

8K x 8/9 Dual-Port Static RAM with SEM, INT, BUSY

Features

- True Dual-Ported memory cells which allow simultaneous reads of the same memory location
- 8K x 8 organization (CY7C144)
- 8K x 9 organization (CY7C145)
- 0.65-micron CMOS for optimum speed/power
- High-speed access: 15ns
- Low operating power: I_{CC} = 160 mA (max.)
- Fully asynchronous operation
- Automatic power-down
- TTL compatible
- Master/Slave select pin allows bus width expansion to 16/18 bits or more
- Busy arbitration scheme provided
- Semaphores included to permit software handshaking between ports
- INT flag for port-to-port communication
- Available in 68-pin PLCC, 64-pin and 80-pin TQFP

Functional Description

The CY7C144 and CY7C145 are high-speed CMOS 8K x 8 and 8K x 9 dual-port static RAMs. Various arbitration schemes are included on the CY7C144/5 to handle situations when multiple processors access the same piece of data. Two ports are provided permitting independent, asynchronous access for reads and writes to any location in memory. The CY7C144/5 can be utilized as a standalone 64/72-Kbit dual-port static RAM or multiple devices can be combined in order to function as a 16/18-bit or wider master/slave dual-port static RAM. An M/S pin is provided for implementing 16/18-bit or wider memory applications without the need for separate master and slave devices or additional discrete logic. Application areas include interprocessor/multiprocessor designs, communications status buffering, and dual-port video/graphics memory.

Each port has independent control pins: chip enable (\overline{CE}), read or write enable (R/W), and output enable (\overline{OE}). Two flags, BUSY and INT, are provided on each port. BUSY signals that the port is trying to access the same location currently being accessed by the other port. The interrupt flag (INT) permits communication between ports or systems by means of a mail box. The semaphores are used to pass a flag, or token, from one port to the other to indicate that a shared resource is in use. The semaphore logic is comprised of eight shared latches. Only one side can control the latch (semaphore) at any time. Control of a semaphore indicates that a shared resource is in use. An automatic power-down feature is controlled independently on each port by a chip enable (\overline{CE}) pin or SEM pin.

Logic Block Diagram

Notes:

1. BUSY is an output in master mode and an input in slave mode.
2. Interrupt: push-pull output and requires no pull-up resistor.

Pin Definitions

Left Port	Right Port	Description
I/O _{0L-7L} (8L)	I/O _{0R-7R} (8R)	Data bus Input/Output
A _{0L-12L}	A _{0R-12R}	Address Lines
CE _L	CE _R	Chip Enable
OE _L	OE _R	Output Enable
R/W _L	R/W _R	Read/Write Enable
SEM _L	SEM _R	Semaphore Enable. When asserted LOW, allows access to eight semaphores. The three least significant bits of the address lines will determine which semaphore to write or read. The I/O ₀ pin is used when writing to a semaphore. Semaphores are requested by writing a 0 into the respective location.
INT _L	INT _R	Interrupt Flag. INT _L is set when right port writes location 1FFE and is cleared when left port reads location 1FFE. INT _R is set when left port writes location 1FFF and is cleared when right port reads location 1FFF.
BUSY _L	BUSY _R	Busy Flag
M/S		Master or Slave Select
V _{CC}		Power
GND		Ground

Read Cycle No. 2 (Either Port CE/OE Access)^[16, 18, 19]

