1 General Description

The EM78468B is an 8-bit microprocessor designed and developed with low-power and high-speed CMOS technology. Integrated onto a single chip are on-chip Watchdog Timer (WDT), Data RAM, ROM, programmable real time clock counter, internal/external interrupt, power-down mode, LCD driver, infrared transmitter function, and tri-state I/O. The series has an on-chip 4K×13-bit Electrical Mask Read Only Memory (Mask-ROM). The EM78468B provides multi-protection bits to prevent intrusion of user's Mask memory code. Seven Code option bits are available to meet user's requirements. Special 13 bits customer ID options are provided as well.

With its enhanced Mask-ROM feature, the EM78468B provides a convenient way of developing and verifying user's programs. 6 Functional Description

6.1 Operational Registers

6.1.1 R0/IAR (Indirect Addressing Register)

(Address: 00h)

R0 is not a physically implemented register. Its major function is to perform as an indirect address pointer. Any instruction using R0 as a register, actually accesses the data pointed by the RAM Select Register (R4).

6.1.2 R1/TCC (Timer Clock Counter)

(Address: 01h)

The Timer Clock Counter is incremented by an external signal edge applied to TCC, or by the instruction cycle clock. It is written and read by the program as any other register.

6.1.3 R2/PC (Program Counter)

(Address: 02h)

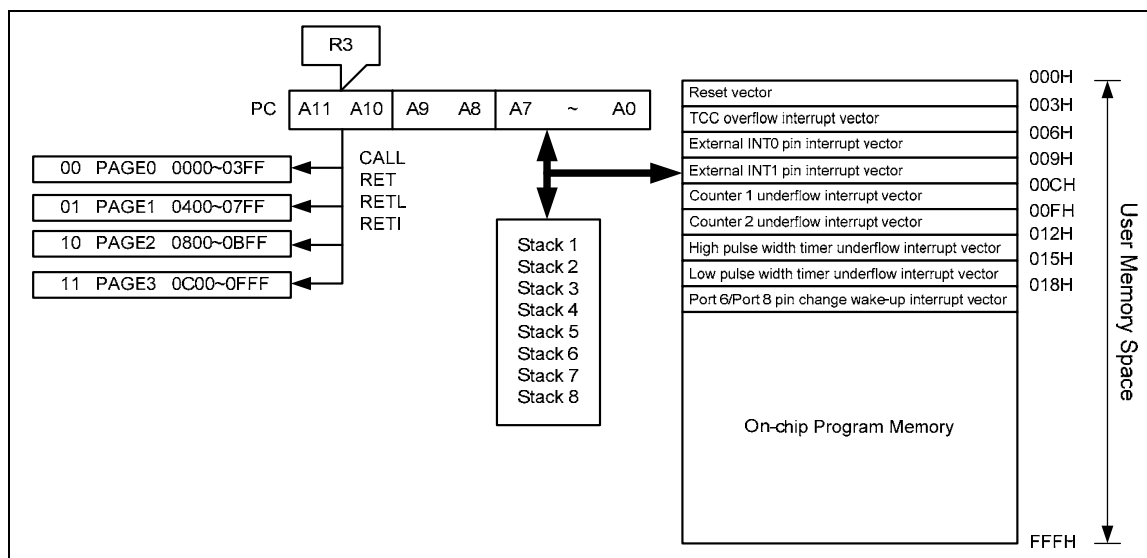

Figure 6-1 Program Counter Organization

- The structure of R2 is depicted in Figure 6-1, *Program Counter Organization*.
- The configuration structure generates 4K×13 bits on-chip ROM addresses to the relative programming instruction codes.
- The contents of R2 are all set to "0"s when a Reset condition occurs.
- "JMP" instruction allows direct loading of the lower 10 program counter bits. Thus, "JMP" allows the PC to jump to any location within a page.

- "CALL" instruction loads the lower 10 bits of the PC and PC+1 are pushed onto the stack. Thus, the subroutine entry address can be located anywhere within a page.
- "RET" ("RETL k", "RETI") instruction loads the program counter with the contents at the top of the stack.
- "ADD R2, A" allows a relative address to be added to the current PC, and the ninth and above bits of the PC will increase progressively.
- "MOV R2, A" allows loading of an address from the "A" register to the lower 8 bits of the PC, and the ninth and tenth bits (A8 ~ A9) of the PC will remain unchanged.
- The most significant bits (A10~A11) will be loaded with the content of PS0~PS1 in the Status register (R3) upon execution of a "JMP" or "CALL" instruction.

