

EN29LV800D (2A)

8 Megabit (1024K x 8-bit / 512K x 16-bit) Flash Memory

Boot Sector Flash Memory, CMOS 3.0 Volt-only

Features

- 3.0V, single power supply operation
- Minimizes system level power requirements
- High performance
- Access times as fast as 70 ns
- Low power consumption (typical values at 5 MHz)
- 9 mA typical active read current
- 20 mA typical program/erase current
- Less than 1 μ A current in standby or automatic sleep mode
- Flexible Sector Architecture:
 - One 16-Kbyte, two 8-Kbyte, one 32-Kbyte, and fifteen 64-Kbyte sectors (byte mode)
 - One 8-Kword, two 4-Kword, one 16-Kword and fifteen 32-Kword sectors (word mode)
- Sector protection :
 - Hardware locking of sectors to prevent program or erase operations within individual sectors
 - Additionally, temporary Sector Group Unprotect allows code changes in previously locked sectors.
- Secured Silicon Sector
 - Provides a 128-words area for code or data that can be permanently protected.
 - Once this sector is protected, it is prohibited to program or erase within the sector again.
- High performance program/erase speed
 - Byte/Word program time: 8 μ s typical
 - Sector erase time: 100ms typical
 - Chip erase time: 2s typical
- JEDEC Standard program and erase commands
- JEDEC standard DATA# polling and toggle bits feature
- Single Sector and Chip Erase
- Sector Unprotect Mode
- Embedded Erase and Program Algorithms
- Erase Suspend / Resume modes: Read and program another Sector during Erase Suspend Mode
- Support JEDEC Common Flash Interface (CFI)
- Low V_{CC} write inhibit $\leq 2.5V$
- minimum 100K program/erase endurance cycle
- Data retention time 20 years
- Package Options
 - 48-pin TSOP (Type 1)
 - 48 ball 6mm x 8mm TFBGA
- Industrial Temperature Range

General Description

The device is a 8-Megabit, electrically erasable, read/write non-volatile flash memory, organized as 1,048,576 bytes or 524,288 words. Any byte can be programmed typically in 8 μ s. The device features 3.0V voltage read and write operation, with access times as fast as 70ns to eliminate the need for WAIT states in high-performance microprocessor systems.

The device has separate Output Enable (OE#), Chip Enable (CE#), and Write Enable (WE#) controls, which eliminate bus contention issues. This device is designed to allow either single Sector or full chip erase operation, where each Sector can be individually protected against program/erase operations or temporarily unprotected to erase or program. The device can sustain a minimum of 100K program/erase cycles on each Sector.

8M Flash Secured Silicon Sector Table³

Description	CE#	OE#	WE#	A18 to A12	A11 to A10	A9 ²	A8	A7	A6	A5 to A2	A1	A0	DQ8 to DQ15	DQ7 to DQ0
Secured Silicon Sector Lock ⁴	L	V_{ID}		X	X	V_{ID}	X	X	L	X	H	L	X	X
Secured Silicon Sector Lock Bit Verification(DQ0) ⁴	L	L	H	X	X	V_{ID}	X	X	L	X	H	L	X	X1h (Locked)
														X0h (Unlocked)

L=logic low= V_{IL} , H=Logic High= V_{IH} , V_{ID} = $9 \pm 0.5V$, X=Don't Care (either L or H, but not floating!), SA=Sector Addresses

Note:

- A8 = H is recommended for Manufacturing ID check. If a manufacturing ID is read with A8=L, the chip will output a configuration code 7Fh.
- A9 = V_{ID} is for HV A9 Autoselect mode only. A9 must be $\leq V_{CC}$ (CMOS logic level) for Command Autoselect Mode.
- 8M Flash Secured Silicon Sector Table is valid only in Secured Silicon Sector.

4. AC Waveform for Secured Silicon Sector Lock / Verification Operations Timings

User Mode Definitions

Word / Byte Configuration

The signal set on the BYTE# Pin controls whether the device data I/O pins DQ15-DQ0 operate in the byte or word configuration. When the Byte# Pin is set at logic '1', then the device is in word configuration, DQ15-DQ0 are active and are controlled by CE# and OE#.

On the other hand, if the Byte# Pin is set at logic '0', then the device is in byte configuration, and only data I/O pins DQ0-DQ7 are active and controlled by CE# and OE#. The data I/O pins DQ8-DQ14 are tri-stated, and the DQ15 pin is used as an input for the LSB (A-1) address function.

