

# Clock Generator for Intel® Alviso Chipset

## Features

- Compliant to Intel® CK410M
- Supports Intel Pentium-M CPU
- Selectable CPU frequencies
- Differential CPU clock pairs
- 100 MHz differential SRC clocks
- 96 MHz differential dot clock
- 48 MHz USB clocks
- 33 MHz PCI clock
- Low-voltage frequency select input
- I<sup>2</sup>C support with readback capabilities
- Ideal Lexmark Spread Spectrum profile for maximum electromagnetic interference (EMI) reduction
- 3.3V power supply
- 56-pin SSOP and TSSOP packages

**Frequency Select Pins (FS\_A, FS\_B and FS\_C)**

Host clock frequency selection is achieved by applying the appropriate logic levels to FS\_A, FS\_B, FS\_C inputs prior to VTT\_PWRGD# assertion (as seen by the clock synthesizer). Upon VTT\_PWRGD# being sampled low by the clock chip (indicating processor VTT voltage is stable), the clock chip

samples the FS\_A, FS\_B and FS\_C input values. For all logic levels of FS\_A, FS\_B and FS\_C, VTT\_PWRGD# employs a one-shot functionality in that once a valid low on VTT\_PWRGD# has been sampled, all further VTT\_PWRGD#, FS\_A, FS\_B and FS\_C transitions will be ignored, except in test mode.

**Serial Data Interface**

To enhance the flexibility and function of the clock synthesizer, a two-signal serial interface is provided. Through the Serial Data Interface, various device functions, such as individual clock output buffers, can be individually enabled or disabled. The registers associated with the Serial Data Interface initializes to their default setting upon power-up, and therefore use of this interface is optional. Clock device register changes are normally made upon system initialization, if any are required. The interface cannot be used during system operation for power management functions.

**Data Protocol**

The clock driver serial protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write/read operation, the bytes must be accessed in sequential order from lowest to highest byte (most significant bit first) with the ability to stop after any complete byte has been transferred. For byte write and byte read operations, the system controller can access individually indexed bytes. The offset of the indexed byte is encoded in the command code, as described in *Table 2*.

The block write and block read protocol is outlined in *Table 3* while *Table 4* outlines the corresponding byte write and byte read protocol. The slave receiver address is 11010010 (D2h).

**Crystal Recommendations**

The CY28411 requires a Parallel Resonance Crystal. Substituting a series resonance crystal will cause the CY28411 to operate at the wrong frequency and violate the ppm specification. For most applications there is a 300-ppm frequency shift between series and parallel crystals due to incorrect loading.

**Crystal Loading**

Crystal loading plays a critical role in achieving low ppm performance. To realize low ppm performance, the total capacitance the crystal will see must be considered to calculate the appropriate capacitive loading (CL).

The following diagram shows a typical crystal configuration using the two trim capacitors. An important clarification for the following discussion is that the trim capacitors are in series with the crystal not parallel. It's a common misconception that load capacitors are in parallel with the crystal and should be approximately equal to the load capacitance of the crystal. This is not true.

**Table 5. Crystal Recommendations**

Frequency (Fund)	Cut	Loading	Load Cap	Drive (max.)	Shunt Cap (max.)	Motional (max.)	Tolerance (max.)	Stability (max.)	Aging (max.)
14.31818 MHz	AT	Parallel	20 pF	0.1 mW	5 pF	0.016 pF	35 ppm	30 ppm	5 ppm

Figure 1. Crystal Capacitive Clarification

### Calculating Load Capacitors

In addition to the standard external trim capacitors, trace capacitance and pin capacitance must also be considered to correctly calculate crystal loading. As mentioned previously, the capacitance on each side of the crystal is in series with the

crystal. This means the total capacitance on each side of the crystal must be twice the specified crystal load capacitance (CL). While the capacitance on each side of the crystal is in series with the crystal, trim capacitors (Ce1,Ce2) should be calculated to provide equal capacitive loading on both sides.

Figure 2. Crystal Loading Example

As mentioned previously, the capacitance on each side of the crystal is in series with the crystal. This means the total capacitance on each side of the crystal must be twice the specified load capacitance (CL). While the capacitance on each side of the crystal is in series with the crystal, trim capacitors (Ce1,Ce2) should be calculated to provide equal capacitance loading on both sides.

Use the following formulas to calculate the trim capacitor values for Ce1 and Ce2.

