Functional Description

The CY7C1059DV33 is a high performance CMOS Static RAM organized as 1M words by 8 bits. Easy memory expansion is provided by an active LOW Chip Enable (\overline{CE}), an active LOW Output Enable (\overline{OE}), and tri-state drivers. To write to the device, take Chip Enable (\overline{CE}) and Write Enable (\overline{WE}) inputs LOW. Data on the eight I/O pins (I/O_0 through I/O_7) is then written into the location specified on the address pins (A_0 through A_{19}).

To read from the device, take Chip Enable (\overline{CE}) and Output Enable (\overline{OE}) LOW while forcing Write Enable (\overline{WE}) HIGH. Under these conditions, the contents of the memory location specified by the address pins appear on the I/O pins.

The eight input or output pins (I/O_0 through I/O_7) are placed in a high impedance state when the device is deselected (\overline{CE} HIGH), the outputs are disabled (\overline{OE} HIGH), or a write operation is in progress (\overline{CE} LOW and \overline{WE} LOW).

The CY7C1059DV33 is available in 44-pin TSOP-II package with center power and ground (revolutionary) pinout.

Notes

5. Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V.
6. t_{POWER} is the minimum amount of time that the power supply must be at stable, typical V_{CC} values until the first memory access can be performed.
7. t_{HZOE} , t_{HZCE} , and t_{HZWE} are specified with a load capacitance of 5 pF as in part (d) of "AC Test Loads and Waveforms" on page 4. Transition is measured when the outputs enter a high impedance state.
8. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
9. The internal write time of the memory is defined by the overlap of $\overline{\text{CE}}$ LOW, and $\overline{\text{WE}}$ LOW. $\overline{\text{CE}}$ and $\overline{\text{WE}}$ must be LOW to initiate a write, and the transition of either of these signals can terminate the write. The input data setup and hold timing must refer to the leading edge of the signal that terminates the Write.
10. The minimum write cycle time for Write Cycle No. 3 ($\overline{\text{WE}}$ controlled, $\overline{\text{OE}}$ LOW) is the sum of t_{HZWE} and t_{SD} .

Figure 5. Read Cycle No. 2 (\overline{OE} Controlled)^[12, 13]

Notes

- 11. Device is continuously selected. \overline{OE} , $\overline{CE} = V_{IL}$.
- 12. \overline{WE} is HIGH for Read cycle.
- 13. Address valid before or coincident with \overline{CE} transition LOW.

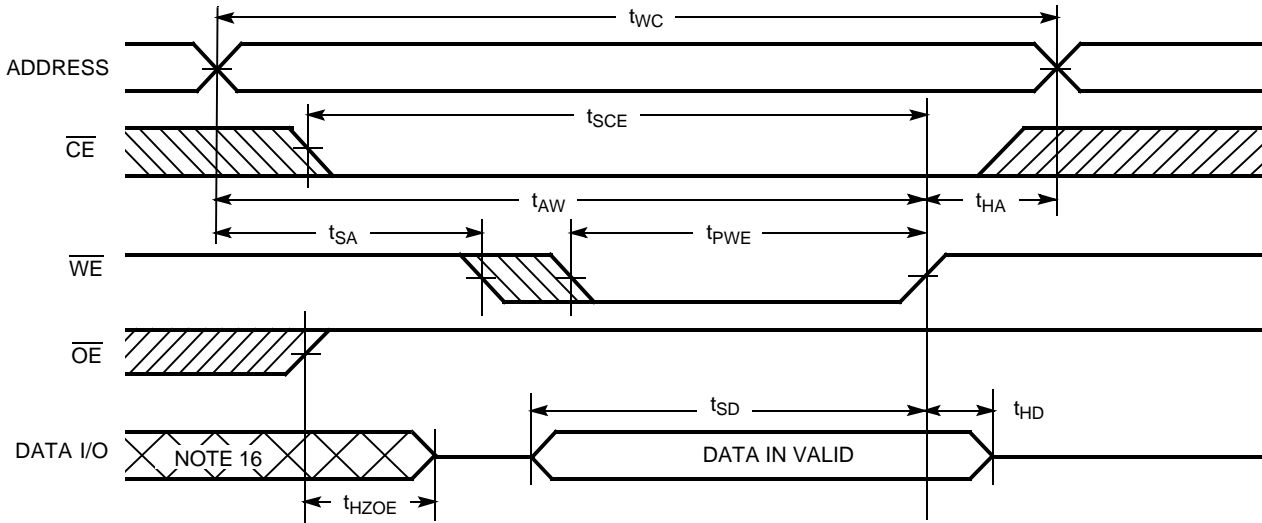

Figure 7. Write Cycle No. 2 (\overline{WE} Controlled, \overline{OE} Low)^[15]

Notes

- 14. Data I/O is high-impedance if $\overline{OE} = V_{IH}$.
- 15. If \overline{CE} goes HIGH simultaneously with \overline{WE} going HIGH, the output remains in a high-impedance state.
- 16. During this period the I/Os are in the output state and input signals must not be applied.
