**Audio Codec with Advanced Accessory Detect**

---

## General Description

The DA7219 is an ultra low-power audio codec with Advanced Accessory Detection (AAD), which supports sample rates up to 96 kHz at 24-bit resolution. It contains a mono microphone to analog to digital converter (ADC) path, and a stereo digital to analog converter (DAC) to headphone (HP) path.

AAD supports the detection and identification of 3-pole (headphone) and 4-pole (headset) jacks, and allows the automatic pin order switching of MIC/GND on CTIA or OMTP headsets. It also supports automatic multiple button detection.

## Key Features

- Android Wired Headset v1.1 compliant
- High performance mono microphone to ADC record path with 90 dB SNR
  - ADC digital filters with Audio and Voice mode high-pass characteristics
  - Low-noise microphone bias regulator with programmable output
- High performance stereo DAC to headphone playback path with 100 dB SNR
  - DAC digital filters with Audio and Voice mode high-pass cutoff and 5-band equalizer
- Advanced Accessory Detect supports
  - 3-pole and 4-pole jack detection
  - MIC/GND polarity switching
  - Multiple button detection
  - Headphone impedance testing
- Microphone input with automatic level control
- Digital sidetone path with gain
- Digital tone generator
- System controller for simplified pop-free start-up and shut-down
- Mixed sample rates of 24 kHz ADC, 48 kHz DAC supported from a single digital interface
- Sample rates of up to 96 kHz at 24-bit resolution
- Shut-down mode for very low current consumption during standby
- Phase locked loop with WCLK tracking to generate system clock
- 4-wire digital audio interface with support for I<sup>2</sup>S, TDM and other audio formats
- 2-wire I<sup>2</sup>C compatible interface with support for High Speed mode up to 3.4 MHz
- 4.5 mm x 1.6 mm WLCSP RouteEasy™ package for low cost PCB manufacture

## Applications

- Chromebooks
- Portable audio applications
- Tablets and eBooks
- All digital distributed systems
- Headphone accessories
- Remote controllers
- Gaming controllers

**1 Terms and Definitions**

AAD	Advanced Accessory Detect
ADC	Analog to Digital Converter
ALC	Automatic Level Control
CMRR	Common Mode Rejection Ratio
CTIA	Cellular Telecommunications Industry Association, (now known as 'The Wireless Association')
DAC	Digital to Analog Converter
DAI	Digital Audio Interface
DMIC	Digital Microphone
DTMF	Dual Tone Multi Frequency
EQ	Equalizer
FS	Sample Rate
HP	Headphones
HPF	High-Pass Filter
I <sup>2</sup> C	Inter-Integrated Circuit Interface
I <sup>2</sup> S	Inter-Integrated Circuit Sound
LDO	Low Dropout Regulator
MCLK	Master Clock
OMTP	Open Mobile Terminals Platform
PC	Program Counter
PGA	Programmable Gain Amplifier
PLL	Phase Locked Loop
PSRR	Power Supply Rejection Ratio
SC	System Controller
SDM	Sigma Delta Modulator
SNR	Signal to Noise Ratio
SRM	Sample Rate Matching
SWG	Sine Wave Generator
TDM	Time Division Multiplexing
THD+N	Total Harmonic Distortion plus Noise
VCO	Voltage-Controlled Oscillator
WCLK	Word Clock

---

## Audio Codec with Advanced Accessory Detect

### 1.1 Terminology

#### Crosstalk (dB)

The level difference between the active path output and the idle path measured signal level, at the test signal frequency. The active path is configured and supplied with an input signal capable of driving a full scale output, with the signal measured at the output of the specified idle path.

#### Mute Attenuation

The difference in level between the full scale output signal and the output with mute applied.

#### Channel Separation (dB) [left-to-right and right-to-left]

The difference in level between the active channel (driven to maximum full scale output) and the signal level measured in the idle channel at the test signal frequency. The active channel is configured and supplied with an input signal capable of driving a full scale output, with the signal measured at the output of the associated idle channel.

#### PSRR

The ratio of a given power supply change relative to the output signal that results from it. PSRR is measured under quiescent signal path conditions.

#### SNR

The difference in level between the maximum full scale output signal and the output with no input signal applied.

#### THD+N

The level of the rms value of the sum of harmonic distortion products plus noise in the specified bandwidth relative to the amplitude of the measured output signal.

All performance measurements carried out with 20 kHz low pass filter, and where noted an A-weighted filter. Failure to use such a filter will result in higher THD and lower SNR readings than are found in the Electrical Characteristics. The low-pass filter removes out of band noise; although it is not audible it may affect dynamic specification values.

### 4 Ballout

Figure 3: DA7219 Ballout Diagram

Table 1: Ball Description

Ball No.	Ball/Pin Name	Type (Table 2)	Description
<b>Microphone Inputs</b>			
B16	MIC_P	AI	Differential analog microphone 1 input (Pos)
A15	MIC_N	AI	Differential analog microphone 1 input (Neg)
B14	MICBIAS	AO	Microphone bias output
<b>Accessory Detect</b>			
D16	JACKDET	DI	Jack Detect Input from socket
A11	SLEEVE	AIO	Socket Sleeve (configured as MIC or GND)
C13	RING2	AIO	Socket Ring 2 (configured as GND or MIC)
B6	SLEEVE_SENSE	AIO	Socket Sleeve (Sense)
B4	RING2_SENSE	AIO	Socket Ring 2 (Sense)
C15	MIC	AIO	Microphone DC input
<b>Headphone Outputs</b>			
A3	HP_L	AO	Single-ended headphone output (Left)
A5	HP_R	AO	Single-ended headphone output (Right)
<b>Charge Pump</b>			
A1	HPCSP	AIO	Charge pump reservoir capacitor (Positive)
C1	HPCSN	AIO	Charge pump reservoir capacitor (Negative)
D2	HPCFP	AIO	Charge pump flying capacitor (Positive)
C3	HPCFN	AIO	Charge pump flying capacitor (Negative)
<b>Digital Interface</b>			
D14	SDA	DIOD	I <sup>2</sup> C bidirectional data
D12	SCL	DI	I <sup>2</sup> C clock

## Audio Codec with Advanced Accessory Detect

Ball No.	Ball/Pin Name	Type (Table 2)	Description
D10	nIRQ	DIOD	Interrupt output (open drain active low)
C7	DATIN	DIO	DAI data input to DA7219
C9	DATOUT	DIO	DAI data output from DA7219
D6	BCLK	DIO	DAI bit clock
D8	WCLK	DIO	DAI word clock
C11	MCLK	DI	Master clock input
<b>References</b>			
B8	DACREF	AIO	DAC reference decoupling capacitor
A9	VMID	AIO	Mid-rail reference decoupling capacitor
A7	VREF	AIO	Bandgap reference decoupling capacitor
<b>Supplies</b>			
C5	VDD	AI	Main analog and digital supply
A13	VDD_MIC	AI	Supply for MICBIAS LDO
D4	VDD_IO	AI	Supply for digital interfaces
<b>Grounds</b>			
B2	GND_CP	AI	Ground
B10	GND	AI	Ground
B12	GND_HP	AI	Ground

**Table 2: Ball/Pin Type Definition**

Ball/Pin Type	Description	Ball/Pin Type	Description
DI	Digital Input	AI	Analog Input
DIO	Digital Input/Output	AO	Analog Output
DIOD	Digital Input/Output open Drain	AIO	Analog Input/Output

### 5 Pin Descriptions

#### 5.1 Microphone Pins

##### 5.1.1 MIC\_P

MIC\_P is the positive differential input for the analog microphone channel. It can be used as a single-ended input if MIC\_N is grounded (see Figure 7).

##### 5.1.2 MIC\_N

MIC\_N is the negative differential input for the analog microphone channel. It should be grounded when using a single-ended analog microphone configuration.

##### 5.1.3 MICBIAS

MICBIAS is the internally generated microphone supply. This must be decoupled with a 1  $\mu$ F capacitor.

#### 5.2 Accessory Detect Pins

##### 5.2.1 JACKDET

JACKDET is used to signal to the device when the Jack is fully inserted into the 3.5 mm jack (or alternative) socket.

The JACKDET pin is designed to be pulled either HIGH or LOW on the insertion of the jack. If using an HPLDET type headset socket additional external circuitry is required.

If not required it should be left unconnected.

##### 5.2.2 SLEEVE

Sleeve is tested during the sense stage and then configured as either the headset microphone input or the headset ground connection.

##### 5.2.3 RING2

RING2 is tested during the sense stage and then configured as either the headset microphone input or the headset ground connection.

##### 5.2.4 SLEEVE\_SENSE

SLEEVE sense line to guarantee accuracy over distance, cables and connectors.

##### 5.2.5 RING2\_SENSE

RING2 sense line to guarantee accuracy over distance, cables and connectors.

##### 5.2.6 MIC

MIC is the DC input for the analog accessory detect.

#### 5.3 Interface Input Pins

##### 5.3.1 MCLK

MCLK is the master clock input pin. It is used as the main system clock either directly or via the PLL.

---

**Audio Codec with Advanced Accessory Detect**
**5.3.2 SCL**

SCL is the Control Interface (I<sup>2</sup>C) clock input and is used in conjunction with SDA to control the device.

**5.3.3 DATIN**

DATIN is the data input pin which forms part of the Digital Audio Interface (DAI). It is used to present audio playback data to the device.

**5.4 Interface Output Pins**
**5.4.1 nIRQ**

nIRQ is the open drain active-low interrupt output to alert the host to either an accessory or a level detect event.

**5.4.2 DATOUT**

DATOUT is the data output pin which forms part of the DAI. It is used to present audio record data to the host.

**5.5 Interface Bidirectional Pins**
**5.5.1 SDA**

SDA is the Control Interface (I<sup>2</sup>C) data input/output and is used in conjunction with SCL to control the device.

**5.5.2 BCLK**

BCLK is the bit clock input/output pin which forms part of the DAI. It is used to clock audio data bits into or out from the device or both.

**5.5.3 WCLK**

WCLK is the word clock input/output pin which forms part of the DAI. It is used to indicate whether the data bits belong to the left or right audio channel.

**5.6 Headphone Output Pins**
**5.6.1 HP\_L**

HP\_L is the left-channel single-ended headphone output. It is ground-centered so the headphone speaker can be connected directly between HP\_L and ground.

**5.6.2 HP\_R**

HP\_R is the right-channel single-ended headphone output. It is ground-centered so the headphone speaker can be connected directly between HP\_R and ground.

**5.7 Charge Pump Pins**
**5.7.1 HPCSP**

HPCSP is the positive output from the headphone charge pump. It should be connected to GND\_CP via a reservoir capacitor.

---

## Audio Codec with Advanced Accessory Detect

### 5.7.2 HPCSN

HPCSN is the negative output from the headphone charge pump. It must be connected to GND\_CP via a reservoir capacitor.

### 5.7.3 HPCFP

HPCFP is one of the flying capacitor connections required by the headphone charge pump. It must be connected to HPCFN via a capacitor.

### 5.7.4 HPCFN

HPCFN is one of the flying capacitor connections required by the headphone charge pump. It must be connected to HPCFP via a capacitor.

## 5.8 References

### 5.8.1 VMID

VMID is the mid-rail reference decoupling capacitor connection.

### 5.8.2 DACREF

DACREF is the DAC reference decoupling capacitor connection.

### 5.8.3 VREF

VREF is the bandgap reference decoupling capacitor connection.

## 5.9 Supply Pins

### 5.9.1 VDD

VDD is main analog supply pin. It supplies all the analog circuits except the MICBIAS output and the HPAMP outputs.

### 5.9.2 VDD\_IO

VDD\_IO is the supply pin for the digital input/output signals. VDD\_IO must be greater than or equal to VDD during device operation.

### 5.9.3 VDD\_MIC

VDD\_MIC is the supply pin for the MICBIAS. VDD\_MIC must be greater than or equal to VDD during device operation.

## 5.10 Ground Pins

### 5.10.1 GND

GND is the main analog ground pin. It is the ground connection for all analog circuits with the exception of the charge pump.

### 5.10.2 GND\_CP

GND\_CP is the ground pin for the charge pump and the digital engine.

**5.10.3 GND\_HP**

GND\_HP is the ground point for the headset. When a headset is connected this pin is automatically connected internally to either RING2 or SLEEVE.