Standby Mode

The device has a CMOS-compatible standby mode, which reduces the current to $< 1\mu\text{A}$ (typical). It is placed in CMOS-compatible standby when the CE# pin is at $V_{CC} \pm 0.5$. RESET# and BYTE# pin must also be at CMOS input levels. The device also has a TTL-compatible standby mode, which reduces the maximum V_{CC} current to $< 1\text{mA}$. It is placed in TTL-compatible standby when the CE# pin is at V_{IH} . When in standby modes, the outputs are in a high-impedance state independent of the OE# input.

Automatic Sleep Mode

The device has an automatic sleep mode, which minimizes power consumption. The devices will enter this mode automatically when the states of address bus remain stable for $t_{ACC} + 30\text{ns}$. I_{CC5} in the DC Characteristics table shows the current specification. With standard access times, the device will output new data when addresses change.

Read Mode

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data. The device is also ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the device enters the Erase Suspend mode. The system can read array data using the standard read timings, except that if it reads at an address within erase-suspended sectors, the device outputs status data. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception. See "Erase Suspend/Erase Resume Commands" for more additional information.

The system must issue the reset command to re-enable the device for reading array data if DQ5 goes high, or while in the autoselect mode. See the "Reset Command" additional details.

Output Disable Mode

When the CE# or OE# pin is at a logic high level (V_{IH}), the output from the device is disabled. The output pins are placed in a high impedance state.

Auto Select Identification Mode

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output on DQ15-DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires V_{ID} (8.5V to 9.5V) on address pin A9. Address pins A6, A1, and A0 must be as shown in Autoselect Codes table. In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits. Refer to the corresponding Sector Address Tables. The Command Definitions table shows the remaining address bits that are don't-care. When all necessary bits have been set as required, the programming equipment may then read the corresponding identifier code on DQ15-DQ0.

To access the autoselect codes in-system; the host system can issue the autoselect command via the command register, as shown in the Command Definitions table. This method does not require V_{ID} . See "Command Definitions" for details on using the autoselect mode.

Write Mode

Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program set-up command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is not required to provide further controls or timings. The device automatically provides internally generated program pulses and verifies the programmed cell margin. The Command Definitions in Table 5 show the address and data requirements for the byte program command sequence.

When the Embedded Program algorithm is complete, the device then returns to reading array data and addresses are no longer latched. The system can determine the status of the program operation by using DQ7 or DQ6. See "Write Operation Status" for information on these status bits.

Any commands written to the device during the Embedded Program Algorithm are ignored.

Programming is allowed in any sequence and across sector boundaries. **A bit cannot be programmed from a "0" back to a "1".** Attempting to do so may halt the operation and set DQ5 to "1", or cause the Data# Polling algorithm to indicate the operation was successful. However, a succeeding read will show that the data is still "0". Only erase operations can convert a "0" to a "1".

Sector Protection/Unprotection

The hardware sector protection feature disables both program and erase operations in any sector. The hardware sector unprotection feature re-enables both program and erase operations in previously protected sectors.

There are two methods to enabling this hardware protection circuitry. The first one requires only that the RESET# pin be at V_{ID} and then standard microprocessor timings can be used to enable or disable this feature. See Flowchart 7a and 7b for the algorithm and Figure 12 for the timings.

When doing Sector Unprotect, all the other sectors should be protected first.

The second method is meant for programming equipment. This method requires V_{ID} be applied to both OE# and A9 pin and non-standard microprocessor timings are used. This method is described in a separate document called device Supplement, which can be obtained by contacting a representative of Eon Silicon Solution, Inc.

Temporary Sector Unprotect

This feature allows temporary unprotection of previously protected sector groups to change data while in-system. The Sector Unprotect mode is activated by setting the RESET# pin to V_{ID} . During this mode, formerly protected sectors can be programmed or erased by simply selecting the sector addresses. Once is removed from the RESET# pin, all the previously protected sectors are protected again. See accompanying figure and timing diagrams for more details.

Notes:

1. All protected sectors unprotected.
2. Previously protected sectors protected again.

Common Flash Interface (CFI)

The common flash interface (CFI) specification outlines device and host systems software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h in word mode (or address AAh in byte mode), any time the device is ready to read array data.

The system can read CFI information at the addresses given in Tables 5-8. In word mode, the upper address bits (A7–MSB) must be all zeros. To terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode and the system can read CFI data at the addresses given in Tables 5–8. The system must write the reset command to return the device to the autoselect mode.

