCI slave.
IRDY#	B24	I/O	PCI Initiator Ready
		l	IRDY# is driven by the master to indicate valid data on a write transaction, or that it is ready to receive data on a read transaction.
		l	When the CS5530A is a PCI slave, IRDY# is an input that can delay the beginning of a write transaction or the completion of a read transaction.
		I	Wait cycles are inserted until both IRDY# and TRDY# are asserted together.
TRDY#	B23	I/O	PCI Target Ready
			TRDY# is asserted by a PCI slave to indicate it is ready to complete the current data transfer.
		l	TRDY# is an input that indicates a PCI slave has driven valid data on a read or a PCI slave is ready to accept data from the CS5530A on a write.
			TRDY# is an output that indicates the CS5530A has placed valid data on AD[31:0] during a read or is ready to accept the data from a PCI master on a write.
		I	Wait cycles are inserted until both IRDY# and TRDY# are asserted together.
STOP#	E26	I/O	PCI Stop
			As an input, STOP# indicates that a PCI slave wants to terminate the current transfer. The transfer is either aborted or retried. STOP# is also used to end a burst.
			As an output, STOP# is asserted with TRDY# to indicate a target discon- nect, or without TRDY# to indicate a target retry. The CS5530A asserts STOP# during any cache line crossings if in single transfer DMA mode or if busy.

2.4 PCI Interfa	ce (Continu	ea)	1
Signal Name	Pin No.	Pin Type	Description
OCK#	C22	I/O	PCI Lock
			LOCK# indicates an atomic operation that may require multiple transactions to complete.
			If the CS5530A is currently the target of a LOCKed transaction, any other PCI master request with the CS5530A as the target is forced to retry the transfer.
			The CS5530A does not generate LOCKed transactions.
EVSEL#	A23	I/O	PCI Device Select
			DEVSEL# is asserted by a PCI slave, to indicate to a PCI master and sub- tractive decoder that it is the target of the current transaction.
			As an input, DEVSEL# indicates a PCI slave has responded to the current address.
		As an output, DEVSEL# is asserted one cycle after the assertion of FRAME# and remains asserted to the end of a transaction as the result of a positive decode. DEVSEL# is asserted four cycles after the assertion of FRAME# if DEVSEL# has not been asserted by another PCI device when the CS5530A is programmed to be the subtractive decode agent. The sub-tractive decode sample point is configured in F0 Index 41h[2:1]. Subtractive decode cycles are passed to the ISA bus.	
PAR	A21	I/O	PCI Parity
			PAR is the parity signal driven to maintain even parity across AD[31:0] and C/BE[3:0]# The CS5530A drives PAR one clock after the address phase and one clock after each completed data phase of write transactions as a PCI master. It also drives PAR one clock after each completed data phase of read transactions as a PCI slave.
PERR#	B22	I/O	PCI Parity Error
			PERR# is pulsed by a PCI device to indicate that a parity error was detected. If a parity error was detected, PERR# is asserted by a PCI slave during a write data phase and by a PCI master during a read data phase.
		When the CS5530A is a PCI master, PERR# is an output during read trans- fers and an input during write transfers. When the CS5530A is a PCI slave, PERR# is an input during read transfers and an output during write trans- fers.	
			Parity detection is enabled through F0 Index 04h[6]. An NMI is generated if I/O Port 061h[2] is set. PERR# can assert SERR# if F0 Index 41h[5] is set.
ERR#	A22	I/O	PCI System Error
		OD	SERR# is pulsed by a PCI device to indicate an address parity error, data parity error on a special cycle command, or other fatal system errors.
			SERR# is an open-drain output reporting an error condition, and an input indicating that the CS5530A should generate an NMI. As an input, SERR# is asserted for a single clock by the slave reporting the error.
			System error detection is enabled with F0 Index 04h[8]. An NMI is generated if I/O Port 061h[2] is set. PERR# can assert SERR# if F0 Index 41h[5] is set

et4U.com

	erface		
Signal Name	Pin No.	Pin Type	Description
SA_LATCH/	AD15	0	Limited ISA Mode: System Address Latch
SA_DIR			This signal is used to latch the destination address, which is multiplexed on bits [15:0] of the SA/SD bus.
			ISA Master Mode: System Address Direction
			Controls the direction of the external 5.0V tolerant transceiver on bits [15:0] of the SA bus. When low, the SA bus is driven out. When high, the SA bus is driven into the CS5530A by the external transceiver.
SA_OE#/	H3	0	Limited ISA Mode: Flat Panel Data Port Line 16
FP_DATA16			Refer to Section 2.2.11 "Display Interface" on page 35 for this signal's definition.
		0	ISA Master Mode: System Address Transceiver Output Enable
			Enables the external transceiver on bits [15:0] of the SA bus.
MASTER#/ FP_DATA17	F3	0	Limited ISA Mode: Flat Panel Data Port Line 17
			Refer to Section 2.2.11 "Display Interface" on page 35 for this signal's definition.
		I	ISA Master Mode: Master
			The MASTER# input asserted indicates an ISA bus master is driving the ISA bus.
SA23/GPIO7	AF23 AE23	I/O	Limited ISA Mode: System Address Bus Lines 23 through 20 or General Purpose I/Os 7 through 4 Data Sheet 40 com These pins can function either as the upper four bits of the SA bus or as general purpose I/Os. Programming is done through F0 Index 43h, bits 6
SA22/GPIO6			
SA21/GPIO5	AC21		
SA20/GPIO4	AD22		and 2.
			Refer to Section 2.2.9 "Game Port and General Purpose I/O Interface" on page 33 for further details when used as GPIOs.
			ISA Master Mode: System Address Bus Lines 23 through 20
			The pins function only as the four MSB (most significant bits) of the SA bus
SA[19:16]	AD10,	I/O	System Address Bus Lines 19 through 16
	AE11, AF12, AD11	(PU)	Refer to SA[15:0] signal description.
SA[15:0]/SD[15:0]	Refer	I/O	Limited ISA Mode: System Address Bus / System Data Bus
	to Table 2-3	(PU)	This bus carries both the addresses and data for all ISA cycles. Initially, the address is placed on the bus and then SA_LATCH is asserted in order for external latches to latch the address. At some time later, the data is put on the bus, for a read, or the bus direction is changed to an input, for a write.
			Pins designated as SA/SD[15:0] are internally connected to a 20-kohm pul up resistor.
			ISA Master Mode: System Data Bus
			These pins perform only as SD[15:0] and pins FP_DATA[15:0] take on the functions of SA[15:0].
			Pins designated as SA/SD[15:0] are internally connected to a 20-kohm pull up resistor.

www.DataSheet4U.com

.2.5 ISA Bus Inte	rface (Co	ntinued)	1
Signal Name	Pin No.	Pin Type	Description
SMEMW#/	E1	0	Limited ISA Mode: Flat Panel Horizontal Sync Output
FP_HSYNC_OUT			Refer to Section 2.2.11 "Display Interface" on page 35 for this signal's defini- tion.
			Note that if Limited ISA Mode of operation is selected, SMEMW# is available on pin AF3 (multiplexed with RTCCS#).
			ISA Master Mode: System Memory Write
			SMEMW# is asserted for any memory write accesses below 1 MB (i.e., A23:A20 set to 0). This enables 8-bit memory slaves to decode the memory address on SA[19:0].
SMEMR#/	E3	0	Limited ISA Mode: Flat Panel Vertical Sync Output
FP_VSYNC_OUT			Refer to Section 2.2.11 "Display Interface" on page 35 for this signal's defini- tion.
			Note that if Limited ISA Mode of operation is selected, SMEMR# is available on pin AD4 (multiplexed with RTCALE).
			ISA Master Mode: System Memory Read
			SMEMR# is asserted for memory read accesses below 1 MB (i.e., A23:A20 set to 0). This enables 8-bit memory slaves to decode the memory address on SA[19:0].
SMEMW#/	AF3	0	System Memory Write / Real-Time Clock Chip Select
RTCCS#			If Limited ISA Mode of operation has been selected, then SMEMW# can be output on this pin. SMEMW# is asserted for any memory write accesses below 1 MB (i.e., A23:A20 set to 0). This enables 8-bit memory slaves to decode the memory address on SA[19:0].
			RTCCS# is a chip select to an external real-time clock chip. This signal is activated on reads or writes to I/O Port 071h.
			Function selection is made through F0 Index 53h[2]: 0 = SMEMW#, 1 = RTCCS#.
SMEMR#/	AD4	0	System Memory Read / Real-Time Clock Address Latch Enable
RTCALE			If Limited ISA Mode of operation has been selected, then SMEMR# can be output on this pin. SMEMR# is asserted for memory read accesses below 1 MB (i.e., A23:A20 set to 0). This enables 8-bit memory slaves to decode the memory address on SA[19:0].
			RTCALE is a signal telling an external real-time clock chip to latch the address, which is on the SD bus.
			Function selection is made through F0 Index 53h[2]: 0 = SMEMR#, 1 = RTCALE.
SBHE#	AE17	I/O	System Bus High Enable
		(PU)	The CS5530A or ISA master asserts SBHE# to indicate that SD[15:8] will be used to transfer a byte at an odd address.
			SBHE# is an output during non-ISA master DMA operations. It is driven as the inversion of AD0 during 8-bit DMA cycles. It is forced low for all 16-bit DMA cycles.
			SBHE# is an input during ISA master operations.
			This pin is internally connected to a 20-kohm pull-up resistor.
BALE	AF9	0	Buffered Address Latch Enable
om			BALE indicates when SA[23:0] and SBHE# are valid and may be latched. For DMA transfers, BALE remains asserted until the transfer is complete.

et4U.com

	rface (Cor			
Signal Name	Pin No.	Pin Type	Description	
IOCHRDY	AF11	I/O	I/O Channel Ready	
		OD	IOCHRDY deasserted indicates that an ISA slave requires additional wait states.	
			When the CS5530A is an ISA slave, IOCHRDY is an output indicating addi- tional wait states are required.	
ZEROWS#	AF10	I	Zero Wait States	
			ZEROWS# asserted indicates that an ISA 8- or 16-bit memory slave can shorten the current cycle. The CS5530A samples this signal in the phase after BALE is asserted. If asserted, it shortens 8-bit cycles to three ISACLKs and 16-bit cycles to two ISACLKs.	
IOCS16#	AF16	Ι	I/O Chip Select 16	
			IOCS16# is asserted by 16-bit ISA I/O devices based on an asynchronous decode of SA[15:0] to indicate that SD[15:0] will be used to transfer data.	
			8-bit ISA I/O devices only use SD[7:0].	
IOR#	AE12	I/O	I/O Read	
		(PU)	IOR# is asserted to request an ISA I/O slave to drive data onto the data bus.	
			This pin is internally connected to a 20-kohm pull-up resistor.	
IOW#	AC11	I/O	I/O Write	
		(PU)	IOW# is asserted to request an ISA I/O slave to accept data from the data bus.	Data
			This pin is internally connected to a 20-kohm pull-up resistor.	
MEMCS16#	AC15	I/O	Memory Chip Select 16	
		OD	MEMCS16# is asserted by 16-bit ISA memory devices based on an asyn- chronous decode of SA[23:17] to indicate that SD[15:0] will be used to trans- fer data.	
			8-bit ISA memory devices only use SD[7:0].	
MEMR#	AE19	I/O	Memory Read	
		(PU)	MEMR# is asserted for any memory read accesses. It enables 16-bit mem- ory slaves to decode the memory address on SA[23:0].	
			This pin is internally connected to a 20-kohm pull-up resistor.	
MEMW#	AF20	I/O	Memory Write	
		(PU)	MEMW# is asserted for any memory write accesses. It enables 16-bit memory slaves to decode the memory address on SA[23:0].	
			This pin is internally connected to a 20-kohm pull-up resistor.	
AEN	AE8	0	Address Enable	
			AEN asserted indicates that a DMA transfer is in progress, informing I/O devices to ignore the I/O cycle.	
IRQ[15:14], [12:9],	Refer	I	ISA Bus Interrupt Request	
[7:3], 1	to Table 2-3		IRQ inputs indicate ISA devices or other devices requesting a CPU interrupt service.	
IRQ8#	AE14	I	Real-Time Clock Interrupt	
			IRQ8# is the (active-low) interrupt that comes from the external RTC chip	

DataSheet4U.com

2.2.5 ISA Bus Interface (Continued)

Signal Name	Pin No.	Pin Type	Description
DRQ[7:5], DRQ[3:0]	Refer to Table 2-3	I	DMA Request - Channels 7 through 5 and 3 through 0 DRQ inputs are asserted by ISA DMA devices to request a DMA transfer. The request must remain asserted until the corresponding DACK is asserted.
DACK[7:5]#, DACK[3:0]#	Refer to Table 2-3	0	DMA Acknowledge - Channels 7 through 5 and 3 through 0 DACK outputs are asserted to indicate when a DRQ is granted and the start of a DMA cycle.
ТС	AF15	0	Terminal Count TC signals the final data transfer of a DMA transfer.

2.2.6 ROM Interface

Signal Name	Pin No.	Pin Type	Description
KBROMCS#	AE4	0	Keyboard/ROM Chip Select
			KBROMCS# is the enable pin for the BIOS ROM and for the keyboard con- troller. For ROM accesses, KBROMCS# is asserted for ISA memory accesses programmed at F0 Index 52h[2:0].
			For keyboard controller accesses, KBROMCS# is asserted for I/O accesses to I/O Ports 060h, 062h, 064h, and 066h.

IDE Interface 227

Signal Name	Pin No.	Pin Type	Description
IDE_RST#	W25	0	IDE Reset
			This signal resets all the devices that are attached to the IDE interface.
IDE_ADDR[2:0]	W24,	0	IDE Address Bits
	U26, U25		These address bits are used to access a register or data port in a device on the IDE bus.
IDE_DATA[15:0]	Refer	I/O	IDE Data Lines
	to Table 2-3		IDE_DATA[15:0] transfers data to/from the IDE devices.
IDE_IOR0#	R26	0	IDE I/O Read for Channels 0 and 1
IDE_IOR1#	R25	0	IDE_IOR0# is the read signal for Channel 0, and IDE_IOR1# is the read signal for Channel 1. Each signal is asserted on read accesses to the corresponding IDE port addresses.
			When in Ultra DMA/33 mode, these signals are redefined: Read Cycle — DMARDY0# and DMARDY1# Write Cycle — STROBE0 and STROBE1
IDE_IOW0#	R24	0	IDE I/O Write for Channels 0 and 1
IDE_IOW1#	T25	0	IDE_IOW0# is the write signal for Channel 0, and IDE_IOW1# is the read signal for Channel 1. Each signal is asserted on write accesses to corresponding IDE port addresses.
			When in Ultra DMA/33 mode, these signals are redefined: Read Cycle STOP0 and STOP1 Write Cycle — STOP0 and STOP1
IDE_CS0#	V26	0	IDE Chip Selects
IDE_CS1#	Y26	0	The chip select signals are used to select the command block registers in an IDE device.
IDE_IORDY0	AD25	I	I/O Ready Channels 0 and 1
IDE_IORDY1	AE26	I	When deasserted, these signals extend the transfer cycle of any host regis- ter access when the device is not ready to respond to the data transfer request.
			When in Ultra DMA/33 mode, these signals are redefined: Read Cycle — STROBE0 and STROBE1 Write Cycle — DMARDY0# and DMARDY1#
IDE_DREQ0	AD26	I	DMA Request Channels 0 and 1
IDE_DREQ1	AC24	I	The DREQ is used to request a DMA transfer from the CS5530A. The direction of the transfers are determined by the IDE_IOR/IOW signals.
IDE_DACK0#	T26	0	DMA Acknowledge Channels 0 and 1
IDE_DACK1#	T24	0	The DACK# acknowledges the DREQ request to initiate DMA transfers.

Signal Name	Pin No.	Pin Type	Description
GPORT_CS#	AD21	0	Game Port Chip Select
			GPORT_CS# is asserted upon any I/O reads or I/O writes to I/O Port 200h and 201h.
GPCS#	AF26	0	General Purpose Chip Select
			GPCS# is asserted upon any I/O access that matches the I/O address in the General Purpose Chip Select Base Address Register (F0 Index 70h) and the conditions set in the General Purpose Chip Select Control Register (F0 Index 72h).
GPIO7/SA23	AF23	I/O	Limited ISA Mode: General Purpose I/Os 7 through 4 or
GPIO6/SA22	AE23		System Address Bus Lines 23 through 20
GPIO5/SA21	AC21		These pins can function either as general purpose I/Os or as the upper four bits of the SA bus. Selection is done through F0 Index 43h[6,2].
GPIO4/SA20	AD22		Refer to GPIO[3:2] signal description for GPIO function description.
			ISA Master Mode: System Address Bus Lines 23 through 20
			These pins function as the four MSB (most significant bits) of the SA bus.
GPIO3	AF24	I/O	General Purpose I/Os 3 and 2
GPIO2	AF25	I/O	GPIOs can be programmed to operate as inputs or outputs via F0 Index 90h. As an input, the GPIO can be configured to generate an external SMI. Additional configuration can select if the SMI# is generated on the rising or falling edge. GPIO external SMI generation/edge selection is done in F0 Index 92h and 97h.

2.2.9 Game Port and General Purpose I/O Interface (Continued)

Signal Name	Pin No.	Pin Type	Description	
GPIO1/	AE24	I/O	General Purpose I/O 1 or Serial Data Input 2	
SDATA_IN2			This pin can function either as a general purpose I/O or as a second serial data input pin if two codecs are used in the system.	
			In order for this pin to function as SDATA_IN2, it must first be configured as an input (F0 Index 90h[1] = 0). Then setting F3BAR+Memory Offset 08h[21] = 1 selects the pin to function as SDATA_IN2.	
			Refer to GPIO[3:2] signal description for GPIO function description.	
GPIO0	AC22	I/O	General Purpose I/O 0	
			Refer to GPIO[3:2] signal description for GPIO function description.	

2.2.10 Audio Interface

Signal Name	Pin No.	Pin Type	Description
BIT_CLK	V2	I	Audio Bit Clock
			The serial bit clock from the codec.
SDATA_OUT	V1	0	Serial Data I/O
			This output transmits audio serial data to the codec.
SDATA_IN	U4	I	Serial Data Input
			This input receives serial data from the codec.
SYNC	U3	0	Serial Bus Synchronization
			This bit is asserted to synchronize the transfer of data between the CS5530A and the AC97 codec.
PC_BEEP	V3	0	РС Веер
			Legacy PC/AT speaker output.

Signal Name	Pin No.	Pin Type	Description
Pixel Port			
PCLK	A13	I	Pixel Clock
			This clock is used to sample data on the PIXEL input port. It runs at the graphics DOT clock (DCLK) rate.
PIXEL[23:0]	Refer	I	Pixel Data Port
	to Table 2-3		This is the input pixel data from the processor's display controller. If F4BAR+Memory Offset 00h[29] is reset, the data is sent in RGB 8:8:8 for- mat. Otherwise, the pixel data is sent in RGB 5:6:5 format which has been dithered by the processor. The other eight bits are used in conjunction with VID_DATA[7:0] to provide 16-bit video data. This bus is sampled by the PCLK input.
ENA_DISP	B1	I	Display Enable Input
			This signal qualifies active data on the pixel input port. It is used to qualify active pixel data for all display modes and configurations and is not specific to flat panel display.
Display CRT			
HSYNC	C6	I	Horizontal Sync Input
			This is the CRT horizontal sync input from the processor's display controller. It is used to indicate the start of a new video line. This signal is pipelined for the appropriate number of clock stages to remain in sync with the pixel data. A separate output (HSYNC_OUT) is provided to re-drive the CRT and flat panel interfaces.
HSYNC_OUT	N1	0	Horizontal Sync Output
			This is the horizontal sync output to the CRT. It represents a delayed version of the input horizontal sync signal with the appropriate pipeline delay relative to the pixel data. The pipeline delay and polarity of this signal are program- mable.
VSYNC	B5	I	Vertical Sync Input
			This is the CRT vertical sync input from the processor's display controller. It is used to indicate the start of a new frame. This signal is pipelined for the appropriate number of clock stages to remain in sync with the pixel data. A separate output (VSYNC_OUT) is provided to re-drive the CRT and flat panel interfaces.
VSYNC_OUT	N2	0	Vertical Sync Output
			This is the vertical sync output to the CRT. It represents a delayed version of the input vertical sync signal with the appropriate pipeline delay relative to the pixel data. The pipeline delay and polarity of this signal are programmable.
DDC_SCL	M2	0	DDC Serial Clock
			This is the serial clock for the VESA Display Data Channel interface. It is used for monitoring communications. The DDC2B standard is supported by this interface.
DDC_SDA	M4	I/O	DDC Serial Data
			This is the bidirectional serial data signal for the VESA Display Data Chan- nel interface. It is used to monitor communications. The DDC2B standard is supported by this interface.

3.0 Functional Description

The Geode CS5530A I/O companion provides many support functions for a GX-series processor (i.e., GX1, GXLV, GXm). This chapter discusses the detailed operations of the CS5530A in two categories: system-level activities and operations/programming of the major functional blocks.

The system-level discussion topics revolve around events that affect the device as a whole unit and as an interface with other chips (e.g., processor): Topics include:

- Processor Interface
 - Display Subsystem Connections
 - PSERIAL Pin Interface
- PCI Bus Interface
 - PCI Initiator
 - PCI Target
 - Special Bus Cycles-Shutdown/Halt
 - PCI Bus Parity
 - PCI Interrupt Routing Support
 - Delayed Transactions
- Resets and Clocks
 - Resets
 - ISA Clock
- DOT Clock
- Power Management
 - CPU Power Management
- APM Support
- Peripheral Power Management

All of the major functional blocks interact with the processor through the PCI bus, or via its own direct interface. The major functional blocks are divided out as:

- PC/AT Compatibility Logic
 - ISA Subtractive Decode
 - ISA Bus Interface
 - ROM Interface
 - Megacells
 - I/O Ports 092h and 061h System Control
 - Keyboard Interface Function
 - External Real-Time Clock Interface
- IDE Controller
 - IDE Interface Signals
 - IDE Configuration Registers
- XpressAUDIO
 - Subsystem Data Transport Hardware
 - VSA Technology Support Hardware
- Display Subsystem Extensions
 - Video Interface Configuration Registers
 - Video Accelerator
 - Video Overlay
 - Gamma RAM
 - Display Interface
- Universal Serial Bus Support
 - USB PCI Controller
 - USB Host Controller
 - USB Power Management

DataSheet4Note2that this Functional Description section of the data book describes many of the registers used for configuration of the CS5530A; however, not all registers are reported in detail. Some tables in the following subsections show only the bits (not the entire register) associated with a specific function being discussed. For access, register, and bit information regarding all CS5530A registers refer to Section 4.0 "Register Descriptions" on page 140. DataShe

Functional Description (Continued)

3.1 PROCESSOR INTERFACE

The CS5530A interface to a GX-series processor consists of seven miscellaneous connections, the PCI bus interface signals, plus the display controller connections. Figure 3-1 shows the interface requirements. Note that the PC/AT legacy pins NMI, WM_RST, and A20M are all virtual functions executed in SMM (System Management Mode) by the BIOS.

- PSERIAL is a one-way serial bus from the processor to the CS5530A used to communicate power management states and VSYNC information for VGA emulation.
- IRQ13 is an input from the processor indicating that a floating point error was detected and that INTR should be asserted.
- INTR is the level output from the integrated 8259 PICs and is asserted if an unmasked interrupt request (IRQn) is sampled active.
- SMI# is a level-sensitive interrupt to the processor that can be configured to assert on a number of different system events. After an SMI# assertion, SMM is entered and program execution begins at the base of the SMM address space. Once asserted, SMI# remains active until the SMI source is cleared.
- SUSP# and SUSPA# are handshake pins for implementing CPU Clock Stop and clock throttling.
- CPU_RST resets the CPU and is asserted for approximately 9 ms after the negation of POR#.
- PCI bus interface signals.
- Display subsystem interface connections.

Note: Refer to Figure 3-3 on page 44 for correct interconnection of PIXEL lines with the processor.

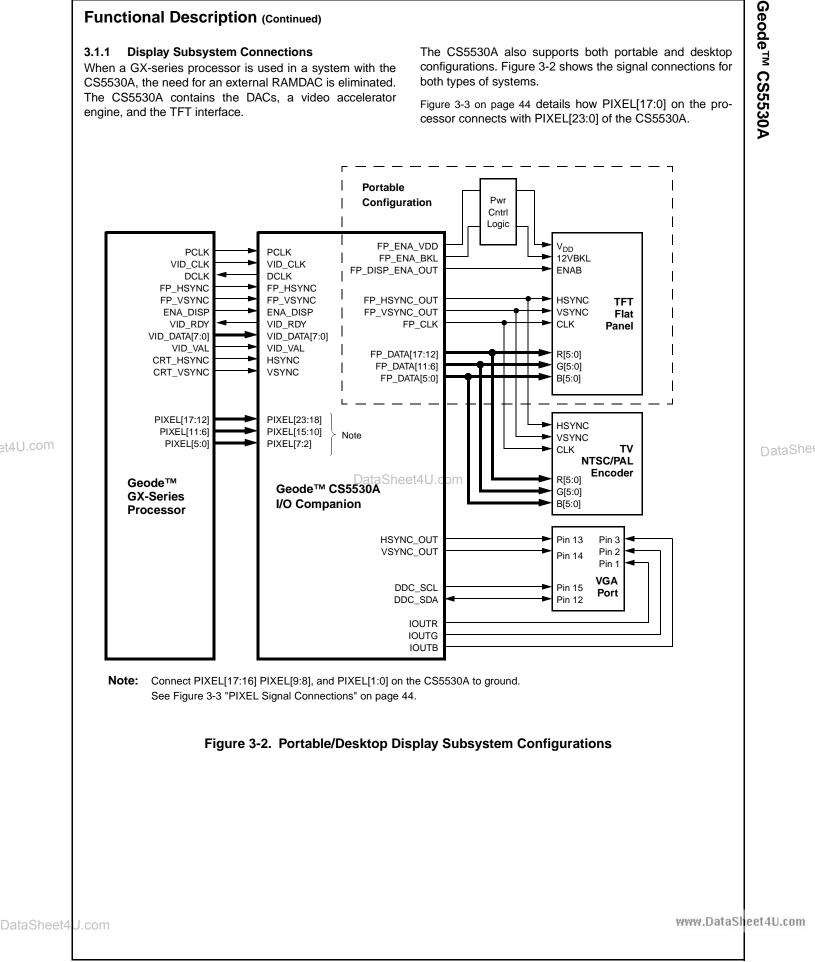

www.DataSheet4U.com

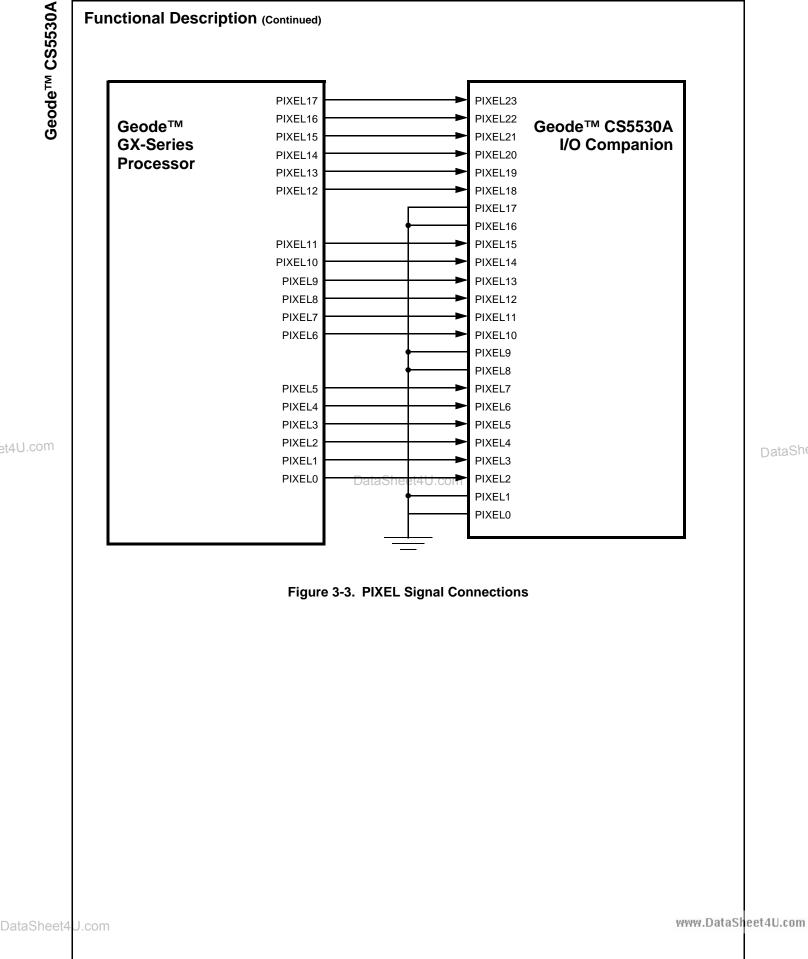

Display Subsystem Connections 3.1.1

When a GX-series processor is used in a system with the CS5530A, the need for an external RAMDAC is eliminated. The CS5530A contains the DACs, a video accelerator engine, and the TFT interface.