## Audio Codec with Advanced Accessory Detect

### 6 Absolute Maximum Ratings

**Table 3: Absolute Maximum Ratings**

Parameter	Description	Conditions (Note 1)	Min	Max	Unit
T <sub>STG</sub>	Storage temperature		-65	+165	°C
T <sub>a</sub>	Operating temperature		-40	+85	°C
V <sub>DD_LIM</sub>	Main supply voltage		-0.3	+2.75	V
V <sub>VDD_IO</sub>	Digital IO supply voltage		-0.3	+5.5	V
V <sub>VDD_MIC</sub>	Microphone bias supply voltage		-0.3	+5.5	V
V <sub>VDDIO</sub>	Digital IO pins: SDA, SCL, BCLK, WCLK, DATIN, DATOUT, MCLK		-0.3	V <sub>VDD_IO</sub> + 0.3	V
V <sub>VJACKDET</sub>	Accessory detect pins: JACKDET		-0.3	V <sub>VDD</sub> + 0.3	V
V <sub>VACCDDET</sub>	Accessory detect pins: RING2, SLEEVE, MIC, RING2_SENSE, SLEEVE_SENSE		-0.3	V <sub>VDD_MIC</sub> + 0.3	V
V <sub>VMIC_P</sub> , V <sub>VMIC_N</sub>	Analog input pins MIC_P and MIC_N		-0.3	V <sub>VDD</sub> + 0.3	V
V <sub>VESD_HBM</sub>	ESD susceptibility	Human body model (HBM)	2000		V
V <sub>VESD_CDM</sub>	ESD susceptibility	Charged device model (CDM)	500		V

**Note 1** Stresses beyond those listed under 'Absolute Maximum Ratings' may cause permanent damage to the device. These are stress ratings only, so functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specification are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### 7 Recommended Operating Conditions

**Table 4: Recommended Operating Conditions**

Parameter	Description	Conditions	Min	Typ	Max	Unit
T <sub>a</sub>	Operating temperature		-25		85	°C
V <sub>VDD</sub>	Main supply voltage		1.7		2.5	V
V <sub>VDD_IO</sub>	Digital IO supply voltage	(Note 1)	V <sub>VDD</sub>		3.6	V
V <sub>VDD_MIC</sub>	Microphone bias supply voltage	(Note 1)	V <sub>VDD</sub>		3.6	V

**Note 1** V<sub>VDD\_IO</sub> and V<sub>VDD\_MIC</sub> must be greater than or equal to V<sub>VDD</sub>.

## Audio Codec with Advanced Accessory Detect

### 8 Electrical Characteristics

Unless otherwise stated, test conditions are as follows:  $V_{DD} = V_{DD\_IO} = 1.8\text{ V}$ ,  $V_{DD\_MIC} = 3.3\text{ V}$ ,  $MCLK = 12.288\text{ MHz}$ ,  $SR = 48\text{ kHz}$ ,  $PLL = \text{Bypass mode}$ ,  $T_a = 25\text{ }^\circ\text{C}$ .

**Table 5: Power Consumption**

Description	Conditions	Min	Typ	Max	Unit
DEEP SLEEP mode			4	10	$\mu\text{A}$
SLEEP mode	AAD on without button detection		185		$\mu\text{A}$
Digital playback to headphone, no load	DAC to HP_L/R, quiescent		3.4		mW
Digital playback to headphone, with load	DAC to HP_L/R, 16 $\Omega$ load, 0.1 mW at 0 dBFS		7.5		mW
Microphone stereo record	MIC P/N to ADCL/R		2.75		mW
Microphone stereo record and digital playback to headphone, no load	MIC P/N to ADCL/R and DACL/R to HP_L/R, quiescent		4.8		mW
Microphone stereo record and digital playback to headphone, with load	MIC P/N to ADCL/R and DACL/R to HP_L/R, 16 $\Omega$ load, 0.1 mW at 0 dBFS		8.9		mW

**Table 6: Microphone Bias**

Parameter	Description	Conditions	Min	Typ	Max	Unit
$V_{MICBIAS}$	Output voltage	No load, $V_{DD\_MIC} > V_{MICBIAS} + 200\text{ mV}$ Level programmable using <a href="#">micbias1_level</a>	1.6		2.9	V
$I_{BIAS}$	Output current	Output voltage droop < 50 mV		2		mA
PSRR	Power supply rejection ratio	20 Hz to 2 kHz 2 kHz to 20 kHz	70 50			dB
$V_{NO}$	Output voltage noise	$V_{MICBIAS} \leq 2.2\text{ V}$		5		$\mu\text{V}_{RMS}$

**Table 7: Microphone Amplifier**

Parameter	Description	Conditions	Min	Typ	Max	Unit
	Full-scale input signal	0 dB, singled-ended 0 dB gain, differential		$0.8 \cdot V_{DD}$ $1.6 \cdot V_{DD}$		$V_{PP}$
	Input resistance		12	15	18	k $\Omega$
	Programmable gain		-6		36	dB
	Gain step size			6		dB
	Absolute gain accuracy	0 dB @ 1 kHz	-1.0		1.0	dB
	Gain step error	20 Hz to 20 kHz	-0.1		0.1	dB
VNI	Input noise level	Inputs connected to GND, 24 dB gain, input-referred, A-weighted		5		$\mu\text{V}_{RMS}$
	Amplitude ripple	20 Hz to 20 kHz	-0.5		0.5	dB
PSRR	Power supply rejection ratio	20 Hz to 2 kHz 2 kHz to 20 kHz	90 70			dB

## Audio Codec with Advanced Accessory Detect

Parameter	Description	Conditions	Min	Typ	Max	Unit
CMRR	Common mode rejection ratio			70		dB

**Table 8: Input Mix Amplifier (mixinamp)**

Parameter	Description	Conditions	Min	Typ	Max	Unit
	Programmable gain		-4.5		+18	dB
	Gain step size			1.5		dB
	Absolute gain accuracy	0 dB @ 1 kHz	-1.0		+1.0	dB
	Gain step error	20 Hz to 20 kHz	-0.1		+0.1	dB
	Amplitude ripple	20 Hz to 20 kHz	-0.5		+0.5	dB

## Audio Codec with Advanced Accessory Detect

### 11 Functional Description

DA7219 is a high-performance, low-power audio codec with in-built Advanced Accessory Detection (AAD). The AAD supports the detection of 3-pole (headphone or lineout) or 4-pole (headset) jacks, with automatic pin order switching of MIC/GND on CTIA and OMTP headsets.

The DA7219 contains a mono analog microphone-to-ADC path and a DAI for input and output. The DAC to headphone path has a ground-centered, single-ended stereo headphone output.

The digital core has an input filter with a high-pass filter (HPF), and automatic level control (ALC), while the output filter has an HPF, and a 5-band equalizer (EQ).

There is also a sidetone path with gain and a tone generator that supports Dual Tone Multi-Frequency (DTMF).

#### 11.1 Device Operating Modes

The DA7219 codec has three operating modes:

##### 11.1.1 DEEP SLEEP

There is no clocking in DEEP SLEEP mode and consequently no functionality available and no accessory detection is performed. The system will awake when `system_active = 1`.

##### 11.1.2 SLEEP

In SLEEP mode and with micbias off, AAD performs jack detection and jack configuration detection. Any button press is detected, but identification of the button cannot be performed until micbias is on. No clocking is performed in SLEEP mode, and playback and record are not supported.

##### 11.1.3 ON

AAD performs full-function accessory detection. Playback and record are supported.

All modes, their maximum current consumption, and functionality are listed in [Table 23](#).

Audio Codec with Advanced Accessory Detect

Table 23: System States, Configuration, and Current Consumption

Mode	Configuration						CODEC				Typical current consumption		Comments
	VDD + VDD_IO	VDD_MIC	system_active	MCLK	PLL mode	AAD config	Internal ref osc	Internal PLL	Audio path	AAD	VDD + VDD_IO	VDD_MIC	
OFF	OFF	OFF	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	None	None	N/A
DEEP SLEEP	ON	ON	0	N/A	N/A	N/A	OFF	OFF	OFF	OFF	<10 µA	0	Wake on system_active= 1.
SLEEP	ON	ON	1	OFF	OFF	AAD on without button detection	ON	OFF	OFF (playback/record not supported)	Jack insertion, jack type and pin order	<200 µA	0	
						AAD on with button detection				As above plus button detection (without identification)	<500 µA	0	
						AAD on with button detection and identification				FULL DETECTION (as above but with button Identification)	<300 µA	Dependent on microphone	
ON	ON	ON	1	OFF	SRM - locks to WCLK if DAI is in slave mode	AAD on with button detection and identification	ON	ON	ON (Playback/record)	FULL DETECTION	Dependent on use case		AAD uses clock on demand to save power
				ON (11.8 MHz or 12.288 MHz)	BYPASS		OFF	OFF					
				ON (Valid Freq 2 MHz to 54 MHz)	Normal - lock to MCLK		OFF	ON					

## 11.2 Input Paths

### 11.2.1 Microphone Input

The DA7219 analog input consists of one set of amplifiers and an ADC as shown in Figure 6.

Figure 6: Analog Inputs Block Diagram

#### 11.2.1.1 Microphone Bias

The device has a microphone bias output, which is a programmable voltage source that can be used to supply analog microphones.

The bias output can be independently programmed from 1.8 V to 2.9 V using `micbias1_level`.

The microphone bias level can only be changed while the associated micbias circuit is disabled (`micbias1_en = 0`).

Disable micbias prior to setting `system_active = 0`. Do not turn off the device with micbias disabled.

Table 24: Microphone Bias Settings

<code>micbias1_level</code>	Output Voltage (V) in Low Noise Mode
000	reserved
001	1.8
010	2.0
011	2.2
100	2.4
101	2.6
110	2.8
111	2.9

Audio Codec with Advanced Accessory Detect

11.2.1.2 Microphone Amplifier

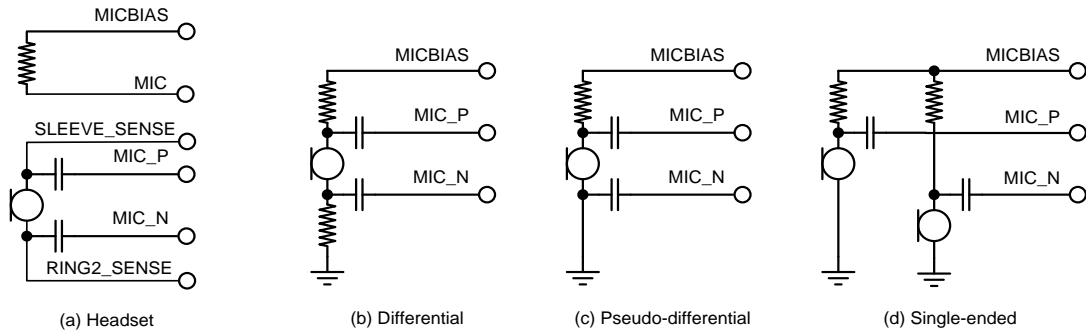

Figure 7: ECM Microphone Configurations

The microphone amplifier can be configured in:

- Headset mode, microphone amplifier is fully differential
- Fully Differential mode for improved common-mode noise rejection
- Pseudo-Differential mode
- Single-Ended mode (MIC\_P or MIC\_N)

All configurations are illustrated in [Figure 7](#).

The configuration of the first microphone amplifier is specified using the [MIC\\_1\\_CTRL](#) register. It is enabled by setting the [mic\\_1\\_amp\\_en](#) bit, and is muted by setting the [mic\\_1\\_amp\\_mute\\_en](#) bit.

The gain of the amplifier can be set in the range of -6 dB to +36 dB in 6 dB steps using [mic\\_1\\_amp\\_gain](#) (see [Table 25](#)):

Table 25: First Microphone Amplifier Gain Settings

<a href="#">mic_1_amp_gain</a>	Amplifier Gain (dB)
000	-6
001	0
010	6
011	12
100	18
101	24
110	30
111	36

11.2.1.3 Input Amplifiers

The input amplifier provides an additional gain stage between the microphone amplifier (see section [11.2.1](#) and [Figure 6](#)) and the ADC input. The input amplifier is enabled by setting [mixin\\_l\\_amp\\_ramp\\_en](#) = 1.

The gain can be set in the range of -4.5 dB to +18 dB in 1.5 dB steps using [mixin\\_l\\_amp\\_gain](#).

Gain updates can be synchronized with signal zero-crossings by setting [mixin\\_l\\_amp\\_zc\\_en](#) = 1. If no zero-crossing is detected within the timeout period of approximately 100 ms, the update is applied unconditionally.

## Audio Codec with Advanced Accessory Detect

As an alternative to zero-cross synchronization, gain updates can be ramped through all intermediate values by setting `mixin_l_amp_ramp_en` = 1. This ramp setting overrides the settings of `mixin_l_amp_zc_en`.

The amplifier can be muted using `mixin_l_amp_mute_en`.

**Table 26: Input Mixer Gain Settings**

<code>mixin_l_amp_gain</code>	Amplifier gain (dB)
0000	-4.5
0001	-3.0
0010	-1.5
0011	0.0
0100	1.5
0101	3.0
0110	4.5
0111	6.0
1000	7.5
1001	9.0
1010	10.5
1011	12.0
1100	13.5
1101	15.0
1110	16.5
1111	18.0

### 11.2.2 Analog to Digital Converter

The DA7219 codec contains a high quality audio ADC. The ADC is clocked at a fixed rate of either 3.072 MHz or 2.8224 MHz, depending on the required input sample rate.

The DA7219 includes a low-power 24-bit high quality audio ADC that supports sampling rates from 8 kHz to 96 kHz. The sample rate is specified using the `SR` register.

The ADC can be enabled and disabled using `adc_l_en`.

The ADC channels offer a configurable digital gain from -83.25 dB to +12 dB in 0.75 dB steps after the digital conversion. Individual gain settings can be programmed via the `adc_l_digital_gain_status` control. The currently active gain settings are stored in the `ADC_L_GAIN_STATUS` register.

Muting, and the ramping of digital gain changes, can be controlled using the dedicated `ADC_L_CTRL` register. If the ramping is enabled using the control bit `adc_l_ramp_en`, the rate of the ramping is controlled using `gain_ramp_rate` in the `GAIN_RAMP_CTRL` register.

### 11.3 Digital Engine

DA7219 contains a digital engine that performs the signal processing and also provides overall system control, see [Figure 8](#).

The input signals from the ADCs are passed to the input filter block which includes an HPF for DC offset removal and wind noise suppression, and an automatic level control.

The signals from the input filters are sent to the digital mixer where they can be combined with signals from the tone generator and the DAI, and routed to the output filters and the DAI. The output

## Audio Codec with Advanced Accessory Detect

filters contain an HPF for DC offset removal, and a fixed 5-band equalizer to adjust the sound of the output signals.

There is also a low latency sidetone path that can take one signal from the ADC and apply gain before passing the signal straight to the output filters. The filter paths are shown in more detail in [Figure 9](#).

A system controller module is included to ensure correct sequencing of the events required to bring up and shut down signal paths without creating pops and clicks.