**Load Capacitance (each side)**

$$C_e = 2 * CL - (C_s + C_i)$$

**Total Capacitance (as seen by the crystal)**

$$CL_e = \frac{1}{\left( \frac{1}{C_{e1} + C_{s1} + C_{i1}} + \frac{1}{C_{e2} + C_{s2} + C_{i2}} \right)}$$

- CL.....Crystal load capacitance
- CL<sub>e</sub>..... Actual loading seen by crystal using standard value trim capacitors
- C<sub>e</sub>..... External trim capacitors
- C<sub>s</sub>..... Stray capacitance (terraced)
- C<sub>i</sub> .....Internal capacitance (lead frame, bond wires etc.)
- CL.....Crystal load capacitance
- CL<sub>e</sub>..... Actual loading seen by crystal using standard value trim capacitors
- C<sub>e</sub>..... External trim capacitors
- C<sub>s</sub>..... Stray capacitance (terraced)
- C<sub>i</sub> .....Internal capacitance (lead frame, bond wires etc.)

**PD (Power-down) Clarification**

The VTT\_PWRGD# /PD pin is a dual function pin. During initial power-up, the pin functions as VTT\_PWRGD#. Once VTT\_PWRGD# has been sampled low by the clock chip, the pin assumes PD functionality. The PD pin is an asynchronous active high input used to shut off all clocks cleanly prior to shutting off power to the device. This signal is synchronized internal to the device prior to powering down the clock synthesizer. PD is also an asynchronous input for powering up the system. When PD is asserted high, all clocks need to be driven to a low value and held prior to turning off the VCOs and the crystal oscillator.

**PD (Power-down) – Assertion**

When PD is sampled high by two consecutive rising edges of CPUC, all single-ended outputs will be held low on their next

high to low transition and differential clocks must held high or Hi-Zd (depending on the state of the control register drive mode bit) on the next diff clock# high to low transition within four clock periods. When the SMBus PD drive mode bit corresponding to the differential (CPU, SRC, and DOT) clock output of interest is programmed to '0', the clock output are held with "Diff clock" pin driven high at 2 x Iref, and "Diff clock#" tri-state. If the control register PD drive mode bit corresponding to the output of interest is programmed to "1", then both the "Diff clock" and the "Diff clock#" are tristate. Note the example below shows CPUT = 133 MHz and PD drive mode = '1' for all differential outputs. This diagram and description is applicable to valid CPU frequencies 100,133,166,200,266,333 and 400MHz. In the event that PD mode is desired as the initial power-on state, PD must be asserted high in less than 10 uS after asserting Vtt\_PwrGd#.

**Figure 3. Power-down Assertion Timing Waveform**

**PD Deassertion**

The power-up latency is less than 1.8 ms. This is the time from the deassertion of the PD pin or the ramping of the power supply until the time that stable clocks are output from the clock chip. All differential outputs stopped in a three-state

condition resulting from power down will be driven high in less than 300 μs of PD deassertion to a voltage greater than 200 mV. After the clock chip's internal PLL is powered up and locked, all outputs will be enabled within a few clock cycles of each other. Below is an example showing the relationship of clocks coming up.

**Figure 4. Power-down Deassertion Timing Waveform**

**CPU\_STP# Assertion**

The CPU\_STP# signal is an active low input used for synchronous stopping and starting the CPU output clocks while the rest of the clock generator continues to function. When the CPU\_STP# pin is asserted, all CPU outputs that are set with the SMBus configuration to be stoppable via assertion of CPU\_STP# will be stopped within two–six CPU clock

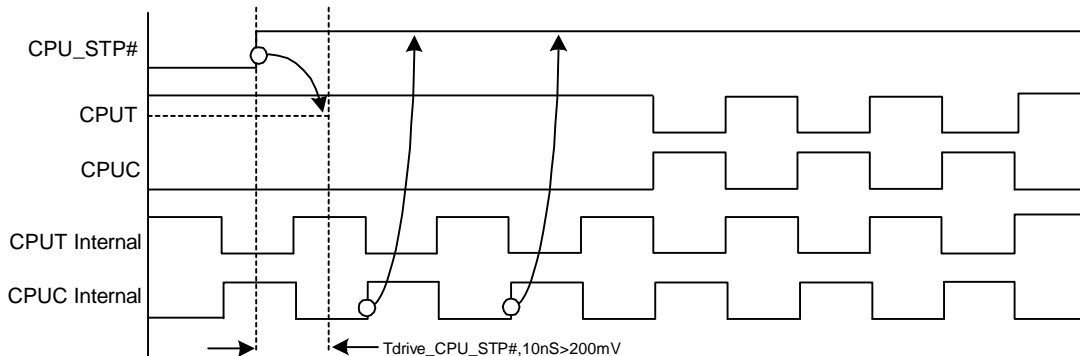

periods after being sampled by two rising edges of the internal CPUC clock. The final states of the stopped CPU signals are CPUT = HIGH and CPUC = LOW. There is no change to the output drive current values during the stopped state. The CPUT is driven HIGH with a current value equal to 6 x (Iref), and the CPUC signal will be Hi-Z.