The CS5530A also supports both portable and desktop configurations. Figure 3-2 shows the signal connections for both types of systems.

Figure 3-3 on page 44 details how PIXEL[17:0] on the processor connects with PIXEL[23:0] of the CS5530A.

3.1.2 PSERIAL Pin Interface

The majority of the system power management logic is implemented in the CS5530A, but a minimal amount of logic is contained within the GX-series processor to provide information that is not externally visible (e.g., graphics controller).

The processor implements a simple serial communications mechanism to transmit the CPU status to the CS5530A. The processor accumulates CPU events in an 8-bit register (defined in Table 3-1) which it transmits serially every 1 to 10 μ s.

The packet transmitter holds the serial output pin (PSE-RIAL) low until the transmission interval timer has elapsed. Once the timer has elapsed, the PSERIAL pin is held high for two clocks to indicate the start of packet transmission. The contents of the Serial Packet Register are then shifted out starting from bit 7 down to bit 0. The PSERIAL pin is held high for one clock to indicate the end of packet transmission and then remains low until the next transmission interval. After the packet transmission is complete, the processor's Serial Packet Register's contents are cleared.

The processor's input clock is used as the clock reference for the serial packet transmitter.

Once a bit in the register is set, it remains set until the completion of the next packet transmission. Successive events of the same type that occur between packet transmissions are ignored. Multiple unique events between packet transmissions accumulate in this register. The processor transpectuum mits the contents of the serial packet only when a bit in the Serial Packet Register is set and the interval timer has elapsed.

For more information on the Serial Packet Register referenced in Table 3-1, refer to the appropriate GX-series processor data book.

The CS5530A decodes the serial packet after each transmission and performs the power management tasks related to video retrace.

Table 3-1.	GX-Series Processor Serial Packet	(
	Register	

Bit	Description
7	Video IRQ: This bit indicates the occurrence of a video vertical sync pulse. This bit is set at the same time that the VINT (Vertical Interrupt) bit gets set in the DC_TIMING_CFG register. The VINT bit has a corresponding enable bit (VIEN) in the DC_TIM_CFG register.
6	CPU Activity: This bit indicates the occurrence of a level 1 cache miss that was not a result of an instruction fetch. This bit has a corresponding enable bit in the PM_CNTL_TEN register.
5:2	Reserved
1	Programmable Address Decode: This bit indicates the occurrence of a programmable memory address decode. The bit is set based on the values of the PM_BASE register and the PM_MASK register. The PM_BASE register can be initialized to any address in the full CPU address range.
0	Video Decode: This bit indicates that the CPU has accessed either the display controller registers or the graphics memory region. This bit has a corresponding enable bit in the PM_CNTRL_TEN.

3.1.2.1 Video Retrace Interrupt

Bit 7 of the "Serial Packet" can be used to generate an SMI whenever a video retrace occurs within the processor. This function is normally not used for power management but for SoftVGA routines.

Setting F0 Index 83h[2] = 1 (bit details on page 163) enables this function. A read only status register located at F1BAR+Memory Offset 00h[5] (bit details on page 183) can be read to see if the SMI was caused by a video retrace event.

et4U.com

et4U.com

Functional Description (Continued)

3.2 PCI BUS INTERFACE

The PCI bus interface is compliant with the PCI Bus Specification Rev. 2.1.

The CS5530A acts as a PCI target for PCI cycles initiated by the processor or other PCI master devices, or as an initiator for DMA, ISA, IDE, and audio master transfer cycles. It supports positive decode for memory and I/O regions and is the subtractive decode agent on the PCI bus. The CS5530A also generates address and data parity and performs parity checking. A PCI bus arbiter is not part of the CS5530A; however, one is included in the GX-series processor.

The PCI Command Register, located at F0 Index 04h (Table 3-2), provides the basic control over the CS5530A's ability to respond and perform PCI bus accesses.

3.2.1 PCI Initiator

_

The CS5530A acts as a PCI bus master on behalf of the DMA controller or ISA, IDE, and audio interfaces. The REQ# and GNT# signals are used to arbitrate for the PCI bus.

Note: In a GX-series processor based system, the REQ#/GNT# signals of the CS5530A must connect to the REQ0#/GNT0# of the processor. This configuration ensures that the CS5530A is treated as a non-preemptable PCI master by the processor.

The CS5530A asserts REQ# in response to a bus mastering or DMA request for ownership of the PCI bus. GNT# is asserted by the PCI arbiter (i.e., processor) to indicate that access to the PCI bus has been granted to the CS5530A. The CS5530A then issues a grant to the DMA controller. This mechanism prevents any deadlock situations across the bridge. Once granted the PCI bus, the ISA master or DMA transfer commences.

If an ISA master executes an I/O access, that cycle remains on the ISA bus and is not forwarded to the PCI bus. The CS5530A performs only single transfers on the PCI bus for legacy DMA cycles.

Table 3-2. PCI Command Register

Bit	Description

Functional Description (Continued)

3.2.2 PCI Target

The CS5530A positively decodes PCI transactions intended for any internal registers, the ROM address range, and several peripheral and user-defined address ranges. For positive-decoded transactions, the CS5530A is a medium responder. Table 3-3 lists the valid C/BE# encoding for PCI target transactions.

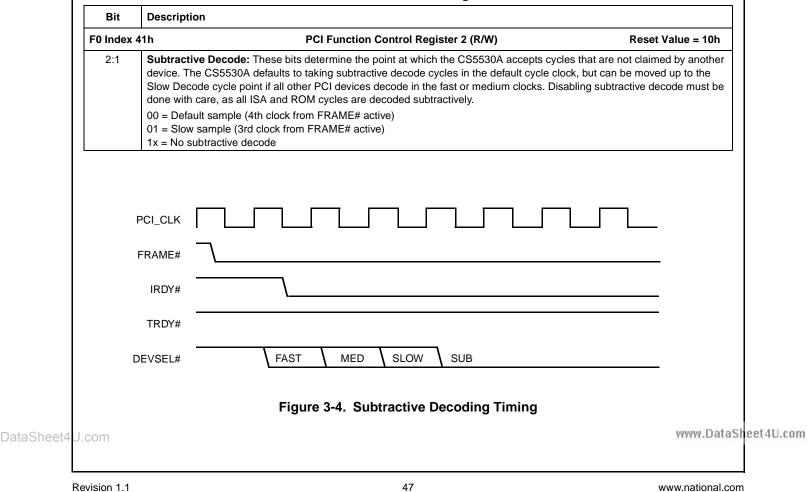

The CS5530A acts as the subtractive agent in the system since it contains the ISA bridge functionality. Subtractive decoding ensures that all accesses not positively claimed by PCI devices are forwarded to the ISA bus. The subtractive-decoding sample point can be configured as slow, default, or disabled via F0 Index 41h[2:1]. Table 3-4 shows these programming bits. Figure 3-4 shows the timing for subtractive decoding.

Note: I/O accesses that are mis-aligned so as to include address 0FFFFh and at least one byte beyond will "wrap" around to I/O address 0000h.

Table 3-3.	PCI Command	Encoding
------------	-------------	----------

C/BE[3:0]#	Command Type
0000	Interrupt Acknowledge

Functional Description (Continued)

3.2.3 Special Bus Cycles–Shutdown/Halt

The PCI interface does not pass Special Bus Cycles to the ISA interface, since special cycles by definition have no destination. However, the PCI interface monitors the PCI bus for Shutdown and Halt Special Bus Cycles.

Upon detection of a Shutdown Special Bus Cycle, a WM RST SMI is generated after a delay of three PCI clock cycles. PCI Shutdown Special Cycles are detected when C/BE[3:0]# = 0001 during the address phase and AD[31:0] = xxxx0000h during the data phase. C/BE[3:0]# are also properly asserted during the data phase.

Upon detection of a Halt Special Bus Cycle, the CS5530A completes the cycle by asserting TRDY#. PCI Halt Special Bus Cycles are detected when CBE[3:0]# = 0001 during the address phase and AD[31:0] = xxxx0001h during the data phase of a Halt cycle. CBE[3:0]# are also properly asserted during the data phase.

3.2.4 PCI Bus Parity

When the CS5530A is the PCI initiator, it generates address parity for read and write cycles. It checks data parity for read cycles and it generates data parity for write cycles. The PAR signal is an even-parity bit that is calculated across 36 bits of AD[31:0] plus C/BE[3:0]#.

By default, the CS5530A does not report parity errors. However, the CS5530A detects parity errors during the data phase if F0 Index 04h[6] is set to 1. If enabled and a data parity error is detected, the CS5530A asserts PERR#. It also asserts SERR# if F0 Index 41h[5] is set to 1. This allows NMI generation.

The CS5530A also detects parity errors during the address phase if F0 Index 04h[6] is set. When parity errors are detected during the address phase, SERR# is asserted internally. Parity errors are reported to the CPU by enabling the SERR# source in I/O Port 061h (Port B) control register. The CS5530A sets the corresponding error bits in the PCI Status Register (F0 Index 06h[15:14]). Table 3-5 shows these programming bits.

If the CS5530A is the PCI master for a cycle and detects PERR# asserted, it generates SERR# internally.

Table 3-5. PERR#/SERR# Associated Register Bits

	04h-05h	PCI Command Register (R/W)	Reset Value = 000Fh
6	Parity Error: Allow th	e CS5530A to check for parity errors on PCI cycles for which it is a ted. 0 = Disable (Default); 1 = Enable.

15	Detected Parity Erro Write 1 to clear.	r: This bit is set whenever a parity error is detected.	
14	Signaled System Err Write 1 to clear.	ror: This bit is set whenever the CS5530A asserts SERR# active.	
F0 Index	41h	PCI Function Control Register 2 (R/W)	Reset Value = 10h
5		R#: Assert SERR# any time that PERR# is asserted or detected a be cascaded to NMI (SMI) generation in the system). 0 = Disable;	

3.2.5 PCI Interrupt Routing Support

The CS5530A allows the PCI interrupt signals INTA#, INTB#, INTC#, and INTD# (also know in industry terms as PIRQx#) to be mapped internally to any IRQ signal via register programming (shown in Table 3-6). Further details are supplied in Section 3.5.4.4 "PCI Compatible Interrupts" on page 101 regarding edge/level sensitivity selection.

3.2.6 Delayed Transactions

The CS5530A supports delayed transactions to prevent slow PCI cycles from occupying too much bandwidth and allows access for other PCI traffic.

Note: For systems which have only the GX-series processor and CS5530A on the PCI bus, system performance is improved if delayed transactions are disabled.

F0 Index 42h[5] and F0 Index 43h[1] are used to program this function. Table 3-7 shows these bit formats.

Functional Description (Continued)

3.3 RESETS AND CLOCKS

The operations of resets and clocks in the CS5530A are described in this section of the Functional Description.

3.3.1 Resets

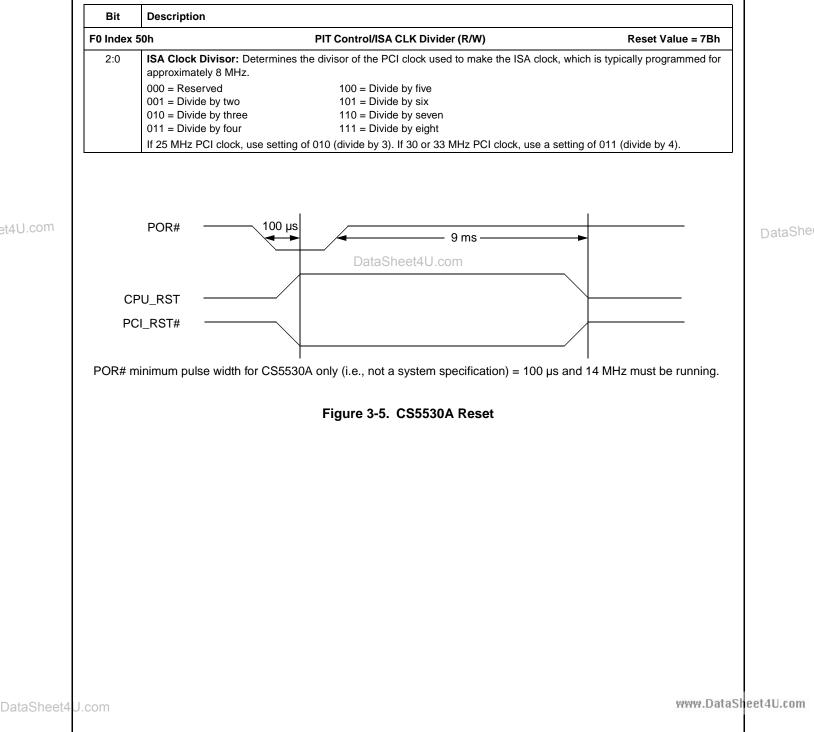

The CS5530A generates two reset signals, PCI_RST# to the PCI bus and CPU_RST to the GX-series processor. These resets are generated after approximately 100 μ s delay from POR# active as depicted in Figure 3-5.

At any state, Power-on/Resume/Reset, the 14.31818 MHz oscillator must be active for the resets to function.

3.3.2 ISA Clock

The CS5530A creates the ISACLK from dividing the PCI-CLK. For ISA compatibility, the ISACLK nominally runs at 8.33 MHz or less. The ISACLK dividers are programmed via F0 Index 50h[2:0] as shown in Table 3-8.

Table 3-8. ISACLK Divider Bits

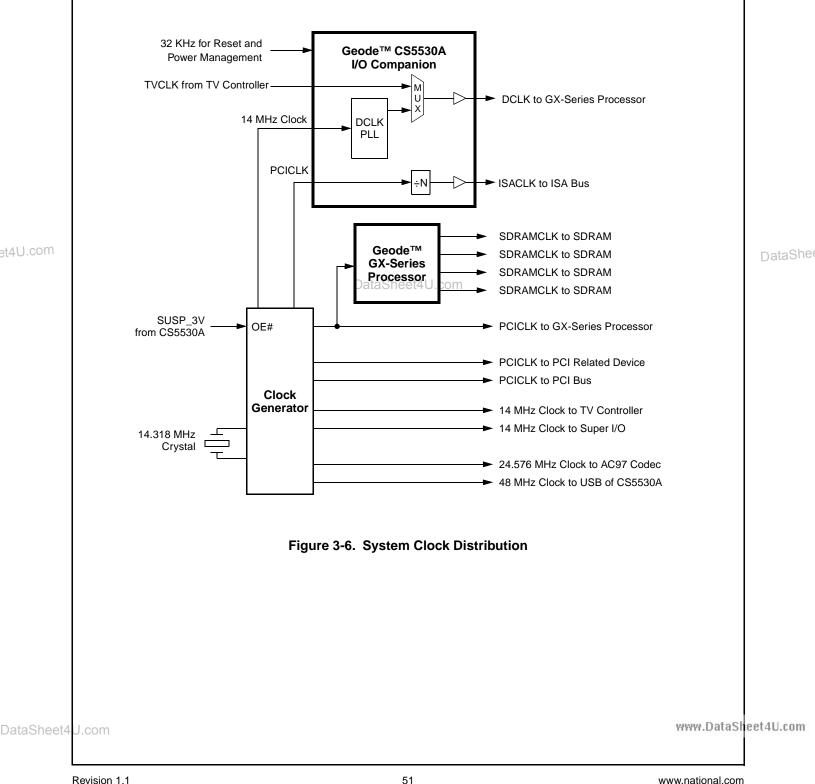

3.3.3 DOT Clock

The DOT clock (DCLK) is generated from the 14.31818 MHz input (CLK_14MHZ). A combination of a phase locked loop (PLL), linear feedback shift register (LFSR) and divisors are used to generate the desired frequencies for the DOT clock. The divisors and LFSR are configurable through the F4BAR+Memory Offset 24h. The minimum frequency of DCLK is 10 MHz and the maximum is 200 MHz.

However, system constraints limit DCLK to 150 MHz when DCLK is used as the graphics subsystem clock.

For applications that do not use the GX-series processor's graphics subsystem, this is an available clock for general purpose use.

The system clock distribution for a CS5530A/GX-series processor based system is shown in Figure 3-6.

Functional Description (Continued)

3.3.3.1 DCLK Programming

The PLL contains an input divider (ID), feedback divider (FD) and a post divider (PD). The programming of the dividers is through F4BAR+Memory Offset 24h (see Table 3-9 on page 53). The maximum output frequency is 300 MHz. The output frequency is given by equation #1:

Equation #1:

DCLK = [CLK_14MHZ * FD] ÷ [PD *ID]

Condition:

140 MHz < [DCLK * PD] < 300 MHz

Where:

CLK_14MHZ is pin P24 FD is derived from N see equation #2 and #3: PD is derived from bits [28:24] ID is derived from bits [2:0]

Equation #2:

If FD is an odd number then: $FD = 2^*N + 1$

Equation #3:

If FD is an even number then: $FD = 2^*N + 0$

Where:

N is derived from bits [22:12] +1 is achieved by setting bit 23 to 1. +0 is achieved by clearing bit 23 to 0.

Example

et4U.com

Define Target Frequency:

Target frequency = 135 MHz

Satisfy the "Condition":

(140 MHz < [DCLK * PD] < 300 MHz) 140 MHz < [135 MHz * 2] < 300 MHz Therefore PD = 2

Solve Equation #1:

DCLK = [CLK_14MHZ * FD] ÷ [PD *ID] 135 = [14.31818 * FD] ÷ [2 * ID] 135 = [7.159 * FD] ÷ ID 18.86 = FD ÷ ID Guess: ID = 7, Solve for FD FD = 132.02

Solve Equation #2 or #3:

FD = 2^*N +1 for odd FD FD = 2^*N +0 for even FD FD is 132, therefore even 132 = 2^*N +0 N = 66

Summarize:

 $\label{eq:pd} \begin{array}{l} \text{PD} = 2 \text{: Bits } [28{:}24] = 00111 \\ \text{ID} = 7 \text{: Bits } [2{:}0] = 101 \\ \text{N} = 66 \text{: Bits } [22{:}12] = 073 \text{h (found in Table 3-10), clear} \\ \text{bit } 23 \end{array}$

Result:

DCLK = 135

DataSheet4 J.com

The BIOS has been provided with a complete table of divisor values for supported graphics clock frequencies. Many combinations of divider values and VCO frequencies are possible to achieve a certain output clock frequency. These BIOS values may be adjusted from time to time to meet system frequency accuracy and jitter requirements. For applications that do not use the GX-series processor's graphics subsystem, this is an available clock for general purpose use.

The transition from one DCLK frequency to another is not guaranteed to be smooth or bounded; therefore, new divider coefficients should only be programmed while the PLL is off line in a situation where the transition characteristics of the clock are "don't care". The steps below describe (in order) how to change the DCLK frequency.

- 1) Program the new clock frequency.
- 2) Program Feedback Reset (bit 31) high and Bypass PLL (bit 8) high.
- 3) Wait at least 500 µs for PLL to settle.
- 4) Program Feedback Reset (bit 31) low.
- 5) Program Bypass PLL (bit 8) low.

3.4 POWER MANAGEMENT

The hardware resources provided by a combined CS5530A/GX-series processor based system support a full-featured power management implementation. The extent to which these resources are employed depends on the application and the discretion of the system designer.

Power management resources can be grouped according to the function they enable or support. The major functions are as follows:

- CPU Power Management
 - On
 - Active Idle
 - Suspend
 - 3 Volt Suspend
 - Off
 - Save-to-Disk/Save-to-RAM
 - Suspend Modulation
- APM Support
- Peripheral Power Management
 - Device Idle Timers and Traps
 - General Purpose Timers
 - ACPI Timer Register

- General Purpose I/O Pins
- Power Management SMI Status Reporting Registers
- Device Power Management Register Programming Summary

Included in the following subsections are details regarding entry Save-to-RAM the registers used for configuring power management features. The majority of these registers are directly accessed through the PCI configuration register space designated as Function 0 (F0). However, included in the discussions are references to F1BAR+Memory Offset 10h. This refers to

the registers accessed through a base address register in Function 1 (F1) at Index 10h (F1BAR). F1BAR sets the base address for the SMI status and ACPI timer support registers as shown in Table 3-11.

CPU Power Management 3.4.1

The three greatest power consumers in a system are the display, hard drive, and CPU. The power management of the first two is relatively straightforward and is discussed in Section 3.4.3 "Peripheral Power Management" on page 63. CPU power management is supported through several mechanisms resulting in five defined system power conditions:

- On
- Active Idle
- Suspend
- 3 Volt Suspend
- Off

There are also three derivative power conditions defined:

- Suspend Modulation
 - Combination of On and Suspend
- Save-to-Disk
 - Off with the ability to return back to the exact system condition without rebooting
- - Extreme 3 Volt Suspend with only the contents of RAM still powered

3.4.1.1 On

System is running and the CPU is actively executing code.

Table 3-11. Base Address Register (F1BAR) for SMI Status and ACPI Timer Support

F1 Index 10h-13h Base Address Register — F1BAR (R/W) Reset Value = 0000000 This register sets the base address of the memory mapped SMI status and ACPI timer related registers. Bits [7:0] are read only (00h indicating a 256-byte memory address range. Refer to Table 4-16 for the SMI status and ACPI timer registers bit formats and reset values. The upper 16 bytes are always mapped to the ACPI timer, and are always memory mapped. Geode[™] CS5530A

et4U.com

Functional Description (Continued)

3.4.1.2 Active Idle

This state is the most powerful power management state because it is an operational state. The CPU has executed a HLT instruction and has asserted the SUSPA# signal. The operating system has control of the entry of this state because the OS has either executed the HLT or made a BIOS call to indicate idle, and the BIOS executed the HLT instruction. The display refresh subsystem is still active but the CPU is not executing code. The clock is stopped to the processing core in this state and considerable power is saved in the processor. The CS5530A takes advantage of this power state by stopping the clock to some of the internal circuitry. This power saving mode can be enabled/disabled by programming F0 Index 96h[4] (see Table 3-12). The CS5530A can still make bus master requests for IDE, audio, USB, and ISA from this state. When the CS5530A or any other device on the PCI bus asserts REQ#, the CPU deasserts SUSPA# for the duration of REQ# activity. Once REQ# has gone inactive and all PCI cycles have stopped, the CPU reasserts SUSPA#. SUSPA# remains active until

the CPU receives an INTR or SMI event which ends the CPU halt condition.

3.4.1.3 Suspend

This state is similar to the Active Idle state except that the CPU enters this state because the CS5530A asserted SUSP#. The CS5530A deasserts SUSP# when an INTR or SMI event occurs. The Suspend Configuration register is shown in Table 3-12, however, also see the tables listed below for a more complete understanding on configuring the Suspend state.

- F0 Index BCh in Table 3-13 "Clock Stop Control Register" on page 57.
- Related registers in Table 3-14 "Suspend Modulation Related Registers" on page 59.

Table 3-12. Suspend Configuration Register

DataSheet4J.com

www.DataSheet4U.com

3.4.1.4 3 Volt Suspend

This state is a non-operational state. To enter this state the display must have been previously turned off. This state is usually used to put the system into a deep sleep to conserve power and still allow the user to resume where they left off.

The CS5530A supports the stopping of the CPU and system clocks for a 3 Volt Suspend state. If appropriately configured, via the Clock Stop Control Register (F0 Index BCh, see Table 3-13), the CS5530A asserts the SUSP_3V pin after it has gone through the SUSP#/SUSPA# handshake. The SUSP_3V pin is a state indicator, indicating that the system is in a low-activity state. This indicator can be used to put the system into a low-power state (the system clock can be turned off).

The SUSP_3V pin is intended to be connected to the output enable of a clock generator or buffer chip, so that the clocks to the CPU and the CS5530A (and most other system devices) are stopped. The CS5530A continues to decrement all of its device timers and respond to external SMI interrupts after the input clock has been stopped, as long as the 32 KHz clock continues to oscillate. Any SMI event or unmasked interrupt pin causes the CS5530A to deassert the SUSP_3V pin, restarting the system clocks. As the CPU or other device might include a PLL, the CS5530A holds SUSP# active for a pre-programmed period of delay (the PLL re-sync delay) that varies from 0 to 15 ms. After this period has expired, the CS5530A deasserts SUSP#, stopping Suspend. SMI# is held active for the entire period, so that the CPU reenters SMM when the clocks are restarted.

Note: The SUSP_3V pin can be active either high or low. The pin is an input during POR, and is sampled to determine its inactive state. This allows a designer to match the active state of SUSP_3V to the inactive state for a clock driver output enable with a pull-up or pull-down resistor.

3.4.1.5 Off

The system is off and there is no power being consumed by the processor or the CS5530A.

7:4 PLL Delay: The programmed value in this field sets the delay (in milliseconds) after a break event occurs before pin is deasserted to the CPU. This delay is designed to allow the clock chip and CPU PLL to stabilize before s tion. This delay is only invoked if the STP_CLK bit (bit 0) was set. The four-bit field allows values from 0 to 15 ms. 0000 = 0 ms 0100 = 4 ms 1000 = 8 ms 1100 = 12 ms 0001 = 1 ms 0101 = 5 ms 1001 = 9 ms 1101 = 13 ms 0010 = 2 ms 0111 = 6 ms 1011 = 10 ms 1111 = 15 ms 0111 = 3 ms 0111 = 7 ms 1011 = 11 ms 1111 = 15 ms 3:1 Reserved: Set to 0. 0 CPU Clock Stop: 0 = Normal SUSP#/ SUSPA# handshake; 1 = Full system Suspend. Note: This register configures the CS5530A to support a 3 Volt Suspend. Setting bit 0 causes the SUSP_3V pin to assert appropriate conditions, stopping the system clocks. A delay of 0 to 15 ms is programmable (bits 7:4) to allow for a clock chip and CPU PLL to stabilize when an event Resumes the system. A write to the CPU Suspend Command Register (F0 Index AEh) with bit 0 written as: 0 = SUSP#/SUSPA# handshake occurs. Functional Description (Continued)

3.4.1.6 Suspend Modulation

Suspend Modulation is a derivative of the On and Suspend states and works by asserting and de-asserting the SUSP# pin to the CPU for a configurable period and duty cycle. By modulating the SUSP# pin, an effective reduction in frequency is achieved. Suspend Modulation is the system power management choice of last resort. However, it is an excellent choice for thermal management. If the system is expected to operate in a thermal environment where the processor could overheat, then Suspend Modulation could be used to reduce power consumption in the overheated condition and thus reduce the processor's temperature.

When used as a power management state, Suspend Modulation works by assuming that the processor is idle unless external activity indicates otherwise. This approach effectively slows down the processor until external activity indicates a need to run at full speed, thereby reducing power consumption.

Suspend Modulation serves as the primary CPU power management mechanism when APM or some other power management software strategy is not present. It can also act as a backup for situations where the power management scheme does not correctly detect an Idle condition in the system.

In order to provide high-speed performance when needed, the SUSP# pin modulation can be temporarily disabled any time system activity is detected. When this happens, the processor is "instantly" converted to full speed for a programmed duration. System activities in the CS5530A are defined in hardware as: any unmasked IRQ, accessing Port 061h, SMI, and/or accessing the graphics controller. Since the graphics controller is integrated in the GX-series processor, the indication of graphics activity is sent to the CS5530A via the serial link (see Section 3.1.2 "PSERIAL Pin Interface" on page 45 for more information on serial link) and is automatically decoded. Graphics activity is defined as any access to the VGA register space, the VGA frame buffer, the graphics accelerator control registers and the configured graphics frame buffer.

The automatic speedup events (IRQ, SMI, and/or graphics) for Suspend Modulation should be used together with software-controlled speedup registers for major I/O events such as any access to the floppy disk controller, hard disk drive, or parallel/serial ports, since these are indications of major system activities. When major I/O events occur, Suspend Modulation can be temporarily disabled using the procedures described in the following subsections.

Bus master internal (Ultra DMA/33, Audio, USB, or ISA) or external requests do not directly affect the Suspend Modulation programming.

Configuring Suspend Modulation

Control of the Suspend Modulation feature is accomplished using the Suspend Modulation OFF Count Register, the Suspend Modulation ON Count Register, and the Suspend Configuration Register (F0 Index 94h, 95h, and 96h, respectively).