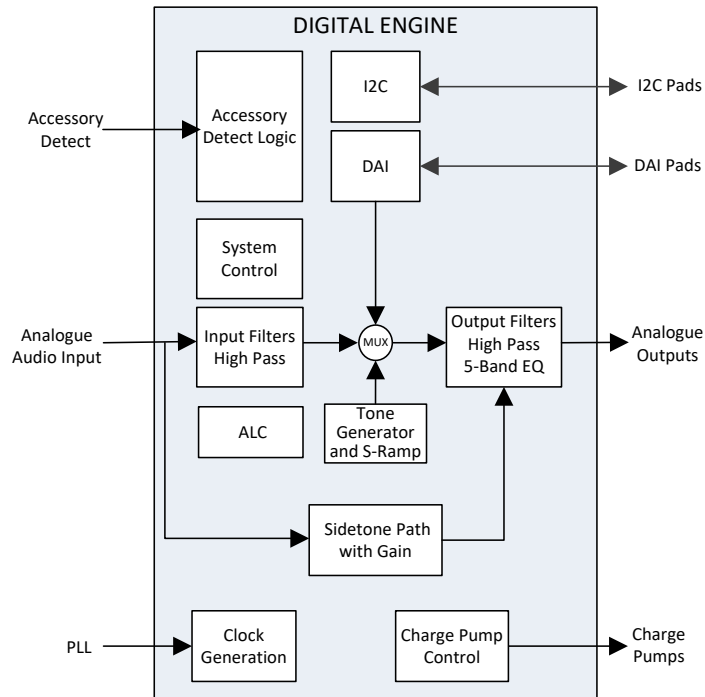

Figure 8: Digital Engine Block Diagram

Figure 9: Digital Filters Block Diagram

**Audio Codec with Advanced Accessory Detect**
**11.3.1 Input Processing**
**11.3.1.1 ADC Digital Gain**

The ADC channels offer a configurable digital gain from -83.25 dB to +12 dB in 0.75 dB steps after the digital conversion. Individual gain settings can be programmed via the `adc_l_digital_gain` control. The currently active gain settings are stored in the `ADC_L_GAIN_STATUS` register.

**11.3.1.2 High-Pass Filter**

Any DC offset from the input path is removed via configurable IIR high-pass filters (HPFs) with typically < 2 Hz roll-off. After reset the filters for both channels are enabled by default, but can be disabled by clearing `adc_hpf_en`. The cutoff frequency of the filters can be programmed using `adc_audio_hpf_corner`.

To improve the quality of microphone recordings, DA7219 provides a programmable HPF engine, enabled via `adc_voice_en` in the `ADC_FILTERS1` register.

In ADC voice mode, `adc_voice_en` must = 1 and `adc_hpf_en` must = 1 in which case the HPF corner frequency is set using `adc_voice_hpf_corner`. The low frequency roll off is configured over a wide range using `adc_voice_hpf_corner`. This allows for flexible removal of wind and pop noise.

For the first filter, in music mode, `adc_voice_en` must = 0 and the HPF corner frequency is set using `adc_audio_hpf_corner`.

The value of the HPF corner frequency also depends on the input sample rate (SR). The sample rates available in the different ADC power modes are summarized in [Table 27](#).

**Table 27: Input HPF Settings**

<code>adc_voice_en</code>	<code>adc_voice_hpf_corner</code>	<code>adc_voice_en</code>	SR Sample Rate (kHz)										
			8	11.025	12	16	22.05	24	32	44.1	48	88.2	96

		011	100	137.8	150	200							
		100	150	206.7	225	300							
		101	200	275.6	300	400							
		110	300	413.4	450	600							
		111	400	551.3	600	800							

**11.3.1.3 Automatic Level Control (ALC)**

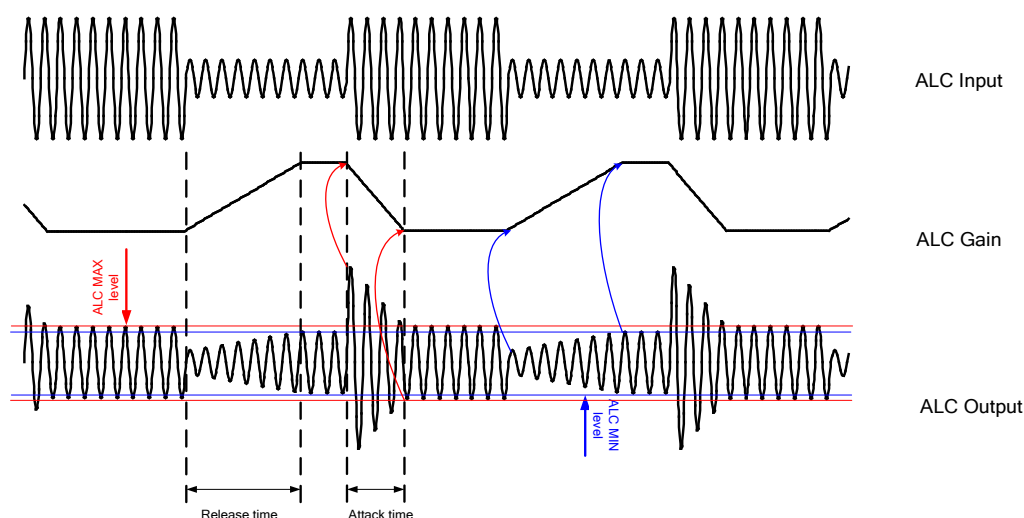

For improved sound recordings of signals with a large volume range, DA7219 offers a fully-configurable automatic recording level control (ALC) for microphone inputs. This is enabled via the

## Audio Codec with Advanced Accessory Detect

`alc_en` control. The ALC monitors the digital signal after the ADC and adjusts the microphones' analog and digital gain to maintain a constant recording level, whatever the analog input signal level.

Operation of ALC is illustrated in Figure 10. When the input signal volume is high, the ALC system will reduce the overall gain until the output volume is below the specified maximum value. When the input signal volume is low, the ALC will increase the gain until the output volume increases above the specified minimum value. If the output signal is within the desired signal range (between the specified minimum and maximum levels), the ALC does nothing.

The maximum and the minimum thresholds that trigger a gain change of the ALC are configured via the `alc_threshold_min` and `alc_threshold_max` controls.

**Figure 10: ALC Principle of Operation**

The ALC can operate in two modes; Digital-Only mode and Hybrid (combined analog and digital gain) mode.

In Digital-Only mode only the digital gain in the ADC is altered. Although the ALC is controlling the gain, it does not modify `adc_l_digital_gain` in the `ADC_L_GAIN` register. This register is ignored while the ALC is in operation. The minimum and maximum levels of digital gain that can be applied by the ALC are controlled using `alc_atten_max` and `alc_gain_max`.

The hybrid analog/digital gain mode (Hybrid mode) can be enabled using `alc_sync_mode`.

In Hybrid mode, the total gain is made up of an analog gain, which is applied to the microphone amplifier, and a digital gain, which is implemented in the filtering stage. The ALC block monitors and controls the gain of the microphone and the ADC.

Hybrid mode offers improved performance and signal tracking over Digital-Only mode. When using the automatic level control (ALC) in Hybrid mode the DC offset between the digital and analog PGAs must be cancelled, see Appendix A.2.

Although the ALC is controlling the gain, it does not modify any of the registers `MIXIN_L_GAIN` or `ADC_L_GAIN`, nor does it modify the digital gain register `ADC_L_GAIN`. These registers are ignored while the ALC is in operation.

Similarly the minimum and maximum levels of analog gain are controlled by `alc_ana_gain_min` and `alc_ana_gain_max`. The rates at which the gain is changed are defined by the attack and decay rates in register `ALC_CTRL2`. When attacking, the gain decreases with `alc_attack` rate. When decaying, the gain increases with `alc_release` rate.

The hold-time is defined by `alc_hold` in the `ALC_CTRL3` register. This controls the length of time that the system maintains the current gain level before starting to decay. This prevents unwanted

## Audio Codec with Advanced Accessory Detect

changes in the recording level when there is a short-lived 'spike' in input volume, for example when recording speech.

Typically the attack rate should be much faster than the decay rate, as it is necessary to reduce rapidly increasing waveforms as quickly as possible and fast release times will result in the signal appearing to 'pump'. The ALC also has an anti-clipping function that applies a very fast attack rate when the input signal is close to full range. This prevents clipping of the signal by reducing the signal gain at a faster rate than would normally be applied. The anti-clipping function is enabled using [alc\\_antipclip\\_en](#), and the threshold above which it is activated is set in the range 0.034 dB/fs to 0.272 dB/fs using [alc\\_antipclip\\_step](#).

A recording noise-gate feature is provided to avoid increasing the gain of the channel when there is no signal, or when only a noise signal is present. Boosting a signal on which only noise is present is known as 'noise pumping'. The noise-gate prevents this. Whenever the level of the input signal drops below the noise threshold configured in [alc\\_noise](#), the channel gain remains constant.

Figure 11: Attack, Delay and Hold Parameters

### 11.3.2 Sidetone Processing

There is a low latency filter channel between inputs and outputs for implementing a sidetone path. The gain is controlled using [sidetone\\_gain](#) and provides gain in the range -42 dB to +0 dB in +3 dB steps. The sidetone path is enabled using [sidetone\\_en](#) and muted using [sidetone\\_mute\\_en](#).

The output from the sidetone channel can be added to left or right (or both) output filters using [outfilt\\_st\\_1l\\_src](#) and [outfilt\\_st\\_1r\\_src](#).

### 11.3.3 Tone Generator

Parameter	Conditions	Min	Typ	Max	Unit
Single-tone frequency	FS = 8,12,16,24,32,48,96 kHz	1		12000	Hz
	FS = 11.025, 22.05, 44.1, 88.2 kHz	1		11025	Hz
Single-tone frequency step			0.2		Hz

## Audio Codec with Advanced Accessory Detect

Parameter	Conditions	Min	Typ	Max	Unit
Dual-tone modulation frequency A			697 770 852 941		Hz
Dual-tone modulation frequency B			1209 1336 1477 1633		Hz
Output signal level			0		dBFS
On/off pulse duration		10		2000	ms
On/off pulse step size	10 ms to 200 ms duration 200 ms to 2000 ms duration		10 50		ms
On/off pulse repeat	Programmable Continuous		1,2,3,4,5,6 $\infty$		Cycles

The tone generator contains two independent sine wave generators, SWG1 and SWG2. Each SWG can generate a sine wave at a frequency (FREQ) from approximately 10 Hz to 12 kHz according to the programmed 16-bit value:

- $FREQ[15:0] = 2^{16} \times f_{SWG}/12000 - 1$ , for  $SR2 = 8, 12, 16, 24, 32, 48, 96$  kHz
- $FREQ[15:0] = 2^{16} \times f_{SWG}/11025 - 1$ , for  $SR2 = 11.025, 22.05, 44.1, 88.2$  kHz

For SWG1, the FREQ value is stored in two 8-bit registers as  $freq1\_u = FREQ[15:8]$  and  $freq1\_l = FREQ[7:0]$ . The SWG2 frequency is programmed in the same way using  $freq2\_u$  and  $freq2\_l$ .

The output of the tone generator can come from either of the SWGs, or from a combination of both of them as specified by  $swg\_sel$ .

In addition the tone generator can produce standard Dual Tone Multi-Frequency (DTMF) tones using the two SWGs if  $dtmf\_en = 1$  and the required key pad value is programmed in  $dtmf\_reg$  as shown in Table 28.

**Table 28: DTMF Tones Corresponding to the  $dtmf\_reg$  Value**

SWG2 Freq (Hz)	SWG1 Frequency (Hz)			
	1209	1336	1477	1633
697	0x1	0x2	0x3	0xA
770	0x4	0x5	0x6	0xB
852	0x7	0x8	0x9	0xC
941	0xE	0x0	0xF	0xD

The tone generator can produce 1, 2, 3, 4, 8, 16, or 32 beeps, or a continuous beep, as determined by  $beep\_cycles$ . Each beep has an on period from 10 ms to 2 s as programmed in  $beep\_on\_per$  and an off period from 10 ms to 2 s as programmed in  $beep\_off\_per$ . The tone generator is started by setting the  $start\_stopn$  bit, and is halted by clearing this bit. If  $start\_stopn$  is cleared, the tone generator stops at the completion of the current beep cycle or at the next zero-cross if the number of beeps is set to continuous ( $beep\_cycles = 110$  or  $= 111$ ). The  $start\_stopn$  bit is automatically cleared once the programmed number of beep cycles has been completed.

Audio Codec with Advanced Accessory Detect

11.3.4 Digital Router

DA7219 includes a digital router which is configured by registers [DIG\\_ROUTING\\_DAI](#) and [DIG\\_ROUTING\\_DAC](#).

The router options are illustrated in [Figure 12](#).

Figure 12: DA7219 Digital Router

[DIG\\_ROUTING\\_DAC](#) is used to select the inputs to go into the DAC filter chain from the router. [DIG\\_ROUTING\\_DAI](#) is used to select the inputs to go into the DAI from the router.

For example, for [dac\\_l\\_src](#), data selection to the DAC\_L path is

- 00 = ADC left output
- 01 = Tone generator
- 10 = DAI input left / DAI mono mix
- 11 = DAI input right / DAI mono mix

The same 2-bit code (00, 01, 10, 11) is used for [dac\\_r\\_src](#), [dai\\_l\\_src](#) and [dai\\_r\\_src](#).

11.3.5 System Control

The system control (SC) automates the sequencing of the multiple blocks required to set up one or more particular audio paths. It is an optional feature, and operates by performing register writes with optimal sequencing and timing, thus eliminating pops and clicks.