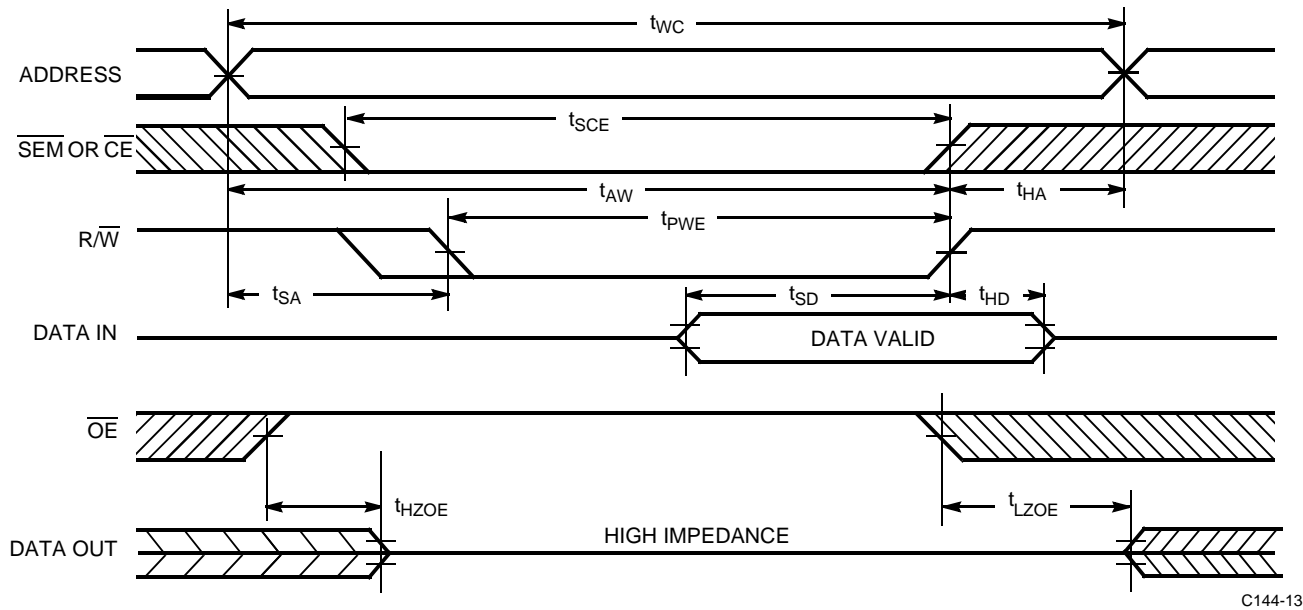

C144-11

Read Timing with Port-to-Port Delay (M/S=L)^[20, 21]

C144-12

Notes:

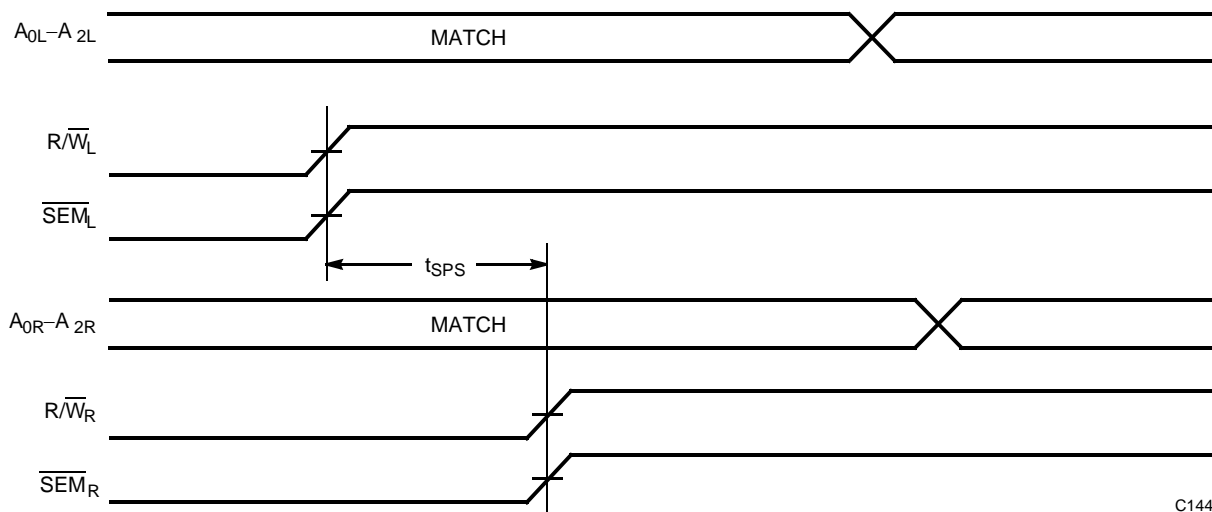

16. \overline{RW} is HIGH for read cycle.
17. Device is continuously selected $\overline{CE} = \text{LOW}$ and $\overline{OE} = \text{LOW}$. This waveform cannot be used for semaphore reads.
18. Address valid prior to or coincident with CE transition LOW.
19. $\overline{CE}_L = \text{L}$, $\overline{SEM} = \text{H}$ when accessing RAM. $\overline{CE} = \text{H}$, $\overline{SEM} = \text{L}$ when accessing semaphores.
20. $\overline{BUSY} = \text{HIGH}$ for the writing port.
21. $\overline{CE}_L = \overline{CE}_R = \text{LOW}$.

Switching Waveforms (continued)
Write Cycle No. 1: \overline{OE} Three-State Data I/Os (Either Port)^[22, 23, 24]

Write Cycle No. 2: $\overline{R/\overline{W}}$ Three-State Data I/Os (Either Port)^[22, 24, 25]

Notes:

22. The internal write time of the memory is defined by the overlap of \overline{CE} or \overline{SEM} LOW and $\overline{R/\overline{W}}$ LOW. Both signals must be LOW to initiate a write, and either signal can terminate a write by going HIGH. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
23. If \overline{OE} is LOW during a $\overline{R/\overline{W}}$ controlled write cycle, the write pulse width must be the larger of t_{PWE} or $(t_{HZWE} + t_{SD})$ to allow the I/O drivers to turn off and data to be placed on the bus for the required t_{SD} . If \overline{OE} is HIGH during a $\overline{R/\overline{W}}$ controlled write cycle (as in this example), this requirement does not apply and the write pulse can be as short as the specified t_{PWE} .
24. $\overline{R/\overline{W}}$ must be HIGH during all address transitions.
25. Data I/O pins enter high impedance when \overline{OE} is held LOW during write.

Switching Waveforms (continued)
Semaphore Read After Write Timing, Either Side^[26]

C144-15

Semaphore Contention^[27, 28, 29]

C144-16

Notes:

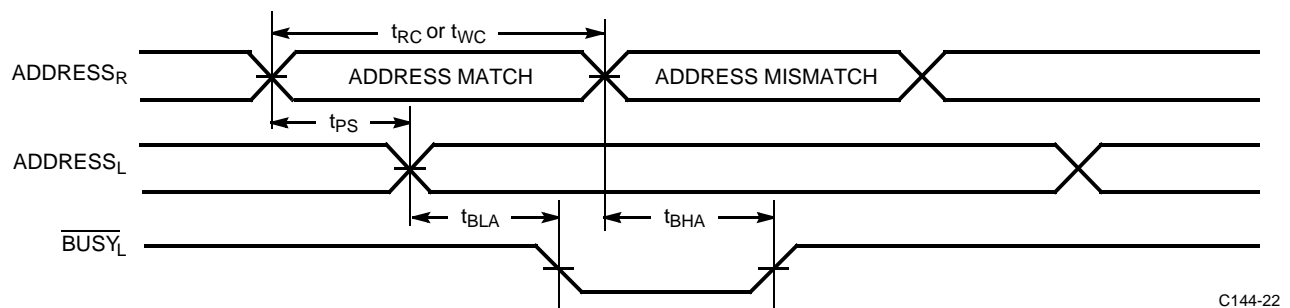

26. $\overline{CE} = \text{HIGH}$ for the duration of the above timing (both write and read cycle).
27. $I/O_{OR} = I/O_{OL} = \text{LOW}$ (request semaphore); $CE_R = CE_L = \text{HIGH}$
28. Semaphores are reset (available to both ports) at cycle start.
29. If t_{SPS} is violated, the semaphore will definitely be obtained by one side or the other, but there is no guarantee which side will control the semaphore.