The Power Management Enable Register 1 (F0 Index 80h) contains the enables for the individual activity speedup timers.

Bit 0 of the Suspend Configuration Register (F0 Index 96h) enables the Suspend Modulation feature. Bit 1 controls how SMI events affect the Suspend Modulation feature. In general this bit should be set to a 1, which causes SMIs to disable Suspend Modulation until it is re-enabled by the SMI handler.

The Suspend Modulation OFF and ON Count Registers (F0 Index 94h and 95h) control two 8-bit counters that represent the number of 32 μ s intervals that the SUSP# pin is asserted and then deasserted to the processor. These counters define a ratio which is the effective frequency of operation of the system while Suspend Modulation is enabled.

$$F_{eff} = F_{GX86} x$$
 Off Count
On Count + Off Count

The IRQ and Video Speedup Timer Count registers (F0 Index 8Ch and 8Dh) configure the amount of time which Suspend Modulation is disabled when the respective events occur.

SMI Speedup Disable

If the Suspend Modulation feature is being used for CPU power management, the occurrence of an SMI disables the Suspend Modulation function so that the system operates at full speed while in SMM. There are two methods used to invoke this via bit 1 of the Suspend Configuration Register.

If F0 Index 96h[1] = 0: Use the IRQ Speedup Timer (F0 Index 8Ch) to temporarily disable Suspend Modulation when an SMI occurs.

If F0 Index 96h[1] = 1: Disable Suspend Modulation when an SMI occurs until a read to the SMI Speedup Disable Register (F1BAR+Memory Offset 08h).

The SMI Speedup Disable Register prevents VSA technology software from entering Suspend Modulation while operating in SMM. The data read from this register can be ignored. If the Suspend Modulation feature is disabled, reading this I/O location has no effect.

Table 3-14 shows the bit formats of the Suspend Modulation related registers

3.4.1.7 Save-to-Disk/Save-to-RAM

This is a derivative of the Off state. The processor and the CS5530A have the capability to save their complete state. This state information can be saved to a hard disk or to RAM and the system can be turned off. When powered back on, the system can be returned exactly back to the state it was in when the save process began. This means that the system does not have to be rebooted in the traditional sense. In both cases, precautions must be taken in the system design to make sure that there is sufficient space on the hard drive or RAM to store the information. In the case of the RAM, it must also be powered at all times and can not be corrupted when the system is powered off and back on.

The PC/AT compatible floppy port is not part of the CS5530A. If a floppy is attached on the ISA bus in a Superl/O or by some other means, some of the FDC registers are shadowed in the CS5530A because they cannot be safely read. The FDC registers are shown in Table 3-15. Additional shadow registers for other functions are described in:

- Table 3-40 "DMA Shadow Register" on page 96
- Table 3-42 "PIT Shadow Register" on page 98
- Table 3-45 "PIC Shadow Register" on page 100
- Table 3-53 "Real-Time Clock Registers" on page 107

Functional Description (Continued)

3.4.2 APM Support

Some IA systems rely solely on an APM (Advanced Power Management) driver for enabling the operating system to power-manage the CPU. APM provides several services which enhance the system power management and is theoretically the best approach; but in its current form, APM is imperfect for the following reasons:

- APM is an OS-specific driver, and may not be available for some operating systems.
- Application support is inconsistent. Some applications in foreground may prevent Idle calls.

• APM does not help with Suspend determination or peripheral power management.

The CS5530A provides two entry points for APM support:

- Software CPU Suspend control via the CPU Suspend Command Register (F0 Index AEh)
- Software SMI entry via the Software SMI Register (F0 Index D0h). This allows the APM BIOS to be part of the SMI handler.

These registers are shown in Table 3-16.

Bit	Description	
F0 Index	AEh CPU Suspend Command Register (WO)	Reset Value = 00h

Peripheral Power Management 3.4.3

The CS5530A provides peripheral power management using a combination of device idle timers, address traps, and general purpose I/O pins. Idle timers are used in conjunction with traps to support powering down peripheral devices. Eight programmable GPIO (general purpose I/O) pins are included for external device power control as well as other functions. All I/O addresses are decoded in 16 bits. All memory addresses are decoded in 32 bits.

3.4.3.1 **Device Idle Timers and Traps**

Idle timers are used to power manage a peripheral by determining when the peripheral has been inactive for a specified period of time, and removing power from the peripheral at the end of that time period.

Idle timers are provided for the commonly-used peripherals (FDC, IDE, parallel/serial ports, and mouse/keyboard). In addition, there are three user-defined timers that can be configured for either I/O or memory ranges. The Power Management enable bit (F0 Index 80h[1]) enables and disables the power management idle timers. The Trap bit in the same register (F0 Index 80h[2]) enables and disables device I/O traps.

The idle timers are 16-bit countdown timers with a 1 second time base, providing a time-out range of 1 to 65536 seconds (1092 minutes) (18 hours). General purpose timers can be programmed to count milliseconds instead of seconds (see Section 3.4.3.2 on page 73 for further information on general purpose timers).

When the idle timers are enabled, the timers are loaded from the timer count registers and start to decrement at the next timebase clock, but cannot trigger an interrupt on that cycle. If an idle timer is initially set to 1, it decrements to 0 on the first cycle and continues counting with 65535 on the next cycle. Starting at 2 gives 1 on the first cycle, and 0 on the second cycle, generating the interrupt. Since the timebase is one second, the minimum interval before the next interrupt from this timer is variable, from one to two seconds with a setting of two.

The idle timers continue to decrement until one of two possibilities occurs: a bus cycle occurs at that I/O or memory range, or the timer decrements to zero.

When a bus cycle occurs, the idle timer is reloaded with its starting value. It then continues to decrement.

When the timer decrements to zero, if power management is enabled (F0 Index 80h[0] = 1), the timer generates an SMI. (F0 Index 80h[0] = 0 does not disable these timers from running, but only from generating SMI.)

When an idle timer generates an SMI, the SMI handler manages the peripheral power, disables the timer, and enables the trap. The next time an event occurs, the trap generates an SMI. This time, the SMI handler applies power to the peripheral, enables the timer (thus reloading its starting value), and disables the trap.

Tables 3-17 through 3-25 show the device associated idle timers and traps programming bits.

Table 3-17. Power Management Global Enabling Bits Power Management Enable Register 1 (R/W) Reset Value = 00h Traps: Globally enable all power management device I/O traps. 0 = Disable; 1 = Enable. This excludes the audio I/O traps. They are enabled at F3BAR+Memory Offset 18h. Idle Timers: Globally enable all power management device idle timers. 0 = Disable; 1 = Enable. Note, disable at this level does not reload the timers on the enable. The timers are disabled at their current counts. This bit has no effect on the Suspend Modulation OFF/ON Timers (F0 Index 94h/95h), nor on the General Purpose (UDEFx) Timers (F0 Index 88h-8Bh). This bit must be set for the command to trigger the SUSP#/SUSPA# feature to function (see F0 **Power Management:** Global power management. 0 = Disable; 1 = Enabled. This bit must be set (1) immediately after POST for some power management resources to function. Until this is done, the

command to trigger the SUSP#/SUSPA# feature is disabled (see F0 Index AEh) and all SMI# trigger events listed for F0 Index 84h-87h are disabled. A '0' in this bit does NOT stop the Idle Timers if bit 1 of this register is a '1', but only prevents

them from generating an SMI# interrupt. It also has no effect on the UDEF traps.

General Purpose Timers 3.4.3.2

The CS5530A contains two general purpose timers, General Purpose Timer 1 (F0 Index 88h) and General Purpose Timer 2 (F0 Index 8Ah). These two timers are similar to the Device Idle Timers in that they count down to zero unless re-triggered, and generate an SMI when they reach zero. However, these are 8-bit timers instead of 16 bits, they have a programmable timebase, they are not enabled or disabled by Global Power Management bits F0 Index 80h[1:0], and the events which reload these timers are configurable. These timers are typically used for an indication of system inactivity for Suspend determination.

General Purpose Timer 1 can be re-triggered by activity to any of the configured user defined devices, keyboard and mouse, parallel and serial, floppy disk, or hard disk.

General Purpose Timer 2 can be re-triggered by a transition on the GPIO7 pin (if GPIO7 is properly configured). Configuration of the GPIO7 is explained in Section 3.4.3.4 "General Purpose I/O Pins" on page 76.

The timebase for both general purpose timers can be configured as either 1 second (default) or 1 millisecond. The registers at F0 Index 89h and 8Bh are the control registers for the general purpose timers. Table 3-28 show the bit formats for these registers.

After a general purpose timer is enabled or after an event reloads the timer, the timer is loaded with the configured count value. Upon expiration of the timer an SMI is generated and a status flag is set. Once expired, this timer must be re-initialized by disabling and enabling it.

The general purpose timer is not loaded immediately, but when the free-running timebase counter reaches its maximum value. Depending on the count at the time, this could be on the next 32 KHz clock (CLK_32K), or after a full count of 32, or 32,768 clocks (approximately 1 msec, or exactly 1 sec). The general purpose timer cannot trigger an interrupt until after the first count. Thus, the minimum time before the next SMI from the timer can be either from 1-2 msec or 1-2 sec with a setting of 02h.

Bit	Description

3.4.3.3 ACPI Timer Register

The ACPI Timer Count Register (F1BAR+Memory Offset 1Ch or a fixed I/O Port at 121Ch) provides the current value of the ACPI timer. The timer counts at 14.31818/4 MHz (3.579545 MHz). If SMI generation is enabled (F0 Index 83h[5] = 1), an SMI is generated when bit 23 toggles. Table 3-29 shows the ACPI Timer Count Register and the ACPI Timer SMI enable bit.

V-ACPI I/O Register Space

Description

Rit

The register space designated as V-ACPI (Virtualized ACPI) I/O does not physically exist in the CS5530A. ACPI is supported in the CS5530A by virtualizing this register space. In order for ACPI to be supported, the V-ACPI module must be included in the BIOS. The register descriptions that follow are supplied here for reference only.

Fixed Feature space registers are required to be implemented by all ACPI-compatible hardware. The Fixed Feature registers in the V-ACPI solution are mapped to normal I/O space starting at Offset AC00h. However, the designer can relocate this register space at compile time, hereafter referred to as ACPI_BASE. Registers within the V-ACPI I/O space must only be accessed on their defined boundaries. For example, BYTE aligned registers must not be accessed via WORD I/O instructions, WORD aligned registers must not be accessed as DWORD I/O instructions, etc.

Table 3-29 summarizes the registers available in the V-ACPI I/O Register Space. The "Reference" column gives the table and page number where the bit formats for the registers are located.

Functional Description (Continued)

3.4.3.4 General Purpose I/O Pins

The CS5530A provides up to eight GPIO (general purpose I/O) pins. Five of the pins (GPIO[7:4] and GPIO1) have alternate functions. Table 3-31 shows the bits used for GPIO pin function selection.

Each GPIO pin can be configured as an input or output. GPIO[7:0] can be independently configured to act as edgesensitive SMI events. Each pin can be enabled and configured to be either positive-edge sensitive or negative-edge sensitive. These pins then cause an SMI to be generated when an appropriate edge condition is detected. The power management status registers indicate that a GPIO external SMI event has occurred.

The GPIO Pin Direction Register 1 (F0 Index 90h) selects whether the GPIO pin is an input or output. The GPIO Pin

Data Register 1 (F0 Index 91h) contains the direct values of the GPIO pins. Write operations are valid only for bits defined as outputs. Reads from this register read the last written value if the pin is an output.

GPIO Control Register 1 (F0 Index 92h) configures the operation of the GPIO pins for their various alternate functions. Bits [5:3] set the edge sensitivity for generating an SMI on the GPIO[2:0] (input) pins respectively. Bits [2:0] enable the generation of an SMI. Bit 6 enables GPIO6 to act as the lid switch input. Bit 7 determines which edge transition will cause General Purpose Timer 2 (F0 Index 8Ah) to reload.

Table 3-32 shows the bit formats for the GPIO pin configuration and control registers.

6	GPIO6 Enabled as Lid Switch: Allow GPIO6 to act as the lid switch input. 0 = GPIO6; 1 = Lid switch.
	When enabled, every transition of the GPIO6 pin causes the lid switch status to toggle and generate an SMI.
	The top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 87h/F7h[3].
	If GPIO6 is enabled as the lid switch, F0 Index 87h/F7h[4] reports the current status of the lid's position.
5	GPIO2 Edge Sense for SMI: Selects which edge transition of the GPIO2 pin generates an SMI. 0 = Rising; 1 = Falling. Bit 2 must be set to enable this bit.
4	GPIO1 Edge Sense for SMI: Selects which edge transition of the GPIO1 pin generates an SMI. 0 = Rising; 1 = Falling.
	Bit 1 must be set to enable this bit.
3	GPIO0 Edge Sense for SMI: Selects which edge transition of the GPIO0 pin generates an SMI. 0 = Rising; 1 = Falling.
-	Bit 1 must be set to enable this bit.
2	Enable GPIO2 as an External SMI Source: Allow GPIO2 to be an external SMI source and generate an SMI on either a rising or falling edge transition (depends upon setting of bit 5). 0 = Disable; 1 = Enable (Note 3). Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[7].
1	Enable GPIO1 as an External SMI Source: Allow GPIO1 to be an external SMI source and generate an SMI on either a rising- or falling-edge transition (depends upon setting of bit 4). 0 = Disable; 1 = Enable (Note 3).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[6].
0	Enable GPIO0 as an External SMI Source: Allow GPIO0 to be an external SMI source and generate an SMI on either a
	rising or falling edge transition (depends upon setting of bit 3). 0 = Disable; 1 = Enable (Note 3)
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[5].
Notes: 1)	For any of the above bits to function properly, the respective GPIO pin must be configured as an input (F0 Index 90h).
2)	GPIO7 can generate an SMI (F0 Index 97h[3]) or re-trigger General Purpose Timer 2 (F0 Index 8Bh[2]) or both.
3)	If GPIO[2:0] are enabled as external SMI sources, they are the only GPIOs that can be used as SMI sources to wake-up the
	system from Suspend when the clocks are stopped.

The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPI03 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPI03 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPI0 pin must be enab	4		e port (I/O Port 200h and 201h)?
Game Port Read SMI generation enabling is at F0 Index 83h[4]. Game Port Write SMI generation enabling is at F0 Index 53h[3]. 3 GPIO7 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO7 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[3]. 2 GPIO5 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO5 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. 1 GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. 1 GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. 0 GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Of			+Memory Offset 00h/02h[0].
 GPIO7 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO7 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[3]. GPIO5 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO5 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPIO pin must be enabled as a GPIO, an input, and to cause an SMI. This register provides status on various power-management SMI events. Reading this register clears the SMI status bits. only (mirror) version of this register exists at F0 Index 84h. 			,
 This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[3]. GPIO5 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO5 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPIO pin must be enabled as a GPIO, an input, and to cause an SMI. This register provides status on various power-management SMI events. Reading this register clears the SMI status bits. only (mirror) version of this register exists at F0 Index 84h. 		Game Port Write SMI generation enabling is at F0 Index 53h[3].	
SMI generation enabling is at F0 Index 97h[3]. GPIO5 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO5 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPIO pin must be enabled as a GPIO, an input, and to cause an SMI. This register provides status on various power-management SMI events. Reading this register clears the SMI status bits. only (mirror) version of this register exists at F0 Index 84h.	3		
 2 GPIO5 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO5 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. 1 GPIO4 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO4 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPIO3 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPIO3 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPIO pin must be enabled as a GPIO, an input, and to cause an SMI. This register provides status on various power-management SMI events. Reading this register clears the SMI status bits. only (mirror) version of this register exists at F0 Index 84h. 			+Memory Offset 00h/02h[0].
This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[2]. I GPI04 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPI04 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPI03 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPI03 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[1]. 0 GPI03 SMI Status (Read to Clear): SMI was caused by transition on (properly-configured) GPI03 pin? 0 = No; 1 = This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 97h[0]. Note: Properly-configured means that the GPIO pin must be enabled as a GPIO, an input, and to cause an SMI. This register provides status on various power-management SMI events. Reading this register clears the SMI status bits. only (mirror) version of this register exists at F0 Index 84h.

Functional Description (Continued)	
------------------------------------	--

Table 3-34. Second Level Pwr Mgmnt SMI Status Reporting Registers (Read to Clear) (Continued)

Bit	Description
F0 Index F	Sh Second Level Power Management Status Register 2 (RC) Reset Value = 00h
7	Video Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the Video Idle Timer Count Register (F0 Index A6h)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[7].
6	User Defined Device 3 (UDEF3) Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the UDEF3 Idle Timer Count Register (F0 Index A4h)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0]. SMI generation enabling is at F0 Index 81h[6].
5	User Defined Device 2 (UDEF2) Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the UDEF2 Idle Timer Count Register (F0 Index A2h)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[5].
4	User Defined Device 1 (UDEF1) Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the UDEF1 Idle Timer Count Register (F0 Index A0h)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[4].
3	Keyboard/Mouse Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the Keyboard/Mouse Idle Timer Count Register (F0 Index 9Eh)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[3].
2	Parallel/Serial Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the Parallel/Serial Port Idle Timer Count Register (F0 Index 9Ch)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[2] ataSheet4U.com
1	Floppy Disk Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the Floppy Disk Idle Timer Count Register (F0 Index 9Ah)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[1].
0	Primary Hard Disk Idle Timer SMI Status (Read to Clear): SMI was caused by expiration of the Primary Hard Disk Idle Timer Count Register (F0 Index 98h)? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported in F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 81h[0].
dura bits	register provides status on the Device Idle Timers to the SMI handler. A bit set here indicates that the device was idle for the ation configured in the Idle Timer Count register for that device, causing an SMI. Reading this register clears the SMI status A read-only (mirror) version of this register exists at F0 Index 85h. If the value of the register must be read without clearing SMI source (and consequently deasserting SMI), F0 Index 85h may be read instead.

3.5 PC/AT COMPATIBILITY LOGIC

The CS5530A's PC/AT compatibility logic provides support for the standard PC architecture. This subsystem also provides legacy support for existing hardware and software. Support functions for the GX-series processor provided by these subsystems include:

- ISA Subtractive Decode
- ISA Bus Interface
- Delayed PCI Transactions
- Limited ISA and ISA Master Modes
- ROM Interface
- Megacells

Rit

- Direct Memory Access (DMA)
- Programmable Interval Timer
- Programmable Interrupt Controller
- PCI Compatible Interrupts

Description

- I/O Ports 092h and 061h System Control
 I/O Port 092h System Control
 - I/O Port 061h System Control

 - SMI Generation for NMI
- Keyboard Interface Function
 Fast Keyboard Gate Address 20 and CPU Reset
- External Real-Time Clock Interface

The following subsections give a detailed description for each of these functions.

3.5.1 ISA Subtractive Decode

The CS5530A provides an ISA bus controller. The CS5530A is the default subtractive-decoding agent, and forwards all unclaimed memory and I/O cycles to the ISA interface. For reads and writes in the first 1 MB of memory (i.e., A23:A20 set to 0), MEMR# or MEMW# respectively will be asserted. However, the CS5530A can be configured using F0 Index 04h[1:0] to ignore either I/O, memory, or all unclaimed cycles (subtractive decode disabled, F0 Index 41h[2:1] = 1x). Table 3-36 shows these programming bits.

Table 3-36. Cycle Configuration Bits

Functional Description (Continued)

3.5.2 ISA Bus Interface

The ISA bus controller issues multiple ISA cycles to satisfy PCI transactions that are larger than 16 bits. A full 32-bit read or write results in two 16-bit ISA transactions or four 8bit ISA transactions. The ISA controller gathers the data from multiple ISA read cycles and returns TRDY# only after all of the data can be presented to the PCI bus at the same time. SA[23:0] are a concatenation of ISA LA[23:17] and SA[19:0] and perform equivalent functionality at a reduced pin count.

Figure 3-8 shows the relationship between a PCI cycle and the corresponding ISA cycle generated.

DataSheet4 J.com

et4U.com

Functional Description (Continued)

3.5.2.2 Limited ISA and ISA Master Modes

The CS5530A supports two modes on the ISA interface. The default mode of the ISA bus is a fully functional ISA mode, but it does not support ISA masters, as shown in Figure 3-10 "Limited ISA Mode". When in this mode, the address and data buses are multiplexed together, requiring an external latch to latch the lower 16 bits of address of the ISA cycle. The signal SA_LATCH is generated when the data on the SA/SD bus is a valid address. Additionally, the upper four address bits, SA[23:20], are multiplexed on GPI0[7:4].

The second mode of the ISA interface supports ISA bus masters, as shown in Figure 3-11. When the CS5530A is placed in the ISA Master mode, a large number of pins are redefined as shown in Table 3-37.

In this mode of operation, the CS5530A cannot support TFT flat panels or TV controllers, since most of the signals used to support these functions have been redefined. This mode is required if ISA slots or ISA masters are used. ISA master cycles are only passed to the PCI bus if they access memory. I/O accesses are left to complete on the ISA bus.

The mode of operation is selected by the strapping of pin P26 (INTR):

- ISA Limited Mode Strap pin P26 (INTR) low through a 10-kohm resistor.
- ISA Master Mode Strap pin P26 (INTR) high through a 10-kohm resistor.

F0 Index 44h[7] (bit details on page 156) reports the strap value of the INTR pin (pin P26) during POR: 0 = ISA Limited; 1 = ISA Master.

This bit can be written after POR# deassertion to change the ISA mode selected. Writing to this bit is not recommended due to the actual strapping done on the board.

ISA memory and ISA refresh cycles are not supported by the CS5530A, although, the refresh toggle bit in I/O Port 061h still exists for software compatibility reasons.

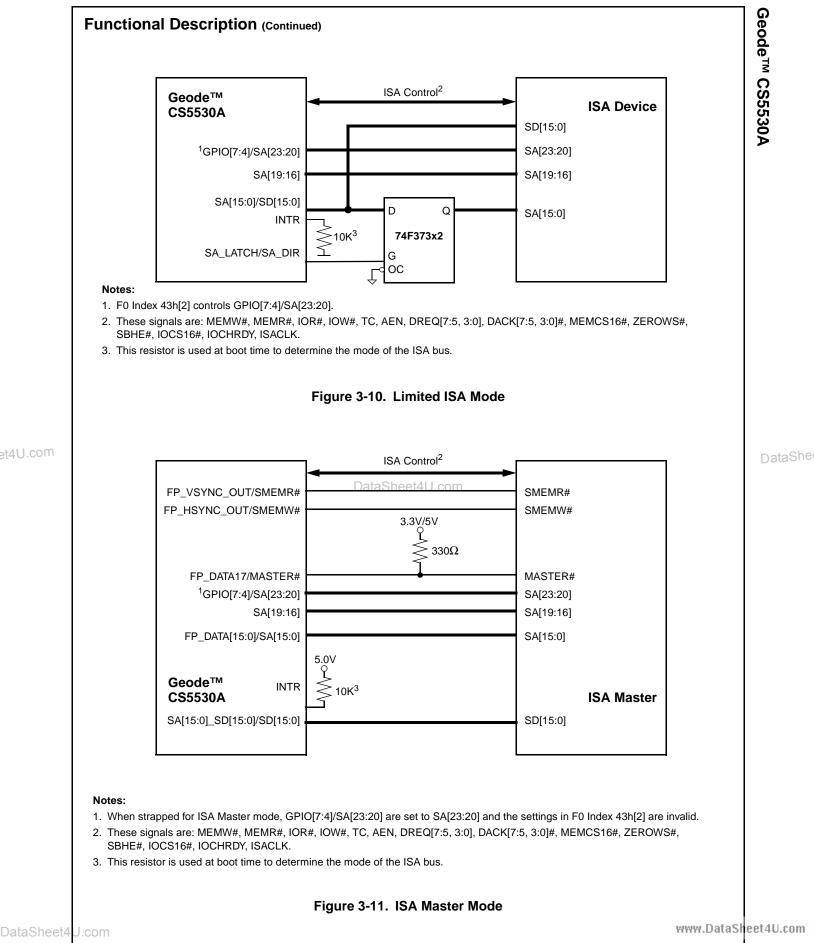

Table 3-37.	Signal	Assignments

Revision 1.1

et4U.com

Functional Description (Continued)

3.5.2.3 ISA Bus Data Steering

The CS5530A performs all of the required data steering from SD[7:0] to SD[15:0] during normal 8-bit ISA cycles, as well as during DMA and ISA master cycles. It handles data transfers between the 32-bit PCI data bus and the ISA bus. 8/16-bit devices can reside on the ISA bus. Various PCcompatible I/O registers, DMA controller registers, interrupt controller registers, and count registers (for loading timers) lie on the on-chip I/O data bus. Either the PCI bus master or the DMA controllers can become the bus owner.

When the PCI bus master is the bus owner, the CS5530A data steering logic provides data conversion necessary for 8/16/32-bit transfers to and from 8/16-bit devices on either the ISA bus or the 8-bit registers on the on-chip I/O data bus. When PCI data bus drivers of the CS5530A are tristated, data transfers between the PCI bus master and PCI bus devices are handled directly via the PCI data bus.

When the DMA requestor is the bus owner, the CS5530A allows 8/16-bit data transfer between the ISA bus and the PCI data bus.

3.5.2.4 I/O Recovery Delays

In normal operation, the CS5530A inserts a delay between back-to-back ISA I/O cycles that originate on the PCI bus. The default delay is four ISACLK cycles. Thus, the second of consecutive I/O cycles is held in the ISA bus controller until this delay count has expired. The delay is measured between the rising edge of IOR#/IOW# and the falling edge of BALE. This delay can be adjusted to a greater delay through the ISA I/O Recovery Control Register (F0 Index 51h, see Table 3-38).

Note: This delay is not inserted for a 16-bit ISA I/O access that is split into two 8-bit I/O accesses.

Bit	Description

Table 3-38. I/O Recovery Programming Register

DataSheet4J.com

www.DataSheet4U.com

3.5.2.5 ISA DMA

DMA transfers occur between ISA I/O peripherals and system memory. The data width can be either 8 or 16 bits. Out of the seven DMA channels available, four are used for 8bit transfers while the remaining three are used for 16-bit transfers. One BYTE or WORD is transferred in each DMA cycle.

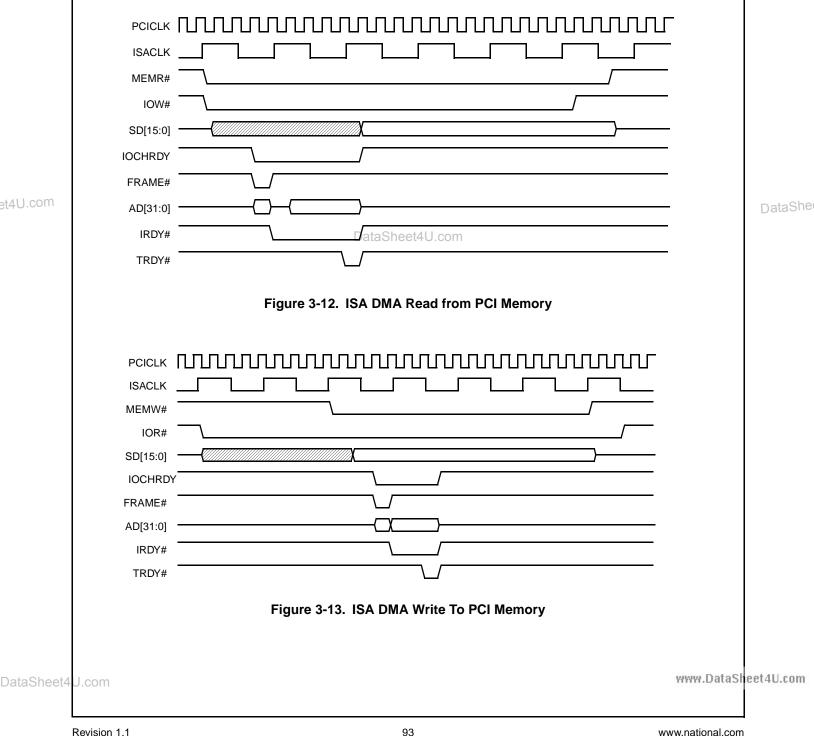

Note: The CS5530A does not support DMA transfers to ISA memory.

The ISA DMA device initiates a DMA request by asserting one of the DRQ[7:5, 3:0] signals. When the CS5530A receives this request, it sends a bus grant request to the

PCI arbiter. After the PCI bus has been granted, the respective DACK# is driven active.

Geode[™] CS5530A

The CS5530A generates PCI memory read or write cycles in response to a DMA cycle. Figures 3-12 and 3-13 are examples of DMA memory read and memory write cycles. Upon detection of the DMA controller's MEMR# or MEMW# active, the CS5530A starts the PCI cycle, asserts FRAME#, and negates an internal IOCHRDY. This assures the DMA cycle does not complete before the PCI cycle has provided or accepted the data. IOCHRDY is internally asserted when IRDY# and TRDY# are sampled active.