The SC for the inputs is configured using [SYSTEM\\_MODES\\_INPUT](#), and for the outputs by using [SYSTEM\\_MODES\\_OUTPUT](#). Writing to the [mode\\_submit](#) field of either of these registers will cause the system controller to process both input and output paths.

Audio Codec with Advanced Accessory Detect

11.3.6 Output Processing

11.3.6.1 DAC Digital Gain

Each channel includes individual gain settings that are configurable in 0.75 dB steps ranging from -78 dB (= mute) to 12 dB using `dac_l_digital_gain` and `dac_r_digital_gain`. The currently active gain settings are stored in `DAC_L_GAIN_STATUS` and `DAC_R_GAIN_STATUS` registers.

11.3.6.2 High-Pass Filter

Any DC offset from the input path is removed via IIR configurable HPFs (typically < 2 Hz roll-off). After reset the filters for both channels are enabled by default, but can be disabled by clearing `dac_hpf_en`. The cutoff frequency of the filters can be programmed using `dac_audio_hpf_corner`.

During playback, dedicated voiceband filtering can be enabled using `dac_voice_en` in the `DAC_FILTERS1` register. In DAC voice mode, `dac_voice_en` must = 1 and `dac_hpf_en` must = 1 in which case the HPF corner frequency is set using `dac_voice_hpf_corner`.

The low frequency roll off is configured over a wide range using the `dac_voice_hpf_corner` control.

In voice mode, the wind noise HPF cutoff frequency is determined by the settings of the `adc_voice_hpf_corner` and the `dac_voice_hpf_corner` register bits, These cutoff frequencies are not fixed and vary with the sample rate being used. Table 29 shows the cutoff frequencies for all valid settings of `adc_voice_hpf_corner` and `dac_voice_hpf_corner`, at all sample rates of 16 kHz and below.

Table 29: Output HPF Settings

dac_voice_en	dac_voice_hpf_corner	dac_audio_hpf_corner	SR Sample Rate (kHz)										
			8	11.025	12	16	22.05	24	32	44.1	48	88.2	96
0		00	0.33	0.46	0.5	0.67	0.92	1	1.33	1.84	2	3.68	4
		01	0.67	0.92	1	1.33	1.84	2	2.67	3.68	4	7.35	8
		10	1.33	1.84	2	2.67	3.68	4	5.33	7.35	8	14.7	16
		11	2.67	3.68	4	5.33	7.35	8	10.67	14.7	16	29.4	32
1	000	2.5	3.45	3.75	5	Voice HPF not available for sample rates above 16 kHz.

	100	150	206.7	225	300								
	101	200	275.6	300	400								
	110	300	413.4	450	600								
	111	400	551.3	600	800								

Audio Codec with Advanced Accessory Detect

11.3.6.3 5-Band Equalizer

The gains of each band can be individually configured, from -10.5 dB to 12.0 dB in 1.5 dB steps, using the `dac_eq_band1`, `dac_eq_band2`, `dac_eq_band3`, `dac_eq_band4`, `dac_eq_band5` controls.

The output filters provide gain or attenuation in each of five separate (fixed) frequency bands using the 5-band equalizer. The equalizer, for both left and right channels, is enabled using `dac_eq_en`.

When the equalizer is enabled, the digital gain is reduced by 12 dB to avoid clipping. If desired the gain can be added back in after the equalizer block via the `DAC_L_GAIN` and `DAC_R_GAIN` registers.

The center or cutoff frequency of each of the five bands depends on the output sample rate as shown in Table 30. The equalizer cannot be used with sample rates greater than 48 kHz

Table 30: Output 5-Band Equalizer Center/Cutoff Frequencies

FS (kHz)	Center Frequency (Hz) at Programmed Setting				
	Band 1	Band 2	Band 3	Band 4	Band 5
8	0	99	493	1528	4000
11.025	0	136	680	2106	5512
12	0	148	740	2293	6000

Figure 17: Equalizer Filter Band 5 Frequency Response at FS = 48 kHz

### 11.3.6.4 DAC Soft Mute

To improve the user's perception of audio reconfigurations, the DAC channel signals may be soft muted by asserting `dac_softmute_en` (in register `DAC_FILTERS5`). The soft mute function attenuates the digital input to the DAC, ramping the gain down in steps of 0.1875 dB from its current level to -77.25 dB, then completely muting the channel. When `dac_softmute_en` is released, the attenuation is set to -77.25 dB, and then ramped up to the previous gain level. Both left and right channels of soft mute enabled output amplifiers are muted simultaneously. The ramping up and down rate is dependent on the audio sample rate and can be individually configured via `dac_softmute_en`.

Setting `dac_softmute_en` = 1 enables a soft mute on both channels.

During active soft muting, the digital gain of the DAC will be different to the value programmed inside controls `dac_l_digital_gain_status` and `dac_r_digital_gain_status`.

## 11.4 Output Paths

### 11.4.1 Digital to Analog Converter

The DA7219 codec includes a stereo audio DAC. Left and right channels of the DAC are independently and automatically enabled whenever the corresponding output filter channel is enabled.

The DAC is clocked at 3.072 MHz or 2.8224 MHz depending on the output sample rate (SR). Left and right channels of the DAC are independently and automatically enabled whenever the corresponding output filter channel is enabled.

The integrated stereo DAC is suitable for high quality audio playback by MP3 players and by portable multimedia players of all kinds.

The left and right channels of the DAC can be individually enabled using controls `dac_l_en` and `dac_r_en`.

Each channel includes individual gain settings that are configurable in 0.75 dB steps from -78 dB to 12 dB using `dac_l_digital_gain` and `dac_r_digital_gain`. The currently active gain settings are stored in `DAC_L_GAIN_STATUS` and `DAC_R_GAIN_STATUS` registers.

On the dedicated `DAC_L_CTRL` and `DAC_R_CTRL` registers, settings such as mute and ramping of gain changes can be configured. If ramping is enabled using the control bits `dac_l_ramp_en` or `dac_r_ramp_en`, the rate of the ramping can be controlled using `gain_ramp_rate` in the `GAIN_RAMP_CTRL` register.

## Audio Codec with Advanced Accessory Detect

A digital HPF for each DAC channel is implemented with a 3 dB cutoff frequency controlled in the `DAC_FILTERS1` register by `dac_audio_hpf_corner`. The HPFs are enabled by control `dac_hpf_en`. After reset, the HPFs for both channels are enabled by default.

### 11.4.2 Headphone Outputs

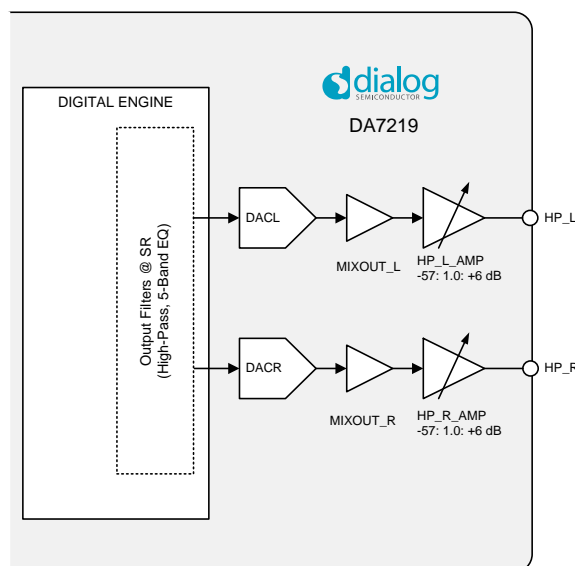

Figure 18: Headphone Output Paths Showing the Two Amplifiers

#### 11.4.2.1 Mixout Amplifier

Each headphone (HP) path has one mixout amplifier which must be enabled when using the headphone outputs. MIXOUT\_L, is enabled by setting `mixout_l_amp_en = 1` and `MIXOUT_L_SELECT = 1`, MIXOUT\_R is enabled by setting `mixout_r_amp_en = 1` and `MIXOUT_R_SELECT = 1`.

#### 11.4.2.2 Headphone Amplifiers

Each headphone (HP) path has one HP amplifier stage providing a gain of  $-57$  dB to  $+6$  dB in 1.0 dB steps.

The amplifiers are configured to operate in single-ended mode. The HP loads are connected between HP\_L and HP\_R, and the internal ground set by the MIC/GND switches during the detect sequence.

The HP amplifiers are configured to operate in true-ground (charge pump) mode. In true-ground supply mode, the charge pump must be enabled to generate the ground-centered supply rails for the amplifiers.

The left-channel HP amplifier (`HP_L_CTRL`) is enabled by setting `hp_l_amp_en = 1`. The output stage is enabled independently by setting `hp_l_amp_oe = 1`. The amplifier gain can be set in the range of  $-57$  dB to  $+6$  dB in 1.0 dB steps using `hp_l_amp_gain`.

Gain updates can be ramped through all intermediate values by setting `hp_l_amp_zc_en = 1`. This ramp setting overrides the settings of `hp_l_amp_zc_en`. To prevent zipper noise when gain ramping is selected, the gain is ramped through additional sub-range gain steps.

As an alternative to gain ramping, gain updates can be synchronized with signal zero-crossings by setting `hp_l_amp_zc_en = 1`. If no zero-crossing is detected within the timeout period, then the gain update is applied unconditionally. The timeout period is approximately 0.1 s, and is not configurable.

The amplifier can be muted by setting `hp_l_amp_mute_en = 1`.

## Audio Codec with Advanced Accessory Detect

The amplifier can be put in its minimum gain configuration by setting `hp_l_amp_min_gain_en = 1`. If either zero-crossing or ramping are enabled when minimum gain is set, the ramping or the zero crossing or both will be performed while activating the minimum gain.

The right-channel HP amplifier (`HP_R_CTRL`) is controlled in the same manner.

### 11.4.3 Charge Pump Control

The charge pump is enabled by asserting `cp_en` in the `CP_CTRL` register. Once enabled, the charge pump can be controlled manually or automatically. When under manual control (`cp_mchange = 00`), the output voltage level is reserved.

The amount of charge stored, and therefore the voltage generated, by the charge pump is controlled by the charge pump controller. As the power consumed by devices such as amplifiers is proportional to  $V^2$ , significant power savings are available by matching the charge pump's output with the system's power requirement.

There are three modes of operation that are determined by the `cp_mchange` setting, as described in [Table 31](#).

**Table 31: Charge Pump Output Voltage Control**

Charge Pump Tracking Mode <code>cp_mchange</code>	Charge Pump Output Voltage	Details
00	Reserved	Reserved
01	Voltage level depends on the programmed gain setting	The charge pump controller monitors the amplifier volume settings, and generates the minimum voltage that is high enough to drive a full-scale signal at the current gain level.
10	Voltage level depends on the DAC signal envelope (DAC Volume Mode)	The charge pump controller monitors the DAC signal, and generates a voltage that is high enough to drive a full-scale output at the current DAC signal volume level
11	Voltage level depends on the signal magnitude and the programmed gain setting (Signal Size Mode)	The charge pump monitors both the programmed volume settings and the actual signal size, and generates the appropriate output voltage. This is the most power-efficient mode of operation.

When `cp_mchange = 10` (tracking DAC signal size) or `cp_mchange = 11` (tracking the output signal size), the charge pump switches its supply between the  $\pm VDD$  rails and the  $\pm VDD/2$  rails depending on its power requirements.

When low output voltages are needed, the charge pump saves power by using the lower voltage  $\pm VDD/2$  rails.

The switching point between using the  $\pm VDD$  rails and the  $\pm VDD/2$  rails is determined by the `cp_thresh_vdd2` register setting. The switching points determined by `cp_thresh_vdd2` vary between the two `cp_mchange` modes, and are summarized in [Table 32](#) and [Full Scale \(FS\) = 1.6 \\* VDD](#)

Table 33.

When the charge pump output voltage is controlled manually (`cp_mchange = 00`) or when it is tracking the PGA gain settings (`cp_mchange = 01`), the charge pump always takes its supply from  $V_{DD\_CP}$ .

**Table 32: `cp_thresh_vdd2` Settings in DAC Volume Mode (`cp_mchange = 10`)**

<code>cp_thresh_vdd2</code> Setting	Approximate Switching Point (Note 1)	<code>cp_thresh_vdd2</code> Setting
0x01	-30 dBFS	Do not use. Very power-inefficient as nearly always $\pm VDD$
0x03	-24 dBFS	Not recommended. Very power-inefficient as nearly always $\pm VDD$

## Audio Codec with Advanced Accessory Detect

<b>cp_thresh_vdd2 Setting</b>	<b>Approximate Switching Point (Note 1)</b>	<b>cp_thresh_vdd2 Setting</b>
0x07	-18 dBFS	Good to use but not power efficient
0x0E	-12 dBFS	Good to use
0x10	-10 dBFS	Recommended setting
0x3F – 0x13		Not recommended

**Note 1** Full Scale (FS) = 1.6 \* VDD

**Table 33: cp\_thresh\_vdd2 Settings in Signal Size Mode (cp\_mchange = 11)**

<b>cp_thresh_vdd2 Setting</b>	<b>Approximate Switching Point (Note 1)</b>	<b>Notes</b>
0x00	Never	Not recommended. Always $\pm V_{DD}$ mode
0x01	Never	Not recommended. Always $\pm V_{DD}$ mode
0x02	-32 dBFS	Not recommended. Very power-inefficient as nearly always $\pm V_{DD}$
0x03	-24 dBFS	Good to use
0x04	-20 dBFS	Good to use
0x05	-17 dBFS	Good to use
0x06	-15 dBFS	Recommended setting
0x07	-13 dBFS	Good to use
0x08	-12 dBFS	Good to use
0x09	-11 dBFS	Good to use
0x0A	-10 dBFS	Good to use
0x0B	-9 dBFS	Not recommended. $\pm V_{DD}/2$ begins to clip
0x0C	Never	Not recommended. Always $\pm V_{DD}/2$ mode
0x0D	Never	Not recommended. Always $\pm V_{DD}/2$ mode
0x0E	Never	Not recommended. Always $\pm V_{DD}/2$ mode
0x0F	Never	Not recommended. Always $\pm V_{DD}/2$ mode

**Note 1** Full Scale (FS) = 1.6 \* V<sub>DD</sub>

### 11.4.4 Tracking the Demands on the Charge Pump Output

There are three points at which the demands on the charge pump can be tracked. These tracking points are determined by `cp_mchange`.