6.1.4 R3/SR (Status Register)

(Address: 03h)

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
–	PS1	PS0	T	P	Z	DC	C
	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit 7: Not used

Bits 6 ~ 5 (PS1 ~ 0): Page select bits

PS1	PS0	ROM Page (Address)
0	0	Page 0 (000H ~ 3FFH)
0	1	Page 1 (400H ~ 7FFH)
1	0	Page 2 (800H ~ BFFH)
1	1	Page 3 (C00H ~ FFFH)

PS0~PS1 are used to select a ROM page. User can use the PAGE instruction (e.g. PAGE 1) or set PS1~PS0 bits to change the ROM page. When executing a "JMP", "CALL", or other instructions which causes the program counter to be changed (e.g. MOV R2, A), PS0~PS1 are loaded into the 11th and 12th bits of the program counter where it selects one of the available program memory pages. Note that RET (RETL, RETI) instruction does not change the PS0~PS1 bits. That is, the return will always be to the page from where the subroutine was called, regardless of the current setting of PS0~PS1 bits.

Bit 4 (T): Time-out bit. Set to 1 by the "SLEP" and "WDTC" commands or during power up and reset to 0 by WDT timeout.

Event	T	P	Remark
WDT wake up from sleep mode	0	0	–
WDT time out (not sleep mode)	0	1	–
/RESET wake up from sleep	1	0	–
Power up	1	1	–
Low pulse on /RESET	1	1	×: don't care

Bit 3 (P): Power down bit. Set to 1 during power on or by a "WDTC" command and reset to 0 by a "SLEP" command.

Bit 2 (Z): Zero flag

Bit 1 (DC): Auxiliary carry flag

Bit 0 (C): Carry flag

6.1.5 R4/RSR (RAM Select Register)

(Address: 04h)

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
RBS1	RBS0	RSR5	RSR4	RSR3	RSR2	RSR1	RSR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 7 ~ 6 (RBS1 ~ RBS0): determine which bank is activated among the four banks. See the data memory configuration in Fig. 6-2. Use the BANK instruction (e.g. BABK 1) to change banks.

Bits 5 ~ 0 (RSR5 ~ RSR0): used to select up to 64 registers (Address: 00~3F) in indirect addressing mode. If no indirect addressing is used, the RSR can be used as an 8-bit general purpose read/writer register.

6.1.6 R5/Port 5 (Port 5 I/O Data and Page of Register Select)

(Address: 05h)

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
R57	R56	R55	R54	-	-	-	IOCPAGE
R/W	R/W	R/W	R/W	-	-	-	R/W

Bits 7~4: Four bits I/O registers of Port 5

User can use the IOC50 register to define each bit either as input or output.

Bits 3~1: Not used

Bit 0 (IOCPAGE): change IOC5 ~ IOCF to another page

IOCPAGE = "0" : Page 0 (select register of IOC 50 to IOC F0)

IOCPAGE = "1" : Page 1 (select register of IOC 61 to IOC E1)

6.1.7 R6/Port 6 (Port 6 I/O Data Register)

R67	R66	R65	R64	R63	R62	R61	R60
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 7~0: 8-bit I/O registers of Port 6

User can use the IOC60 register to define each bit either as input or output.