Functional Description (Continued)

3.5.3 ROM Interface

The CS5530A positively decodes memory addresses 000F0000h-000FFFFFh (64 KB) and FFFC0000h-FFFFFFFh (256 KB) at reset. These memory cycles cause the CS5530A to claim the cycle, and generate an ISA bus memory cycle with KBROMCS# asserted. The CS5530A can also be configured to respond to memory addresses FF000000h-FFFFFFFFh (16 MB) and 000E0000h-000FFFFFh (128 KB).

Flash ROM is supported in the CS5530A by enabling the KBROMCS# signal on write accesses to the ROM region. Normally only read cycles are passed to the ISA bus, and the KBROMCS# signal is suppressed. When the ROM Write Enable bit (F0 Index 52h[1]) is set, a write access to the ROM address region causes an 8-bit write cycle to occur with MEMW# and KBROMCS# asserted. Table 3-39 shows the ROM interface related programming bits.

3.5.4 Megacells

The CS5530A core logic integrates:

- Two 8237-equivalent DMA controllers (DMAC) with full 32-bit addressing for DMA transfers.
- Two 8259-equivalent interrupt controllers providing 13 individually programmable external interrupts.
- An 8254-equivalent timer for refresh, timer, and speaker logic.
- NMI control and generation for PCI system errors and all parity errors.
- Support for standard AT keyboard controllers, reset control, and VSA technology audio.

Functional Description (Continued)

3.5.4.1 Direct Memory Access (DMA)

The 8237-compatible DMA controllers in the CS5530A control transfers between ISA I/O devices and system memory. They generate a bus request to the PCI bus when an I/O device requests a DMA operation. Once they are granted the bus, the DMA transfer cycle occurs. DMA transfers can occur over the entire 32-bit address range of the PCI bus. Software DMA is not supported.

The CS5530A contains registers for driving the high address bits (high page) and registers for generating the middle address bits (low page) output by the 8237 controller.

DMA Controllers

The CS5530A supports seven DMA channels using two standard 8237-equivalent controllers. DMA Controller 1 contains Channels 0 through 3 and supports 8-bit I/O adapters. These channels are used to transfer data between 8-bit peripherals and PCI memory or 8/16-bit ISA memory. Using the high and low page address registers, a full 32-bit PCI address is output for each channel so they can all transfer data throughout the entire 4 GB system address space. Each channel can transfer data in 64 KB pages.

DMA Controller 2 contains Channels 4 through 7. Channel 4 is used to cascade DMA Controller 1, so it is not available externally. Channels 5 through 7 support 16-bit I/O adapters to transfer data between 16-bit I/O adapters and 16-bit system memory. Using the high and low page address registers, a full 32-bit PCI address is output for each channel so they can all transfer data throughout the entire 4 GB system address space. Each channel can transfer data in 128 KB pages. Channels 5, 6, and 7 transfer 16-bit WORDs on even byte boundaries only.

DMA Transfer Modes

Each DMA channel can be programmed for single, block, demand or cascade transfer modes. In the most commonly used mode, single transfer mode, one DMA cycle occurs per DRQ and the PCI bus is released after every cycle. This allows the CS5530A to timeshare the PCI bus with the CPU. This is imperative, especially in cases involving large data transfers, so that the CPU does not get locked out for too long.

In block transfer mode, the DMA controller executes all of its transfers consecutively without releasing the PCI bus.

In demand transfer mode, DMA transfer cycles continue to occur as long as DRQ is high or terminal count is not reached. In this mode, the DMA controller continues to execute transfer cycles until the I/O device drops DRQ to indicate its inability to continue providing data. For this case, the PCI bus is held by the CS5530A until a break in the transfers occurs.

In cascade mode, the channel is connected to another DMA controller or to an ISA bus master, rather than to an I/O device. In the CS5530A, one of the 8237 controllers is designated as the master and the other as the slave. The HOLD output of the slave is tied to the DRQ0 input of the

master (Channel 4), and the master's DACK0# output is tied to the slave's HLDA input.

In each of these modes, the DMA controller can be programmed for read, write, or verify transfers.

Both DMA controllers are reset at Power On Reset (POR) to fixed priority. Since master Channel 0 is actually connected to the slave DMA controller, the slave's four DMA channels have the highest priority, with Channel 0 as highest and Channel 3 as the lowest. Immediately following slave Channel 3, master Channel 1 (Channel 5) is the next highest, followed by Channels 6 and 7.

DMA Controller Registers

The DMA controller can be programmed with standard I/O cycles to the standard register space for DMA. The I/O addresses of all registers for the DMA controller are listed in Table 4-27 "DMA Channel Control Registers" on page 220.

Addresses under Master are for the 16-bit DMA channels, and Slave corresponds to the 8-bit channels. When writing to a channel's address or word-count register, the data is written into both the base register and the current register simultaneously. When reading a channel address or word count register, only the current address or word count can be read. The base address and base word count are not accessible for reading.

DMA Transfer Types

Each of the seven DMA channels may be programmed to perform one of three types of transfers: read, write, or verify. The transfer type selected defines the method used to transfer a BYTE or WORD during one DMA bus cycle.

For read transfer types, the CS5530A reads data from memory and writes it to the I/O device associated with the DMA channel.

For write transfer types, the CS5530A reads data from the I/O device associated with the DMA channel and writes to the memory.

The verify transfer type causes the CS5530A to execute DMA transfer bus cycles, including generation of memory addresses, but neither the Read nor Write command lines are activated. This transfer type was used by DMA Channel 0 to implement DRAM refresh in the original IBM PC/XT.

DMA Priority

The DMA controller may be programmed for two types of priority schemes: fixed and rotate (I/O Ports 008h[4] and 0D0h[4]), as shown in Table 4-27 "DMA Channel Control Registers" on page 220.

In fixed priority, the channels are fixed in priority order based on the descending values of their numbers. Thus, Channel 0 has the highest priority. In rotate priority, the last channel to get service becomes the lowest-priority channel with the priority of the others rotating accordingly. This prevents a channel from dominating the system.

www.DataSheet4U.com

et4U.com

The address and word count registers for each channel are 16-bit registers. The value on the data bus is written into the upper byte or lower byte, depending on the state of the internal addressing byte pointer. This pointer can be cleared by the Clear Byte Pointer command. After this command, the first read/write to an address or word count register will read/write to the low byte of the 16-bit register and the byte pointer will point to the high byte. The next read/write to an address or word-count register will read or write to the high byte of the 16-bit register and the byte pointer will point back to the low byte.

When programming the 16-bit channels (Channels 5, 6, and 7), the address which is written to the base address register must be the real address divided by two. Also, the base word count for the 16-bit channels is the number of 16-bit WORDs to be transferred, not the number of bytes as is the case for the 8-bit channels.

The DMA controller allows the user to program the active level (low or high) of the DRQ and DACK# signals. Since the two controllers are cascaded together internally on the chip, these signals should always be programmed with the DRQ signal active high and the DACK# signal active low.

DMA Shadow Registers

The CS5530A contains a shadow register located at F0 Index B8h (Table 3-40) for reading the configuration of the DMA controllers. This read-only register can sequence to read through all of the DMA registers.

DMA Addressing Capability

DMA transfers occur over the entire 32-bit address range of the PCI bus. This is accomplished by using the DMA controller's 16-bit memory address registers in conjunction with an 8-bit DMA Low Page register and an 8-bit DMA High Page register. These registers, associated with each channel, provide the 32-bit memory address capability. A write to the Low Page register clears the High Page register, for backward compatibility with the PC/AT standard. The starting address for the DMA transfer must be programmed into the DMA controller registers and the channel's respective Low and High Page registers prior to beginning the DMA transfer.

DMA Page Registers and Extended Addressing

The DMA Page registers provide the upper address bits during DMA cycles. DMA addresses do not increment or decrement across page boundaries. Page boundaries for the 8-bit channels (Channels 0 through 3) are every 64 KB and page boundaries for the 16-bit channels (Channels 5, 6, and 7) are every 128 KB.

Before any DMA operations are performed, the Page Registers must be written at the I/O Port addresses shown in Table 4-28 "DMA Page Registers" on page 223 to select the correct page for each DMA channel. The other address locations between 080h and 08Fh and 480h and 48Fh are not used by the DMA channels, but can be read or written by a PCI bus master. These registers are reset to zero at POR. A write to the Low Page register clears the High Page register, for backward compatibility with the PC/AT standard.

For most DMA transfers, the High Page register is set to zeros and is driven onto PCI address bits AD[31:24] during DMA cycles. This mode is backward compatible with the PC/AT standard. For DMA extended transfers, the High Page register is programmed and the values are driven onto the PCI addresses AD[31:24] during DMA cycles to allow access to the full 4 GB PCI address space.

DataSheet DMA Address Generation

The DMA addresses are formed such that there is an upper address, a middle address, and a lower address portion.

The upper address portion, which selects a specific page, is generated by the Page registers. The Page registers for each channel must be set up by the system before a DMA operation. The DMA Page register values are driven on PCI address bits AD[31:16] for 8-bit channels and AD[31:17] for 16-bit channels.

DataShe

et4U.com

The middle address portion, which selects a block within the page, is generated by the DMA controller at the beginning of a DMA operation and any time the DMA address increments or decrements through a block boundary. Block sizes are 256 bytes for 8-bit channels (Channels 0 through 3) and 512 bytes for 16-bit channels (Channels 5, 6, and 7). The middle address bits are driven on PCI address bits AD[15:8] for 8-bit channels and AD[16:9] for 16-bit channels

The lower address portion is generated directly by the DMA controller during DMA operations. The lower address bits are output on PCI address bits AD[7:0] for 8-bit channels and AD[8:1] for 16-bit channels.

SBHE# is configured as an output during all DMA operations. It is driven as the inversion of AD0 during 8-bit DMA cycles and forced low for all 16-bit DMA cycles.

3.5.4.2 Programmable Interval Timer

The CS5530A contains an 8254-equivalent Programmable Interval Timer (PIT) configured as shown in Figure 3-14. The PIT has three timers/counters, each with an input frequency of 1.19318 MHz (OSC divided by 12), and individually programmable to different modes.

Geode[™] CS5530A

The gates of Counter 0 and 1 are usually enabled, however, they can be controlled via F0 Index 50h (see Table 3-41). The gate of Counter 2 is connected to I/O Port 061h[0]. The output of Counter 0 is connected internally to IRQ0. This timer is typically configured in Mode 3 (square wave output), and used to generate IRQ0 at a periodic rate to be used as a system timer function. The output of Counter 1 is connected to I/O Port 061h[4]. The reset state of I/O Port 061h[4] is 0 and every falling edge of Counter 1 output causes I/O Port 061h[4] to flip states. The output of Counter 2 is brought out to the PC_BEEP output. This output is gated with I/O Port 061h[1].

Functional Description (Continued)

PIT Registers

The PIT registers are summarized and bit formats are in Table 4-29 "Programmable Interval Timer Registers" on page 224.

PIT Shadow Register

The PIT registers are shadowed to allow for Save-to-Disk/RAM to save/restore the PIT state by reading the PIT's counter and write-only registers. The read sequence for the shadow register is listed in F0 Index BAh, Table 3-42.

3.5.4.3 Programmable Interrupt Controller

The CS5530A includes an AT-compatible Programmable Interrupt Controller (PIC) configuration with two 8259equivalent interrupt controllers in a master/slave configuration (Figure 3-15). These PIC devices support all x86 modes of operation except Special Fully Nested Mode.

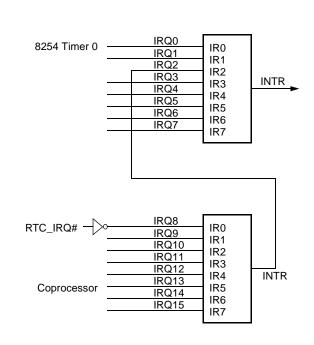

Figure 3-15. PIC Interrupt Controllers

DataSheet4U.com

Of the 16 IRQs, four are mapped as shown in Table 3-43, leaving 12 external interrupts. The two controllers are cascaded through IRQ2. The internal 8254 PIT connects to IRQ0. The real-time clock interface chip (see Figure 3-18 "External RTC Interface" on page 107) and the external coprocessor interface (see Figure 3-1 "Processor Signal Connections" on page 42) connect to IRQ8# and IRQ13 respectively.

Table 3-43.	PIC Interrupt	Mapping
-------------	---------------	---------

Master IRQ#	Mapping
IRQ0	Connected to the OUT0 (system timer) of the internal 8254 PIT.
IRQ2	Connected to the slave's INTR for a cascaded configuration.
IRQ8#	Connected to external real-time clock.
IRQ13	Connected to the coprocessor interface.
IRQ[15:14, 12:9, 7:3, 1]	External interrupts.

The CS5530A allows the PCI interrupt signals INTA#-INTD# (also known in industry terms as PIRQx#) to be routed internally to any IRQ signal. The routing can be modified through the CS5530A's configuration registers. If this is done, the IRQ input must be configured to be levelrather than edge-sensitive. IRQ inputs may be individually programmed to be active low, level-sensitive with the Interrupt Sensitivity configuration registers at I/O address space 4D0h and 4D1h. PCI interrupt configuration is discussed in further detail in Section 3.5.4.4 "PCI Compatible Interrupts" on page 101.

PIC Interrupt Sequence

A typical AT-compatible interrupt sequence is as follows. Any unmasked interrupt generates the INTR signal to the CPU. The interrupt controller then responds to the interrupt acknowledge (INTA) cycles from the CPU. On the first INTA cycle the cascading priority is resolved to determine which of the two 8259 controllers output the interrupt vector onto the data bus. On the second INTA cycle the appropriate 8259 controller drives the data bus with the correct interrupt vector for the highest priority interrupt.

By default, the CS5530A responds to PCI INTA cycles because the system interrupt controller is located within the CS5530A. This may be disabled with F0 Index 40h[7] (see Table 3-44). When the CS5530A responds to a PCI INTA cycle, it holds the PCI bus and internally generates the two INTA cycles to obtain the correct interrupt vector. It then asserts TRDY# and returns the interrupt vector.

PIC I/O Registers

Each PIC contains registers located in the standard I/O address locations, as shown in Table 4-30 "Programmable Interrupt Controller Registers" on page 225.

An initialization sequence must be followed to program the interrupt controllers. The sequence is started by writing Initialization Command Word 1 (ICW1). After ICW1 has been written, the controller expects the next writes to follow in the sequence ICW2, ICW3, and ICW4 if it is needed. The Operation Control Words (OCW) can be written after initialization. The PIC must be programmed before operation begins.

Since the controllers are operating in cascade mode, ICW3 of the master controller should be programmed with a value indicating that IRQ2 input of the master interrupt controller is connected to the slave interrupt controller rather than an I/O device as part of the system initialization code. In addition, ICW3 of the slave interrupt controller should be programmed with the value 02h (slave ID) and corresponds to the input on the master controller.

Functional Description (Continued)

3.5.4.4 **PCI Compatible Interrupts**

The CS5530A allows the PCI interrupt signals INTA#, INTB#, INTC#, and INTD# (also known in industry terms as PIRQx#) to be mapped internally to any IRQ signal with the PCI Interrupt Steering Registers 1 and 2, F0 Index 5Ch and 5Dh (Table 3-46). This reassignment does not disable the corresponding IRQ pin. Two interrupt signals may not be assigned to the same IRQ.

PCI interrupts are low-level sensitive, whereas PC/AT interrupts are positive-edge sensitive; therefore, the PCI interrupts are inverted before being connected to the 8259.

Although the controllers default to the PC/AT-compatible mode (positive-edge sensitive), each IRQ may be individually programmed to be edge or level sensitive using the Interrupt Edge/Level Sensitivity registers in I/O Port 4D0h and 4D1h, as shown in Table 3-47. However, if the controllers are programmed to be level-sensitive via ICW1, all interrupts must be level-sensitive. Figure 3-16 shows the PCI interrupt mapping for the master/slave 8259 interrupt controller.

3.5.5 I/O Ports 092h and 061h System Control

The CS5530A supports control functions of I/O Ports 092h (Port A) and 061h (Port B) for PS/2 compatibility. I/O Port 092h allows a fast assertion of the A20M# or CPU_RST. I/O Port 061h controls NMI generation and reports system status. Table 3-48 shows these register bit formats.

The CS5530A does not use a pin to control A20 Mask when used together with a GX-series processor. Instead, it generates an SMI for every internal change of the A20M# state and the SMI handler sets the A20M# state inside the CPU. This method is used for both the Port 092h (PS/2) and Port 061h (keyboard) methods of controlling A20M#.

Table 3-48.	I/O Ports 061h and 092h

Functional Description (Continued)

I/O Port 092h System Control 3.5.5.1

I/O Port 092h allows for a fast keyboard assertion of an A20# SMI and a fast keyboard CPU reset. Decoding for this register may be disabled via F0 Index 52h[3] (Table 3-49).

The assertion of a fast keyboard A20# SMI is controlled by either I/O Port 092h or by monitoring for the keyboard command sequence (see Section 3.5.6.1 "Fast Keyboard Gate Address 20 and CPU Reset" on page 106). If bit 1 of I/O Port 092h is cleared, the CS5530A internally asserts an A20M# SMI, which in turn causes an SMI to the processor. If bit 1 is set, A20M# SMI is internally deasserted again causing an SMI.

The assertion of a fast keyboard reset (WM_RST SMI) is controlled by bit 0 in I/O Port 092h or by monitoring for the keyboard command sequence. If bit 0 is changed from a 0 to a 1, the CS5530A generates a reset to the processor by generating a WM_RST SMI. When the WM_RST SMI occurs, the BIOS jumps to the Warm Reset vector. This bit

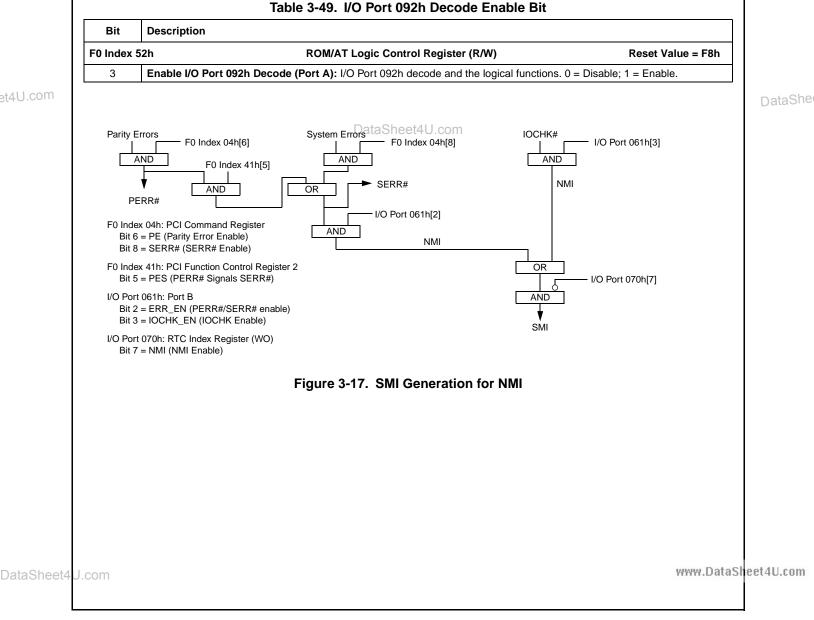

remains set until the CS5530A is externally reset, or this bit is cleared by program control. Note that Warm Reset is not a pin; it is under SMI control.

3.5.5.2 I/O Port 061h System Control

Through I/O Port 061h, the speaker output can be enabled, NMI from IOCHK# or SERR# can be enabled, the status of IOCHK# and SERR# can be read, and the state of the speaker data (Timer2 output) and refresh toggle (Timer1 output) can be read back. Note that NMI is under SMI control. Even though the hardware is present, the IOCHK# pin does not exist so an NMI from IOCHK# can not happen.

3.5.5.3 SMI Generation for NMI

Figure 3-17 shows how the CS5530A can generate an SMI for an NMI. Note that NMI is not a pin.

www.national.com

3.5.6 **Keyboard Interface Function**

Description

The CS5530A actively decodes the keyboard controller I/O Ports 060h and 064h, and generate an ISA I/O cycle with KBROMCS# asserted. Access to I/O Ports 062h and 066h must be enabled for KBROMCS# to be asserted. The CS5530A also actively decodes the keyboard controller I/O Ports 062h and 066h if F0 Index 5Bh[7] is set. Keyboard

if positive decode is enabled, the port exists on the ISA bus.

positive decoding can be disabled if F0 Index 5Ah[1] is cleared. Table 3-50 shows these two decoding bits.

Table 3-51 lists the standard keyboard control I/O registers and their bit formats.

Reset Value = 03h Keyboard Controller Positive Decode: Selects PCI positive or subtractive decoding for accesses to I/O Port Note: Positive decoding by the CS5530A speeds up the I/O cycle time. These I/O Ports do not exist in the CS5530A. It is assumed that Reset Value = 20h Keyboard I/O Port 062h/066h Decode: This alternate port to the keyboard controller is provided in support of the 8051SI

	notebook keyboard controller mailbox. 0 = Disable; 1 = Enable.

Geode[™] CS5530A

Functional Description (Continued)

3.5.6.1 Fast Keyboard Gate Address 20 and CPU Reset

The CS5530A monitors the keyboard I/O Ports 064h and 060h for the fast keyboard A20M# and CPU reset control sequences. If a write to I/O Port 060h[1] = 1 after a write takes place to I/O Port 064h with data of D1h, then the CS5530A asserts the A20M# signal. A20M# remains asserted until cleared by:

- (1) a write to bit 1 of I/O Port 092h,
- (2) a CPU reset of some kind, or
- (3) write to I/O Port 060h[1] = 0 after a write takes place to I/O Port 064h with data of D1h.

The CS5530A also monitors the keyboard ports for the CPU reset control sequence. If a write to I/O Port 060h with data bit 0 set occurs after a write to I/O Port 064h with data of D1h, the CS5530A asserts a WM_RST SMI.

The fast keyboard A20M# and CPU reset can be disabled through F0 Index 52h[7]. By default, bit 7 is cleared, and the fast keyboard A20M# and CPU reset monitor logic is active. If bit 7 is clear, the CS5530A forwards the commands to the keyboard controller.

By default, the CS5530A forces the deassertion of A20M# during a warm reset. This action may be disabled if F0 Index 52h[4] is cleared.

Table 3-52. A20 Associated Programming Bits

Bit	Description

3.5.7 External Real-Time Clock Interface

I/O Ports 070h and 071h decodes are provided to interface to an external real-time clock controller. I/O Port 070h, a write only port, is used to set up the address of the desired data in the controller. This causes the address to be placed on the ISA data bus, and the RTCALE signal to be triggered. A read of I/O Port 071h causes an ISA I/O read cycle to be performed while asserting the RTCCS# signal. A write to I/O Port 071h causes an ISA I/O write cycle to be performed with the desired data being placed on the ISA bus and the RTCCS# signal to be asserted. RTCCS#/ SMEMW# and RTCALE/SMEMR# are multiplexed pins. The function selection is made through F0 Index 53h[2].

The connection between the CS5530A and an external real-time clock is shown in Figure 3-18.

The CS5530A also provides the RTC Index Shadow Register (F0 Index BBh) to store the last write to I/O Port 070h.

Table 3-53 shows the bit formats for the associated registers for interfacing with an external real-time clock.

Revision 1.1

Functional Description (Continued)

3.6 IDE CONTROLLER

The CS5530A integrates a fully-buffered, 32-bit, ANSI ATA-4-compliant (Ultra DMA33) IDE interface. The IDE interface supports two channels, primary and secondary, each supporting two devices that can operate in PIO Modes 1, 2, 3, 4, Multiword DMA, or Ultra DMA/133.

The IDE interface provides a variety of features to optimize system performance, including 32-bit disk access, post write buffers, bus master, Multiword DMA, look-ahead read buffer, and prefetch mechanism for each channel respectively.

The IDE interface timing is completely programmable. Timing control covers the command active and recover pulse widths, and command block register accesses. The IDE data-transfer speed for each device on each channel can

be independently programmed allowing high-speed IDE peripherals to coexist on the same channel as older, compatible devices.

The CS5530A also provides a software-accessible buffered reset signal to the IDE drive, F0 Index 44h[3:2] (Table 3-54). The IDE_RST# signal is driven low during reset to the CS5530A and can be driven low or high as needed for device-power-off conditions.

3.6.1 **IDE Interface Signals**

The CS5530A has two completely separate IDE control signals, however, the IDE_RST#, IDE_ADDR[2:0] and IDE_DATA[15:0] are shared. The connections between the CS5530A and IDE devices are shown as Figure 3-19.

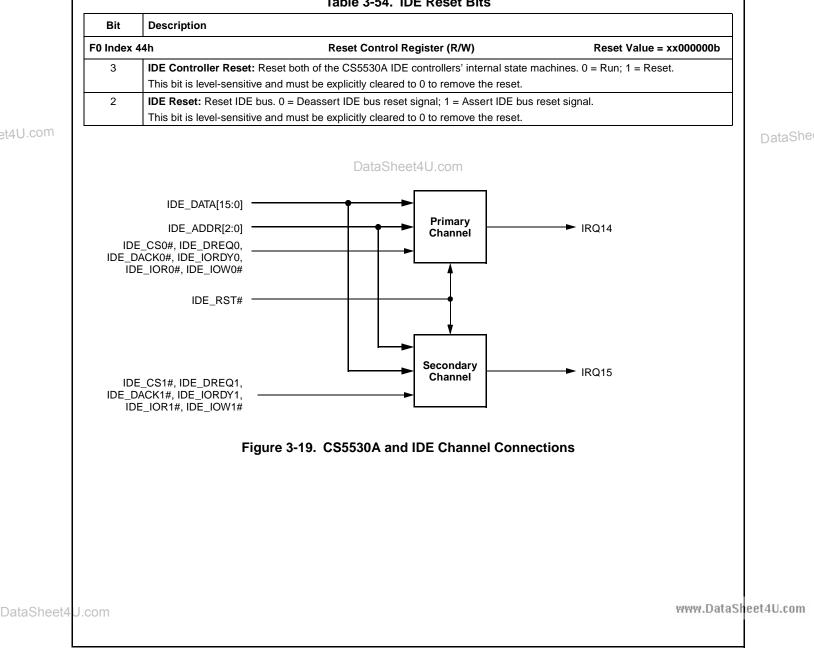

Table 3-54. IDE Reset Bits

www.national.com

3.6.2 IDE Configuration Registers

Registers for configuring the IDE interface are accessed through F2 Index 20h, the Base Address Register (F2BAR) in Function 2. F2BAR sets the base address for the IDE Controllers Configuration Registers as shown in Table 3-55. For complete bit information, refer to Section 4.3.3 "IDE Controller Registers - Function 2" on page 188.

The following subsections discuss CS5530A operational/programming details concerning PIO, Bus Master, and Ultra DMA/33 modes.

3.6.2.1 PIO Mode

The IDE data port transaction latency consists of address latency, asserted latency and recovery latency. Address latency occurs when a PCI master cycle targeting the IDE data port is decoded, and the IDE_ADDR[2:0] and IDE_CS# lines are not set up. Address latency provides the setup time for the IDE_ADDR[2:0] and IDE_CS# lines prior to IDE_IOR# and IDE_IOW#.

Asserted latency consists of the I/O command strobe assertion length and recovery time. Recovery time is provided so that transactions may occur back-to-back on the IDE interface without violating minimum cycle periods for the IDE interface.

If IDE_IORDY is asserted when the initial sample point is reached, no wait states are added to the command strobe assertion length. If IDE_IORDY is negated when the initial sample point is reached, additional wait states are added to be added to

Recovery latency occurs after the IDE data port transactions have completed. It provides hold time on the IDE_ADDR[2:0] and IDE_CS# lines with respect to the read and write strobes (IDE_IOR# and IDE_IOW#). The PIO portion of the IDE registers is enabled through:

- Channel 0 Drive 0 Programmed I/O Register (F2BAR+I/O Offset 20h)
- Channel 0 Drive 1 Programmed I/O Register (F2BAR+I/O Offset 28h)
- Channel 1 Drive 0 Programmed I/O Register (F2BAR+I/O Offset 30h)
- Channel 1 Drive 1 Programmed I/O Register (F2BAR+I/O Offset 38h)

The IDE channels and devices can be individually programmed to select the proper address setup time, asserted time, and recovery time.

The bit formats for these registers are shown in Table 3-56. Note that there are different bit formats for each of the PIO programming registers depending on the operating format selected: Format 0 or Format 1.