#### 11.4.4.1 `cp_mchange = 01` (Tracking the PGA Gain Setting)

If `cp_mchange = 01`, it is the PGA gain setting that is tracked, and which provides the feedback to boost the clock frequency when necessary.

#### 11.4.4.2 `cp_mchange = 10` (Tracking the DAC Signal Setting)

If `cp_mchange = 10`, it is the size of the DAC signal that is tracked, and which provides the feedback to boost the clock frequency when necessary.

## Audio Codec with Advanced Accessory Detect

### 11.4.4.3 `cp_mchange = 11` (Tracking the Output Signal Magnitude)

If `cp_mchange = 11`, it is the magnitude of the output signal that is tracked, and which provides the feedback to boost the clock frequency when necessary.

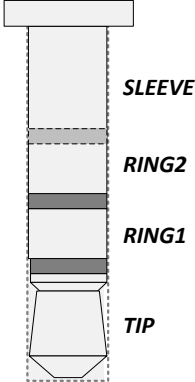

## 11.5 Advanced Accessory Detection

If the DA7219 is configured for advanced accessory detection (AAD), the insertion of a jack wakes the system up. No external clocking is required to detect a jack insertion, and the clock is only requested if the input is changing and if debouncing is required. This ensures the lowest possible power consumption with no digital leakage.

Once a jack has been inserted, the AAD differentiates between a 3-pole jack (used on headphones and lineouts) and a 4-pole jack (used on headsets). Two-pole jacks are detected as a 3-pole jack, and will work as designed as a mono output.

There are two combinations of 4-pole jack available in the market, both of which are supported by the AAD. The jack configurations are shown in [Figure 19](#).

	Jack Type	
Position	CTIA	OMTP
SLEEVE	MIC	GND
RING2	GND	MIC
RING1	HP_R	HP_R
TIP	HP_L	HP_L

**Figure 19: Jack Socket Variants**

On detecting the insertion of a jack, the DA7219 moves to the microphone-detect state where it drives current down the SLEEVE pin and measures the impedance to the RING2 pin, which will be connected to GND\_HP by the internal GND switch.

#### NOTE

In order to detect a jack insertion the headphone amplifiers must be disabled

If the impedance measured between the SLEEVE and RING2 pins is below 500  $\Omega$  (default, threshold configurable via [mic\\_det\\_thresh](#)), the DA7219 detects the connected accessory as a 3-pole jack. The DA7219 then returns to the jack detection state to poll for removal, but continues to periodically pulse current down the SLEEVE pin to verify that the connected accessory is 3-pole. This continued polling avoids an incorrect detection, for example, if a 4-pole accessory is inserted with a button depressed.

#### NOTE

A two-pole jack is detected as a 3-pole jack and will work as a mono output.

If the impedance measured between the SLEEVE and RING2 pins is below the value set in [mic\\_det\\_thresh](#), the DA7219 detects the connected accessory as a 4-pole jack. The DA7219 then moves to the pin order-detect state, where it first drives current down the SLEEVE and then the RING2 pins, and compares the voltages measured in each case. The pin that develops the largest voltage will be deemed to be the accessory's microphone, and the other pin as the ground.

## Audio Codec with Advanced Accessory Detect

The headphone impedance can also be used to determine whether the output is to a headphone or to a line output. Impedance measurements below a pre-set threshold are deemed to be headphones, and impedances above the threshold are line outputs.

The DA7219 will then move to the button detect state, where polling is carried out to detect button presses. If a button is pressed while MICBIAS is off, the DA7219 can only detect that a button has been pressed, but cannot distinguish between the buttons.

To distinguish which one of up to four buttons was pressed, the MICBIAS rail must be enabled so that the impedance can be measured between the MIC and GND pins. See section 11.5.6 for further details.

While any of the four possible buttons is being pressed, any further button presses are ignored. Only once the first button has been released can a second or subsequent button press be detected.

Detection of the jack type and its configuration, detection of the number of buttons, detection of a mic input, and detection of headphone or line outputs are all performed automatically when the AAD block is enabled.

On detecting a button press, the DA7219 can identify all buttons as defined in the Android Wired Headset Specification (v1.1) when MICBIAS is present.

The DA7219 also offers the possibility of overriding the automatically detected accessories, and of setting them manually.

A full cross-reference of the DA7219's functionality and power consumption in different modes is listed in Table 23.

### 11.5.1 Configuring Advanced Accessory Detection

AAD is enabled by setting `accdet_en = 1`.

Within the AAD block, all individual accessory detection measurements can be enabled or disabled, and all accessory detect interrupt signals can be masked.

All accessory detection measurements can be manually overridden, and the current statuses of all measurements can be interrogated from the status register fields.

Jack type detection, jack configuration detection, and button detection are all based on measurements of resistance between different pins. The resistance thresholds for every measurement type are all configurable by using the relevant register fields.

A signal timing diagram is illustrated in Figure 20. These features are summarized in Table 34, and Table 35 are described in greater detail in the following sections.

## Audio Codec with Advanced Accessory Detect

Table 34: DA7219 Advanced Accessory Detection Feature Summary

Feature	DA7219 support	Configuration	Host Reporting
<b>Jack Insertion/Removal Detection</b>	Yes	Enabled when <code>system_active</code> and <code>accdet_en</code> are both 1. Jack insertion latency set by <code>jackdet_debounce</code> (1 ms <--> 1 s).	Host notification via <code>e_jack_inserted</code> and <code>e_jack_removed</code> IRQ events.
<b>Jack Type Detection</b>	Yes - 3-pole / 4-pole	Jack type detection runs on insertion, duration set by <code>jack_detect_rate</code> . Host configurable microphone detection impedance threshold <code>mic_det_thresh</code> (100, 200, 500, 750 Ω). Optional host manual type override provided.	Host notification via <code>e_jack_detect_complete</code> IRQ event. <code>jack_type_sts</code> register available for host readback (3-pole or 4-pole reported), data is qualified by <code>e_jack_detect_complete</code>
<b>Pin Order Detection</b>	Yes - CTIA/OMTP	Detection with GND switching runs on insertion if a 4-pole jack is detected. Optional host manual pin order override provided.	Host notification via <code>e_jack_detect_complete</code> IRQ event. register available for host readback (LRGM or LRMG reported), data is qualified by <code>e_jack_detect_complete</code> .
<b>Button Press Detection</b>	Yes - press / release detection for A,B,C and D button impedances with +/- 1 % accuracy, as per Google Chromebook Headset Accessory Electrical Specification.	Button detection enable and frequency (2 ms<--> 500 ms) set by <code>button_config</code> . Host controlled <code>A_D_BUTTON_THRESH</code> , <code>D_B_BUTTON_THRESH</code> , <code>B_C_BUTTON_THRESH</code> , and <code>C_MIC_BUTTON_THRESH</code> set the ADC voltage thresholds for button press impedance measurements = $(R_{LOAD} / (R_{LOAD} + R_{MICBIAS}))$	Host notification via <code>e_button*_pressed</code> and <code>e_button*_released</code> IRQ events, (where * = a/b/c/d). <code>button_type_sts</code> 8-bit ADC measurement result also available for host readback.
<b>Interrupt Reporting</b>	Yes - single dedicated h/w interrupt line.	All events are maskable and are 'Write 1 to clear'.	Interrupt line asserted to host when any unmasked events are captured. Interrupt line is de-asserted when all unmasked events have been cleared by host.
<b>MICBIAS Isolation</b>	Yes - both on insertion and removal.	Host control when the MICBIAS rail can be enabled (requires <code>V<sub>DD_MIC</sub></code> ) with <code>micbias1_en</code> . AAD will automatically enable the MICBIAS LDO following <code>e_jack_detect_complete</code> if <code>jack_type_sts</code> reports 4-pole. MICBIAS is auto-disabled, discharged and isolated on <code>e_jack_removed</code> to prevent audible artefacts on HPs during a fast jack removal.	<code>micbias_up_sts</code> available for host readback to report MICBIAS rail is up.
<b>HP_L Impedance Measurement</b>	Yes - supported by DA7219 using s/w controlled sequence following insertion.	N/A	N/A
<b>HP_L / HP_R to GND when Device Unpowered</b>	Yes - supported by DA7219 using pulldown on HPs.	N/A	N/A

## Audio Codec with Advanced Accessory Detect

Figure 20: Signal Timing Diagram for the AAD Function

**NOTE**

$V_{DD\_MIC}$  must always be greater than  $V_{DD}$

### 11.5.2 Detection of Jack Insertion or Removal

Whenever a jack is inserted, a jack insertion event is flagged by `e_jack_inserted` = 1. Similarly, a jack removal event is flagged by `e_jack_removed` = 1. The presence or absence of a jack is recorded in `jack_insertion_sts`.

Any jack insertion will be detected, and is recorded by the setting of `jack_insertion_sts`. The register field `jack_insertion_sts` = 1 if a jack has been inserted, and `jack_insertion_sts` = 0 if no jack has been inserted.

Jack detection latency, that is, the time from an `e_jack_inserted` event to the point where `e_jack_detect_complete` is asserted, is configurable using `jack_detect_rate`. The jack detection latency times are different for 3-pole and 4-pole jacks, and are listed in Table 35.

The JACKDET pin is designed to be pulled either HIGH or LOW on the insertion of the jack. If using an HPLDET type headset socket additional external circuitry is required.

**Audio Codec with Advanced Accessory Detect**
**Table 35: Jack Detection Latency Timings Controlled by `jack_detect_rate`.**

<code>jack_detect_rate</code> value	3-pole jacks (ms)	4-pole jacks (ms)
00	32	64
01	64	128
10	128	256
11	256	512

Debouncing is available on jack insertion and removal events. Debounce on jack insertion is specified using `jackdet_debounce`, and on jack removal using `jackdet_rem_deb`. The debounce times are listed in [Table 36](#) and [Table 37](#).

**Table 36: Debounce Settings for Jack Insertion Events**

<code>jackdet_debounce</code>	Debounce Time (ms)
000	5
001	10
010	20 (default)
011	50
100	100
101	200
110	500
111	1

**Table 37: Debounce Settings for Jack Removal Events**

<code>jackdet_rem_deb</code>	Debounce Time (ms)
00	1 (default)
01	5
10	10
11	20

The jack insertion, jack removal, and jack complete interrupts can be masked using the register fields in the `ACCDDET_IRQ_MASK_A` register. The jack insertion interrupt is masked by setting `m_jack_inserted = 1`, the jack removal interrupt is masked by setting `m_jack_removed = 1`, and the jack detection complete interrupt is masked by setting `m_jack_detect_complete = 1`. These masking fields mask the interrupt signals, but do not prevent updating of the event fields or the status fields previously described.

### 11.5.3 Three-Pole or Four-Pole Jack Insertion

The type of jack inserted can be determined automatically by setting `jack_type_det_en = 1`.

Once the jack insertion measurement has been completed, `e_jack_detect_complete = 1`, the AAD determines whether a 3-pole or a 4-pole jack has been inserted. This is done by measuring the resistance between the SLEEVE and the RING2 pins.

- If the measured impedance is below the threshold setting, a 3-pole jack is deemed to have been inserted.
- If the resistance is above this threshold setting, a 4-pole jack is deemed to have been inserted.

If a mono 2-pole jack is inserted, the AAD will detect this as a 3-pole jack, but the 2-pole jack will work as designed, that is, as a mono output.

## Audio Codec with Advanced Accessory Detect

The threshold setting used to determine whether a 3-pole or a 4-pole jack has been inserted is set using `mic_det_thresh`. The settings are listed in [Table 38](#).

**Table 38: Resistance Threshold Settings for Three-Pole and Four-Pole Jack Determination**

<code>mic_det_thresh</code>	Resistance Threshold ( $\Omega$ )
00	200
01	500 (default)
10	750
11	1000

Once the jack type has been successfully determined, the type of jack is recorded in `jack_type_sts`. A 3-pole jack is indicated by `jack_type_sts = 0`, and a 4-pole jack by `jack_type_sts = 1`.

The jack type status recorded in the register field `jack_type_sts` is not valid until the measurement has been completed. Measurement completion is indicated when `e_jack_detect_complete = 1`.

The assertion of `e_jack_detect_complete` indicates the completion of both the `jack_type_sts` measurement and the `jack_pin_order_sts` measurement.

The measurement of the type of jack, which is performed automatically when `jack_type_det_en = 1`, can be overridden if required. To do this, set `jack_type_det_en = 0` to prevent the measurement taking place, and then use the `jack_type_force` register field to force the jack type. A 3-pole jack is specified by setting `jack_type_force = 0`, and a 4-pole jack by setting `jack_type_force = 1`.

### 11.5.4 Jack Pin Order Detection with Four-Pole Jacks

Two different polarities are widely used with 4-pole jacks. These are the CTIA tip-ring-ring-sleeve configuration of LEFT-RIGHT-GND-MIC, and the OMTP configuration of LEFT-RIGHT-MIC-GND.

If `pin_order_det_en = 1`, the detection of jack configuration is performed automatically. The measurement of jack configuration can be overridden by setting `pin_order_det_en = 0`, and using `pin_order_force = 0` to specify the CTIA configurations. Setting `pin_order_force = 1` specifies the OMTP configuration.