■ CPU Operation Mode

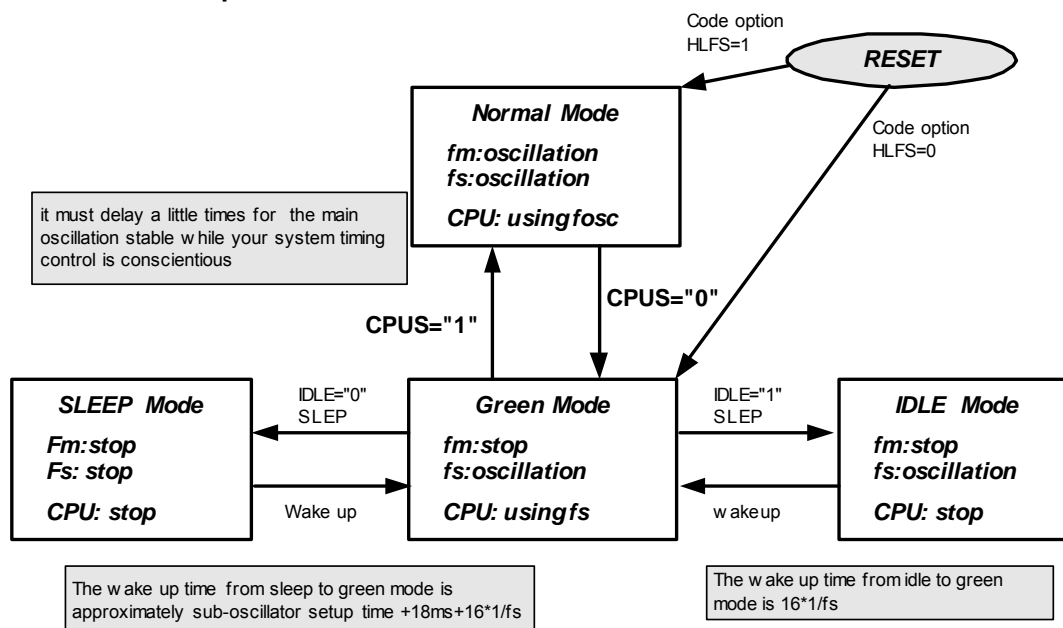

Figure 6-3 CPU Operation Mode

Note

(*) If the watchdog function is enabled before going into sleep mode, it would must stop counting.

(**)

Switching Operation Mode at Idle → Green:

If the clock source of timer is *Fs*, the timer/counter must stop counting at sleep mode, and, the clock source of timer is *Fs*, the timer/counter can continue to count at Idle mode.

Switching Operation Mode at Green → Normal:

If the clock source of timer is *Fm*, the timer must stop counting at green mode. Then, the timer can continue to count until the clock source is stable at normal mode. That clock source is stable means the CPU starts to work at normal mode.

6.3 TCC and WDT Prescaler

Two 8-bit counters are available as prescalers for the TCC (Time Clock Counter) and WDT (Watchdog Timer). The TCCP2~TCCP0 bits of the IOC71 register are used to determine the ratio of the TCC prescaler. Likewise, the WDTP2~WDTP0 bits of the IOC81 register are used to determine the WDT prescaler. The TCC prescaler (TCCP2~TCCP0) is cleared by the instructions each time they are written into TCC, while the WDT prescaler is cleared by the “WDTC” and “SLEP” instructions. Fig.7 depicts the circuit diagram of TCC and WDT.

R1 (TCC) is an 8-bit timer/counter. The clock source of TCC can be selected by internal instruction clock or external signal input (edge selectable from the TCC control register). If the TCC signal source is from the internal instruction clock, the TCC will be incremented by 1 at every instruction cycle (without prescaler). If the TCC signal source is from an external clock input, the TCC will be incremented by 1 at every falling edge or rising edge of the TCC pin.

The Watchdog Timer is a free running on sub-oscillator. The WDT will keep on running even after the oscillator driver has been turned off. During Normal mode, Green mode, or Idle mode operation, a WDT time-out (if enabled) will cause the device to reset. The WDT can be enabled or disabled at any time during the Normal mode and Green mode by software programming. Refer to WDTE bit of IOC81 register. The WDT time-out period is equal to (prescaler \times 256 / (Fs/2)).

6.4 I/O Ports

The I/O registers, (Port 5, Port 6, Port 7 and Port 8), are bi-directional tri-state I/O ports. Port 6 and Port 8 are pulled-high internally by software; Port 6 is also pulled-low internally by software. Furthermore, Port 6 has its open-drain output also through software. Port 6 and Port 8 features an input status changed interrupt (or wake-up) function and is pulled-high by software. Each I/O pin can be defined as "input" or "output" pin by the I/O control register (IOC50 ~ IOC80). The I/O registers and I/O control registers are both readable and writable. The I/O interface circuits are shown in Figure 6-5.

Note: Open-drain, pull-high, and pull down are not shown in the figure.