F2BAR+I/O Offset 24h[31] (Channel 0 Drive 0 — DMA Control Register) sets the format of the PIO register. If bit 31 = 0, Format 0 is used and it selects the slowest PIO-MODE (bits [19:16]) per channel for commands. If bit 31 = 1, Format 1 is used and it allows independent control of command and data.

Also listed in the bit formats are recommended values for the different PIO modes.

Note: These are only recommended settings and are not 100% tested.

3.6.2.2 Bus Master Mode

Two IDE bus masters are provided to perform the data transfers for the primary and secondary channels. The CS5530A off-loads the CPU and improves system performance in multitasking environments.

The bus master mode programming interface is an extension of the standard IDE programming model. This means that devices can always be dealt with using the standard IDE programming model, with the master mode functionality used when the appropriate driver and devices are present. Master operation is designed to work with any IDE device that supports DMA transfers on the IDE bus. Devices that work in PIO mode can only use the standard IDE programming model.

The IDE bus masters use a simple scatter/gather mechanism allowing large transfer blocks to be scattered to or gathered from memory. This cuts down on the number of interrupts to and interactions with the CPU.

Physical Region Descriptor Table Address

Before the controller starts a master transfer it is given a pointer (shown in Table 3-57) to a Physical Region Descriptor Table. This pointer sets the starting memory location of the Physical Region Descriptors (PRDs). The PRDs describe the areas of memory that are used in the data transfer. The PRDs must be aligned on a 4-byte boundary and the table cannot cross a 64 KB boundary in memory.

Primary and Secondary IDE Bus Master Registers

The IDE Bus Master Registers for each channel (primary and secondary) have an IDE Bus Master Command Register and Bus Master Status Register. These registers must be accessed individually; a 32-bit DWORD access attempting to include both the Command and Status registers may not operate correctly. Bit formats of these registers are given in Table 3-58.

Physical Region Descriptor Format

Each physical memory region to be transferred is described by a Physical Region Descriptor (PRD) as illustrated in Table 3-59. When the bus master is enabled (Command Register bit 0 = 1), data transfer proceeds until each PRD in the PRD table has been transferred. The bus master does not cache PRDs.

The PRD table consists of two DWORDs. The first DWORD contains a 32-bit pointer to a buffer to be transferred. This pointer must be 16-byte aligned. The second DWORD contains the size (16 bits) of the buffer and the EOT flag. The size must be in multiples of 16 bytes. The EOT bit (bit 31) must be set to indicate the last PRD in the PRD table.

Programming Model

The following steps explain how to initiate and maintain a bus master transfer between memory and an IDE device.

- Software creates a PRD table in system memory. Each PRD entry is 8 bytes long, consisting of a base address pointer and buffer size. The maximum data that can be transferred from a PRD entry is 64 KB. A PRD table must be aligned on a 4-byte boundary. The last PRD in a PRD table must have the EOT bit set.
- 2) Software loads the starting address of the PRD table by programming the PRD Table Address Register.

- Software must fill the buffers pointed to by the PRDs with IDE data.
- 4) Write 1 to the Bus Master Interrupt bit and Bus Master Error (Status Register bits 2 and 1) to clear the bits.
- 5) Set the correct direction to the Read or Write Control bit (Command Register bit 3).
- 6) Engage the bus master by writing a "1" to the Bus Master Control bit (Command Register bit 0).
- 7) The bus master reads the PRD entry pointed to by the PRD Table Address Register and increments the address by 08h to point to the next PRD. The transfer begins.
- 8) The bus master transfers data to/from memory responding to bus master requests from the IDE device. At the completion of each PRD, the bus master's next response depends on the settings of the EOT flag in the PRD. If the EOT bit is set, then the IDE bus master clears the Bus Master Active bit (Status Register bit 0) and stops. If any errors occurred during the transfer, the bus master sets the Bus Master Error bit (Status Register bit 1).

Functional Description (Continued)

3.6.2.3 Ultra DMA/33 Mode

The CS5530A supports Ultra DMA/33. It utilizes the standard IDE Bus Master functionality to interface, initiate, and control the transfer. Ultra DMA/33 definition also incorporates a Cyclic Redundancy Check (CRC) error checking protocol to detect errors.

The Ultra DMA/33 protocol requires no extra signal pins on the IDE connector. The CS5530A redefines three standard IDE control signals when in Ultra DMA/33 mode. These definitions are shown in Table 3-60.

	-	
CS5530A IDE Channel Signal	Ultra DMA/33 Read Cycle	Ultra DMA/33 Write Cycle
IDE_IOW#	STOP	STOP
IDE_IOR#	DMARDY#	STROBE
IDE_IORDY	STROBE	DMARDY#

Table 3-60. Ultra DMA/33 Signal Definitions

All other signals on the IDE connector retain their functional definitions during the Ultra DMA/33 operation.

IDE_IOW# is defined as STOP for both read and write transfers to request to stop a transaction.

IDE_IOR# is redefined as DMARDY# for transferring data from the IDE device to the CS5530A. It is used by the CS5530A to signal when it is ready to transfer data and to add wait states to the current transaction. IDE_IOR# signal is defined as STROBE for transferring data from the CS5530A to the IDE device. It is the data strobe signal driven by the CS5530A on which data is transferred during each rising and falling edge transition.

IDE_IORDY is redefined as STROBE for transferring data from the IDE device to the CS5530A during a read cycle. It is the data strobe signal driven by the IDE device on which data is transferred during each rising and falling edge transition. IDE_IORDY is defined as DMARDY# during a write cycle for transferring data from the CS5530A to the IDE device. It is used by the IDE device to signal when it is ready to transfer data and to add wait states to the current transaction.

Ultra DMA/33 data transfer consists of three phases, a startup phase, a data transfer phase and a burst termination phase.

The IDE device begins the startup phase by asserting IDE_DREQ. When ready to begin the transfer, the CS5530A asserts IDE_DACK#. When IDE_DACK# is asserted, the CS5530A drives IDE_CS0# and IDE_CS1# asserted, and IDE_ADDR[2:0] low. For write cycles, the CS5530A negates STOP, waits for the IDE device to assert DMARDY#, and then drives the first data WORD and STROBE signal. For read cycles, the CS5530A negates STOP, and asserts DMARDY#. The IDE device then sends the first data WORD and asserts STROBE.

DataSheet4U.com

The data transfer phase continues the burst transfers with the CS5530A and the IDE via providing data, toggling STROBE and DMARDY#. IDE_DATA[15:0] is latched by the receiver on each rising and falling edge of STROBE. The transmitter can pause the burst cycle by holding STROBE high or low, and resume the burst cycle by again toggling STROBE. The receiver can pause the burst cycle by negating DMARDY# and resumes the burst cycle by asserting DMARDY#.

The current burst cycle can be terminated by either the transmitter or the receiver. A burst cycle must first be paused as described above before it can be terminated. The CS5530A can then stop the burst cycle by asserting STOP, with the IDE device acknowledging by negating IDE_DREQ. The IDE device stops the burst cycle by negating IDE_DREQ and the CS5530A acknowledges by asserting STOP. The transmitter then drives the STROBE signal to a high level. The CS5530A then puts the result of the CRC calculation onto IDE_DATA[15:0] while deasserting IDE_DACK#.

The CRC value is used for error checking on Ultra DMA/33 transfers. The CRC value is calculated for all data by both the CS5530A and the IDE device during the Ultra DMA/33 burst transfer cycles. This result of the CRC calculation is based on all data transferred with a valid STROBE edge while IDE_DACK# is asserted. At the end of the burst transfer, the CS5530A drives the result of the CRC calculation onto IDE_DATA[15:0] which is then strobed by the deassertion of IDE_DACK#. The IDE device compares the CRC result of the CS5530A to its own and reports an error if there is a mismatch.

The timings for Ultra DMA/33 are programmed into the DMA control registers:

- Channel 0 Drive 0 DMA Control Register (F2BAR+I/O Offset 24h)
- Channel 0 Drive 1 DMA Control Register (F2BAR+I/O Offset 2Ch)
- Channel 1 Drive 0 DMA Control Register (F2BAR+I/O Offset 34h)
- Channel 1 Drive 1 DMA Control Register (F2BAR+I/O Offset 3Ch)

The bit formats for these registers are given in Table 3-61. Note that F2BAR+I/O Offset 24h[20] is used to select either Multiword or Ultra DMA mode. Bit 20 = 0 selects Multiword DMA mode. If bit 20 = 1, then Ultra DMA/33 mode is selected. Once mode selection is made using this bit, the remaining DMA Control Registers also operate in the selected mode.

Also listed in the bit formats are recommended values for both Multiword DMA Modes 0-2 and Ultra DMA/33 Modes 0-2.

Note: These are only recommended settings and are not 100% tested.

Functional Description (Continued)

3.7 XPRESSAUDIO

Through XpressAUDIO, the CS5530A offers a combined hardware/software support solution to meet industry standard audio requirements. XpressAUDIO uses Virtual System Architecture[®] (VSATM) technology along with additional hardware features to provide the necessary support for industry standard 16-bit stereo synthesis and OPL3 emulation.

The hardware portion of XpressAUDIO is for transporting streaming audio data to/from the system memory and an AC97 codec. This hardware includes:

- Six (three inbound/three outbound) buffered PCI bus mastering engines that drive specific AC97 interface slots.
- Interfaces to AC97 codecs (e.g., National's LM4548) for audio input/output.

Additional hardware provides the necessary functionality for VSA technology. This hardware includes the ability to:

- Generate an SMI to alert software to update required data. An SMI is generated when either audio buffer is half empty or full. If the buffers become completely empty or full, the Empty bit is asserted.
- Generate an SMI on I/O traps.
- Trap accesses for sound card compatibility at either I/O Port 220h-22Fh, 240h-24Fh, 260h-26Fh, or 280h-28Fh.
- Trap accesses for FM compatibility at I/O Port 388h-38Bh.
- Trap accesses for MIDI UART interface at I/O Port 300h-301h or 330h-331h.

Address Range (Read Only)

- Trap accesses for serial input and output at COM2 (I/O Port 2F8h-2FFh) or COM4 (I/O Port 2E8h-2EFh).
- Support trapping for low (I/O Port 00h-0Fh) and/or high (I/O Port C0h-DFh) DMA accesses.
- Support hardware status register reads in CS5530A, minimizing SMI overhead.
- Support is provided for software-generated IRQs on IRQ 2, 3, 5, 7, 10, 11, 12, 13, 14, and 15.

Included in the following subsections are details regarding the registers used for configuring the audio interface. The registers are accessed through F3 Index 10h, the Base Address Register (F3BAR) in Function 3. F3BAR sets the base address for XpressAUDIO support registers as shown in Table 3-62.

3.7.1 Subsystem Data Transport Hardware

The data transport hardware can be broadly divided into two sections: bus mastering and the codec interface.

3.7.1.1 Audio Bus Masters

The CS5530A audio hardware includes six PCI bus masters (three for input and three for output) for transferring digitized audio between memory and the external codec. With these bus master engines, the CS5530A off-loads the CPU and improves system performance.

The programming interface defines a simple scatter/gather mechanism allowing large transfer blocks to be scattered to or gathered from memory. This cuts down on the number of interrupts to and interactions with the CPU.

Table 3-62. Base Address Register (F3BAR) for XpressAUDIO Registers

Bus Master Audio Configuration Registers

The format for the bus master audio configuration registers is similar in that each bus master has a Command Register, an SMI Status Register and a PRD Table Address Register. Programming of the bus masters is generic in many ways, although specific programming is required of bit 3 in the Command Register. This bit selects read or write control and is dependent upon which Audio Bus Master is being programmed. For example, Audio Bus Master 0 is defined as an output only, so bit 3 of Audio Bus Master 0 Command Register (F3BAR+Memory Offset 20h[3]) must always be set to 1.

et4U.com

Table 3-63. Generic Bit Formats for Audio Bus Master Configuration Registers DataSheet4U.com

DataShe

	Command Register (R/W)
7:4	Reserved: Set to 0. Must return 0 on reads.
3	Read or Write Control: Set the transfer direction of Audio Bus Master X: 0 = Memory reads performed (output to codec); 1 = Memory writes performed (input from codec).
	This bit should not be changed when the bus master is active. The setting of this bit is dependent upon the assigned bus master.
2:1	Reserved: Set to 0. Must return 0 on reads.
0	Bus Master Control: Controls the state of the Audio Bus Master X: 0 = Disable; 1 = Enable.
	Setting this bit to 1 enables the bus master to begin data transfers. When writing this bit to 0, the bus master must either be paused or have reached EOT. Writing this bit to 0 while the bus master is operating results in unpredictable behavior including the possibility of the bus master state machine crashing. The only recovery from this condition is a PCI reset.
Note: Th	is register must be read and written as a BYTE.
	SMI Status Register (RC)
7:2	Reserved (Read to Clear)
1	Bus Master Error (Read to Clear): Hardware encountered a second EOP (end of page) before software has cleared the first? 0 = No; 1 = Yes.
	If hardware encounters a second EOP before software has cleared the first, it causes the bus master to pause until this reg- ister is read to clear the error.
	Must be R/W as a byte.
0	End of Page (Read to Clear): Bus master transferred data which is marked by EOP bit in the PRD table (bit 30)? 0 = No; 1 = Yes.
lote: M	ust be read and written as a BYTE.
	PRD Table Address (R/W)
31:2	PRD Table Address (R/W) Pointer to the Physical Region Descriptor Table: This register is a PRD table pointer for Audio Bus Master X.
31:2	Pointer to the Physical Region Descriptor Table: This register is a PRD table pointer for Audio Bus Master X. When written, this register points to the first entry in a PRD table. Once Audio Bus Master X is enabled (Command Register bit 0 = 1], it loads the pointer and updates this register to the next PRD by adding 08h.
31:2 om	Pointer to the Physical Region Descriptor Table: This register is a PRD table pointer for Audio Bus Master X. When written, this register points to the first entry in a PRD table. Once Audio Bus Master X is enabled (Command Register

Net - D'C			

3.7.1.2 Physical Region Descriptor Table Address

Before the bus master starts a master transfer it must be programmed with a pointer (PRD Table Address Register) to a Physical Region Descriptor Table. This pointer sets the starting memory location of the Physical Region Descriptors (PRDs). The PRDs describe the areas of memory that are used in the data transfer. The descriptor table entries must be aligned on a 4-byte boundary and the table cannot cross a 64 KB boundary in memory.

3.7.1.3 Physical Region Descriptor Format

Each physical memory region to be transferred is described by a Physical Region Descriptor (PRD) as illustrated in Table 3-65. When the bus master is enabled (Command Register bit 0 = 1), data transfer proceeds until each PRD in the PRD table has been transferred. The bus master does not cache PRDs.

The PRD table consists of two DWORDs. The first DWORD contains a 32-bit pointer to a buffer to be transferred. The second DWORD contains the size (16 bits) of the buffer and flags (EOT, EOP, JMP). The description of the flags are as follows:

- EOT bit If set in a PRD, this bit indicates the last entry in the PRD table (bit 31). The last entry in a PRD table must have either the EOT bit or the JMP bit set. A PRD can not have both the JMP and EOT bits set.
- EOP bit If set in a PRD and the bus master has completed the PRD's transfer, the End of Page bit is set (Status Register bit 0 = 1) and an SMI is generated. If a second EOP is reached due to the completion of another PRD before the End of Page bit is cleared, the Bus Master Error bit is set (Status Register bit 1 = 1) and the bus master pauses. In this paused condition, reading the Status Register clears both the Bus Master Error and the End of Page bits and the bus master continues.
- JMP bit This PRD is special. If set, the Memory Region Physical Base Address is now the target address of the JMP. There is no data transfer with this PRD. This PRD allows the creation of a looping mechanism. If a PRD table is created with the JMP bit set in the last PRD, the PRD table does not need a PRD with the EOT bit set. A PRD can not have both the JMP and EOT bits set.

Functional Description (Continued)

Programming Model 3.7.1.4

The following discussion explains, in steps, how to initiate and maintain a bus master transfer between memory and an audio slave device.

In the steps listed below, the reference to "Example" refers to Figure 3-20, PRD Table Example.

Software creates a PRD table in system memory. 1) Each PRD entry is 8 bytes long; consisting of a base address pointer and buffer size. The maximum data that can be transferred from a PRD entry is 64 KB. A PRD table must be aligned on a 4-byte boundary. The last PRD in a PRD table must have the EOT or JMP bit set

Example - Assume the data is outbound. There are three PRDs in the example PRD table. The first two PRDs (PRD_1, PRD_2) have only the EOP bit set. The last PRD (PRD_3) has only the JMP bit set. This example creates a PRD loop.

2) Software loads the starting address of the PRD table by programming the PRD Table Address Register.

Example - Program the PRD Table Address Register with Address 3.

Software must fill the buffers pointed to by the PRDs 3) with audio data. It is not absolutely necessary to fill the buffers; however, the buffer filling process must stay ahead of the buffer emptying. The simplest way to do DataSheet4U.com

this is by using the EOP flags to generate an SMI when a PRD is empty.

Example - Fill Audio Buffer_1 and Audio Buffer_2. The SMI generated by the EOP from the first PRD allows the software to refill Audio Buffer_1. The second SMI will refill Audio Buffer_2. The third SMI will refill Audio Buffer_1 and so on.

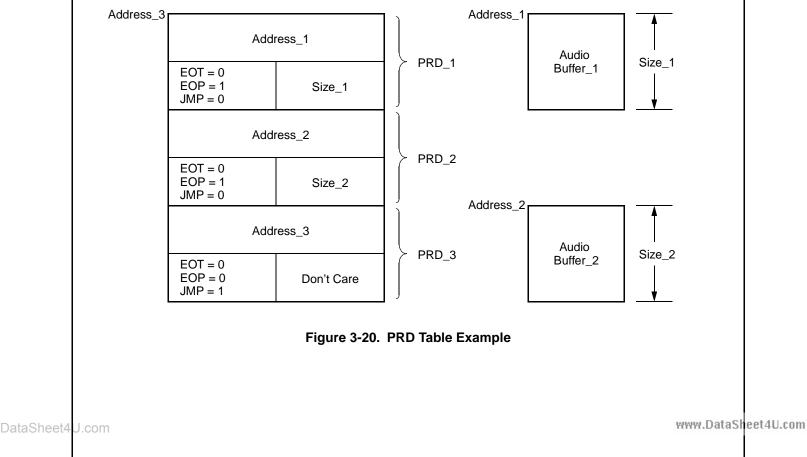

Read the SMI Status Register to clear the Bus Master 4) Error and End of Page bits (bits 1 and 0).

Set the correct direction to the Read or Write Control bit (Command Register bit 3). Note that the direction of the data transfer of a particular bus master is fixed and therefore the direction bit must be programmed accordingly. It is assumed that the codec has been properly programmed to receive the audio data.

Engage the bus master by writing a "1" to the Bus Master Control bit (Command Register bit 0).

The bus master reads the PRD entry pointed to by the PRD Table Address Register and increments the address by 08h to point to the next PRD. The transfer begins.

Example - The bus master is now properly programmed to transfer Audio Buffer_1 to a specific slot(s) in the AC97 interface.

The bus master transfers data to/from memory 5) responding to bus master requests from the AC97 interface. At the completion of each PRD, the bus master's next response depends on the settings of the flags in the PRD.

Example - At the completion of PRD_1 an SMI is generated because the EOP bit is set while the bus master continues on to PRD 2. The address in the PRD Table Address Register is incremented by 08h and is now pointing to PRD_3. The SMI Status Register is read to clear the End of Page status flag. Since Audio Buffer_1 is now empty, the software can refill it.

At the completion of PRD_2 an SMI is generated because the EOP bit is set. The bus master then continues on to PRD_3. The address in the PRD Table Address Register is incremented by 08h. The DMA SMI Status Register is read to clear the End of Page status flag. Since Audio Buffer_2 is now empty, the software can refill it. Audio Buffer_1 has been refilled from the previous SMI.

PRD_3 has the JMP bit set. This means the bus master uses the address stored in PRD_3 (Address_3) to locate the next PRD. It does not use the address in the PRD Table Address Register to get the next PRD. Since Address_3 is the location of PRD_1, the bus master has looped the PRD table.

Stopping the bus master can be accomplished by not reading the SMI Status Register End of Page status eet4U.com flag. This leads to a second EOP which causes a Bus Master Error and pauses the bus master. In effect, once a bus master has been enabled it never needs to be disabled, just paused. The bus master cannot be disabled unless the bus master has been paused or has reached an EOT.

3.7.1.5 AC97 Codec Interface

The CS5530A provides an AC97 Specification Revision 1.3, 2.0, and 2.1 compatible interface. Any AC97 codec which supports sample rate conversion (SRC) can be used with the CS5530A. This type of codec allows for a design which meets the requirements for PC97 and PC98-compliant audio as defined by Microsoft Corporation.

The AC97 codec (e.g., National's LM4548) is the master of the serial interface and generates the clocks to CS5530A, Figure 3-21 shows the codec and CS5530A signal connections. For specifications on the serial interface, refer to the appropriate codec manufacturer's data sheet.

For PC speaker synthesis, the CS5530A outputs the PC speaker signal on the PC_BEEP pin which is connected to the PC_BEEP input of the AC97 codec.

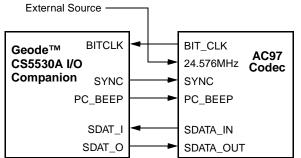

Figure 3-21. AC97 Signal Connections

Codec Configuration/Control Registers

The codec related registers consist of four 32-bit registers:

- Codec GPIO Status Register
- Codec GPIO Control Register
- Codec Status Register
- Codec Command Register

Codec GPIO Status and Control Registers (F3BAR+ Memory Offset 00h and 04h)

The Codec GPIO Status and Control Registers are used for codec GPIO related tasks such as enabling a codec GPIO interrupt to cause an SMI.

Codec Status Register (F3BAR+Memory Offset 08h)

The Codec Status Register stores the codec status word. It updates every valid Status Word slot.

Codec Control Register (F3BAR+Memory Offset 0Ch)

The Codec Control Register writes the control word to the codec. By writing the appropriate control words to this port, the features of the codec can be controlled. The contents of this register are written to the codec during the Control Word slot.

The bit formats for these registers are given in Table 3-66.

Functional Description (Continued)

3.7.2 VSA Technology Support Hardware

The CS5530A I/O companion incorporates the required hardware in order to support the Virtual System Architecture (VSA) technology for capture and playback of audio using an external codec. This eliminates much of the hardware traditionally associated with industry standard audio functions.

XpressAUDIO software provides 16-bit compatible sound. This software is available to OEMs for incorporation into the system BIOS ROM.

3.7.2.1 VSA Technology

VSA technology provides a framework to enable software implementation of traditionally hardware-only components. VSA technology software executes in System Management Mode (SMM), enabling it to execute transparently to the operating system, drivers, and applications.

The VSA technology design is based upon a simple model for replacing hardware components with software. Hardware to be virtualized is merely replaced with simple access detection circuitry which asserts the SMI# (System Management Interrupt) pin when hardware accesses are detected. The current execution stream is immediately preempted, and the processor enters SMM. The SMM system software then saves the processor state, initializes the VSA technology execution environment, decodes the SMI source and dispatches handler routines which have registered requests to service the decoded SMI source. Once all handler routines have completed, the processor state is ee restored and normal execution resumes. In this manner, hardware accesses are transparently replaced with the execution of SMM handler software.

Historically, SMM software was used primarily for the single purpose of facilitating active power management for notebook designs. That software's only function was to manage the power up and down of devices to save power. With high performance processors now available, it is feasible to implement, primarily in SMM software, PC capabilities traditionally provided by hardware. In contrast to power management code, this virtualization software generally has strict performance requirements to prevent application performance from being significantly impacted.

3.7.2.2 Audio SMI Related Registers

The SMI related registers consist of:

- Second Level Audio SMI Status Registers
- I/O Trap SMI and Fast Write Status Register
- I/O Trap SMI Enable Register

The Top SMI Status Mirror and Status Registers are the top level of hierarchy for the SMI handler in determining the source of an SMI. These two registers are at F1BAR+Memory Offset 00h (Status Mirror) and F1BAR+Memory Offset 02h (Status). The registers are identical except that reading the register at F1BAR+Memory Offset 02h clears the status.

Second Level Audio SMI Status Registers

The second level of audio SMI status reporting is set up very much like the top level. There are two status reporting registers, one "read only" (mirror) and one "read to clear". The data returned by reading either offset is the same (i.e., SMI was caused by an audio related event). The difference between F3BAR+Memory Offset 12h and 10h (mirror) is in the ability to clear the SMI source at 10h.

Figure 3-22 shows an SMI tree for checking and clearing the source of an audio SMI. Only the audio SMI bit is detailed here. For details regarding the remaining bits in the Top SMI Status Mirror and Status Registers refer to Table 4-17 "F1BAR+Memory Offset xxh: SMI Status and ACPI Timer Registers" on page 183.

I/O Trap SMI and Fast Write Status Register

This 32-bit read-only register (F3BAR+Memory Offset 14h) not only indicates if the enabled I/O trap generated an SMI, but also contains Fast Path Write related bits.

I/O Trap SMI Enable Register

The I/O Trap SMI Enable Register (F3BAR+Memory Offset 18h) allows traps for specified I/O addresses and configures generation for I/O events. It also contains the enabling bit for Fast Path Write/Read features.

If Status Fast Path Read is enabled, the CS5530A intercepts and responds to reads to several status registers. This speeds up operations, and prevents SMI generation for reads to these registers. Status Fast Path Read is enabled via F3BAR+Memory Offset 18h[4].

In Status Fast Path Read the CS5530A responds to reads of the following addresses:

388h-38Bh

2x0h, 2x1h, 2x2h, 2x3h, 2x8h, and 2x9h

Note that if neither sound card nor FM I/O mapping is enabled, then status read trapping is not possible.

If Fast Path Write is enabled, the CS5530A captures certain writes to several I/O locations. This feature prevents two SMIs from being asserted for write operations that are known to take two accesses (the first access is an index and the second is data). Fast Path Write is enabled via F3BAR+Memory Offset 18h[11].

Fast Path Write captures the data and address bit 1 (A1) of the first access, but does not generate an SMI. A1 is stored in F3BAR+Memory Offset 14h[15]. The second access causes an SMI, and the data and address are captured as in a normal trapped I/O.

In Fast Path Write, the CS5530A responds to writes to the following addresses:

388h, 38Ah, and 38Bh 2x0h, 2x2h, and 2x8h

Functional Description (Continued)

3.7.2.3 IRQ Configuration Registers

The CS5530A provides the ability to set and clear IRQs internally through software control. If the IRQs are configured for software control, they will not respond to external hardware. There are three registers provided for this feature:

- Internal IRQ Enable Register
- Internal IRQ Mask Register
- Internal IRQ Control Register

Internal IRQ Enable Register

This register configures the IRQs as internal (software) interrupts or external (hardware) interrupts. Any IRQ used as an internal software driven source must be configured as internal.

Internal IRQ Mask Register

Each bit in the Mask register individually disables the corresponding bit in the Control Register.

Internal IRQ Control Register

This register allows individual software assertion/deassertion of the IRQs that are enabled as internal and unmasked.

The bit formats for these registers are given in Table 3-70.

Table 3-70.	IRQ	Configuration	Registers	

Bit	Description

Functional Description (Continued)

3.8.2 Video Accelerator

The CS5530A off-loads the processor from several computing-intensive tasks related to the playback of full motion video. By incorporating this level of hardware-assist, a CS5530A/GX-series processor based system can sustain 30 frames-per-second of MPEG quality video.

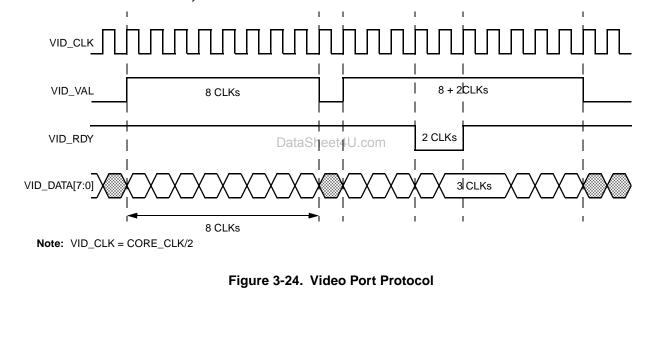

3.8.2.1 Line Buffers

The CS5530A accepts an 8-bit video stream from the processor and provides three full MPEG resolution line buffers (3x360x32-bit). MPEG source horizontal resolutions up to 720 pixels are supported. By having three line buffers, the display pipeline can read from two lines while the next line of data is being loaded from the processor. This minimizes memory bandwidth utilization by requiring that a source line be transferred only once per frame. Peak bandwidth is also reduced by requiring that the video source line be transferred within the horizontal line time rather than forcing the transfer to occur during the active video window. This efficient utilization of memory bandwidth allows the processor and graphics accelerator an increased opportunity to access the memory subsystem and improves overall system performance during video playback.

