## **DS8907 AM/FM Digital Phase-Locked Loop Frequency Synthesizer**

## **General Description**

The DS8907 is a PLL synthesizer designed specifically for use in AM/FM radios. It contains the reference oscillator, a phase comparator, a charge pump, a 120 MHz ECL/I<sup>2</sup>L dual modulus programmable divider, and an 18-bit shift register/latch for serial data entry. The device is designed to operate with a serial data controller generating the necessary division codes for each frequency, and logic state information for radio function inputs/outputs.

The Colpitts reference oscillator for the PLL operates at 4 MHz. A chain of dividers is used to generate a 500 kHz clock signal for the external controller. Additional dividers generate a 25 kHz reference signal for FM and a 10 kHz reference signal for AM. One of these reference signals is selected by the data from the controller for use by the phase comparator.

Data is transferred between the frequency synthesizer and the controller via a 3 wire bus system. This consists of a data input line, an enable line, and a clock line. When the enable line is low, data can be shifted from the controller into the frequency synthesizer. When the enable line is transitioned from low to high, data entry is disabled and data present in the shift register is latched.

From the controller 20-bit data stream, the first 2 bits address the device permitting other devices to share the same bus. Of the remaining 18-bit data word, the next 13 bits are used for the PLL divide code. The remaining 5 bits are connected via latches to output pins. These 5 bits can be used to drive radio functions such as gain, mute, FM, AM and stereo only. These outputs are open collector. Bit 16 is used internally to select the AM or FM local oscillator input and to select between the 10 kHz and 25 kHz reference. A high level at bit 16 indicates FM and a low level indicates AM.

The PLL consists of a 13-bit programmable I<sup>2</sup>L divider, an ECL phase comparator, an ECL dual modulus (p/p+1) prescaler, and a high speed charge pump. The programmable divider divides by (N+1), N being the number loaded into the shift register (bits 1-13 after address). It is clocked by the AM input via an ECL  $\div$  7/8 prescaler, or through a  $\div$  <sup>63</sup>/<sub>64</sub> prescaler from the FM input. The AM input will work at frequencies up to 15 MHz, while the FM input works up to 120 MHz. The AM band is tuned with a frequency resolution of 10 kHz and the FM band is tuned with a resolution of 25 kHz. The buffered AM and FM inputs are self biased and can be driven directly by the VCO through a capacitor. The ECL phase comparator produces very accurate resolution of the phase difference between the input signal and the reference oscillator. The high speed charge pump consists of a switchable constant current source (-0.3 mA) and a switchable constant current sink (+0.3 mA). If the VCO frequency is low, the charge pump will source current, and sink current if the VCO frequency is high. When using an AFC the charge pump output may be forced into TRI-STATE® by applying a low level to the charge pump enable input.

A separate  $V_{CCM}$  pin (typically drawing 1.5 mA) powers the oscillator and reference chain to provide controller clocking frequencies when the balance of the PLL is powered down.

## Features

- Uses inexpensive 4 MHz reference crystal
- FIN capability greater than 120 MHz allows direct synthesis at FM frequencies
- FM resolution of 25 kHz allows usage of 10.7 MHz ce-ramic filter distribution
- Serial data entry for simplified control
- 50 Hz output for "time-of-day" reference driven from separate low power V<sub>CCM</sub>
- 5-open collector buffered outputs for controlling various radio functions
- Separate AM and FM inputs. AM input has 15 mV (typical) hysteresis