6.5 Reset and Wake-up

A reset can be activated by

- POR (Power-on Reset)
- WDT timeout (if enabled)
- /RESET pin goes to low
- The oscillator is running, or will be started
- The program counter (R2/PC) is set to all "0"
- All I/O port pins are configured as input mode (high-impedance state)
- The TCC/Watchdog timer and prescaler are cleared
- When power is on, Bits 5 and 6 of R3 and the upper two bits of R4 are cleared.
- Bits of the IOC71 register are set to all "1" except for Bit 6 (INT flag)
- For other registers, see Table 2

6.6 Oscillator

6.6.1 Oscillator Modes

The EM78468B can operate in three different oscillator modes:

- Main oscillator (R-OSCI, OSCO), such as RC oscillator with external resistor and Internal capacitor mode (ERIC)
- Crystal oscillator mode
- PLL operation mode (R-OSCI connected to 0.01 μ F capacitor to Ground). User can select which mode by programming FMMD1 and FMMD0 in the Code Options Register. The sub-oscillator can be operated in Crystal mode and ERIC mode. Table 3 below shows how these three modes are defined.

6.6.3 Crystal Oscillator/Ceramic Resonators (Crystal)

This LSI can be driven by an external clock signal through the R-OSCI pin as shown in Fig. 6-7 below. In most applications, the R-OSCI pin and the OSCO pin can be connected with a crystal or ceramic resonator to generate oscillation. Fig. 6-8 depicts such circuit. Table 5 provides the recommended values of C1 and C2. Since each resonator has its own attribute, user should refer to its specification for appropriate values of C1 and C2. RS, a serial resistor, may be necessary for AT strip cut crystal or low frequency mode.

6.6.4 RC Oscillator Mode with Internal Capacitor

If both precision and cost are taken into consideration, this LSI also offers a special oscillation mode, which has an on-chip internal capacitor and an external resistor connected to VDD. The internal capacitor functions as temperature compensator. In order to obtain more accurate frequency, a precise resistor is recommended.

6.7 Power-on Considerations

Any microcontroller (as with this LSI) is not warranted to start operating properly before the power supply stabilizes in a steady state. This LSI has an on-chip Power-on Reset (POR) with detection level range as shown on the table below. The circuitry eliminates the extra external reset circuit but will work well only if the VDD rises quickly enough (50 ms or less). However, under critical applications, extra devices are still required to assist in solving power-on problems.

Power-on voltage detector provided

IC	Voltage Range
EM78468B	1.7V to 1.9V

6.7.1 External Power-on Reset Circuit

This circuit implements an external RC to produce a reset pulse (see Figure 6-10). The pulse width (time constant) should be kept long enough to allow VDD to reach minimum operation voltage. This circuit is used when the power supply rise time is slow. Because the current leakage from the /RESET pin is $\pm 5 \mu\text{A}$, it is recommended that R should not be greater than 40K. In this way, the voltage at Pin /RESET is held below 0.2V. The diode (D) acts as a short circuit at power-down. The capacitor, C, is discharged rapidly and fully. Rin, the current-limited resistor, prevents high current discharge or ESD (electrostatic discharge) from flowing into Pin /RESET.

Figure 6-10 External Power-on Reset Circuit

6.7.2 Residue-Voltage Protection

When battery is replaced, device power (VDD) is disconnected but residue-voltage remains. The residue-voltage may trips below minimum VDD, but above zero. This condition may cause poor power on reset. Figure 6-11 and Figure 6-12 show how to build a residue-voltage protection circuit

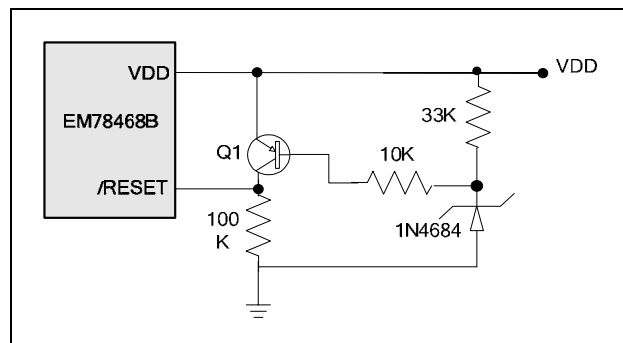

Figure 6-11 Residue Voltage Protection Circuit 1

Figure 6-12 Residue Voltage Protection Circuit 2

6.8 Interrupt

This LSI has eight interrupt sources as listed below:

- TCC overflow interrupt.
- External interrupt P5.4/INT0 pin
- External interrupt P5.5/INT1 pin
- Counter 1 underflow interrupt
- Counter 2 underflow interrupt
- High-pulse width timer underflow interrupt
- Low-pulse width timer underflow interrupt
- Port 6, Port 8 input status change wake-up

This IC has internal interrupts which are falling edge triggered as follows:

- TCC timer overflow interrupt
- Four 8-bit down counter/timer underflow interrupt

If these interrupt sources change signal from high to low, the RF register will generate a “1” flag to the corresponding register if the IOCF0 register is enabled.