Interrupt Timing Diagrams
Left Side Sets $\overline{\text{INT}}_R$:

Right Side Clears $\overline{\text{INT}}_R$:

Right Side Sets $\overline{\text{INT}}_L$:

Left Side Clears $\overline{\text{INT}}_L$:

Notes:

31. t_{HA} depends on which enable pin ($\overline{\text{CE}}_L$ or $\overline{\text{R/W}}_L$) is deasserted first.
 32. t_{INS} or t_{INR} depends on which enable pin ($\overline{\text{CE}}_L$ or $\overline{\text{R/W}}_L$) is asserted last.

Architecture

The CY7C144/5 consists of an array of 8K words of 8/9 bits each of dual-port RAM cells, I/O and address lines, and control signals (CE, OE, R/W). These control pins permit independent access for reads or writes to any location in memory. To handle simultaneous writes/reads to the same location, a BUSY pin is provided on each port. Two interrupt (INT) pins can be utilized for port-to-port communication. Two semaphore (SEM) control pins are used for allocating shared resources. With the M/S pin, the CY7C144/5 can function as a Master (BUSY pins are outputs) or as a slave (BUSY pins are inputs). The CY7C144/5 has an automatic power-down feature controlled by CE. Each port is provided with its own output enable control (OE), which allows data to be read from the device.

Functional Description

Write Operation

Data must be set up for a duration of t_{SD} before the rising edge of R/W in order to guarantee a valid write. A write operation is controlled by either the OE pin (see Write Cycle No. 1 waveform) or the R/W pin (see Write Cycle No. 2 waveform). Data can be written to the device t_{HZOE} after the OE is deasserted or t_{HZWE} after the falling edge of R/W. Required inputs for non-contention operations are summarized in Table 1.

If a location is being written to by one port and the opposite port attempts to read that location, a port-to-port flowthrough delay must be met before the data is read on the output; otherwise the data read is not deterministic. Data will be valid on the port t_{DDD} after the data is presented on the other port.

Read Operation

When reading the device, the user must assert both the OE and CE pins. Data will be available t_{ACE} after CE or t_{DOE} after OE are asserted. If the user of the CY7C144/5 wishes to access a semaphore flag, then the SEM pin must be asserted instead of the CE pin.

Interrupts

The interrupt flag (\overline{INT}) permits communications between ports. When the left port writes to location 1FFF, the right port's interrupt flag (\overline{INT}_R) is set. This flag is cleared when the right port reads that same location. Setting the left port's interrupt flag (\overline{INT}_L) is accomplished when the right port writes to location 1FFE. This flag is cleared when the left port reads location 1FFE. The message at 1FFF or 1FFE is user-defined. See Table 2 for input requirements for INT. \overline{INT}_R and \overline{INT}_L are push-pull outputs and do not require pull-up resistors to operate.

Busy

The CY7C144/5 provides on-chip arbitration to alleviate simultaneous memory location access (contention). If both ports' CEs are asserted and an address match occurs within t_{PS} of each other the Busy logic will determine which port has access. If t_{PS} is violated, one port will definitely gain permission to the location, but it is not guaranteed which one. BUSY will be asserted t_{BLA} after an address match or t_{BLC} after CE is taken LOW. \overline{BUSY}_L and \overline{BUSY}_R

in master mode are push-pull outputs and do not require pull-up resistors to operate.

Master/Slave

An $\overline{M/S}$ pin is provided in order to expand the word width by configuring the device as either a master or a slave. The BUSY output of the master is connected to the BUSY input of the slave. This will allow the device to interface to a master device with no external components. Writing of slave devices must be delayed until after the BUSY input has settled. Otherwise, the slave chip may begin a write cycle during a contention situation. When presented a HIGH input, the $\overline{M/S}$ pin allows the device to be used as a master and therefore the BUSY line is an output. BUSY can then be used to send the arbitration outcome to a slave.

