Functional Description

The CY7C1034DV33 is a high performance CMOS static RAM organized as 256K words by 24 bits. This device has an automatic power-down feature that significantly reduces power consumption when deselected.

To write to the device, enable the chip ($\overline{CE}_1$ LOW, CE_2 HIGH, and $\overline{CE}_3$ LOW) while forcing the Write Enable ($\overline{WE}$) input LOW.

To read from the device, enable the chip by taking $\overline{CE}_1$ LOW, CE_2 HIGH, and $\overline{CE}_3$ LOW, while forcing the Output Enable ($\overline{OE}$) LOW and the Write Enable ($\overline{WE}$) HIGH. See the Truth Table on page 7 for a complete description of Read and Write modes.

The 24 IO pins (IO_0 to IO_{23}) are placed in a high impedance state when the device is deselected ($\overline{CE}_1$ HIGH, CE_2 LOW, or $\overline{CE}_3$ HIGH) or when the output enable ($\overline{OE}$) is HIGH during a write operation. ($\overline{CE}_1$ LOW, CE_2 HIGH, $\overline{CE}_3$ LOW, and $\overline{WE}$ LOW).

Notes

4. Valid SRAM operation does not occur until the power supplies reach the minimum operating V_{DD} (3.0 V). 100 µs (t_{power}) after reaching the minimum operating V_{DD}, normal SRAM operation begins including reduction in V_{DD} to the data retention (V_{CCDR}, 2.0 V) voltage.
5. Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, and input pulse levels of 0 to 3.0V. Test conditions for the read cycle use output loading as shown in part a) of the AC Test Loads and Waveform [4], unless specified otherwise.
6. t_{POWER} gives the minimum amount of time that the power supply is at typical V_{CC} values until the first memory access is performed.
7. t_{HZOE}, t_{HZCE}, t_{HZWE}, t_{LZOE}, t_{LZCE}, and t_{LZWE} are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads and Waveform [4]. Transition is measured ±200 mV from steady state voltage.
8. These parameters are guaranteed by design and are not tested.

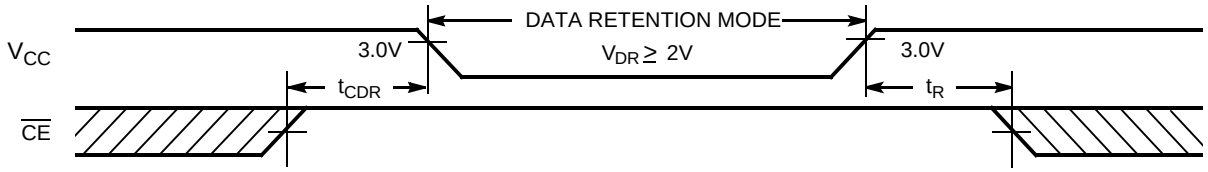
Figure 2. Data Retention Waveform



Notes

9. The internal write time of the memory is defined by the overlap of $\overline{CE_1}$ LOW, CE_2 HIGH, $\overline{CE_3}$ LOW, and $\overline{WE}$ LOW. Chip enables must be active and $\overline{WE}$ must be LOW to initiate a write and the transition of any of these signals terminates the write. The input data setup and hold timing are referenced to the leading edge of the signal that terminates the write.
10. The minimum write cycle time for Write Cycle No. 3 ($\overline{WE}$ controlled, $\overline{OE}$ LOW) is the sum of t_{HZWE} and t_{SD}.
11. Tested initially and after any design or process changes that may affect these parameters.
12. Full device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)} \geq 50\,\mu s$ or stable at $V_{CC(min)} \geq 50\,\mu s$.

Notes
13. Device is continuously selected. $\overline{OE}$, $\overline{CE}$ = V_{IL}.
14. $\overline{WE}$ is HIGH for read cycle.
15. Address valid before or similar to $\overline{CE}$ transition LOW.
16. Data IO is high impedance if $\overline{OE}$ = V_{IH}.
17. If $\overline{CE}$ goes HIGH simultaneously with $\overline{WE}$ going HIGH, the output remains in a high impedance state.