RF is the interrupt status register. It records the interrupt request in flag bit. IOCF0 is the interrupt mask register. Global interrupt is enabled by ENI instruction and disabled by DISI instruction. When one of the interrupts (when enabled) is generated, it will cause the next instruction to be fetch from Address 0003H~0018H according to interrupt source.

With this LSI, each individual interrupt source has its own interrupt vector as depicted in Table 3. Before the interrupt subroutine is executed, the contents of the ACC and the R3 register are initially saved by the hardware. After the interrupt service routine is completed, the ACC and R3 are restored. The existing interrupt service routine does not allow other interrupt service routine to be executed. Hence, if other interrupts occur while an existing interrupt service routine is being executed, the hardware will save the later interrupts. Only after the existing interrupt service routine is completed that the next interrupt service routine is executed.

6.9 LCD Driver

This LSI can drive an LCD of up to 32 segments and 4 commons that can drive a total of 4×32 dots. The LCD block is made up of an LCD driver, display RAM, segment output pins, common output pins, and LCD operating power supply pins. This circuit works on normal mode, green mode and idle mode. The LCD duty; bias; the number of segment; the number of common and frame frequency are determined by the LCD controller register.

The basic structure contains a timing control that uses a subsystem clock to generate the proper timing for different duty and display accesses. The R9 register is a command register for the LCD driver which includes LCD enable/disable, Bias (1/2 and 1/3), Duty (1/2, 1/3, 1/4), and LCD frame frequency control. The register RA is an LCD contrast and LCD RAM address control register. The register RB is an LCD RAM data buffer. LCD booster circuit can change the operation frequency to improve VLCD2 and VLCD3 drive capability. The control register is described as follows.

6.10 Infrared Remote Control Application/PWM Waveform Generation

This LSI can output infrared carrier in user-friendly or in PWM standard waveform. The IR and PWM waveform generated functions include an 8-bit down count timer/counter, high-pulse width timer, low-pulse width timer, and IR control register. The IR system block diagram is shown in Figure 6-20. The IROUT pin waveform is determined by IR control register (RE), IOC90 (Counters 1 and 2 control register), IOCA0 (high-pulse width timer, low-pulse width timer control register), IOCC0 (Counter 2 preset), IOCD0 (high-pulse width timer preset register), and IOCE0 (low-pulse width timer preset register). Details on $F_{carrier}$, high-pulse time, and low pulse time are explained as follows:

If Counter 2 clock source is F_T (this clock source can be set by IOC91), then

$$F_{carrier} = \frac{F_T}{2 \times (1 + \text{decimal of Counter 2 preset value (IOCC 0)}) \times \text{prescaler}}$$

If the high-pulse width timer clock source is F_T (this clock source can be set by IOCA1), then

$$T_{high\ pulse\ time} = \frac{\text{prescaler} \times (1 + \text{decimal of high pulse width timer value (IOCD 0)})}{F_T}$$

If the low-pulse width timer clock source is F_T (this clock source can be set by IOCA1);

$$T_{low\ pulse\ time} = \frac{\text{prescaler} \times (1 + \text{decimal of low pulse width timer value (IOCE 0)})}{F_T}$$