3.8.2.2 Video Port Protocol

The video port operates at one-half the processor's core clock rate and utilizes a two-wire handshake protocol. The VID_VAL input signal indicates that valid data has been placed on the VID_DATA[7:0] bus. When the CS5530A is ready to accept data, it asserts VID_RDY to indicate that a line buffer is free to accept the next line. When both VID_VAL and VID_RDY are asserted, VID_DATA advances.

The VID_RDY signal is driven by the CS5530A one clock early to the processor while the VID_VAL signal is driven by the processor coincident with valid data on VID_DATA. A sample timing diagram is shown in Figure 3-24.

DataShe

DataSheet4U.com

3.8.2.3 Video Format

The video input data can be in interleaved YUV 4:2:2 or RGB 5:6:5 format. The sequence of the individual YUV components is selectable to one of four formats via bits

[3:2] in the Video Configuration Register (F4BAR+Memory Offset 00h[3:2]). The decode for these bits is shown in Table 3-72.

Geode[™] CS5530A

et4U.com

Functional Description (Continued)

3.8.2.4 X and Y Scaler / Filter

The CS5530A supports horizontal and vertical scaling of the video stream up to eight times the source resolution. The scaler uses a Digital-Differential-Analyzer (DDA) based upon the values programmed in the Video Scale Register (F4BAR+Memory Offset 10h, see Table 3-73)

The scaled video stream is then passed through horizontal and vertical filters which perform a 2-tap, 8-phase bilinear filter on the resulting stream. The filtering function removes the "blockiness" of the scaled video thereby significantly improving the quality of the displayed image.

By performing the scaling and filtering function in hardware, video performance is substantially improved over pure software implementations by requiring that the decompression software only output the video stream at the native source resolution. This saves both processor overhead and memory bandwidth.

3.8.2.5 Color-Space-Converter

After scaling and filtering have been applied, the YUV video data is passed through the color-space converter to obtain 24-bit RGB video data. The color-space conversion equations are based on the CCIR Recommendation 601-1 as follows:

 $\begin{array}{l} \mathsf{R} = 1.164(\mathsf{Y}{-}16) + 1.596(\mathsf{V}{-}128) \\ \mathsf{G} = 1.164(\mathsf{Y}{-}16) - 0.813(\mathsf{V}{-}128) - 0.391(\mathsf{U}{-}128) \\ \mathsf{B} = 1.164(\mathsf{Y}{-}16) + 2.018(\mathsf{U}{-}128) \end{array}$

The color-space converter clamps inputs to acceptable limits if the data is not well behaved. The color-space converter is bypassed for overlaying 16 bpp RGB graphics data.

Table 3-73. Video Scale Register

DataShe

DataSheet4U.com

3.8.3 Video Overlay

The video data from the color-space converter is then mixed with the graphics data based upon the video window position. The video window position is programmable via the Video X and Y Position Registers (F4BAR+Memory Offset 08h and 0Ch). A color-keying mechanism is employed to compare either the source (video) or destination (graphics) color to the color key programmed via the Video Color Key Register (FBAR+Offset 14h) and to select the appropriate pixel for display within the video window. The range of the color key is programmable by setting the appropriate bits in the Video Color Mask Register (F4BAR+Memory Offset 18h). This mechanism greatly

reduces the software overhead for computing visible pixels, and ensures that the video display window may be partially occluded by overlapping graphics data. Tables 3-74 and 3-75 show the bit formats for these registers

The CS5530A accepts graphics data over the PIXEL[23:0] interface from the GX-series processor at the screen DOT clock rate. The CS5530A is capable of displaying graphics resolutions up to 1600x1200 at color depths up to 24 bits per pixel (bpp) while simultaneously overlaying a video window. However, system maximum resolution is not determined by the CS5530A since it is not the source of the graphics data and timings.

Functional Description (Continued)

3.8.4 Gamma RAM

Either the graphics or video stream may be routed through an on-chip gamma RAM (3x256x8-bit) which can be used for gamma-correction of either data stream, or contrast/brightness adjustments in the case of video data.

A bypass path is provided for either the graphics or video stream (depending on which is sent through the gamma

RAM). The two streams are merged based on the results of the color key compare.

Configuration for this feature and the display interface are through the Display Configuration Register (F4BAR+Memory Offset 04h). Table 3-76 shows the bit formats for this register.

Table 3-76. Display Configuration Register

0	Display Enable: Enables the graphics display pipeline. It is used as a reset for the display control logic. 0 = Reset display control logic; 1 = Enable display control logic.

3.8.5 Display Interface

The CS5530A interfaces directly to a variety of display devices including conventional analog CRT displays, TFT flat panels, the National's Geode CS9211 graphics companion (a flat panel display controller), or optionally to digital NTSC/PAL encoder devices.

3.8.5.1 Video DACs

The CS5530A incorporates three 8-bit video Digital-to-Analog Converters (DACs) for interfacing directly to CRT displays. The video DACs meet the VESA specification and are capable of operation up to 157.5 MHz for supporting up to 1280x1024 display at a 85 Hz refresh rate and are VESA compliant.

3.8.5.2 VESA DDC2B / DPMS

The CS5530A supports the VESA DDC2B and DPMS standards for enhanced monitor communications tandeet power management support.

3.8.5.3 Flat Panel Support

The CS5530A also interfaces directly to industry standard 18-bit Active Matrix Thin-Film-Transistor (TFT) flat panels. The CS5530A includes 24-bit to 18-bit dithering logic to increase the apparent number of colors displayed on 18-bit flat panels.

In addition, the CS5530A incorporates power sequencing logic to simplify the design of a portable system.

The flat panel port of the CS5530A may optionally drive the CS9211 graphics companion device for color dual-scan display (DSTN) support. If flat panel support is not required, the flat panel output port may be used to supply digital video data to one of several types of NTSC/PAL encoder devices on the market.

Flat Panel Power-Up/Down Sequence

When the Flat Panel Power Enable bit (F4BAR+Memory Offset 04h[6]) transitions from a 0 to 1, the FP_ENA_VDD signal is enabled. This is followed by the data bus (including syncs and ENA_DISP). Finally, FP_ENA_BKL is enabled. The time between each of these successive stages is set by the value of the Power Sequence Delay bits (F4BAR+Memory Offset 04h[19:17]). The value in these bits refer to the number of graphics frames that will elapse between each successive enabling of the TFT signals. For example, if the Power Sequence Delay is set to 3h (011b), then three frame times will elapse between the time when FP ENA VDD is transitioned and the data bus is transitioned. Likewise, three frame times will elapse between the data bus getting enabled and the FP_ENA_BKL is transitioned. If the panel is being refreshed at 100 Hz, each frame lasts 1 ms. So, if the Power Sequence Delay is set to 3, 3 ms will elapse between transitions. When powering off the panel, the signals are transitioned in the opposite order (FP_ENA_BKL, data bus, FP_ENA_VDD) using the same Power Sequence Delay in the power-down sequence.

Functional Description (Continued)

3.9 UNIVERSAL SERIAL BUS SUPPORT

The CS5530A integrates a Universal Serial Bus (USB) controller which supports two ports. The USB controller is OpenHCI compliant, a standard developed by Compaq, Microsoft, and National Semiconductor. The USB core consists of three main interface blocks: the USB PCI interface controller, the USB host controller, and the USB interface controller. Legacy keyboard and mouse controllers are also supported for DOS compatibility with those USB devices.

This document must be used along with the following public domain reference documents for a complete functional description of the USB controller:

- USB Specification Revision 1.0
- OpenHCI Specification, Revision 1.0
- PCI Specification, Version 2.1

3.9.1 USB PCI Controller

The PCI controller interfaces the host controller to the PCI bus. As a master, the PCI controller is responsible for running cycles on the PCI bus on behalf of the host controller. As a target, the PCI controller monitors the cycles on the PCI bus and determines when to respond to these cycles. The USB core is a PCI target when it decodes cycles to its internal PCI configuration registers or to its internal PCI memory mapped I/O registers.

The USB core is implemented as a unique PCI device in the CS5530A. It has its own PCI Header and Configuration space. It is a single-function device, containing only Function #0. Depending on the state of the HOLD_REQ# strap pin at reset, its PCI Device Number for Configuration accesses varies:

If HOLD_REQ# is low, it uses pin AD29 as its IDSEL input, appearing as Device #13h in a Geode system.

If HOLD_REQ# is high, it uses pin AD27 as its IDSEL input, appearing as Device #11h in a Geode system.

The USB core is also affected by some bits in registers belonging to the other (Chipset) device of the CS5530A. In particular, the USB device can be disabled through the Chipset device, F0 Index 43h[0], and its IDSEL can be remapped by changing F0 Index 44h[6] (though this also affects the Chipset device's IDSEL and is not recommended).

All registers can be accessed via 8-, 16-, or 32-bit cycles (i.e., each byte is individually selected by the byte enables). Registers marked as Reserved, and reserved bits within a register are not implemented and should not be modified. These registers are summarized in Table 3-77. For complete bit information, see Table 4-25 "USB Index xxh: USB PCI Configuration Registers" on page 210.

48h-FFh		Reserved

Table 3-77. USB PCI Configuration Registers

www.DataSheet4U.com

DataSheet4 J.com

3.9.2 USB Host Controller

In the USB core is the operational control block. It is responsible for the host controller's operational states (Suspend, Disable, Enable), special USB signals (Reset, Resume), status, interrupt control, and host controller configuration.

The host controller interface registers are memory mapped registers, mapped by USB F0 Index 10h (Base Address Register). These memory mapped registers are summarized in Table 3-78. For bit definitions, refer to Table 4-26 "USB BAR+Memory Offset xxh: USB Controller Registers" on page 213.

3.9.3 USB Power Management

At this time, USB supports minimal system level power management features. The only power management feature implemented is the disabling of the USB clock generator in USB Suspend state. Additional power management features require slight modifications.

The design supports PCICLK frequencies from 0 to 33 MHz. Synchronization between the PCI and USB clock domains is frequency independent. Remote wakeup of USB is asynchronously implemented from the USB Ports to PCI INTA#.

The design needs USBCLK to be operational at all times. If it is necessary to stop the 48 MHz clock, the system design requires that the signal used to enable/disable the USB clock generators is also used to wake the 48 MHz clock source. Currently, the RemoteWakeupConnected and RemoteWakeupEnable bits in the HcControl register are not implemented.

4.0 Register Descriptions

The Geode CS5530A is a multi-function device. Its register space can be broadly divided into four categories in which specific types of registers are located:

- 1) Chipset Register Space (F0-F4)
- 2) USB Controller Register Space (PCIUSB)
- 3) ISA Legacy I/O Register Space (I/O Port)
- 4) V-ACPI I/O Register Space (I/O Port)

The Chipset and the USB Controller Register Spaces are accessed through the PCI interface using the PCI Type One Configuration Mechanism.

The **Chipset Register Space** of the CS5530A is comprised of five separate functions (F0-F4) each with its own register space consisting of PCI header registers and memory or I/O mapped registers.

F0: Bridge Configuration Registers

- F1: SMI Status and ACPI Timer Registers
- F2: IDE Controller Registers

F3: XpressAUDIO Subsystem Registers

F4: Video Controller Registers

The PCI header is a 256-byte region used for configuring a PCI device or function. The first 64 bytes are the same for all PCI devices and are predefined by the PCI specification. These registers are used to configure the PCI for the device. The rest of the 256-byte region is used to configure the device or function itself.

The **USB Controller Register Space** consists of the stanneet4U.com dard PCI header registers. The USB controller supports two ports and is OpenHCI-compliant.

The **ISA Legacy I/O Register Space** contains all the legacy compatibility I/O ports that are internal, trapped, shadowed, or snooped.

The V-ACPI I/O Register Space contains two types of registers: Fixed Feature and General Purpose. These registers are emulated by the SMI handling code rather than existing in physical hardware. To the ACPI-compliant operating system, the SMI-base virtualization is transparent. An ACPI compliant system is one whose underlying BIOS, device drivers, chipset and peripherals conform to revision 1.0 or newer of the Advanced Control and Power Interface specification.

The CS5530A V-ACPI (Virtual ACPI) solution provides the following support:

- CPU States C1, C2
- Sleep States S1, S2, S4, S4BIOS, S5
- Embedded Controller (Optional) SCI and SWI event inputs
- General Purpose Events Fully programmable GPE0 Event Block registers

The remaining subsections of this chapter are as follows:

- A brief discussion on how to access the registers located in the PCI Configuration Space
- Register summary

Detailed bit formats of all registers

Register Descriptions (Continued)

4.1 PCI CONFIGURATION SPACE AND ACCESS METHODS

Configuration cycles are generated in the processor. All configuration registers in the CS5530A are accessed through the PCI interface using the PCI Type One Configuration Mechanism. This mechanism uses two DWORD I/O locations at 0CF8h and 0CFCh. The first location (0CF8h) references the Configuration Address Register. The second location (0CFCh) references the Configuration Data Register.

To access PCI configuration space, write the Configuration Address (0CF8h) Register with data that specifies the CS5530A as the device on PCI being accessed, along with the configuration register offset. On the following cycle, a read or write to the Configuration Data Register (CDR) causes a PCI configuration cycle to the CS5530A. BYTE, WORD, or DWORD accesses are allowed to the CDR at 0CFCh, 0CFDh, 0CFEh, or 0CFFh.

The CS5530A has six configuration register sets, one for each function (F0-F4) and USB (PCIUSB). Base Address Registers (BARs) in the PCI header registers are pointers for additional I/O or memory mapped configuration registers.

Table 4-1 shows the PCI Configuration Address Register (0CF8h) and how to access the PCI header registers.

Table 4-14. V-ACPI I/O Register Space Summary

et4U.com

DataSheet4U.com

DataShe

DataSheet4U.com

4.3 CHIPSET REGISTER SPACE

The Chipset Register Space of the CS5530A is comprised of five separate functions (Function 0 through 4, F0-F4), each with its own register space and PCI header registers. F1-F4 have memory or I/O mapped registers from a Base Address Register (BAR). The PCI header registers in all functions are very similar.

- F0: Bridge Configuration Register Space
- F1: SMI Status and ACPI Timer Register Space
- F2: IDE Controller Register Space
- F3: XpressAUDIO Subsystem Register Space
- F4: Video Controller Register Space

_

Bridge Configuration Registers - Function 0 4.3.1

The register space designated as Function 0 (F0) contains registers used to configure features (e.g., power management) and functionality unique to the CS5530A. All registers in Function 0 are directly accessed (i.e., there are no memory or I/O mapped registers in F0). Table 4-15 gives the bit formats for these registers.

The registers at F0 Index 50h-FFh can also be accessed at F1BAR+Memory Offset 50h-FFh. The preferred method is to program these registers through the F0 register space.

If the F0 PCI Configuration Trap bit (F0 Index 41h[0]) is enabled and an access is attempted to any of the F0 PCI header and bridge configuration registers except F0 Index 40h-43h, an SMI is generated instead.

Bit	Description	
Index 00h	-01h Vendor Identification Register (RO)	Reset Value = 1078h

	Table 4-15. F0 Index xxh: PCI Header and Bridge Configuration Registers (Continued)
Bit	Description
1	F4 Video Configuration Trap: 0 = Disable; 1 = Enable.
	If this bit is enabled and an access is attempted to one of the F4 PCI header registers, an SMI is generated instead.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[9].
	Second level SMI status is reported at F1BAR+Memory Offset 04h/06h[5].
0	F3 Audio Configuration Trap: 0 = Disable; 1 = Enable.
	If this bit is enabled and an access is attempted to one of the F3 PCI header registers, an SMI is generated instead.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[9].
	Second level SMI status is reported at F1BAR+Memory Offset 04h/06h[5].
ex 43ł	n USB Shadow Register (R/W) Reset Value = 03h
7	Reserved: Set to 0.
6	Enable SA20: Pin AD22 configuration. 0 = GPIO4; 1 = SA20. If bit 6 or bit 2 is set to 1, then pin AD22 = SA20.
5	Legacy Cycles Assert HOLD_REQ#: Allow legacy cycles to cause HOLD_REQ# to be asserted. 0 = Disable; 1 = Enable.
	Note: The HOLD_REQ# signal function is no longer applicable, this bit must remain at its reset value (i.e., disable).
4	Read Cycles Assert HOLD_REQ#: Allow read cycles to cause HOLD_REQ# to be asserted. 0 = Disable; 1 = Enable.
	Note: The HOLD_REQ# signal function is no longer applicable, this bit must remain at its reset value (i.e., disable).
3	Any Cycle Asserts HOLD_REQ#: Allow any cycle to cause HOLD_REQ# to be asserted. 0 = Disable; 1 = Enable.
	Note: The HOLD_REQ# signal function is no longer applicable, this bit must remain at its reset value (i.e., disable).
2	Enable SA[23:20]: Pins AF23, AE23, AC21, and AD22 configuration. 0 = GPIO[7:4]; 1 = SA[23:20]. If F0 Index 43h bit 6 or bit 2 is set to 1, then pin AD22 = SA20.
1	PCI Retry Cycles: When the CS5530A is a PCI target and the PCI buffer is not empty, allow the PCI bus to retry cycles. 0 = Disable; 1 = Enable.
	This bit works in conjunction with PCI bus delayed transactions bit. F0 Index 42h[5] must = 1 for this bit to be valid.
0	USB Core: 0 = Disable; 1 = Enable.
ex 44ł	n Reset Control Register (R/W) Reset Value = 01h
7	ISA Mode: This bit is set to read back the strap value of the INTR pin (pin P26) during POR.
	0 = ISA Limited; 1 = ISA Master.
	This bit can be written after POR# deasserts to change the ISA mode selected. However, writing to this bit is not recom-
	mended due to the actual strapping done on the board.
6	IDSEL Mode: This bit is set to read back the strap value of the HOLD_REQ# pin (pin H26) during POR. 0 = AD28 is IDSEL for Chipset Register Space and AD29 is IDSEL for USB Register Space; 1 = AD26 is IDSEL for Chipset Register Space and AD27 is IDSEL for USB Register Space.
	This bit can be written after POR# deasserts to change the IDSEL settings. However, writing to this bit is not recommended due to the actual strapping done on the board.
5:4	Clock 32K Control: Controls the source of the CLK_32K pin (AE3). 00 = CLK_32K is internally derived from CLK_14MHZ (pin P24) and is not output on pin AE3 (Default) 01 = CLK_32K is internally derived from CLK_14MHZ (pin P24) and is output on pin AE3 10 = CLK_32K is an input 11 = Invalid
3	IDE Controller Reset: Reset both of the CS5530A IDE controllers' internal state machines. 0 = Run; 1 = Reset.
	This bit is level-sensitive and must be explicitly cleared to 0 to remove the reset.
2	IDE Reset: Reset IDE bus. 0 = Deassert IDE bus reset signal; 1 = Assert IDE bus reset signal.
	This bit is level-sensitive and must be explicitly cleared to 0 to remove the reset.
1	PCI Reset: Reset PCI bus. 0 = Disable; 1 = Enable.
	When set, the CS5530A PCI_RST# output signal (pin C14) is asserted and all devices on the PCI bus including PCIUSB are reset. No other function within the CS5530A is affected by this bit. It does not reset PCI registers.
	Write 0 to clear. This bit is level-sensitive and must be cleared after the reset is enabled.
0	X-Bus Warm Start: Reading and writing this bit has two different meanings/functions.
	Reading this bit: Has a warm start occurred since power-up? 0 = Yes; 1 = No
	Writing this bit: $0 = NOP$; $1 = Execute system wide reset (used only for clock configuration at power-up).$

Bit Index 80h	Description Power Management Enable Register 1 (R/W) Reset Value =
	Power Management Enable Register 1 (R/W) Reset Value = Reserved: Set to 0.
7:6 5	Codec SDATA_IN SMI: Allow AC97 codec to generate an SMI due to codec producing a positive edge on SDATA_IN
	0 = Disable; 1 = Enable. Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 87h/F7h[2].
4	 Video Speedup: Any video activity, as decoded from the serial connection (PSERIAL register, bit 0) from the GX-serial cessor disables clock throttling (via SUSP#/SUSPA# handshake) for a configurable duration when the system is power aged using CPU Suspend modulation. 0 = Disable; 1 = Enable.
	The duration of the speedup is configured in the Video Speedup Timer Count Register (F0 Index 8Dh). Detection of a external VGA access (3Bxh, 3Cxh, 3Dxh and A000h-B7FFh) on the PCI bus is also supported. This configuration is r standard, but it does allow the power management routines to support an external VGA chip.
3	IRQ Speedup: Any unmasked IRQ (per I/O Port 021h/0A1h) or SMI disables clock throttling (via SUSP#/SUSPA# has shake) for a configurable duration when the system is power managed using CPU Suspend modulation. 0 = Disable; 1 = Enable.
	The duration of the speedup is configured in the IRQ Speedup Timer Count Register (F0 Index 8Ch).
2	Traps: Globally enable all power management device I/O traps. 0 = Disable; 1 = Enable.
	This excludes the audio I/O traps. They are enabled at F3BAR+Memory Offset 18h.
1	Idle Timers: Globally enable all power management device idle timers. 0 = Disable; 1 = Enable.
	Note, disable at this level does not reload the timers on the enable. The timers are disabled at their current counts.
	This bit has no effect on the Suspend Modulation OFF/ON Timers (F0 Index 94h/95h), nor on the General Purpose (UI Timers (F0 Index 88h-8Bh). This bit must be set for the command to trigger the SUSP#/SUSPA# feature to function (s Index AEh).
0	Power Management: Global power management. 0 = Disable; 1 = Enabled.
	This bit must be set (1) immediately after POST for some power management resources to function. Until this is done command to trigger the SUSP#/SUSPA# feature is disabled (see F0 Index AEh) and all SMI# trigger events listed for F0 Index 84h-87h are disabled. A '0' in this bit does NOT stop the Idle Timers if bit 1 of this register is a '1', but only pre them from generating an SMI# interrupt. It also has no effect on the UDEF traps.

Register Descriptions (Continued)

Index 91h	Bower Management Enable Register 2 (R/M) Beset Value – 00b
Index 81h	
7	Video Access Idle Timer Enable: Load timer from Video Idle Timer Count Register (F0 Index A6h) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
l	If an access occurs in the video address range (sets bit 0 of the GX-series processor's PSERIAL register) the timer is reloaded with the programmed count.
l	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0].
	Second level SMI status is reported at F0 Index 85h/F5h[7].
6	User Defined Device 3 (UDEF3) Idle Timer Enable: Load timer from UDEF3 Idle Timer Count Register (F0 Index A4h) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	If an access occurs in the programmed address range the timer is reloaded with the programmed count. UDEF3 address programming is at F0 Index C8h (base address register) and CEh (control register).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0].
	Second level SMI status is reported at F0 Index 85h/F5h[6].
5	User Defined Device 2 (UDEF2) Idle Timer Enable: Load timer from UDEF2 Idle Timer Count Register (F0 Index A2h) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	If an access occurs in the programmed address range the timer is reloaded with the programmed count. UDEF2 address programming is at F0 Index C4h (base address register) and CDh (control register).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0].
4	Second level SMI status is reported at F0 Index 85h/F5h[5]. User Defined Device 1 (UDEF1) Idle Timer Enable: Load timer from UDEF1 Idle Timer Count Register (F0 Index A0h) and
	generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
l	If an access occurs in the programmed address range the timer is reloaded with the programmed count. UDEF1 address programming is at F0 Index C0h (base address register) and CCh (control register).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0].
3	Second level SMI status is reported at F0 Index 85h/F5h[4].
J	Keyboard/Mouse Idle Timer Enable: Load timer from Keyboard/Mouse Idle Timer Count Register (F0 Index 9Eh) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	If an access occurs in the address ranges (listed below) the timer is reloaded with the programmed count. Keyboard Controller: I/O Ports 060h/064h
	COM1: I/O Port 3F8h-3FFh (if F0 Index 93h[1:0] = 10 this range is included)
I	COM2: I/O Port 2F8h-2FFh (if F0 Index 93h[1:0] = 11 this range is included)
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 85h/F5h[3].
2	Parallel/Serial Idle Timer Enable: Load timer from Parallel/Serial Port Idle Timer Count Register (F0 Index 9Ch) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
I	If an access occurs in the address ranges (listed below) the timer is reloaded with the programmed count.
	LPT1: I/O Port 378h-37Fh, 778h-77Ah LPT2: I/O Port 278h-27Fh, 678h-67Ah
ı	COM1: I/O Port 3F8h-3FFh (if F0 Index 93h[1:0] = 10 this range is excluded)
l	COM2: I/O Port 2F8h-2FFh (if F0 Index 93h[1:0] = 11 this range is excluded) COM3: I/O Port 3E8h-3EFh
l	COM4: I/O Port 2E8h-2EFh
I	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 85h/F5h[2].
1	Floppy Disk Idle Timer Enable: Load timer from Floppy Disk Idle Timer Count Register (F0 Index 9Ah) and generate an
l	SMI when the timer expires. 0 = Disable; 1 = Enable. If an access occurs in the address ranges (listed below) the timer is reloaded with the programmed count.
I	Primary floppy disk: I/O Port 3F2h, 3F4h, 3F5h, and 3F7
l	Secondary floppy disk: I/O Port 372h, 373h, 375h, and 377h
<u> </u>	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 85h/F5h[1].
0	Primary Hard Disk Idle Timer Enable: Load timer from Primary Hard Disk Idle Timer Count Register (F0 Index 98h) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
I	If an access occurs in the address ranges selected in F0 Index 93h[5], the timer is reloaded with the programmed count.
1	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 85h/F5h[0].

Register Descriptions (Continued)

Description

Geode[™] CS5530A

	1

dex 83h	Power Management Enable Register 4 (R/W) Reset Value = 00h
7	Secondary Hard Disk Idle Timer Enable: Load timer from Secondary Hard Disk Idle Timer Count Register (F0 Index ACh) and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	If an access occurs in the address ranges selected in F0 Index 93h[4], the timer is reloaded with the programmed count.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 86h/F6h[4].
6	Secondary Hard Disk Trap: 0 = Disable; 1 = Enable.
	If this bit is enabled and an access occurs in the address ranges selected in F0 Index 93h[4], an SMI is generated.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 86h/F6h[5].
5	ACPI Timer SMI: Allow SMI generation for MSB toggles on the ACPI Timer (F1BAR+Memory Offset 1Ch or I/O Port 121Ch). 0 = Disable; 1 = Enable.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 87h/F7h[0].
4	Game Port Read SMI: Allow SMI generation on reads to game port (I/O Port 200h and 201h). 0 = Disable; 1 = Enable.
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 84h/F4h[4].
	For "Game Port Write SMI" see F0 Index 53h[3].
3	VGA Timer Enable: Turn on VGA Timer and generate an SMI when the timer reaches 0. 0 = Disable; 1 = Enable.
	VGA Timer programming is at F0 Index 8Eh and F0 Index 8Bh[6].
	To reload the count in the VGA timer, disable it, optionally change the count value in F0 Index 8Eh[7:0], and reenable it before enabling power management.
	SMI Status reporting is at F1BAR+Memory Offset 00h/02h[6] (only).
	Although grouped with the power management Idle Timers, the VGA Timer is not a power management function. The VGA Timer counts whether power management is enabled or disabled.
2	Video Retrace Interrupt SMI: Allow SMI generation whenever video retrace occurs. 0 = Disable; 1 = Enable.
	This information is decoded from the serial connection (PSERIAL register, bit 7) from the GX-series processor. This function is normally not used for power management but for softVGA routines.
	SMI status reporting is at F1BAR+Memory Offset 00h/02h[5] (only).
1	General Purpose Timer 2 (GP Timer 2) Enable: Turn on GP Timer 2 and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	This idle timer is reloaded from the assertion of GPIO7 (if programmed to do so). GP Timer 2 programming is at F0 Index 8Ah and 8Bh[5,3,2].
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[9]. Second level SMI status is reported at F1BAR+Memory Offset 04h/06h[1].
0	General Purpose Timer 1 (GP Timer 1) Enable: Turn on GP Timer 1 and generate an SMI when the timer expires. 0 = Disable; 1 = Enable.
	This idle timer's load is multi-sourced and is reloaded any time an enabled event (F0 Index 89h[6:0]) occurs. GP Timer 1 programming is at F0 Index 88h and 8Bh[4].
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[9]. Second level SMI status is reported at F1BAR+Memory Offset 04h/06h[0]

T	able 4-15. F0 Index xxh: PCI Header and Bridge Configuration Registers (Continued)
Bit	Description
Index 87h	Second Level Power Management Status Mirror Register 4 (RO) Reset Value = 00h
7	GPIO2 SMI Status (Read Only): SMI was caused by transition on (properly-configured) GPIO2 pin? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 92h[2].
6	GPIO1 SMI Status (Read Only): SMI was caused by transition on (properly-configured) GPIO1 pin? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 92h[1].
5	GPIO0 SMI Status (Read Only): SMI was caused by transition on (properly-configured) GPIO0 pin? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[0].
	SMI generation enabling is at F0 Index 92h[0].
4	Lid Position (Read Only): This bit maintains the current status of the lid position. If the GPIO6 pin is configured as the lid switch indicator, this bit reflects the state of the pin.
3	Lid Switch SMI Status (Read Only): SMI was caused by a transition on the GPIO6 (lid switch) pin? 0 = No; 1 = Yes.
	For this to happen, the GPIO6 pin must be configured both as an input (F0 Index 90h[6] = 0) and as the lid switch (F0 Index 92h[6] =1).
2	Codec SDATA_IN SMI Status (Read Only): SMI was caused by AC97 codec producing a positive edge on SDATA_IN?