The jack configuration status recorded in the register field `jack_pin_order_sts` is not valid until the measurement has been completed. Measurement completion is indicated when `e_jack_detect_complete = 1`.

The assertion of `e_jack_detect_complete` indicates the completion of both `jack_type_sts` and `jack_pin_order_sts` measurements.

### 11.5.5 Headphone Output and Line Output

The DA7219 can detect whether the output is a headphone (HP) or a line output. This is enabled by setting `hptest_en = 1`.

The impedance is measured between HP\_L (or HP\_R) and the local GND connection on either SLEEVE or RING2 (depending on the jack configuration) to determine whether the output is to an HP or to a lineout. Impedance measurements below a pre-set threshold are deemed to be HP, and impedances above the threshold are line outputs.

The threshold value is set between 1 k $\Omega$  and 10 k $\Omega$  by setting `hptest_res_sel` appropriately. The threshold settings available are listed in [Table 39](#).

The Tone Generator is used to develop a slow S-ramp of the signal amplitude at a frequency below the audible range on the HP outputs. The S-ramp profile is configurable for maximum flexibility.

The device monitors the current drawn by the HP amps during this process, and reports back the load as either above or below the threshold level. The accuracy of the measurement is  $\pm 40\%$ .

The host AP must control the test by:

1. Programming the S-ramp profile

Audio Codec with Advanced Accessory Detect

2. Initializing the DA7219 signal path and outputs
3. Initiating the S-ramp function
4. Reading back the impedance detection status register for the load condition

**Table 39: Resistance Threshold Settings for Headphone and Lineout Determination**

hptest_res_sel Setting	Test Threshold Impedance (kΩ)
00	1.0
01	2.5
10	5.0
11	10.0

The result of the headphone threshold test is stored in hptest\_comp.

**11.5.6 Detection of Buttons**

After successful detection of the insertion of a 4-pole jack (`e_jack_detect_complete` = 1 and `jack_type_sts` = 1), the DA7219 will move to the button detect state, where polling is carried out for button presses. If a button is pressed while MICBIAS is off, the DA7219 can only detect that a button has been pressed, and cannot distinguish between the buttons. On detecting a button press, the DA7219 can identify all buttons as defined in the Android Wired Audio Headset Specification (v1.1) when MICBIAS is present.

The Android Wired Audio Headset Specification (v1.1) specifies the impedance associated with any button press. The impedance is measured between the MIC and GND.

While any of the four possible buttons is being pressed, any further button presses are ignored. Only after the first button has been released can a second or subsequent button press be detected.

**Figure 21: Measuring the Impedance of a Button Press**

## Audio Codec with Advanced Accessory Detect

The Android Wired Audio Headset Specification (v1.1) stipulates the functions and names of the four possible buttons on a headset. These are listed in [Table 40](#).

**Table 40: Button Names and Functions in Android Devices**

Button	Function
Function A	Play, pause, or hook (short press) Trigger assist (long press) Next (double-press)
Function B	Volume +
Function C	Volume -
Function D	Google voice search feature

Headsets with only one button must implement Function A.

Headsets with multiple buttons must implement functions according to the following patterns:

- Two functions: Functions A and D
- Three functions: Functions A, B, and C
- Four functions: Functions A, B, C, and D

Whenever a button is pressed, a button press event is flagged by `e_button_<a|b|c|d>_pressed = 1`.

Similarly, a button release event is flagged by `e_button_<a|b|c|d>_released = 1`.

The measured impedance of the last button press is recorded in `button_type_sts`. The impedance measurements can be averaged using `button_average`. Averaging in this manner provides greater immunity to spurious measurements caused by noise, but at a cost of consuming more power and of increasing the measurement latency (every extra measurement used in the averaging takes approximately 1 ms to perform). The number of measurements that are used in the averaging are listed in [Table 41](#).

**Table 41: Setting the Number of Measurements Used in Averaging**

<code>button_average</code> Setting	Number of Measurements Used in Averaging
00	1
01	2
10	4
11	8

The button press interrupts can be masked by asserting the register fields `m_button_<a|b|c|d>_pressed`. The button released interrupts can be masked by setting `m_button_<a|b|c|d>_released = 1`. These masking fields mask the interrupt signals, but do not prevent updating of the event fields or the status fields previously described.

The impedance threshold between Button A and Button D is specified via `A_D_BUTTON_THRESH`, and is specified as  $(R_{LOAD} / R_{LOAD} + R_{MICBIAS})$ .

Similarly, the impedance threshold between Button D and Button B is specified using `D_B_BUTTON_THRESH`, and is specified in the same manner  $(R_{LOAD} / R_{LOAD} + R_{MICBIAS})$ . The impedance threshold between Button B and Button C is specified using `B_C_BUTTON_THRESH`, and is specified in the same manner  $(R_{LOAD} / R_{LOAD} + R_{MICBIAS})$ .

The impedance threshold between Button C and MIC is specified using `C_MIC_BUTTON_THRESH` and is again specified in the same manner  $(R_{LOAD} / R_{LOAD} + R_{MICBIAS})$ .

The time between the periodic button press measurements is specified using `button_config`. The inter-measurement period can be between 2 ms and 500 ms.

## Audio Codec with Advanced Accessory Detect

The `button_config` register is only active after a 4-pole jack has been detected. Setting `button_config = 0` also disables the button measurements.

### 11.6 Clocking

The internal system clock (SYSCLK) from which all other clocks are derived is always at one of two possible frequencies:

- 12.288 MHz for SR from the 48 kHz family (8, 12, 16, 24, 32, 48, 96 kHz)
- 11.2896 MHz for SR from the 44.1 kHz family (11.025, 22.05, 44.1, 88.2 kHz).

DA7219 can run with or without an applied MCLK. If no MCLK is applied, the internal reference oscillator will clock the device. However when using the DAI an MCLK must be provided and correctly configured.

The DA7219 contains a phase-locked loop (PLL), which supports a range of clocking modes and input clock (MCLK) frequencies.

#### 11.6.1 MCLK Input

MCLK is the master clock input which must be in the range of 2 MHz to 54 MHz.

MCLK can be applied as a full-amplitude square wave, or as a low-amplitude sine wave if the MCLK squarer circuit has been enabled. The clock squarer circuit is enabled by writing `pll_mclk_sqr_en = 1`. This clock squarer allows a sine wave or other low amplitude clock (down to 300 mVpp) to be applied to the chip. The MCLK input is AC coupled on chip when using the clock squarer mode.

##### 11.6.1.1 MCLK Detection

A clock detection circuit will set bit [0] of `pll_srm_status = 1` whenever the applied MCLK frequency is above the minimum detection frequency of approximately 1 MHz. Whenever this bit is high, the MCLK signal is selected as the clock input to the PLL.

#### 11.6.2 Audio Reference Oscillator

For best audio performance, a system clock within the specified range is required. The DA7219 codec has an internal reference oscillator that provides the system clock when there is no valid MCLK signal.

The reference oscillator is automatically enabled whenever the codec is in ACTIVE mode and the MCLK frequency is below the minimum frequency of 1 MHz. When the codec enters STANDBY mode, the oscillator is automatically disabled to save power.

#### 11.6.3 PLL Bypass Mode

If an MCLK signal at 11.2896/12.288 MHz or 22.5792/24.576 MHz or 45.1584/49.152 MHz is available, the PLL is not required and should be disabled to save power. PLL bypass mode is activated by setting `pll_mode = 00`.

In this mode the PLL is bypassed and an audio frequency clock is applied to the MCLK pin of the codec. The required clock frequency depends on the sample rate at which the audio DACs and ADCs are operating. These clock frequencies are summarized in [Table 42](#) for the range of DAC and ADC sample rates that can be configured using the [SR](#) register.

**Table 42: Sample Rate Control Register and Corresponding System Clock Frequency**

Sample Rate, FS (kHz)	SR Register	System Clock Frequency (MHz)
8	0001	12.288
11.025	0010	11.2896
12	0011	12.288

## Audio Codec with Advanced Accessory Detect

16	0101	12.288
22.05	0110	11.2896
24	0111	12.288
32	1001	12.288
44.1	1010	11.2896
48	1011	12.288
88.2	1110	11.2896
96	1111	12.288

If digital playback or record is required in bypass mode then the MCLK frequency should be set to 11.2896/12.288 MHz, or to 22.5792/24.576 MHz, or to 45.1584/49.152 MHz and pll\_indiv should be programmed accordingly.

If no valid MCLK is detected, the output of the internal reference oscillator is used instead. However in this case only analog bypass paths may be used.

### 11.6.4 PLL Normal Mode (DAI Master)

The DA7212 contains a phase locked loop (PLL) that can be used to generate the required 11.2896 MHz or 12.288 MHz internal system clock when a frequency of between 2 MHz and 54 MHz is applied to MCLK. This allows sharing of clocks between devices in an application, reducing total system cost. For example, the codec may operate from a common 13 MHz or 19.2 MHz system clock frequency.

The PLL is enabled by asserting pll\_mode = 01. Once the PLL is enabled and has achieved phase lock, PLL bypass mode is disabled, and the output of the PLL is used as the system clock.

The PLL input divider register (pll\_indiv) is used to reduce the PLL reference frequency to the usable range of 2 MHz to 54 MHz as shown in Table 43, this reduces the PLL reference frequency according to the following equation:

$$FREF = FMCLK \div N$$

**Table 43: PLL Input Divider**

MCLK Input Frequency (MHz)	Input Divider, ( $\div N$ )	pll_indiv Register (0x27 [3:2])
2 – 5	$\div 1$	000
5 – 10	$\div 2$	001
10 – 20	$\div 4$	010
20 – 40	$\div 8$	011
40 – 54	$\div 16$	100

The value of the PLL feedback divider is used to set the voltage controlled oscillator (VCO) frequency to eight times the required system clock frequency (see Table 37).

$$FVCO = FREF \times \text{PLL feedback divider}$$

The value of the PLL feedback divider is an unsigned number in the range of 0 to 128. It consists of seven integer bits and 13 fractional bits split across three registers:

- PLL\_INTEGER holds the seven integer bits
- PLL\_FRAC\_TOP holds the top bits (MSB) of the fractional part of the divisor
- PLL\_FRAC\_BOT holds the bottom bits (LSB) of the fractional part of the divisor

**Audio Codec with Advanced Accessory Detect**
**11.6.5 Example Calculation of the Feedback Divider Setting**

A codec is operating with  $F_s$  (sample rate) = 48 kHz and a reference input clock frequency of 12.288 MHz. The required output frequency = 98.304 MHz.

The reference clock input = 12.288 MHz, which falls in the range 10 MHz to 20 MHz, so `pll_indiv` will be set to 0b010 (dividing the reference input frequency by four, see [Table 43](#)).

The formula for calculating the feedback divider is:

$$\text{Feedback divider (F)} = (\text{VCO output frequency} * \text{input divider (pll\_indiv)}) / \text{reference input clock}$$

$$\text{Feedback divider} = (98.304 * 4) / 12.288 = 32$$

So

- `pll_fbdiv_integer` (holding the seven integer bits) = 0x20
- `pll_fbdiv_frac_top` (holding the top bits (MSB) of the fractional part of the divisor) = 0x00
- `pll_fbdiv_frac_bot` (holding the bottom bits (LSB) of the fractional part of the divisor) = 0x00

[Table 44](#) shows example register settings that will configure the PLL when using a 13 MHz, 15 MHz or 19.2 MHz clock. Any MCLK input frequency between 2 MHz and 54 MHz is supported. `pll_indiv` must be used to reduce the PLL reference frequency to the usable range of 2 MHz to 5 MHz as shown in [Table 43](#).

**Table 44: Example PLL Configurations**

MCLK input frequency (MHz)	System clock frequency (MHz)	pll_mode register	PLL_FRAC_TOP register	PLL_FRAC_BOT register
13	11.2896	0x01	0x19	0x45
13	12.288	0x01	0x07	0xEA
15	11.2896	0x01	0x02	0xB4
15	12.288	0x01	0x06	0xDC
19.2	11.2896	0x01	0x1A	0x1C
19.2	12.288	0x01	0x0F	0x5C

**11.6.6 PLL SRM Mode (DAI Slave)**

SRM mode enables the PLL output clock to be synchronized to the incoming WCLK signal on the DAI. The SRM PLL mode is enabled by setting `pll_mode = 10`.

When using the DAI in slave mode with the SRM enabled, removing and re-applying the DAI interface word clock WCLK may cause the PLL lock to be lost. To re-lock the PLL it is recommended that you disable the SRM (`pll_mode = 00`), reset the PLL by re-writing to register `PLL_INTEGER`, and then re-enable the SRM (`pll_mode = 10`) after the DAI WCLK has been reapplied.

When switching sample rates between 44.1 kHz and 48 kHz (or between the multiples of these sample rates), SRM must be disabled and then re-enabled using register bit `pll_mode`.

## Audio Codec with Advanced Accessory Detect

### 11.7 Reference Generation

#### 11.7.1 Voltage References

The audio circuits use supply-derived references of  $0.45 \cdot V_{DD}$  (VMID) and  $0.9 \cdot V_{DD}$  (DACREF). There is also a bandgap-derived fixed voltage reference of 1.2 V (VREF). All three voltage references require off-chip decoupling capacitors (see Appendix B.6).

Both VREF and VMID are automatically enabled whenever the device enters ACTIVE mode. They are automatically disabled when entering STANDBY mode.

The VMID reference comes from a high-resistance voltage divider, which combines with the decoupling capacitor to create a large RC (resistance-capacitance) time constant. This ensures a noise-free VMID reference.

To minimize start-up time, set `vmid_fast_charge` = 1. This enables a low resistance path to charge the decoupling capacitor faster.