Table 5. CFI Query Identification String

Addresses (Word Mode)	Addresses (Byte Mode)	Data	Description
10h 11h 12h	20h 22h 24h	0051h 0052h 0059h	Query Unique ASCII string “QRY”

4Bh	96h	0000h	Burst Mode Type 00 = Not Supported, 01 = Supported
4Ch	98h	0000h	Page Mode Type 00 = Not Supported, 01 = 4 Word Page, 02 = 8 Word Page

Hardware Data protection

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes as seen in the Command Definitions table. Additionally, the following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by false system level signals during V_{CC} power up and power down transitions, or from system noise.

Secured Silicon Sector

The device features an OTP memory region where the system may access through a command sequence to create a permanent part identification as so called Electronic Serial Number (ESN) in the device. Once this region is programmed and then locked by writing the Secured Silicon Sector Lock command (refer to Table 4 on page 9), any further modification in the region is impossible. The secured silicon sector is 128 words in length, and the Secured Silicon Sector Lock Bit (DQ0) is used to indicate whether the Secured Silicon Sector is locked or not.

The system accesses the Secured Silicon Sector through a command sequence (refer to “Enter Secured Silicon/Exit Secured Silicon Sector command Sequence which are in Table 9 on page 15). After the system has written the Enter Secured Silicon Sector command sequence, it may read the Secured Silicon Sector by using the address normally occupied by the last sector SA34 (for EN29LV800DT) or first sector SA0 (for EN29LV800DB). Once entry the Secured Silicon Sector the operation of boot sectors and main sectors are disabled, the system must write Exit Secured Silicon Sector command sequence to return to read and write within the remainder of the array. This mode of operation continues until the system issues the Exit Secured Silicon Sector command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending command to sector SA0.

Low V_{CC} Write Inhibit

When V_{CC} is less than V_{LKO} , the device does not accept any write cycles. This protects data during V_{CC} power up and power down. The command register and all internal program/erase circuits are disabled, and the device resets. Subsequent writes are ignored until V_{CC} is greater than V_{LKO} . The system must provide the proper signals to the control pins to prevent unintentional writes when V_{CC} is greater than V_{LKO} .

Write Pulse “Glitch” protection

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

Logical Inhibit

Write cycles are inhibited by holding any one of OE# = V_{IL} , CE# = V_{IH} , or WE# = V_{IH} . To initiate a write cycle, CE# and WE# must be a logical zero while OE# is a logical one. If CE#, WE#, and OE# are all logical zero (not recommended usage), it will be considered a read.

Power-up Write Inhibit

During power-up, the device automatically resets to READ mode and locks out write cycles. Even with CE# = V_{IL} , WE# = V_{IL} and OE# = V_{IH} , the device will not accept commands on the rising edge of WE#.

Command Definitions

The operations of the device are selected by one or more commands written into the command register to perform Read/Reset Memory, Read ID, Read Sector Protection, Program, Sector Erase, Chip Erase, Erase Suspend and Erase Resume. Commands are made up of data sequences written at specific addresses via the command register. The sequences for the specified operation are defined in the Command Definitions table (Table 5). Incorrect addresses, incorrect data values or improper sequences will reset the device to Read Mode.

Table 9. Device Command Definitions

Command Sequence			Cycles	Bus Cycles												
				1 st		2 nd		3 rd		4 th		5 th		6 th		
				Write Cycle		Write Cycle		Write Cycle		Write Cycle		Write Cycle		Write Cycle		
				Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	
Read			1	RA	RD											
Reset			1	xxx	F0

	Byte		AAA		555		AAA		xxx	00						

Address and Data values indicated in hex

RA = Read Address: address of the memory location to be read. This is a read cycle.

RD = Read Data: data read from location RA during Read operation. This is a read cycle.

PA = Program Address: address of the memory location to be programmed. X = Don't-Care

PD = Program Data: data to be programmed at location PA

SA = Sector Address: address of the Sector to be erased or verified. Address bits A18-A12 uniquely select any Sector.

Reading Array Data

The device is automatically set to reading array data after power up. No commands are required to retrieve data. The device is also ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

Following an Erase Suspend command, Erase Suspend mode is entered. The system can read array data using the standard read timings, with the only difference in that if it reads at an address within erase suspended sectors, the device outputs status data. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception.

The Reset command must be issued to re-enable the device for reading array data if DQ5 goes high, or while in the autoselect mode. See next section for details on Reset.

Reset Command

Writing the reset command to the device resets the device to reading array data. Address bits are don't-care for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the device to reading array data. Once erasure begins, however, the device ignores reset commands until the operation is complete. The reset command may be written between the sequence cycles in a program command sequence before programming begins. This resets the device to reading array data (also applies to programming in Erase Suspend mode). Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to reading array data (also applies to autoselect during Erase Suspend).

If DQ5 goes high during a program or erase operation, writing the reset command returns the device to reading array data (also applies during Erase Suspend).

