Functional Description

CY7C1061G^[1] is a high-performance CMOS fast static RAM automotive part with embedded ECC. ECC logic can detect and correct single-bit error in read data word during read cycles.

This device has single chip enable input and is accessed by asserting the chip enable input (CE) LOW.

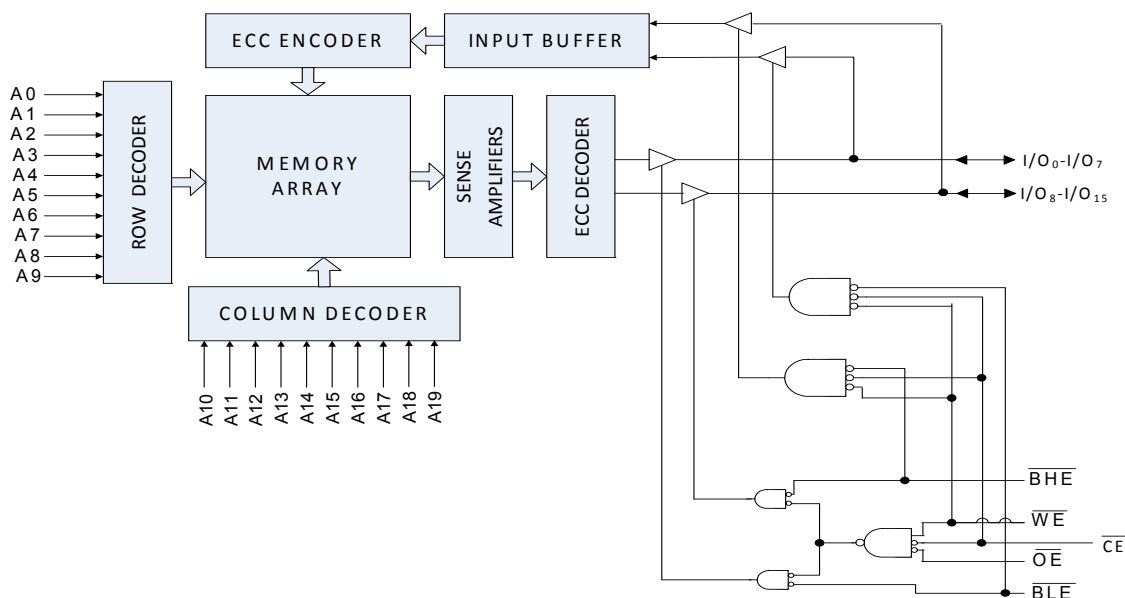

To perform data writes, assert the Write Enable (\overline{WE}) input LOW and provide the data and address on the device data pins (I/O₀ through I/O₁₅) and address pins (A₀ through A₁₉) respectively. The Byte High Enable (BHE) and Byte Low Enable (BLE), inputs control byte writes and write data on the corresponding I/O lines to the memory location specified. \overline{BHE} controls I/O₈ through I/O₁₅ and BLE controls I/O₀ through I/O₇.

To perform data reads, assert the Output Enable (\overline{OE}) input and provide the required address on the address lines. Read data is accessible on I/O lines (I/O₀ through I/O₁₅). You can perform byte accesses by asserting the required byte enable signal (BHE or BLE) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O₀ through I/O₁₅) are placed in a high-impedance state when the device is deselected (CE HIGH), or control signals are de-asserted (OE, BLE, BHE). Refer to the below logic block diagram.

The CY7C1061G automotive device is available in 48-ball VFBGA and 48-pin TSOP I packages.

Note

1. The device does not support automatic write-back on error detection.

Notes

10. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{\text{CC}} \geq 3\text{ V}$) and $V_{\text{CC}}/2$ (for $V_{\text{CC}} < 3\text{ V}$), and input pulse levels of 0 to 3 V (for $V_{\text{CC}} \geq 3\text{ V}$) and 0 to V_{CC} (for $V_{\text{CC}} < 3\text{ V}$). Test conditions for the read cycle use the output loading shown in part (a) of Figure 3 on page 5, unless specified otherwise.
11. t_{POWER} gives the minimum amount of time that the power supply is at stable V_{CC} until the first memory access is performed.
12. t_{HZOE} , t_{HZCE} , t_{HZWE} , and t_{HZBE} are specified with a load capacitance of 5 pF, as shown in part (b) of Figure 3 on page 5. Hi-Z, Lo-Z transition is measured $\pm 200\text{ mV}$ from steady state voltage.
13. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
14. These parameters are guaranteed by design and are not tested.
15. The internal write time of the memory is defined by the overlap of $\overline{\text{WE}} = V_{\text{IL}}$, $\overline{\text{CE}} = V_{\text{IL}}$ and $\overline{\text{BHE}}$, or $\overline{\text{BLE}} = V_{\text{IL}}$. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
16. The minimum write pulse width for Write Cycle No. 2 ($\overline{\text{WE}}$ Controlled, $\overline{\text{OE}}$ LOW) should be sum of t_{HZWE} and t_{SD} .

Notes

- 17. The device is continuously selected, $\overline{OE} = V_{IL}$, $\overline{CE} = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} .
- 18. \overline{WE} is HIGH for read cycle.
- 19. Address valid prior to or coincident with \overline{CE} LOW transition.

Notes

20. The internal write time of the memory is defined by the overlap of $\overline{\text{WE}} = V_{IL}$, $\overline{\text{CE}} = V_{IL}$, and $\overline{\text{BHE}}$ or $\overline{\text{BLE}} = V_{IL}$. These signals must be LOW to initiate a write and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.

21. Data I/O is in high-impedance state if $\overline{\text{CE}} = V_{IH}$, $\overline{\text{OE}} = V_{IH}$ or $\overline{\text{BHE}}$, and/or $\overline{\text{BLE}} = V_{IH}$.

22. During this period, the I/Os are in output state. Do not apply input signals.

23. The minimum write pulse width for Write Cycle No. 2 ($\overline{\text{WE}}$ Controlled, $\overline{\text{OE}}$ LOW) should be sum of t_{HZWE} and t_{SD} .

Switching Waveforms (continued)

Figure 9. Write Cycle No. 3 (\overline{WE} Controlled) [24, 25]

Notes

24. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE} = V_{IL}$, and \overline{BHE} or $\overline{BLE} = V_{IL}$. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.

25. Data I/O is in high impedance state if $\overline{CE} = V_{IH}$, or $\overline{OE} = V_{IH}$ or \overline{BHE} , and/or $\overline{BLE} = V_{IH}$.

26. During this period the I/Os are in output state. Do not apply input signals.

Switching Waveforms (continued)

Notes

- 27. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE} = V_{IL}$, and \overline{BHE} or $\overline{BLE} = V_{IL}$. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
- 28. Data I/O is in high-impedance state if $\overline{CE} = V_{IH}$, or $\overline{OE} = V_{IH}$ or \overline{BHE} , and/or $\overline{BLE} = V_{IH}$.
- 29. During this period, the I/Os are in output state. Do not apply input signals.