Fast charge (`vmid_fast_charge`) must be disabled after start-up as it will increase the noise on the VMID reference.

The bandgap reference VREF also takes time to charge its decoupling capacitor, but an internal timer ensures that no circuit that requires VREF is enabled until VREF has reached 1.2 V.

The DACREF voltage reference is produced from VMID by a times-two buffer so is capable of charging its decoupling capacitor quickly.

#### 11.7.2 Bias Currents

DA7219 has a master bias current generation block, enabled by default, controlled using the `bias_en` bit. Each subsystem has its own local current generation block, which is automatically enabled whenever any of its subblocks are enabled.

#### 11.7.3 Voltage Levels

##### 11.7.3.1 IO Voltage Level

The digital input/output pins can be set to operate in either a high voltage (2.5 V to 3.6 V) or low voltage (1.5 V to 2.5 V) range using the `io_voltage_level` bit. See Table 45.

**Table 45: IO Voltage Level Setting**

<code>io_voltage_level</code> Setting	Digital I/O Voltage Range (V)
0	2.5 to 3.6
1	1.2 to 2.5

### 11.8 I<sup>2</sup>C Control Interface

DA7219 is completely software-controlled from the host by registers accessed via an I<sup>2</sup>C compliant serial control interface. Data is shifted into or out of the DA7219 under the control of the host processor, which also provides the serial clock.

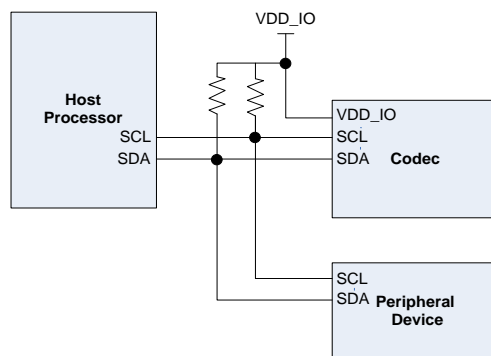

The I<sup>2</sup>C clock is supplied by the SCL line and the bidirectional I<sup>2</sup>C data is carried by the SDA line. The I<sup>2</sup>C interface is open-drain supporting multiple devices on a single line. The bus lines have to be pulled HIGH by external pull-up resistors (1 kΩ to 20 kΩ range). The attached devices only drive the bus lines LOW by connecting them to ground. This means that two devices cannot conflict if they drive the bus simultaneously.

**Audio Codec with Advanced Accessory Detect**
**Table 46: Device I<sup>2</sup>C Slave Addresses**

Register cif_i2c_addr_cfg	Device I <sup>2</sup> C Address
00	0x18
01	0x19
10	0x1A (default)
11	0x1B

In Standard/Fast mode the highest frequency of the bus is 1 MHz. The exact frequency can be determined by the application and does not have any relation to the DA7219 internal clock signals. DA7219 will follow the host clock speed within the described limitations and does not initiate any clock arbitration or slow-down.

In High-Speed mode the maximum frequency of the bus can be increased up to 3.4 MHz. This mode is supported if the SCL line is driven with a push-pull stage from the host and if the host enables an external 3 mA pull-up at the SDA pin to decrease the rise time of the data. In this mode the SDA line on DA7219 is able to sink up to 12 mA. In all other respects the High-Speed mode behaves as the Standard/Fast mode. Communication on the I<sup>2</sup>C bus always takes place between two devices, one acting as the master and the other as the slave. The DA7219 will only operate as a slave. The I<sup>2</sup>C interface has direct access to the whole register map of the DA7219.

**Figure 22: Schematic of the I<sup>2</sup>C Control Interface Bus**

All data is transmitted across the I<sup>2</sup>C bus in groups of eight bits. To send a bit the SDA line is driven to the intended state while the SCL is LOW (a LOW on SCL indicates a zero bit). Once the SDA has settled, the SCL line is brought HIGH and then LOW. This pulse on SCL clocks the SDA bit into the receiver's shift register.

A two byte serial protocol is used containing one byte for address and one byte for data. Data and address transfer is transmitted MSB first for both read and write operations. All transmission begins with the START condition from the master while the bus is in the IDLE state (the bus is free). It is initiated by a HIGH to LOW transition on the SDA line while the SCL is in the HIGH state (a STOP condition is indicated by a LOW to HIGH transition on the SDA line while the SCL line is in the HIGH state).

**Figure 23: I<sup>2</sup>C START and STOP Conditions**

## Audio Codec with Advanced Accessory Detect

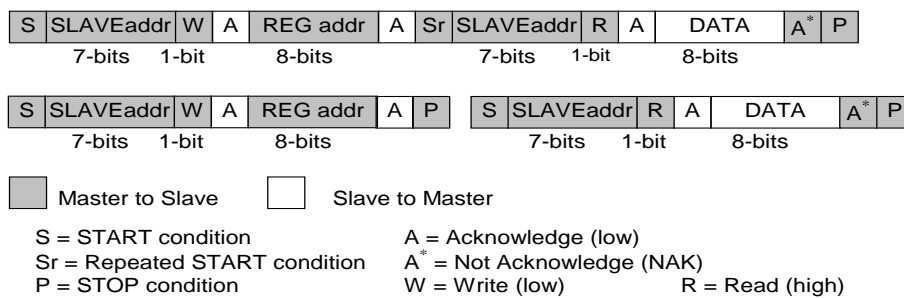

The I<sup>2</sup>C bus is monitored by DA7219 for a valid slave address whenever the interface is enabled. It responds with an Acknowledge immediately when it receives its own slave address. The Acknowledge is done by pulling the SDA line LOW during the following clock cycle (white blocks marked with 'A' in Figure 24 to Figure 28).

The protocol for a register write from master to slave consists of a START condition, a slave address with read/write bit and the 8-bit register address followed by 8 bits of data terminated by a STOP condition (DA7219 responds to all bytes with Acknowledge). This is illustrated in Figure 24

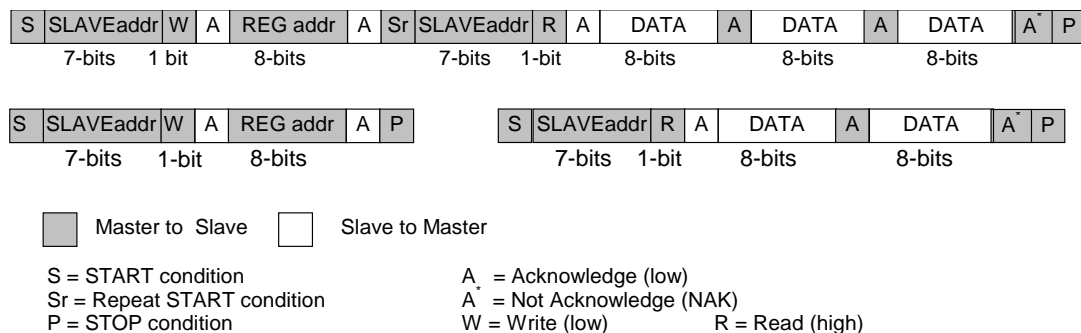

**Figure 24: I<sup>2</sup>C Byte Write (SDA line)**

When the host reads data from a register it first has to write access DA7219 with the target register address and then read access DA7219 with a repeated START, or alternatively a second START condition. After receiving the data the host sends a Not Acknowledge (NAK) and terminates the transmission with a STOP condition:

**Figure 25: Examples of the I<sup>2</sup>C Byte Read (SDA line)**

Consecutive (Page) Read-Out mode (`cif_i2c_write_mode = 0`) is initiated from the master by sending an Acknowledge instead of Not Acknowledge (NAK) after receipt of the data word. The I<sup>2</sup>C control block then increments the address pointer to the next I<sup>2</sup>C address and sends the data to the master. This enables an unlimited read of data bytes until the master sends an NAK directly after the receipt of data, followed by a subsequent STOP condition. If a non-existent I<sup>2</sup>C address is read out, the DA7219 will return code zero.

**Figure 26: Examples of I<sup>2</sup>C Page Read (SDA line)**

In Page mode the slave address after Sr (Repeated START condition) must be the same as the previous slave address.

Consecutive (Page) Write mode (`cif_i2c_write_mode = 0`) is supported if the master sends several data bytes following a slave register address. The I<sup>2</sup>C control block then increments the address

## Audio Codec with Advanced Accessory Detect

pointer to the next I<sup>2</sup>C address, stores the received data and sends an Acknowledge until the master sends the STOP condition.

**Figure 27: I<sup>2</sup>C Page Write (SDA line)**

An alternative Repeated-Write mode that uses non-consecutive slave register addresses is available using the `cif_i2c_write_mode` register. In this Repeat Mode (`cif_i2c_write_mode = 1`), the slave can be configured to support a host's repeated write operations into several non-consecutive registers. Data is stored at the previously received register address. If a new START or STOP condition occurs within a message, the bus returns to Idle mode. This is illustrated in [Figure 28](#).

**Figure 28: I<sup>2</sup>C Repeated Write (SDA line)**

In Page mode (`cif_i2c_write_mode = 0`), both Page mode reads and writes using auto-incremented addresses, and Repeat mode reads and writes using non auto-incremented addresses, are supported. In Repeat mode (`cif_i2c_write_mode = 1`) however, only Repeat mode reads and writes are supported.

## Audio Codec with Advanced Accessory Detect

### 11.9 Digital Audio Interface

DA7219 provides one DAI to input DAC data or to output ADC data. It is enabled by asserting `dai_en`. The DSP provides flexible routing options allowing each interface to be connected to different signal paths as desired in each application.

The DAI consists of a four-wire serial interface, with bit clock (BCLK), word clock (WCLK), data in (DATIN) and data out (DATOUT) pins. Both master and slave clock modes are supported by the DA7219. Master mode is enabled by setting register `dai_clk_en = 1`. In Master mode, the bit clock and word clock signals are outputs from the codec. In Slave mode these are inputs to the codec.

Figure 29: Master Mode (`dai_clk_en = 1`)

Figure 30: Slave Mode (`dai_clk_en = 0`)

The internal serialized DAI data is 24 bits wide. Serial data that is not 24 bits wide is either shortened or zero-filled at input to, or at output from, the DAI's internal 24-bit data width. The serial data word length can be configured to be 16, 20, 24 or 32 bits wide using the `dai_word_length` register bits.

Four different data formats are supported by the DAI. The data format is determined by the setting of the `dai_format` register bits.

The internal serialized DAI data is 24 bits wide. Serial data that is not 24 bits wide is either shortened or zero-filled at input to, or at output from, the DAI's internal 24-bit data width. The serial data word length can be configured to be 16, 20, 24 or 32 bits wide using the `dai_word_length` register bits.

Four different data formats are supported by the DAI. The data format is determined by the setting of the `dai_format` register bits:

- 00 = I<sup>2</sup>S mode
- 01 = Left justified mode
- 10 = Right justified mode
- 11 = DSP mode

## Audio Codec with Advanced Accessory Detect

Time division multiplexing (TDM) is available in any of these modes to support the case where multiple devices are communicating simultaneously on the same bus. TDM is enabled by asserting the dai\_tdm\_mode\_en bit.

### 11.9.1 DAI Channels

The DAI supports one or two channels, even in non-TDM modes. The number of channels required is specified by setting dai\_ch\_num which controls the position of the channels.

In TDM mode, each of the two channels can be individually enabled using the dai\_tdm\_ch\_en register.

### 11.9.2 I<sup>2</sup>S Mode

In I<sup>2</sup>S mode (dai\_format = 0), the MSB of the left channel is valid on the second rising edge of the bit clock after the falling edge of the word clock. The MSB of the right channel is valid on the second rising edge of the bit clock after the rising edge of the word clock.

Figure 31: I<sup>2</sup>S Mode

### 11.9.3 Left Justified Mode

In left-justified mode (dai\_format = 1), the MSB of the right channel is valid on the rising edge of the bit clock following the falling edge of the word clock. The MSB of the left channel is valid on the rising edge of the bit clock following the rising edge of the word clock.

Figure 32: Left Justified Mode

### 11.9.4 Right Justified Mode

In right-justified mode (dai\_format = 2), the LSB of the left channel is valid on the rising edge of the bit clock preceding the falling edge of word clock. The LSB of the right channel is valid on the rising edge of the bit clock preceding the rising edge of the word clock.

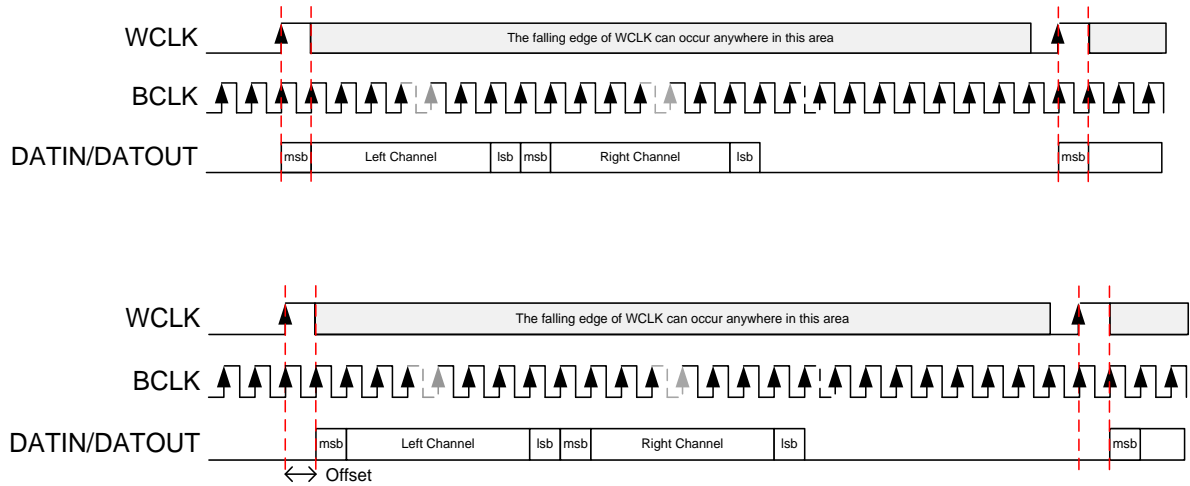

Figure 33: Right Justified Mode

### Audio Codec with Advanced Accessory Detect

#### 11.9.5 DSP Mode

In DSP mode (`dai_format = 3`), the rising edge of the word clock starts the data transfer with the left channel data first and immediately followed by the right channel data. Each data bit is valid on the falling edge of the bit clock.