 SMI generation configuration is at F0 Index 83h[5].

 Note:
 Properly-configured means that the GPIO pin must be enabled as a GPIO (if multiplexed pin), an input, and to cause an SMI. This register provides status on several miscellaneous power management events that generate SMIs, as well as the status of the Lid Switch. It is called a Mirror register since an identical register exists at F0 Index F7h. Reading this register does not clear the status, while reading its counterpart at F0 Index F7h does clear the status.

This is the second level of status is reporting. The top level status is reported at F1BAR+Memory Offset 00h/02h[0].

This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[0].

This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[0].

RTC Alarm (IRQ8) SMI Status (Read Only): SMI was caused by an RTC interrupt? 0 = No; 1 = Yes.

ACPI Timer SMI Status (Read Only): SMI was caused by an ACPI Timer MSB toggle? 0 = No; 1 = Yes.

This SMI event can only occur while in 3V Suspend and an RTC interrupt occurs.

Index 88h	General Purpose Timer 1 Count Register (R/W)	Reset Value = 00h
7:0	General Purpose Timer 1 Count: This register holds the load value for GP Timer 1. This value can bit or 16-bit timer (selected at F0 Index 8Bh[4]). It is loaded into the timer when the timer is enabled Once enabled, an enabled event (configured in F0 Index 89h[6:0]) reloads the timer.	
	The timer is decremented with each clock of the configured timebase. Upon expiration of the timer, a the top level SMI status is reported at F1BAR+Memory Offset 00h/02h[9]. The second level SMI stat F1BAR+Memory Offset 04h/06h[0]).	0
	Once expired, this timer must be re-initialized by either disabling and enabling it, or writing a new co	unt value here.
	This timer's timebase can be configured as 1 msec or 1 sec at F0 Index 89h[7].

0	GPIO0 Data: Reflects the level of GPIO0. 0 = Low; 1 = High.
	register contains the direct values of GPIO[7:0] pins. Write operations are valid only for bits defined as output. Reads from register read the last written value if the pin is an output. The pins are configured as inputs or outputs in F0 Index 90h.
Index 92h	GPIO Control Register 1 (R/W) Reset Value = 00h
7	GPIO7 Edge Sense for Reload of General Purpose Timer 2: Selects which edge transition of GPIO7 causes GP Timer 2 to reload. 0 = Rising; 1 = Falling (Note 2).
6	GPIO6 Enabled as Lid Switch: Allow GPIO6 to act as the lid switch input. 0 = GPIO6; 1 = Lid switch.
	When enabled, every transition of the GPIO6 pin causes the lid switch status to toggle and generate an SMI.
	The top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status is reported at F0 Index 87h/F7h[3].
	If GPIO6 is enabled as the lid switch, F0 Index 87h/F7h[4] reports the current status of the lid's position.
5	GPIO2 Edge Sense for SMI: Selects which edge transition of the GPIO2 pin generates an SMI. 0 = Rising; 1 = Falling.
	Bit 2 must be set to enable this bit.
4	GPIO1 Edge Sense for SMI: Selects which edge transition of the GPIO1 pin generates an SMI. 0 = Rising; 1 = Falling. Bit 1 must be set to enable this bit.
3	GPIO0 Edge Sense for SMI: Selects which edge transition of the GPIO0 pin generates an SMI. 0 = Rising; 1 = Falling.
-	Bit 1 must be set to enable this bit.
2	Enable GPIO2 as an External SMI Source: Allow GPIO2 to be an external SMI source and generate an SMI on either a rising or falling edge transition (depends upon setting of bit 5). 0 = Disable; 1 = Enable (Note 3).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[7].
1	Enable GPIO1 as an External SMI Source: Allow GPIO1 to be an external SMI source and generate an SMI on either a rising- or falling-edge transition (depends upon setting of bit 4). 0 = Disable; 1 = Enable (Note 3).
	Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[6].
0	Enable GPIO0 as an External SMI Source: Allow GPIO0 to be an external SMI source and generate an SMI on either a rising or falling edge transition (depends upon setting of bit 3). 0 = Disable; 1 = Enable (Note 3)
0	
	rising or falling edge transition (depends upon setting of bit 3). $0 = Disable; 1 = Enable (Note 3)$ Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0].
Notes: 1) F	rising or falling edge transition (depends upon setting of bit 3). 0 = Disable; 1 = Enable (Note 3) Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[0]. Second level SMI status reporting is at F0 Index 87h/F7h[5].

the	register provides status on several miscellaneous power management events that generate SMIs id Switch. Reading this register clears the SMI status bits. A read-only (mirror) version of this reg ndex 87h.	
ndex F8h-	FFh Reserved	Reset Value = xxh

Register Descriptions (Continued)

4.3.2 SMI Status and ACPI Timer Registers - Function 1

The register space for the SMI status and ACPI Timer registers is divided into two sections. The first section is used to configure the PCI portion of this support hardware. A Base Address Register at F1 Index 10h (F1BAR) points to the base address of where the second portion of the register space is located. This second section contains the SMI status and ACPI timer support registers.

Note: The ACPI Timer Count Register is accessible through F1BAR+Memory Offset 1Ch and I/O Port 121Ch.

Table 4-16 shows the PCI header registers of F1. The memory mapped registers accessed through F1BAR are shown in Table 4-17.

If the Power Management Configuration Trap bit (F0 Index 41h[3]) is enabled, an access to the PCI header registers causes an SMI. Access through F1BAR is not affected by this bit.

Register Descriptions (Continued)

4.3.3 IDE Controller Registers - Function 2

The register space for the IDE controllers is divided into two sections. The first section is used to configure the PCI portion of the controller. A Base Address Register at F2 Index 20h points to the base address of where the second portion of the register space is located. This second section contains the registers used by the IDE controllers to carry out operations. Table 4-18 shows the PCI header registers of F2. The I/O mapped registers, accessed through F2BAR, are shown in Table 4-19.

If the IDE Configuration Trap bit (F0 Index 41h[6]) is set, access to the PCI header registers causes an SMI. Access through F2BAR is not affected by this bit.

Register Descriptions (Continued)

4.3.4 XpressAUDIO Registers - Function 3

The register space for XpressAUDIO is divided into two sections. The first section is used to configure the PCI portion of the audio interface hardware. A Base Address Register at F3 Index 10h (F3BAR) points to the base address of where the second portion of the register space is located. This second section contains the control and data registers of the audio interface.

Table 4-20 shows the PCI header registers of F3. The memory mapped registers accessed through F3BAR are shown in Table 4-21.

If the F3 Audio Configuration Trap bit (F0 Index 42h[0]) is enabled, an access to the PCI header registers causes an SMI. Access through F3BAR is not affected by this bit.

Table 4-20. F3 Index xxh: PCI Header Registers for XpressAUDIO

Bit	Description

•	ter Descriptions (Continued) able 4-21. F3BAR+Memory Offset xxh: XpressAUDIO Configuration Registers (Continued)
Bit	Description
Offset 1	0h-11h Second Level Audio SMI Status Register (RC) Reset Value = 00
15:8	Reserved: Set to 0.
7	Audio Bus Master 5 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 5?
	0 = No; 1 = Yes. This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation is enabled when Audio Bus Master 5 is enabled (F3BAR+Memory Offset 48h[0] = 1). An SMI is then
	generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 49h[0] = 1).
6	Audio Bus Master 4 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 4? 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation is enabled when Audio Bus Master 4 is enabled (F3BAR+Memory Offset 40h[0] = 1). An SMI is then
5	generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 41h[0] = 1). Audio Bus Master 3 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 3?
5	0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation is enabled when Audio Bus Master 3 is enabled (F3BAR+Memory Offset 38h[0] = 1). An SMI is then generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 39h[0] = 1).
4	Audio Bus Master 2 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 2?
	0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation is enabled when Audio Bus Master 2 is enabled (F3BAR+Memory Offset 30h[0] = 1). An SMI is then generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 31h[0] = 1).
3	Audio Bus Master 1 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 1?
	0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1]. SMI generation is enabled when Audio Bus Master 1 is enabled (F3BAR+Memory Offset 28h[0] = 1). An SMI is then
	generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 29h[0] = 1).
2	Audio Bus Master 0 SMI Status (Read to Clear): SMI was caused by an event occurring on Audio Bus Master 0?
	0 = No; 1 = Yes. This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation is enabled when Audio Bus Master 0 is enabled (F3BAR+Memory Offset 20h[0] = 1). An SMI is then
	generated when the End of Page bit is set in the SMI Status Register (F3BAR+Memory Offset 21h[0] = 1).
1	Codec Serial or GPIO Interrupt SMI Status (Read to Clear): SMI was caused by a serial or GPIO interrupt from cod 0 = No; 1 = Yes.
	This is the second level of SMI status reporting. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation enabling for codec serial interrupt: F3BAR+Memory Offset 08h[23] = 1.
0	SMI generation enabling for codec GPIO interrupt: F3BAR+Memory Offset 00h[30] = 1.
0	I/O Trap SMI Status (Read to Clear): SMI was caused by an I/O trap? 0 = No; 1 = Yes. This is the second level of SMI status reporting. The next level (third level) of SMI status reporting is at F3BAR+Memo
	Offset 14h. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
Note: F	Reading this register clears the status bits. Note that bit 0 has another level (third) of SMI status reporting.
	read-only "Mirror" version of this register exists at F3BAR+Memory Offset 12h. If the value of the register must be read wi learing the SMI source (and consequently deasserting SMI), the Mirror register may be read instead.

Table 4-21. F3BAR+Memory Offset xxh: XpressAUDIO Configuration Registers (Continued)

Offset 14h	-17h I/O Trap SMI and Fast Write Status Register (RO/RC) Reset Value = 00000000h
31:24	Fast Path Write Even Access Data (Read Only): These bits contain the data from the last Fast Path Write Even access.
23:16	These bits change only on a fast write to an even address. Fast Path Write Odd Access Data (Read Only): These bits contain the data from the last Fast Path Write Odd access.
	These bits change on a fast write to an odd address, and also on any non-fast write.
15	Fast Write A1 (Read Only): This bit contains the A1 value for the last Fast Write access.
14	Read or Write I/O Access (Read Only): Last trapped I/O access was a read or a write? 0 = Read; 1 = Write.
13	Sound Card or FM Trap SMI Status (Read to Clear): SMI was caused by a trapped I/O access to the sound card or FM I/O Trap? 0 = No; 1 = Yes. (Note)
	Fast Path Write must be enabled, F3BAR+Memory Offset 18h[11] = 1, for the SMI to be reported here. If Fast Path Write is disabled, the SMI is reported in bit 10 of this register.
	This is the third level of SMI status reporting.
	The second level of SMI status is reported at F3BAR+Memory Offset 10h/12h[0]. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation enabling is at F3BAR+Memory Offset 18h[2].
12	DMA Trap SMI Status (Read to Clear): SMI was caused by a trapped I/O access to the DMA I/O Trap?
	0 = No; 1 = Yes. (Note) This is the third level of SMI status reporting.
	The second level of SMI status is reported at F3BAR+Memory Offset 10h/12h[0].
	The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation enabling is at F3BAR+Memory Offset 18h[8:7].
11	MPU Trap SMI Status (Read to Clear): SMI was caused by a trapped I/O access to the MPU I/O Trap? 0 = No; 1 = Yes. (Note)
	This is the third level of SMI status reporting.
	The second level of SMI status is reported at F3BAR+Memory Offset 10h/12h[0].
	The top level is reported at F1BAR+Memory Offset 00h/02h[1].com
	SMI generation enabling is at F3BAR+Memory Offset 18h[6:5].
10	Sound Card or FM Trap SMI Status (Read to Clear): SMI was caused by a trapped I/O access to the sound card or FM I/O Trap? 0 = No; 1 = Yes. (Note)
	Fast Path Write must be disabled, F3BAR+Memory Offset 18h[11] = 0, for the SMI to be reported here. If Fast Path Write is enabled, the SMI is reported in bit 13 of this register.
	This is the third level of SMI status reporting.
	The second level of SMI status is reported at F3BAR+Memory Offset 10h/12h[0]. The top level is reported at F1BAR+Memory Offset 00h/02h[1].
	SMI generation enabling is at F3BAR+Memory Offset 18h[2].
9:0	X-Bus Address (Read Only): Bits [9:0] contain the captured ten bits of X-Bus address.
	the four SMI status bits (bits [13:10]), if the activity was a fast write to an even address, no SMI is generated regardless of the
	A, MPU, or sound card status. If the activity was a fast write to an odd address, an SMI is generated but bit 13 is set to a 1.

Table 4-21. F3BAR+Memory Offset xxh: XpressAUDIO Configuration Registers (Continued)

I/O Trap SMI Enable Register (R/W)

Fast Path Write Enable: Fast Path Write (an SMI is not generated on certain writes to specified addresses).

Fast Read: These two bits hold part of the response that the CS5530A returns for reads to several I/O locations.

If this bit is enabled and an access occurs at I/O Port C0h-DFh, an SMI is generated.

If this bit is enabled and an access occurs at I/O Port 00h-0Fh, an SMI is generated.

If this bit is enabled and an access occurs at I/O Port 330h and 331h, an SMI is generated.

If this bit is enabled and an access occurs at I/O Port 300h and 301h, an SMI is generated.

If this bit is enabled and an access occurs at I/O Port 388h to 38Bh, an SMI is generated.

Fast Path Read Enable/SMI Disable: Read Fast Path (an SMI is not generated on reads from specified addresses).

Note that if neither sound card nor FM I/O mapping is enabled, then status read trapping is not possible.

If this bit is enabled and an access occurs in the address ranges selected by bits [1:0], an SMI is generated.

Sound Card Address Range Select: These bits select the address range for the sound card I/O trap.

10 = I/O Port 260h-26Fh

11 = I/O Port 280h-28Fh

In Fast Path Read the CS5530A responds to reads of the following addresses: 388h-38Bh; 2x0h, 2x1h, 2x2h, 2x3h, 2x8h

Top level SMI status is reported at F1BAR+Memory Offset 00h/02h[1]. Second level SMI status is reported at F3BAR+Memory Offset 10h/12h[0]. Third level SMI status is reported at F3BAR+Memory Offset 14h[12].

Audio Bus	Master 5: Input from Codec; 16-Bit; Slot 6 or 11 (F3BAR+Memory Offset 08h[20] selects slot).
31:2	Pointer to the Physical Region Descriptor Table: This register is a PRD table pointer for Audio Bus Master 5. When written, this register points to the first entry in a PRD table. Once Audio Bus Master 5 is enabled (Command Regis bit 0 = 1], it loads the pointer and updates this register to the next PRD by adding 08h. When read, this register points to the next PRD.

Register Descriptions (Continued)

4.3.5 Video Controller Registers - Function 4

The register space for the video controller is divided into two sections. The first section is used to configure the PCI portion of the controller. A Base Address Register at F4 Index 10h (F4BAR) points to the base address of where the second portion of the register space is located. The second section contains the registers used by the video controller to carry out video operations. Table 4-22 shows the PCI header registers of F4. The memory mapped registers accessed through F4BAR, and shown in Table 4-23, must be accessed using DWORD operations. When writing to one of these 32-bit registers, all four bytes must be written.

If the F4 Video Configuration Trap bit (F0 Index 42h[1]) is set, access to the PCI header registers causes an SMI. Access through F4BAR is not affected by this bit.

Table 4-22. F4 Index xxh: PCI Header Registers for Video Controller Configuration

	Description	
Index 00h-	01h Vendor Identification Register (RO)	Reset Value = 1078h
Index 02h-	03h Device Identification Register (RO)	Reset Value = 0104h
Index 04h-	05h PCI Command Register (R/W)	Reset Value = 0000h
15:2	Reserved (Read Only)	
1	Memory Space: Allow CS5530A to respond to memory cycles from the PCI bus. 0 = I	Disable; 1 = Enable.
	This bit must be enabled to access memory offsets through F4BAR (F4 Index 10h).	
0	Reserved (Read Only)	
Index 06h-	07h PCI Status Register (RO)	Reset Value = 0280h
Index 08h	Device Revision ID Register (RO)	Reset Value = 00h
Index 09h-	0Bh PCI Class Code Register (RO)	Reset Value = 030000h

Register Descriptions (Continued)

4.4 USB REGISTERS

The USB Host Controller exists logically as its own PCI "Device", separate from the Chipset functions. It is a single-function device, and so it contains a PCI Configuration space for only Function 0. Depending on the state of the HOLD_REQ# pin on reset, the USB Controller will respond to one of two Device numbers for access to its PCI Configuration registers:

HOLD_REQ# low: Responds to pin AD29 high (Device 13h in a Geode system).

HOLD_REQ# high: Responds to pin AD27 high (Device 11h in a Geode system).

The PCI Configuration registers are listed in Table 4-25. They can be accessed as any number of bytes within a single 32-bit aligned unit. They are selected by the PCI-standard Index and Byte-Enable method. Registers marked as "Reserved", and reserved bits within a register, should not be changed by software.

In the PCI Configuration space, there is one Base Address Register (BAR), at Index 10h, which is used to map the USB Host Controller's operational register set into a 4K memory space. Once the BAR register has been initialized, and the PCI Command register at Index 04h has been set to enable the Memory space decoder, these "USB Controller" registers are accessible.

The memory-mapped USB Controller Registers are listed in Table 4-26. They follow the Open Host Controller Interface (OHCI) specification.

Table 4-25.	USB Index xxh: USB PCI Configuration Registers	

Bit Description						
Index 00h	-01h Vendor Identification Register (RO)	Reset Value = 0E11h				
Index 02h	-03h Device Identification Register (RO)	Reset Value = A0F8h				
Index 04h	-05h Command Register (R/W)	Reset Value = 0000h				
15:10	Reserved: Set to 0.					
9	Fast Back-to-Back Enable (Read Only): USB only acts as a master to a single device, so this functionality is not needed It is always disabled (must always be set to 0).					
8	SERR#: USB asserts SERR# when it detects an address parity error. 0 = Disable; 1 = Enable.					
7	Wait Cycle Control: USB does not need to insert a wait state between the address and data on the AD lines. It is always disabled (bit is set to 0).					
6	 Parity Error: USB asserts PERR# when it is the agent receiving data and it detects a data parity error. 0 = Disable; 1 = Enable. 					
5	VGA Palette Snoop Enable (Read Only): USB does not support this function. It is always disabled (bit is set to 0).					
4	Memory Write and Invalidate: Allow USB to run Memory Write and Invalidate commands. 0 = Disable; 1 = Enable.					
	The Memory Write and Invalidate command will only occur if the cache line size is set to 32 bytes and the memory write exactly one cache line.					
	If the CS5530A is being used in a GX-series processor based system, this bit must be s	set to 0.				
3	Special Cycles: USB does not run special cycles on PCI. It is always disabled (bit is se	et to 0).				
2	PCI Master Enable: Allow USB to run PCI master cycles. 0 = Disable; 1 = Enable.					
1	Memory Space: Allow USB to respond as a target to memory cycles. 0 = Disable; 1 = E	Enable.				
0	I/O Space: Allow USB to respond as a target to I/O cycles. 0 = Disable; 1 = Enable.

Register Descriptions (Continued)

4.5 CS5530A ISA LEGACY I/O REGISTER SPACE

The bit formats for the ISA Legacy I/O Registers plus two chipset-specific configuration registers used for interrupt mapping in the CS5530A are given in this section. These registers reside in the ISA I/O address space in the address range from 000h to FFFh and are accessed through typical input/output instructions (i.e., CPU direct R/W) with the designated I/O port address and 8-bit data. The registers are separated into the following categories:

- DMA Channel Control Registers, see Table 4-27
- DMA Page Registers, see Table 4-28

- Programmable Interval Timer Registers, see Table 4-29
- Programmable Interrupt Controller Registers, see Table 4-30
- Keyboard Controller Registers, see Table 4-31
- Real Time Clock Registers, see Table 4-32
- Miscellaneous Registers, see Table 4-33 (includes 4D0h and 4D1h Interrupt Edge/Level Select Registers and ACPI Timer Count Register at I/O Port 121Ch)

	er Descriptions (Continued)	
	Table 4-31. Keyboard Controller Registers	
Bit	Description	
O Port 0(60h (R/W) External Keyboard Controller Data Register	
eyboard ires are e	Controller Data Register: All accesses to this port are passed to the ISA bus. If the fast keyboard gate A20 and reset enabled through bit 7 of the ROM/AT Logic Control Register (F0 Index 52h[7]), the respective sequences of writes to this A20M# pin or cause a warm CPU reset.	
O Port 06	61h (R/W) Port B Control Register Reset Value = 00x01	100b
7	PERR#/SERR# Status (Read Only): Was a PCI bus error (PERR#/SERR#) asserted by a PCI device or by the CS55 0 = No; 1 = Yes.	530A?
	This bit can only be set if ERR_EN (bit 2) is set 0. This bit is set 0 after a write to ERR_EN with a 1 or after reset.	
6	IOCHK# Status (Read Only): Is an I/O device reporting an error to the CS5530A? 0 = No; 1 = Yes. This bit can only be set if IOCHK_EN (bit 3) is set 0. This bit is set 0 after a write to IOCHK_EN with a 1 or after reset	
5	PIT OUT2 State (Read Only): This bit reflects the current status of the PIT Counter 2 (OUT2).	•
4	Toggle (Read Only): This bit toggles on every falling edge of Counter 1 (OUT1).	
3		
Ū	0 = Generates an NMI if IOCHK# is driven low by an I/O device to report an error. Note that NMI is under SMI control. 1 = Ignores the IOCHK# input signal and does not generate NMI.	
2	PERR#/SERR# Enable: Generates an NMI if PERR#/SERR# is driven active to report an error. 0 = Enable; 1 = Disable	
1	PIT Counter2 (SPKR): 0 = Forces Counter 2 output (OUT2) to zero; 1 = Allows Counter 2 output (OUT2) to pass to t speaker.	he
0	PIT Counter2 Enable: 0 = Sets GATE2 input low; 1 = Sets GATE2 input high.	
O Port 06	62h (R/W) External Keyboard Controller Mailbox Register	
	Controller Mailbox Register: Accesses to this port will assert KBROMCS# if the Port 062h/066h decode is enabled th Decode Control Register 2 (F0 Index 5Bh[7]).	rough
O Port 06	64h (R/W) External Keyboard Controller Command Register

Register Descriptions (Continued)

4.6 V-ACPI I/O REGISTER SPACE

The register space designated as V-ACPI I/O does not physically exist in the CS5530A. ACPI is supported in the CS5530A by virtualizing this register space, called V-ACPI. In order for ACPI to be supported, the V-ACPI VSA module must be included in the BIOS. The register descriptions that follow, are supplied here for reference only.

Fixed Feature Space registers are required to be implemented by all ACPI-compatible hardware. The Fixed Feature registers in the VSA/ACPI solution are mapped to normal I/O space starting at offset AC00h; however, the designer can relocate this register space at compile time, hence are hereafter referred to as ACPI_BASE. Registers within V-ACPI (Virtualized ACPI) I/O space must only be accessed on their defined boundaries. For example, byte aligned registers must not be accessed via WORD I/O instructions, WORD aligned registers must not be accessed as DWORD I/O instructions, etc.

The V-ACPI I/O Register Space can be broken up into major blocks:

- PM Event Block 1A (PM1A_EVT_BLK)
- PM Event Block 1A Control (PM1A_CNT_BLK)
- Processor Register Block (P_BLK)
- Command Block (CMD_BLK)
- Test/Setup Block (TST/SETUP_BLK)
- General Purpose Enable 0 Block (GPE0_BLK)
 DataSheet

PM1A_EVT_BLK is 32-bit aligned and contains two 16-bit registers, PM1A_STS and PM1A_EN.

PM1A_CNT_BLK is 32-bit aligned and contains one 16-bit register, PM1A_CNT. PM1A_CNT contains the Fixed Feature control bits used for various power management

enables and as communication flags between $\ensuremath{\mathsf{BIOS}}$ and the $\ensuremath{\mathsf{ACPI}}\xspace$ OS.

P_BLK is 32-bit aligned (one register block per processor) and contains two registers P_CNT and P_LVL2. P_LVL3 is currently not supported.

- P_CNT (Processor Control) 16-bit register, Controls process duty cycle via CPU clock throttling.
 DUTY_WIDTH = 3 (can be widened)
 DUTY_OFFSET = 0
- P_LVL2 (Enter C2 Power State) 8-bit, read only register. When read, causes the processor to enter C2 power state.

CMD_BLK contains one 8-bit register SMI_CMD which interprets and processes the ACPI commands (defined in Fixed ACPI Description Table, refer to ACPI Specification, Section 5.2.5).

TST/SETUP_BLK is provided by the VSA technology code and contains two registers, SETUP_IDX and SETUP_DATA for the purpose of configuring the CS5530A. Specifically, this pair of registers enables system software to map GPIO pins on the CS5530A to PM1A_STS and GPE0_STS register bits.

GPE0_BLK has registers used to enable system software to configure GPIO (General Purpose I/O) pins to generate SCI interrupts. GPE0_BLK is a 32-bit block aligned on a 4byte boundary. It contains two 16-bit registers, GPE0_STS and GPE0_EN, each of which must be configured by the BIOS POST. In order for a GPE0_STS bit to generate an SCI, the corresponding enable bit in GPE0_EN must be set.

Table 4-34 gives the bit formats of the V-ACPI I/O registers.