Autoselect Command Sequence

The autoselect command sequence allows the host system to access the manufacturer and devices codes, and determine whether or not a sector is protected. The Command Definitions table shows the address and data requirements. This is an alternative to the method that requires V_{ID} on address bit A9 and is intended for PROM programmers.

Two unlock cycles followed by the autoselect command initiate the autoselect command sequence. Autoselect mode is then entered and the system may read at addresses shown in Table 4 any number of times, without needing another command sequence.

The system must write the reset command to exit the autoselect mode and return to reading array data.

Word / Byte Programming Command

The device can be programmed by byte or by word, depending on the state of the Byte# Pin. Programming the device is performed by using a four-bus-cycle operation (two unlock write cycles followed by the Program Setup command and Program Data Write cycle). When the program command is executed, no additional CPU controls or timings are necessary. An internal timer terminates the program operation automatically. Address is latched on the falling edge of CE# or WE#, whichever is last; data is latched on the rising edge of CE# or WE#, whichever is first.

Programming status can be checked by sampling data on DQ7 (DATA# polling) or on DQ6 (toggle bit). When the program operation is successfully completed, the device returns to read mode and the user can read the data programmed to the device at that address. Note that data can not be programmed from a "0" to a "1". Only an erase operation can change a data from "0" to "1". When programming time limit is exceeded, DQ5 will produce a logical "1" and a Reset command can return the device to Read mode.

Chip Erase Command

Chip erase is a six-bus-cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. The Command Definitions table shows the address and data requirements for the chip erase command sequence.

Any commands written to the chip during the Embedded Chip Erase algorithm are ignored.

The system can determine the status of the erase operation by using DQ7, DQ6, or DQ2. See “Write Operation Status” for information on these status bits. When the Embedded Erase algorithm is complete, the device returns to reading array data and addresses are no longer latched.

Flowchart 4 illustrates the algorithm for the erase operation. See the Erase/Program Operations tables in “AC Characteristics” for parameters, and to the Chip/Sector Erase Operation Timings for timing waveforms.

Sector Erase Command Sequence

Sector erase is a six bus cycle operation. The sector erase command sequence is initiated by writing two un-lock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the address of the sector to be erased, and the sector erase command. The Command Definitions table shows the address and data requirements for the sector erase command sequence.

Once the sector erase operation has begun, only the Erase Suspend command is valid. All other commands are ignored.

When the Embedded Erase algorithm is complete, the device returns to reading array data and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6, or DQ2. Refer to “Write Operation Status” for information on these status bits. Flowchart 4 illustrates the algorithm for the erase operation. Refer to the Erase/Program Operations tables in the “AC Characteristics” section for parameters, and to the Sector Erase Operations Timing diagram for timing waveforms.

Erase Suspend / Resume Command

The Erase Suspend command allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. This command is valid only during the sector erase operation. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm. Addresses are don't-cares when writing the Erase Suspend command.

When the Erase Suspend command is written during a sector erase operation, the device requires a maximum of 20 μ s to suspend the erase operation.

After the erase operation has been suspended, the system can read array data from or program data to any sector not selected for erasure. (The device “erase suspends” all sectors selected for erasure.) Normal read and write timings and command definitions apply. Reading at any address within erase-suspended sectors produces status data on DQ7–DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. See “Write Operation Status” for information on these status bits.

After an erase-suspended program operation is complete, the system can once again read array data within non-suspended sectors. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard program operation. See “Write Operation Status” for more information. The Autoselect command is not supported during Erase Suspend Mode.

The system must write the Erase Resume command (address bits are don't-care) to exit the erase suspend mode and continue the sector erase operation. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the device has resumed erasing.

Write Operation Status

DQ7

DATA# Polling

The device provides DATA# polling on DQ7 to indicate the status of the embedded operations. The DATA# polling feature is active during Byte Programming, Sector Erase, Chip Erase, and Erase Suspend. (See Table 10)

When the embedded Programming is in progress, an attempt to read the device will produce the complement of the data written to DQ7. Upon the completion of the Byte Programming, an attempt to read the device will produce the true data written to DQ7. For the Byte Programming, DATA# polling is valid after the rising edge of the fourth WE# or CE# pulse in the four-cycle sequence.

When the embedded Erase is in progress, an attempt to read the device will produce a “0” at the DQ7 output. Upon the completion of the embedded Erase, the device will produce the “1” at the DQ7 output during the read cycles. For Chip Erase, the DATA# polling is valid after the rising edge of the sixth WE# or CE# pulse in the six-cycle sequence. DATA# polling is valid after the last rising edge of the WE# or CE# pulse for chip erase or sector erase.