**Figure 34 DSP Mode**

## Audio Codec with Advanced Accessory Detect

## 13 Package Information

Figure 35: DA7219 Package Outline Drawing

---

**Audio Codec with Advanced Accessory Detect****14 Ordering Information**

The ordering number consists of the part number followed by a suffix indicating the packing method. For details and availability, please consult Dialog Semiconductor's [customer portal](#) or your local sales representative.

**Table 172: Ordering Information**

Part Number	Package	Size (mm)	Shipment Form	Pack Quantity
DA7219-02VBA	32 WLCSP	4.5 x 1.64 mm	Tape and reel	4,500
DA7219-02VB6	32 WLCSP	4.5 x 1.64 mm	Tray/Waffle Pack (engineering samples only - not for mass production)	98

---

## Audio Codec with Advanced Accessory Detect

### Appendix A Applications Information

#### A.1 Codec Initialization

Depending on the specific application, some general settings need to be set. Examples of these settings include the sample rate, the PLL, and the DAI. Then the amplifiers, the mixers and channels of the ADC/DAC have to be configured and enabled using their respective control registers.

An example sequence is shown below:

1. Configure clock mode as required for operation, (for example PLL bypass, PLL or SRM mode).
2. Configure the DAI.
3. Configure the charge pump if the headphone path is in use.
4. Set input and output mixer paths and gains.
5. Enable input and output paths using the system controller.

#### A.2 Automatic ALC Calibration

When using the automatic level control (ALC) in hybrid mode the DC offset between the digital and analog PGAs must be cancelled. This is performed automatically if the following steps are followed:

1. Enable microphone amplifiers unmuted
2. Mute microphones
3. Enable input mixer and ADC unmuted
4. Enable AIF interface
5. Set [alc\\_auto\\_calib\\_en](#) in ALC\_CTRL1 to '1' (ALC\_CTRL1 = 0x2F). This bit will auto clear when calibration is complete.
6. When calibration is complete, enable the ALC with [alc\\_sync\\_mode](#) and [alc\\_offset\\_en](#) (ALC\_CTRL1 = 0x2F)
7. Unmute microphones

## Appendix B Components

The following recommended components are examples selected from requirements of a typical application. The electrical characteristics (that is, the supported voltage/current ranges) have to be cross-checked and component types may need to be adapted from the individual needs of the target circuitry.

### B.1 Audio Inputs

**Table 173: Audio Inputs**

Pin Name	Bump/Pin	Power Domain	Description	Type
MIC_N	A15	VDD	Differential mic. input (negative) / single-ended mic. input	Analog input
MIC_P	B16	VDD	Differential mic. input (positive) / single-ended mic. input	Analog input
MIC	C15	N/A	Supply input for headset microphone power	Analog input

DA7219 microphone inputs can be configured to accommodate single-ended or differential analog microphones, line inputs or digital microphones.

When using the inputs in an analog configuration, a DC blocking capacitor is required for each input bump used in the target application. The choice of capacitor is determined by the filter that is formed between that capacitor and the input impedance of the input pin, see [Table 7](#).

$$C = \frac{1}{2\pi \cdot R \cdot F_c}$$

Where  $F_c$  is the 3 dB cutoff frequency of the low-pass filter (typically 20 Hz for audio applications). A 1  $\mu$ F capacitor is suitable for most applications.

Due to their high stability, tantalum capacitors are particularly suitable for this application. Ceramic equivalents with an X5R dielectric are recommended as a cost effective alternative. Care should be taken to ensure that the desired capacitance is maintained over operating temperature and voltage.

Z5U dielectric ceramics should be avoided due to their susceptibility to microphonic effects.

Unused input bumps can be left floating or connected via a capacitor to ground.

The MIC pin would normally be connected to MICBIAS using a 2k2 resistor. This pin is an input to supply the microphone power when a headset is connected to the headset socket. The polarity of the microphone pin is determined by the accessory detect circuitry and the power is switched internally in the device to allow the microphone bias to be provided from this pin.

## Audio Codec with Advanced Accessory Detect

### B.2 Microphone Bias

**Table 174: Microphone Bias**

Pin Name	Bump/Pin	Power Domain	Description	Type
MICBIAS	B14	VDD_MIC	Microphone bias output (Note 1)	Analog output
MIC	C15	VDD_MIC	Microphone bias input to AccDet	Analog Input

**Note 1** A 1  $\mu$ F capacitor to GND should be used to decouple the MICBIAS output.

**Note 2** The recommended value for R<sub>BIAS</sub> = 2.2 k $\Omega$

**Figure 36: MICBIAS Decoupling**

### B.3 Audio Outputs

**Table 175: Headset**

Pin Name	Bump/Pin	Power Domain	Description	Type
HP_L	A5	VDD	headphone output (left)	Analog output
HP_R	A3	VDD	headphone output (right)	Analog output
RING2	C13	VDD_MIC	Connection to RING2 on headset jack	Analog input/ground
RING2_SENSE	B4	VDD_MIC	Ring2 sense line	Analog input/ground
SLEEVE	A11	VDD_MIC	Connection to SLEEVE on headset jack	Analog input/ground
SLEEVE_SENSE	B6	VDD_MIC	Sleeve sense line	Analog input/ground
JACKDET	D16	VDD	Jack insertion detect pin (Note 1)	Analog input
MIC_P	B16	VDD	Microphone input (P)	Analog Input
MIC_N	A15	VDD	Microphone input (N)	Analog Input

**Note 1** The JACKDET pin is designed to be pulled either HIGH or LOW on the insertion of the jack. If using an HPLDET type headset socket additional external circuitry is required.

Audio Codec with Advanced Accessory Detect

Figure 37: Recommended Headphone Layout

B.4 Headphone Charge Pump

Table 176: Headphone Charge Pump

Pin name	Bump/pin	Power Domain	Description	Type
HPCSP	A1	VDD	Charge pump reservoir capacitor (pos)	Charge pump
HPCSN	C1	VDD	Charge pump reservoir capacitor (neg)	Charge pump
HPCFP	D2	VDD	Charge pump flying capacitor (pos)	Charge pump
HPCFN	C3	VDD	Charge pump flying capacitor (neg)	Charge pump

A 1  $\mu\text{F}$  reservoir capacitor is required between the HPCSP and GND and between HPCSN and GND. For best performance the capacitors should be fitted as near to the device as possible.

Figure 38: Charge Pump Decoupling

A 1  $\mu\text{F}$  flying capacitor is required between HPCFP and HPCFN. For best performance the capacitor should be fitted as near to the device as possible.

Figure 39: Charge Pump Flying Capacitor

To ensure stable charge pump operation the effective series resistance of the flying capacitor should be kept to a minimum. This can be achieved by selecting an appropriate capacitor dielectric (X5R, X7R) and ensuring that the capacitor is placed as near to the device as possible. Ideally the connection between the pins and the capacitor should not run through vias (connected on top layer of PCB only).

**Audio Codec with Advanced Accessory Detect**
**B.5 Digital Interfaces**
**Table 177: Digital Interfaces – I<sup>2</sup>C**

Pin name	Bump/pin	Power domain	Description	Type
SDA	D14	VDD_IO	I <sup>2</sup> C bidirectional data	Digital input / output
SCL	D12	VDD_IO	I <sup>2</sup> C clock input	Digital input

The I<sup>2</sup>C data and clock lines are powered from VDD\_IO. Both I<sup>2</sup>C lines require a pull up to VDD\_IO. The value of this pull up is dependent on I<sup>2</sup>C bus speed, bus length and supply voltage. A 2.2 k $\Omega$  resistor is satisfactory in most applications.

**Figure 40: I<sup>2</sup>C Pull Ups**
**Table 178: Digital Interfaces - I<sup>2</sup>S**

Pin name	Bump/pin	Power domain	Description	Type
DATIN	C7	VDD_IO	DAI data input	Digital input
DATOUT	C9	VDD_IO	DAI data output	Digital output
BCLK	D6	VDD_IO	DAI bit clock	Digital input / output
WCLK	D8	VDD_IO	DAI word clock (L/R select)	Digital input / output
MCLK	C11	VDD_IO	Master clock	Digital input

The DAI interface pins should be treated as clock signals and the appropriate layout rules for routing clocks should be adhered to.

**B.6 References**
**Table 179: References**

Pin name	Bump/pin	Power domain	Description	Type
VMID	A9	VDD	Audio mid-rail reference capacitor	Reference
VREF	A7	VDD	Bandgap reference capacitor	Reference
DACREF	B8	VDD	Audio DAC reference capacitor	Reference

A 1  $\mu$ F capacitor should be connected between each of the references and GND. For best performance the capacitors should be fitted as near to the device as possible.

## Audio Codec with Advanced Accessory Detect

Figure 41: Reference Capacitors

### B.7 Supplies

Table 180: Power Supplies

Pin Name	Bump/Pin	Power Domain	Description	Type
VDD	C5	Min: 1.7 V Max: 2.65 V	Supply for analog and digital circuits / Supply for headphone charge pump	Power supply
VDD_IO	D4	Min: 1.7 V Max: 3.6 V	Supply for digital interfaces. $V_{DD\_IO}$ must be greater than or equal to $V_{DD}$	Power supply
VDD_MIC	A13	Min: 1.8 V* Max: 3.6 V	Supply for microphone bias circuits. $V_{DD\_MIC}$ must be greater than or equal to $V_{DD}$	Power supply

**Note:** Both  $V_{DD\_IO}$  and  $V_{DD\_MIC}$  must be greater or equal to  $V_{DD}$ .

Decoupling capacitors are recommended between all supplies and GND. These capacitors should be located as near to the device as possible.

Figure 42: Power Supply Decoupling

### B.8 Ground

Table 181: Ground

Pin name	Bump/pin	Power domain	Description	Type
GND	B10		Analog ground	Power ground
GND_HP	B12		Headphone ground	Power ground
GND_CP	B2		Charge pump/digital ground	Power ground

GND, GND\_HP and GND\_CP should be connected directly to the system ground. In addition, GND\_HP and GND\_CP should be routed separately and connected to the system GND plane by their own separate vias.

#### Appendix C PCB Layout Guidelines

DA7219 uses Dialog Semiconductor's RouteEasy™ technology allowing the device to be routed using conventional, low cost, PCB technology. All device balls are routable on the top level and conventional plated through hole vias can be used throughout.

This design is fully realizable using a two-layer PCB. For optimum performance it is recommended that a four-layer PCB is used with layers two and three as solid ground planes.

Decoupling and reference capacitors should be located as close to the device as possible and appropriately sized tracks should be used for all power connections.

Figure 43: DA7219 Example Layout

#### C.1 Layout and Schematic Support

Copies of the evaluation board schematics and layout are available on request to aid in PCB development. Dialog Semiconductor also offer a schematic and layout review service for all designs using Dialog's devices. Please contact your local Dialog Semiconductor Office if you wish to use this service.

#### C.2 General Recommendations

- Appropriate trace width and number of vias should be used for all power supply paths.
- A common ground plane should be used, which allows proper electrical and thermal performance.
- Noise-sensitive analog signals such as feedback lines or clock connections should be kept away from traces carrying pulsed analog or digital signals. This can be achieved by separation (distance) or by shielding with quiet signals or ground traces.
- Decoupling capacitors should be X5R ceramics and should be placed as near to the device as possible.
- Charge pump capacitors should be X5R ceramics and should be placed as near to the device as possible.

## Audio Codec with Advanced Accessory Detect

### C.3 Capacitor Selection

Ceramic capacitors are manufactured with a variety of dielectrics, each with a different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate to ensure the minimum capacitance over the necessary temperature range, dc bias conditions and low Equivalent Series Resistance (ESR). X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended for best performance. Y5V and Z5U dielectrics are not recommended for use because of their poor temperature and dc bias characteristics.

The worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage is calculated using the following equation:

$$C_{EFF} = C_{OUT} \times (1 - TEMP_{CO}) \times (1 - TOL)$$

where:  $C_{EFF}$  is the effective capacitance at the operating voltage.  $TEMP_{CO}$  is the worst-case capacitor temperature coefficient.  $TOL$  is the worst-case component tolerance. These figures can be found in the manufacturer's datasheet.

In the example below, the worst-case temperature coefficient ( $TEMP_{CO}$ ) over  $-55^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  is assumed to be 15%. The tolerance of the capacitor ( $TOL$ ) is assumed to be 10%, and  $C_{OUT}$  is  $0.65 \mu\text{F}$  at 1.8 V.

Substituting these values in the equation yields

$$C_{EFF} = 0.65 \mu\text{F} \times (1 - 0.15) \times (1 - 0.1) = 0.497 \mu\text{F}$$

**Table 182: Recommended Capacitor Values**

Application	Value	Size	Temp. Char.	Tolerance	Rated Voltage	Type
VDD, VDD_IO, VDD_MIC, DACREF, VMID, VREF, HPCFP/HPCFN, HPCSP, HPCSN, MICBIAS	10 x 1 $\mu\text{F}$	0201	X5R +/- 15 %	+/-10 %	6.3 V	Murata GRM033R60J105M