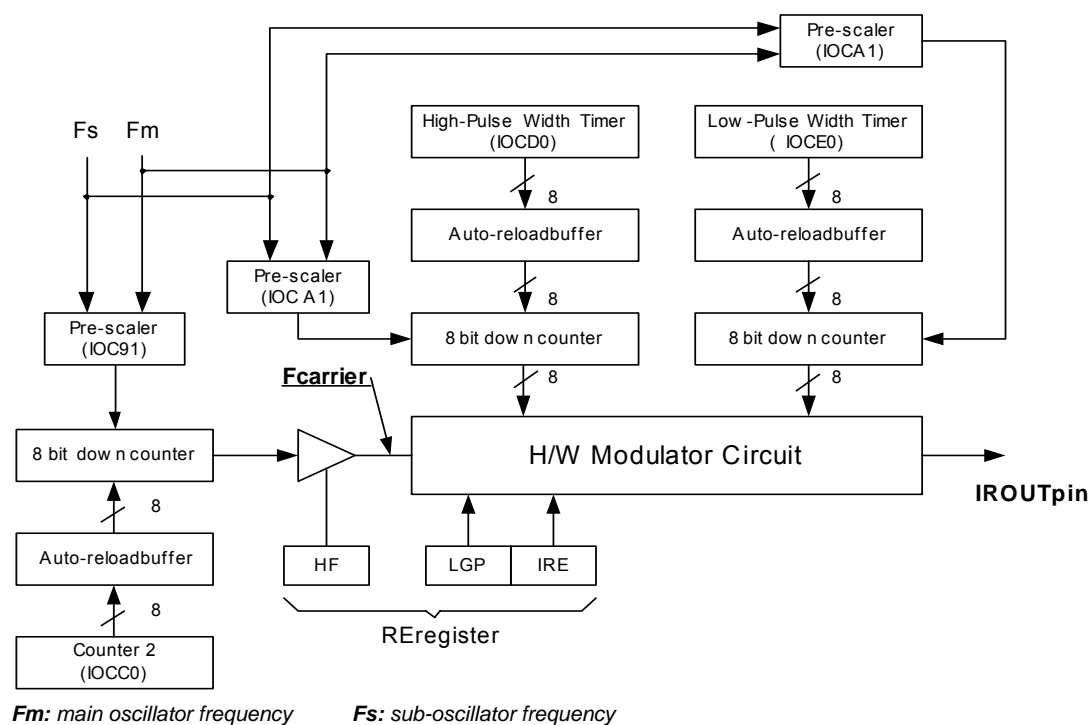

Figure 6-20 IR/PWM System Block Diagram

The IROUT output waveform is further explained in the following figures:

Fig. 6-21 LGP=0, HF=1, the IROUT waveform can modulate Fcarrier waveform when in low-pulse width time.

Fig. 6-22 LGP=0, HF=0, the IROUT waveform cannot modulate Fcarrier waveform when in low-pulse width time. So IROUT waveform is determined by high-pulse time and low-pulse time. This mode can produce standard PWM waveform.

Fig. 6-23 LGP=0, HF=1, the IROUT waveform can modulate Fcarrier waveform when in low-pulse width time. When IRE goes from high to low, the output waveform of IROUT will keep on transmitting until high-pulse width timer interrupt occurs.

Fig. 6-24 LGP=0, HF=0, the IROUT waveform can not modulate Fcarrier waveform when in low-pulse width time. So IROUT waveform is determined by high-pulse time and low-pulse time. This mode can produce standard PWM waveform. When IRE goes from high to low, the output waveform of IROUT will keep on transmitting till high-pulse width timer interrupt occurs.

Fig.6-25 LGP=1, when this bit is set to high level, the high-pulse width timer is ignored. So IROUT waveform output from low-pulse width timer is established.

Bit 3~0: Not used.

These bits are set to "0" all the time.

6.12 Instruction Set

Each instruction in the instruction set is a 13-bit word divided into an OP code and one or more operands. Normally, all instructions are executed within one single instruction cycle (one instruction consists of 2 oscillator periods), unless the program counter is changed by instruction "MOV R2,A", "ADD R2,A", or by instructions of arithmetic or logic operation on R2 (e.g. "SUB R2,A", "BS(C) R2,6", "CLR R2", ...). In this case, the execution takes two instruction cycles.

If for some reasons, the specification of the instruction cycle is not suitable for certain applications, try modifying the instruction as follows:

Execute within two instruction cycles the "JMP", "CALL", "RET", "RETL", & "RETI" instructions, or the conditional skip instructions ("JBS", "JBC", "JZ", "JZA", "DJZ", "DJZA") which were tested to be true. Also execute within two instruction cycles the instructions that are written to the program counter.

Additionally, the instruction set offers the following features:

- (1) Every bit of any register can be set, cleared, or tested directly.
- (2) The I/O register can be regarded as general register. That is, the same instruction can operate on I/O register.

Convention:

R = Register designator that specifies which one of the registers (including operation and general purpose registers) is to be utilized by the instruction.

b = Bit field designator that selects the value for the bit located in the register *R* and which affects the operation.

k = 8 or 10-bit constant or literal value