Bit

Register Descriptions (Continued)

Description

Table 4-34. V-ACPI Registers (Continued)

Reset Value = 0000h ACPI_BASE 08h-09h PM1A_STS — PM1A Status Register (R/W) 15 WAKE_STS: Wake Status - Set when system was in sleep state and an enabled wakeup occurs. 14:11 Reserved 10 RTC STS: Real Time Clock Status - This bit changes to 1 if an RTC alarm causes a wake up event. This bit is only set upon wakeup from a sleep state and IRQ8 is asserted by the RTC. Refer to Table 4-37. SLPBTN_STS: Sleep Button Status (Optional) - This bit changes to 1 when the sleep button is pressed. If SLPBTN_EN is 9 set, an SCI interrupt is generated. This bit must be configured to be set by a GPIO pin using SETUP_IDX values 0x10-0x17 in order to be set. Refer to Table 4-36 8 PWRBTN_STS: Power Button Status - This bit is set when power button is pressed. If PWRBTN_EN is set, an SCI interrupt is asserted. This bit must be configured to be set by a GPIO pin using SETUP_IDX values 0x10-0x17 in order to be set. Refer to Table 4-36 Reserved 7:6 5 GBL_STS: Global Status - The BIOS sets GBL_STS to 1 to release its global lock and return control to the ACPI OS. At the same time GBL_STS is set, the BIOS generates an SCI. 4 BM_STS: Bus Master Status - This bit is not supported by V-ACPI. Reserved 3:1 0 TMR_STS: ACPI Timer Status - This bit changes to 1 whenever bit 23 of the ACPI timer (F1BAR+Memory Offset 1Ch or I/O Port 121Ch) changes state. The ACPI OS is responsible for clearing TMR_STS. If TMR_EN (ACPI_BASE 0Ah[0] is also set, then a SCI interrupt is asserted. Note: Status bits are "sticky". A write of a one (1) to a given bit location will reset the bit. PM1A_EN — PM1A Enable Register (R/W) ACPI BASE 0Ah-0Bh Reset Value = 0000h 15:11 Reserved 10 RTC_EN: Real Time Clock Enable - If set, an SCI is asserted when RTC_STS changes to 1. 9 SLPBTN_EN: Sleep Button Enable (Optional) - If set, an SCI is asserted when SLPBTN_STS changes to 1. PWRBTN_EN: Power Button Enable - If set, an SCI is asserted when PWRBTN_STS changes to 1. 8 7:6 Reserved GBL_EN: Global Lock Enable - If set, writing a 1 to GBL_STS causes an SCI to be asserted. 5 4:1 Reserved 0 TMR_EN: ACPI Timer Enable - If set, an SCI is asserted when bit 23 of the ACPI timer (F1BAR+Memory Offset 1Ch or I/O Port 121Ch) changes state. ACPI_BASE 0Ch-0Dh PM1A_CNT — PM1A Control Register (R/W) Reset Value = 0000h 15:14 Reserved SLP_EN (WO): Sleep Enable (Write Only) - Setting this bit causes the system to enter the sleep state defined by 13 SLP_TYPx. Reads of this bit always return zero. 12:10 SLP_TYPx: Sleep Type - Defines the type of sleep state the system enters when SLP_EN (bit 13) is set. 000 = Sleep State S0 (Full on) 100 = Sleep State S4 001 = Sleep State S1 101 = Sleep State S5 (Soft off) 010 = Sleep State S2 110 = Reserved 011 = Reserved 111 = Reserved 9:3 Reserved 2 GBL_RLS (WO): Global Lock Release (Write Only) - Used by ACPI OS to raise an event to the BIOS software (SMI). Used by ACPI driver to indicate a release of the global lock and the setting of the pending bit in the FACS table (refer to ACPI Specification, Section 5.2.8). BM_RLD: This bit is not supported by V-ACPI. 1 SCI_EN: System Controller Interrupt Enable - Selects whether power management events are SCI or SMI. Set by hardware 0 based on an ACPI_ENABLE/ACPI_DISABLE written to the SMI_CMD port. ACPI_BASE 0Eh-0Fh SETUP_IDX — Setup Index Register (R/W) Reset Value = 0000h SETUP_IDX is a 16-bit register that references an internal setting in the VSA (refer to Table 4-35). A read of SETUP_IDX returns the last value written to SETUP_IDX. A write of SETUP_IDX selects the index for a corresponding write to SETUP_DATA. Writes of any unde-fined index values to SETUP_IDX are ignored. If the current value of SETUP_IDX is invalid, a read of SETUP_DATA returns of www.DataSheet4U.com

Register Descriptions (Continued)

Table 4-37. IRQ Wakeup Status Mapping (0x30-0x3F)

SETUP_ DATA	Function
0	Do not wakeup on IRQ activity.
0x0a	Assign IRQ Wake to bit 10 in PM1A_STS register
0x10	Assign IRQ Wake to bit 0 in GPE0_STS register
0x11	Assign IRQ Wake to bit 1 in GPE0_STS register
0x12	Assign IRQ Wake to bit 2 in GPE0_STS register
0x13	Assign IRQ Wake to bit 3 in GPE0_STS register
0x14	Assign IRQ Wake to bit 4 in GPE0_STS register
0x15	Assign IRQ Wake to bit 5 in GPE0_STS register
0x16	Assign IRQ Wake to bit 6 in GPE0_STS register
0x17	Assign IRQ Wake to bit 7 in GPE0_STS register
0x18	Assign IRQ Wake to bit 8 in GPE0_STS register
0x19	Assign IRQ Wake to bit 9 in GPE0_STS register
0x1A	Assign IRQ Wake to bit 10 in GPE0_STS register
0x1B	Assign IRQ Wake to bit 11 in GPE0_STS register
0x1C	Assign IRQ Wake to bit 12 in GPE0_STS register
0x1D	Assign IRQ Wake to bit 13 in GPE0_STS register
0x1E	Assign IRQ Wake to bit 14 in GPE0_STS register
0x1F	Assign IRQ Wake to bit 15 in GPE0_STS register
and	en the ability to wakeup on an IRQ is desired use Index 0x31 through 0x3F. This will allow sensing of interrupts while sleeping waking of the system when activity occurs. The desired GPE0 Status bit will only be set if the system is sleeping and a wake nt occurs. The system will only wake if the status bit is enabled in the corresponding enable register.

IRQ8 (RTC) is assigned to the RTC_STS bit in the PM1A_STS register by default and should **NOT** be changed. For enabling and selection of the GPE0 Status bit to be set when Wake on IRQ Activity is desired, use the SETUP_DATA values listed above.

Table 4-38. Commands (0x41-0x43, and 0x50)

Index	Function
0x41	Configure IRQ to be used for SCI: When mapping the SCI interrupt SETUP_IDX contains the number of the IRQ to be used for the SCI. Valid values are 3-7, 9-12, and 14-15. Invalid values will not change the assignment of the SCI IRQ. The default value for the SCI IRQ is 9.
0x42	Enable Reads of ACPI Registers: Prior to the issuance of this command only WRITES can be performed to the V-ACPI Fixed feature registers. This command MUST be issued to enable reading of the registers. This is to prevent the User Def 1 hook on NON-ACPI systems from interfering with system functions.
0x43	Do Atomic I/O Sequence: This command allows a sequence of I/O operations to be done with no interruption. Certain SuperI/O chips must receive unlock codes with NO intervening I/O. In addition other SuperI/O chips do not allow I/O to devices while in configuration mode. This command will insure that I/O operations are completed without interruption. The address of a sequence of I/O commands is placed in the SETUP_DATA register. The command sequence will then be processed immediately.
	The I/O command sequence consists of two parts: the signature/length block and the I/O block. There is only one signa- ture/length block. There may be one or more I/O blocks.
	The signature block consists of four DWORDs (see Table 4-39).
	The I/O block consists of four bytes followed by three DWORDs (see Table 4-40).
0x50	Video Power: This command will control the power to the SoftVGA. If SETUP_DATA is written with a 0, power will be turned off. If a 1 is written, power will be turned on.

DataSheet4U.com

www.DataSheet4U.com

	Table 4-39. Signature/Length Block for 0x43	ML
Byte Offset	Value	Geode™ CS5530A
0	Signature: Always 0x00000070	553
4	Length: The length of the entire buffer including the signature block in bytes.	ÔA
8	Reserved: Set to 0	
12	Reserved: Set to 0	
	Table 4-40. I/O Block for 0x43	
Byte Offset	Description	
0	BYTE: Operation Type. 1 = Read 2 = Write 3 = Read/And/Or/Write 4 = Define index and data ports In addition, values may be OR'ed in to the upper two bits of this byte to indicate that special functions are desired. 0x80 = Do not perform this operation (convert to NO-OP). 0x40 = This is an index operation.	
1	BYTE: Reserved set to 0	
2	BYTE: I/O Length - Determines whether a BYTE, WORD or DWORD operation is performed. 1 = BYTE operation 2 = WORD operation 3 = DWORD operation If BYTE 0 is a 4, then this field is used to indicate the size of the index write.	Da
3	BYTE: Reserved set to 0 DataSheet4U.com	
4	DWORD: I/O Address - This is the address in the I/O space to be used. It is always a WORD value. If this is a define index/data port operation, this DWORD contains the I/O address of the index port. If this is an index operation, other than define, this DWORD contains the value to be written to the index port.	
8	DWORD: I/O Data - The meaning depends on the operation type. Read = This is where the data read from the I/O port will be placed. Write = This is the data to write to the I/O port. Read/AND/OR/Write = This is the data that will be ANDed with the data read from the I/O port. Define index/data port - This DWORD contains the I/O address of the data port.	
12	DWORD: OR Data - This field is only used in a Read/AND/OR/Write operation. It contains the data that will be OR'ed after the data read was AND'ed with the previous field. After the OR is done, the data will be re-written to the I/O port.	
	all cases if the data called for is shorter than the field, the data will be stored or retrieved from the least significant portion of the /ORD.

5.0 **Electrical Specifications**

This section provides information on electrical connections, absolute maximum ratings, recommended operating conditions, and DC/AC characteristics for the Geode CS5530A. All voltage values in the electrical specifications are with respect to V_{SS} unless otherwise noted.

For detailed information on the PCI bus electrical specification refer to Chapter 4 of the PCI Bus Specification, Revision 2.1.

ELECTRICAL CONNECTIONS 5.1

5.1.1 Pull-Up Resistors

Table 5-1 lists the pins that are internally connected to a 20-kohm pull-up resistor. When unused, these inputs do not require connection to an external pull-up resistor.

Table 5-1. Pins with Weak Internal Pull-Up

Signal Name	Туре	Pin No.
IOR#	I/O	AE12
IOW#	I/O	AC11
MEMR#	I/O	AE19
MEMW#	I/O	AF20
SBHE#	I/O	AE17
SA[19:0]/ I/O SD[19:0]		AD10, AE11, AF12, AD11, AE25, AD24, AD22, AE21, AF21, AC20, AD19, AF19, AF4, AF5, AD5, AF6, AC6, AD9, AE6, AD9

5.1.2 **Unused Input Pins**

All inputs not used by the system designer and not listed in Table 5-1 should be kept at either V_{SS} or V_{DD} . To prevent possible spurious operation, connect active-high inputs to ground through a 20-kohm (±10%) pull-down resistor and active-low inputs to V_{DD} through a 20-kohm (±10%) pull-up resistor.

NC-Designated Pins 5.1.3

Pins designated NC should be left disconnected. Connecting an NC pin to a pull-up resistor, pull-down resistor, or an active signal could cause unexpected results and possible circuit malfunctions.

Power/Ground Connections and Decoupling 5.1.4

Testing and operating the CS5530A requires the use of standard high frequency techniques to reduce parasitic effects. These effects can be minimized by filtering the DC power leads with low-inductance decoupling capacitors, using low-impedance wiring, and by using all of the VDD and V_{SS} pins.

5.2 ABSOLUTE MAXIMUM RATINGS

Table 5-2 lists absolute maximum ratings for the CS5530A. Stresses beyond the listed ratings may cause permanent damage to the device. Exposure to conditions beyond these limits may (1) reduce device reliability and (2) result in premature failure even when there is no immediately apparent sign of failure. Prolonged exposure to conditions at or near the absolute maximum ratings may also result in reduced useful life and reliability These are stress ratings only and do not imply that operation under any conditions other than those listed under Table 5-3 is possible.

5.3 OPERATING CONDITIONS

Table 5-3 lists the recommended operating conditions for the CS5530A.

Table 5-2. Absolute Maximum Ratings

Parameter	Min	Max	Units	Comments
Operating Case Temperature	0	110	°C	Power Applied
Storage Temperature	-65	150	°C	No Bias
Supply Voltage		4.0	V

5.4.1 Definition of System Conditions for Measuring "On" Parameters

The current of the CS5530A is highly dependent on the DCLK (DOT clock). Table 5-5 shows how these factors are controlled when measuring the typical average and abso-

lute maximum CS5530A current parameters. Table 5-6 provides the CS5530A's core, DAC, and PLL DC characteristics during various power states.

Table 5-5. System Conditions Used to Determine CS5530A's Current Used During the "On" State

	System C	conditions		
CPU Current Measurement	V _{DD} (Note 1)	DCLK Frequency (Note 2)		
Typical Average	Nominal	50 MHz (Note 3)		
Absolute Maximum	Max	135 MHz (Note 4)		

1. See Table 5-3 on page 237 for nominal and maximum voltages.

2. Not all system designs support display modes that require a DCLK of 157 MHz. Therefore, absolute maximum current will not be realized in all system designs.

- 3. A DCLK frequency of 50 MHz is derived by setting the display mode to 800x600x8 bpp at 75 Hz, using a display image of vertical stripes (4-pixel wide) alternating between black and white with power management disabled.
- 4. A DCLK frequency of 157 MHz is derived by setting the display mode to 1280x1024x8 bpp at 85 Hz, using a display image of vertical stripes (1-pixel wide) alternating between black and white with power management disabled.

5.5 AC CHARACTERISTICS

The following tables list the AC characteristics including output delays, input setup requirements, input hold requirements and output float delays. The rising-clock-edge reference level, V_{REF} and other reference levels are shown in Table 5-7. Input or output signals must cross these levels during testing.

Input setup and hold times are specified minimums that define the smallest acceptable sampling window for which a synchronous input signal must be stable for correct operation.

5.6 DISPLAY CHARACTERISTICS

The following tables and figures describe the characteristics of the CRT, TFT/TV and MPEG Display interfaces. It is divided into the following categories:

- CRT Display Recommended Operating Conditions
- CRT Display Analog (DAC) Characteristics

Display Miscellaneous Characteristics

• CRT, TFT/TV and MPEG Display Timing Additionally, Figure 5-13 on page 252 is provided showing a typical video connection diagram.

Symbol	Parameter	Min	Тур	Max	Units	Comments			
AV _{DD}	Power Supply connected to AV_{DD1} , AV_{DD2} and AV_{DD3}	3.14	3.3	3.46	V				
RL	Output Load on each of the pins IOUTR, IOUTG and IOUTB		37.5		Ohms	R1, R2, and R3 as shown in Figure 5-13 on page 252			
I _{OUT}	Output Current on each of the pins IOUTR, IOUTG and IOUTB			21	mA				
R _{SET}	Value of the full-scale adjust resistor connected to IREF		680		Ohms	This resistor should have a 1% tolerance.			
VEXT _{REF}	External voltage reference con- nected to the EXTVREFIN pin		1.235		V				

Table 5-14. CRT Display Recommended Operating Conditions

6.0 Test Mode Information

The CS5530A provides two test modes:

- The NAND tree test mode for board-level automatic test equipment (ATE).
- 2) The I/O test mode for system design testing.

6.1 NAND TREE TEST MODE

The NAND tree mode is used to test input and bidirectional pins which will be part of the NAND tree chain. Table 6-1 shows how to set the device for the NAND tree test.

The output of the NAND tree is multiplexed on the SUSP# output (pin K26). After a POR# (pin K24) pulse, all inputs in Table 6-2 on page 254 are initialized to a "1" and then are successively pulled and held to a "0" starting with SUSP_3V (the first input pin in the tree). The output wave-

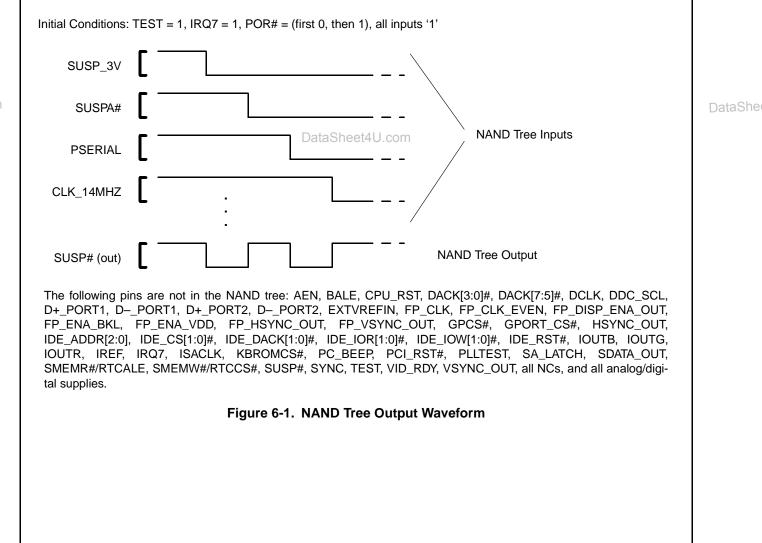

form on SUSP# will toggle on each input change as shown in Figure 6-1.

POR# is included as an input during the NAND Tree test, after being used to trigger the test first. IRQ7 (pin AD14) and TEST (pin D3) must be held high throughout the test.

Table 6-1. NAND Tree Test Selection

Signal Name	Pin No.	Setting
POR#	K24	0 -> 1
TEST	D3	1
IRQ7	AD14	1

Example: Beginning of NAND Tree Test Sequence

Test Mode Information (Continued)

6.2 I/O TEST

This test affects all output and bidirectional pins. To trigger the I/O test, set the TEST and IRQ[3:7] pins according to Table 6-3, while holding POR# low. The test begins when POR# is brought high. Starting with the next rising edge of PCICLK, the states listed in Table 6-4 are entered by all digital output and I/O pins on successive PCICLK pulses:

Signal Name	Pin No.	Setting
POR#	K24	Х
TEST	D3	1
IRQ3	AC14	0
IRQ4	AE15	1
IRQ5	AE13	1
IRQ6	AF14	0
IRQ7	AD14	1

Table 6-3. I/O Test Selection

Table 6-4. I/O Test Sequence

Clock #	Output Pin States
Before 1	Undefined DataSh
1	Floating
2	High
3	Low
4	Floating
5	Low
6	High
7	Floating
8 and beyond	Undefined

The following pins are INCLUDED in this test:

- AD[31:0], AEN, BALE, C/BE[3:0]#, CLK_32K, CPU_RST, DACK[7:5,3:0], DDC_SCL, DDC_SDA, DEVSEL#, FP_CLK, FP_CLK_EVEN, FP_DATA[17:0], FP_DISP_ENA_OUT, FP_ENA_BKL, FP_ENA_VDD, FP_HSYNC_OUT, FP_VSYNC_OUT, FRAME#, GPCS#, GPIO[7:0], GPORT_CS#, HOLD_REQ#, HSYNC_OUT, IDE_ADDR[2:0], IDE_CS[1:0]#, IDE_DACK[1:0]#, IDE_DATA[15:0], IDE_IOR[1:0]#, IDE_IOW[1:0]#, IDE_RST#, INTR, IOCHRDY, IOR#, IOW#, IRDY#, ISACLK, KBROMCS#, LOCK#, MEMCS16#, MEMR#, MEMW#, PAR, PCI_RST#, PC_BEEP, PERR#, POWER_EN, REQ#, SA/SD[15:0], SA[19:16], SA_LATCH, SBHE#, SDATA_OUT, SERR#, SMEMR#, SMEMW#, SMI#, STOP#, SUSP#, SUSP_3V, SYNC, TC, TRDY#, VID_RDY, VSYNC_OUT
- **Note:** The SA/SD and SA bus, IOR#, IOW#, MEMR#, MEMW# and SBHE# pins never actually float, because they have internal weak pull-up devices that remain active.

The following pins are EXCLUDED from this test:

 Input-only pins: BIT_CLK, CLK_14MHZ, DRQ[7:5,3:0], ENA_DISP, FP_HSYNC, FP_VSYNC, GNT#, HSYNC, IDE_DREQ[1:0], IDE_IORDY[1:0], INTA#, INTB#, INTC#, INTD#, IOCS16#, IRQ1, IRQ[7:3], IRQ8#, IRQ[15:9], OVER_CUR#, PCICLK, PCLK, PIXEL[23:0],

POR#, PSERIAL, SDATA_IN, SUSPA#, TEST, TVCLK, USBCLK, VID_CLK, VID_DATA[7:0], VID_VAL, VSYNC, ZEROWS#.

- USB pins: D+_PORT1, D-_PORT1, D+_PORT2, D-_PORT2, AV_{DD}_USB, AV_{SS}_USB.
- Time-critical output: DCLK.
- Analog pins (including supplies): EXTVREFIN, IOUTB, IOUTG, IOUTR, IREF, PLLAGD, PLLDGN, PLLDVD, PLLTEST, AV_{DDx}, AV_{SSx}.
- Digital supply pins (V_{DD}, V_{SS}) and No Connects (NC).

Appendix A Support Documentation

A.1 REVISION HISTORY

This document is a report of the revision/creation process of the architectural specification for the CS5530A I/O Com-

panion. Any revisions (i.e., additions, deletions, parameter corrections, etc.) are recorded in the table(s) below.

Revision # (PDF Date)	Revisions / Comments
0.1 (4/2/00)	Completed formatting first-pass of spec. Current spec is updated version of CS5530 data book with additional inputs from engineering. Differences between this spec's revision and the CS5530 data book are denoted with a change bar in the margin. Still need to proof-read for "ripple effects" made by engineering changes for next rev.
0.2 (6/16/00)	Corrections from Issues 1.3.
0.3 (6/27/00)	Further corrections from Issues 1.3. Partly indexed.
0.4 (7/5/00)	Corrections from Issues 1.3 and 1.5. Some issues remain to be resolved. Index markers inserted through AT chapter.
0.5 (7/19/00)	TME/Tech Pubs edits. See document revision 0.5 for revision history.
0.6 (8/7/00)	TME/Tech Pubs edits. See document revision 0.6 for revision history details.
0.7(9/18/00)	TME/Tech Pubs/Engr edits. See document revision 0.7 for revision history details.
	Note: Next revision to include section on "recommended soldering parameters" in Section 7.0 "Physical Dimensions".
1.0 (11/10/00)	TME/Tech Pubs/Engr edits. See document revision 1.0 for revision history details.
	Note: Will create separate applications note on "recommended soldering parameters" as opposed to adding as subsection in data book.
1.1 (5/1/01)	TME/Engr edits. See Table A-2 for details.
	Note: Will not create separate applications note on "recommended soldering parameters". Applications is fulfilling any customer inquiries with a document supplied by National's Quality Group.

Geode[™] CS5530A

Section Description Section 2.0 "Signal Definitions" Section 2.2.2 "Clock Interface" Changed last sentence of DCLK signal description on page 23. Did say: "However, system constraints limit DCLK to 150 MHz when DCLK is used as the graphics subsystem clock." Now says: "However, when DCLK is used as the graphics subsystem clock, the Geode processor determines the maximum DCLK frequency." Section 2.2.11 "Dis- play Interface" Changed resistor value in IREF signal description (from 732 ohm to 680 ohm) on page 36. Play Interface" Section 3.8.3 "Video Added sentence to last paragraph on page 135:
Section 2.2.2 "Clock Interface" Changed last sentence of DCLK signal description on page 23. Did say: "However, system constraints limit DCLK to 150 MHz when DCLK is used as the graphics subsystem clock." Now says: "However, when DCLK is used as the graphics subsystem clock, the Geode processor determines the maximum DCLK frequency." Section 2.2.11 "Display Subsystem Extensions" Changed resistor value in IREF signal description (from 732 ohm to 680 ohm) on page 36. Section 3.8.3 "Video Overlay" Added sentence to last paragraph on page 135:
Interface" Did say: "However, system constraints limit DCLK to 150 MHz when DCLK is used as the graphics subsystem clock." Now says: "However, when DCLK is used as the graphics subsystem clock, the Geode processor determines the maximum DCLK frequency." Section 2.2.11 "Display Subsystem Extensions" Changed resistor value in IREF signal description (from 732 ohm to 680 ohm) on page 36. Play Interface" Section 3.8.3 "Video Added sentence to last paragraph on page 135:
Section 2.2.11 "Display Interface" • Changed resistor value in IREF signal description (from 732 ohm to 680 ohm) on page 36. Section 3.8 "Display Subsystem Extensions" • Added sentence to last paragraph on page 135: — "However, system maximum resolution is not determined by the CS5530A since it is not the source of the graphics data and timings." Section 3.8.3 "Video Overlay" • Added sentence to last paragraph on page 135: — "However, system maximum resolution is not determined by the CS5530A since it is not the source of the graphics data and timings." Section 5.0 "Electrical Specifications" • Section 5.5 "AC Characteristics" on page 242: — Removed 8 mA, DOTCLK, and FP_CLK t _{LH} and t _{HL} parameters. Section 5.5 "AC Characteristics" • Table 5-8 "AC Characteristics" on page 246: — Removed 3 mA, DOTCLK, and FP_CLK t _{LH} and t _{HL} parameters. • Table 5-10 "DCLK PLL Specifications" on page 246: — Changed t _{SMI} max value from 9 ns to 16 ns. — Changed t _{SUSPAHdia} min value from 1 ns to 3 ns. • Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: — Added V _{OC} max value of 0.735V. — Added V _{OC} max value of 2.5 ns. — Removed U _{RISE} max value for 3 to 3.8 ns.
Section 3.8.3 "Video Overlay" Added sentence to last paragraph on page 135:
Overlay" - "However, system maximum resolution is not determined by the CS5530A since it is not the source of the graphics data and timings." • Section 3.8.5.3 "Flat Panel Support" on page 137 - Added subsection titled "Flat Panel Power-Up/Down Sequence". Section 5.0 "Electrical Specifications" Section 5.5 "AC Characteristics" • Table 5-8 "AC Characteristics" on page 242: - Removed 8 mA, DOTCLK, and FP_CLK t _{LH} and t _{HL} parameters. • Table 5-10 "DCLK PLL Specifications" on page 246: - Removed Jitter, Sigma One parameter from table (completely). • Table 5-11 "CPU Interface Timing" on page 246: - Changed t _{SMI} max value from 9 ns to 16 ns. - Changed t _{SMI} max value from 9 ns to 3 ns. • Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: - Added V _{OM} max value of 0.735V. - Added t _{FS} max value of 2.5 ns. - Removed C _{OUT} parameter from table (completely). - Changed t _{RISE} max value from 3 to 3.8 ns.
Section 5.0 "Electrical Specifications" Section 5.5 "AC Characteristics" • Table 5-8 "AC Characteristics" on page 242: — Removed 8 mA, DOTCLK, and FP_CLK t _{LH} and t _{HL} parameters. • Table 5-10 "DCLK PLL Specifications" on page 246: — Removed Jitter, Sigma One parameter from table (completely). • Table 5-11 "CPU Interface Timing" on page 246: — Changed t _{SMI} max value from 9 ns to 16 ns. — Changed t _{SUSPAHold} min value from 1 ns to 3 ns. • Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: — Added V _{OM} max value of 0.735V. — Added t _{FS} max value of 2.5 ns. — Removed C _{OUT} parameter from table (completely).
 Section 5.5 "AC Characteristics" on page 242: — Removed 8 mA, DOTCLK, and FP_CLK t_{LH} and t_{HL} parameters. Table 5-10 "DCLK PLL Specifications" on page 246: — Removed Jitter, Sigma One parameter from table (completely). Table 5-11 "CPU Interface Timing" on page 246: — Changed t_{SMI} max value from 9 ns to 16 ns. — Changed t_{SUSPAHold} mit value from 1 ns to 3 ns. Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: — Added V_{OM} max value of 0.735V. — Added V_{CC} max value of 20 mA. — Added t_{FS} max value of 2.5 ns. — Removed C_{OUT} parameter from table (completely).
acteristics" — Removed 8 mA, DOTCLK, and FP_CLK t _{LH} and t _{HL} parameters. • Table 5-10 "DCLK PLL Specifications" on page 246: — Removed Jitter, Sigma One parameter from table (completely). • Table 5-11 "CPU Interface Timing" on page 246: — Changed t _{SMI} max value from 9 ns to 16 ns. • Changed t _{SUSPAHold} min value from 1 ns to 3 ns. • Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: • Added V _{OM} max value of 0.735V. — Added V _{OC} max value of 20 mA. • Added t _{FS} max value of 2.5 ns. — Removed C _{OUT} parameter from table (completely). • Changed t _{RISE} max value from 3 to 3.8 ns.
 Removed Jitter, Sigma One parameter from table (completely). Table 5-11 "CPU Interface Timing" on page 246: Changed t_{SMI} max value from 9 ns to 16 ns. Changed t_{SUSPAHold} min value from 1 ns to 3 ns. Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: Added V_{OM} max value of 0.735V. Added V_{OC} max value of 20 mA. Added t_{FS} max value of 2.5 ns. Removed C_{OUT} parameter from table (completely). Changed t_{RISE} max value from 3 to 3.8 ns.
 Changed t_{SMI} max value from 9 ns to 16 ns. Changed t_{SUSPAHold} min value from 1 ns to 3 ns. Table 5-15 "CRT Display Analog (DAC) Characteristics" on page 249: Added V_{OM} max value of 0.735V. Added V_{OC} max value of 20 mA. Added t_{FS} max value of 2.5 ns. Removed C_{OUT} parameter from table (completely). Changed t_{RISE} max value from 3 to 3.8 ns.
 Added V_{OM} max value of 0.735V. Added V_{OC} max value of 20 mA. Added t_{FS} max value of 2.5 ns. Removed C_{OUT} parameter from table (completely). Changed t_{RISE} max value from 3 to 3.8 ns.
 Added t_{FALL} max value of 3.8 ns. Changed R_{SET} value in Note 2 from 732 ohms to 680 ohms.
 Table 5-17 "CRT, TFT/TV and MPEG Display Timing" on page 250: Changed t_{DisplaySetup} min value from 2.5 ns to 2.2 ns. Changed t_{VID_VALSetup} min value from 3.75 ns to 3.0 ns. Changed t_{VID_VALHold} min value from 0 ns to 0.8 ns. Changed t_{VID_DATASetup} min value from 0 ns to 0.8 ns. Changed t_{VID_CLKMin} parameter description from "VID_CLK Minimum Pulse Width" to "VID_CLK Minimum Clock Period". Changed FPOUT_{MinDelay}, FPOUT_{MaxDelay} min value from 0.1 ns to 0.5 and max value from 5.2 ns to 4.5 ns.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.

2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