**Figure 5. CPU\_STP# Assertion Waveform**

**CPU\_STP# Deassertion**

The deassertion of the CPU\_STP# signal will cause all CPU outputs that were stopped to resume normal operation in a synchronous manner meaning that no short or stretched clock pulses will be produce when the clock resumes. The maximum latency from the deassertion to active outputs is no more than two CPU clock cycles.

**Figure 6. CPU\_STP# Deassertion Waveform**

**Figure 7. CPU\_STP#= Driven, CPU\_PD = Driven, DOT\_PD = Driven**

Figure 8. CPU\_STOP# = Hi-Z, CPU\_PD = Hi-Z, DOT\_PD = tHi-Z

**PCI\_STOP# Assertion<sup>[1]</sup>**

The PCI\_STOP# signal is an active LOW input used for synchronous stopping and starting the PCI outputs while the rest of the clock generator continues to function. The set-up

time for capturing PCI\_STOP# going LOW is 10 ns ( $t_{SU}$ ). (See Figure 9.) The PCIF clocks will not be affected by this pin if their corresponding control bit in the SMBus register is set to allow them to be free running.

Figure 9. PCI\_STOP# Assertion Waveform

**PCI\_STOP# Deassertion**

The deassertion of the PCI\_STOP# signal will cause all PCI and stoppable PCIF clocks to resume running in a synchronous manner within two PCI clock periods after PCI\_STOP# transitions to a high level.

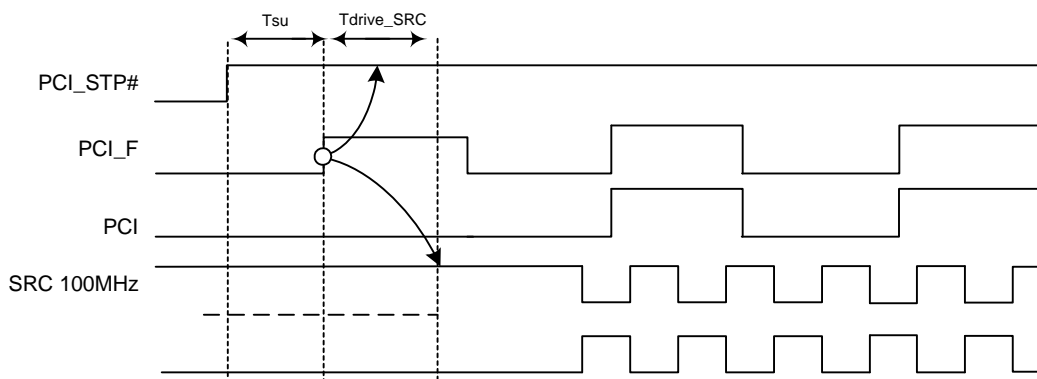

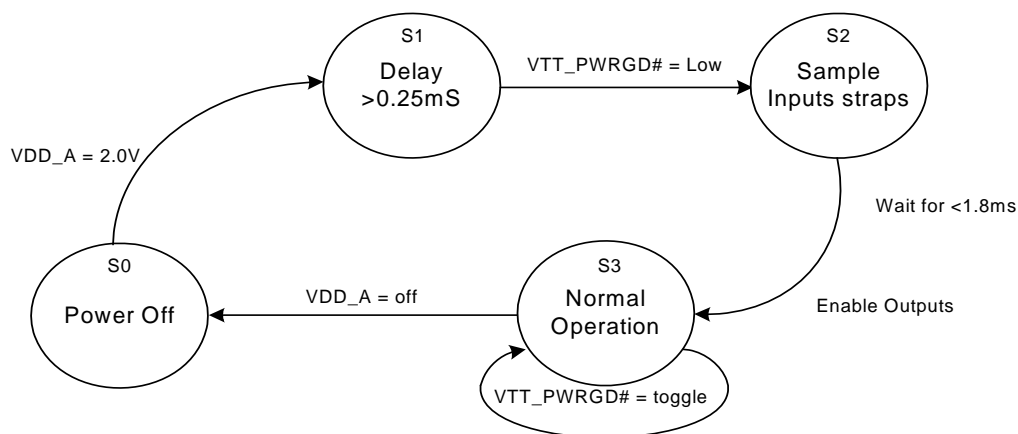

Figure 10. PCI\_STOP# Deassertion Waveform

**Note:**

1. The PCI STOP function is controlled by two inputs. One is the device PCI\_STOP# pin number 34 and the other is SMBus byte 0 bit 3. These two inputs are logically OR'ed. If either the external pin or the internal SMBus register bit is set low then the stoppable PCI clocks will be stopped in a logic low state. Reading SMBus Byte 0 Bit 3 will return a 0 value if either of these control bits are set LOW thereby indicating the device's stoppable PCI clocks are not running.