Semaphore Operation

The CY7C144/5 provides eight semaphore latches which are separate from the dual-port memory locations. Semaphores are used to reserve resources that are shared between the two ports. The state of the semaphore indicates that a resource is in use. For example, if the left port wants to request a given resource, it sets a latch by writing a 0 to a semaphore location. The left port then verifies its success in setting the latch by reading it. After writing to the semaphore, SEM or OE must be deasserted for t_{SOP} before attempting to read the semaphore. The semaphore value will be available $t_{SWRD} + t_{DOE}$ after the rising edge of the semaphore write. If the left port was successful (reads a 0), it assumes control over the shared resource, otherwise (reads a 1) it assumes the right port has control and continues to poll the semaphore. When the right side has relinquished control of the semaphore (by writing a 1), the left side will succeed in gaining control of the semaphore. If the left side no longer requires the semaphore, a 1 is written to cancel its request.

Semaphores are accessed by asserting \overline{SEM} LOW. The \overline{SEM} pin functions as a chip enable for the semaphore latches (CE must remain HIGH during SEM LOW). A_{0-2} represents the semaphore address. OE and R/W are used in the same manner as a normal memory access. When writing or reading a semaphore, the other address pins have no effect.

When writing to the semaphore, only I/O₀ is used. If a 0 is written to the left port of an unused semaphore, a 1 will appear at the same semaphore address on the right port. That semaphore can now only be modified by the side showing 0 (the left port in this case). If the left port now relinquishes control by writing a 1 to the semaphore, the semaphore will be set to 1 for both sides. However, if the right port had requested the semaphore (written a 0) while the left port had control, the right port would immediately own the semaphore as soon as the left port released it. Table 3 shows sample semaphore operations.

When reading a semaphore, all eight/nine data lines output the semaphore value. The read value is latched in an output register to prevent the semaphore from changing state during a write from the other port. If both ports attempt to access the semaphore within t_{SPS} of each other, the semaphore will definitely be obtained by one side or the other, but there is no guarantee which side will control the semaphore.

Initialization of the semaphore is not automatic and must be reset during initialization program at power-up. All Semaphores on both sides should have a one written into them at initialization from both sides to assure that they will be free when needed.

Table 1. Non-Contending Read/Write

Inputs				Outputs	Operation
CE	R/W	OE	SEM	I/O _{0-7/8}	
H	X	X	H	High Z	Power-Down
H	H	L	L	Data Out	Read Data in Semaphore
X	X	H	X	High Z	I/O Lines Disabled
H		X	L	Data In	Write to Semaphore
L	H	L	H	Data Out	Read
L	L	X	H	Data In	Write
L	X	X	L		Illegal Condition

Table 2. Interrupt Operation Example (assumes $\overline{\text{BUSY}}_L = \overline{\text{BUSY}}_R = \text{HIGH}$)

Function	Left Port					Right Port				
	R/W	CE	OE	A ₀₋₁₂	INT	R/W	CE	OE	A ₀₋₁₂	INT
Set Left INT	X	X	X	X	L	L	L	X	1FFE	X
Reset Left INT	X	L	L	1FFE	H	X	L	L	X	X
Set Right INT	L	L	X	1FFF	X	X	X	X	X	L
Reset Right INT	X	X	X	X	X	X	L	L	1FFF	H

Table 3. Semaphore Operation Example

Function	I/O _{0-7/8} Left	I/O _{0-7/8} Right	Status
No action	1	1	Semaphore free
Left port writes semaphore	0	1	Left port obtains semaphore
Right port writes 0 to semaphore	0	1	Right side is denied access
Left port writes 1 to semaphore	1	0	Right port is granted access to semaphore
Left port writes 0 to semaphore	1	0	No change. Left port is denied access
Right port writes 1 to semaphore	0	1	Left port obtains semaphore
Left port writes 1 to semaphore	1	1	No port accessing semaphore address
Right port writes 0 to semaphore	1	0	Right port obtains semaphore
Right port writes 1 to semaphore	1	1	No port accessing semaphore
Left port writes 0 to semaphore	0	1	Left port obtains semaphore
Left port writes 1 to semaphore	1	1	No port accessing semaphore