DATA# Polling must be performed at any address within a sector that is being programmed or erased and not a protected sector. Otherwise, DATA# polling may give an inaccurate result if the address used is in a protected sector.

Just prior to the completion of the embedded operations, DQ7 may change asynchronously when the output enable (OE#) is low. This means that the device is driving status information on DQ7 at one instant of time and valid data at the next instant of time. Depending on when the system samples the DQ7 output, it may read the status of valid data. Even if the device has completed the embedded operations and DQ7 has a valid data, the data output on DQ0-DQ6 may be still invalid. The valid data on DQ0-DQ7 will be read on the subsequent read attempts.

The flowchart for DATA# Polling (DQ7) is shown on Flowchart 5. The DATA# Polling (DQ7) timing diagram is shown in Figure 8.

RY/BY#: Ready/Busy

The RY/BY# is a dedicated, open-drain output pin that indicates whether an Embedded Algorithm is in progress or completed. The RY/BY# status is valid after the rising edge of the final WE# pulse in the command sequence. Since RY/BY# is an open-drain output, several RY/BY# pins can be tied together in parallel with a pull-up resistor to V_{CC}.

In the output-low period, signifying Busy, the device is actively erasing or programming. This includes programming in the Erase Suspend mode. If the output is high, signifying the Ready, the device is ready to read array data (including during the Erase Suspend mode), or is in the standby mode.

DQ6

Toggle Bit I

The device provides a “Toggle Bit” on DQ6 to indicate the status of the embedded programming and erase operations. (See Table 6)

During an embedded Program or Erase operation, successive attempts to read data from the device at any address (by active OE# or CE#) will result in DQ6 toggling between “zero” and “one”. Once the embedded Program or Erase operation is completed, DQ6 will stop toggling and valid data will be read on the next successive attempts. During embedded Programming, the Toggle Bit is valid after the rising edge of the fourth WE# pulse in the four-cycle sequence. During Erase operation, the Toggle Bit is valid after the rising edge of the sixth WE# pulse for sector erase or chip erase.

In embedded Programming, if the sector being written to is protected, DQ6 will toggle for about 2 μ s, then stop toggling without the data in the sector having changed. In Sector Erase or Chip Erase, if all selected sectors are protected, DQ6 will toggle for about 100 μ s. The chip will then return to the read mode without changing data in all protected sectors.

The flowchart for the Toggle Bit (DQ6) is shown in Flowchart 6. The Toggle Bit timing diagram is shown in Figure 9.

DQ5 Exceeded Timing Limits

DQ5 indicates whether the program or erase time has exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a “1.” This is a failure condition that indicates the program or erase cycle was not successfully completed. Since it is possible that DQ5 can become a 1 when the device has successfully completed its operation and has returned to read mode, the user must check again to see if the DQ6 is toggling after detecting a “1” on DQ5.

The DQ5 failure condition may appear if the system tries to program a “1” to a location that is previously programmed to “0.” **Only an erase operation can change a “0” back to a “1.”** Under this condition, the device halts the operation, and when the operation has exceeded the timing limits, DQ5 produces a “1.” Under both these conditions, the system must issue the reset command to return the device to reading array data.

DQ3 Sector Erase Timer

After writing a sector erase command sequence, the output on DQ3 can be used to determine whether or not an erase operation has begun. (The sector erase timer does not apply to the chip erase command.) When sector erase starts, DQ3 switches from “0” to “1.” This device does not support multiple sector erase command sequences so it is not very meaningful since it immediately shows as a “1” after the first 30h command. Future devices may support this feature.

DQ2 Erase Toggle Bit II

The “Toggle Bit” on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence. DQ2 toggles when the system reads at addresses within those sectors that have been selected for erasure. (The system may use either OE# or CE# to control the read cycles.) But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to Table 5 to compare outputs for DQ2 and DQ6.

Flowchart 6 shows the toggle bit algorithm, and the section “DQ2: Toggle Bit” explains the algorithm. See also the “DQ6: Toggle Bit I” subsection. Refer to the Toggle Bit Timings figure for the toggle bit timing diagram. The DQ2 vs. DQ6 figure shows the differences between DQ2 and DQ6 in graphical form.

Reading Toggle Bits DQ6/DQ2

Refer to Flowchart 6 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ7–DQ0 at least twice in a row to determine whether a toggle bit is toggling. Typically, a system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ7–DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (top of Flowchart 6).

Write Operation Status

Operation		DQ7	DQ6	DQ5	DQ3	DQ2	RY/BY#
Standard Mode	Embedded Program Algorithm	DQ7#	Toggle	0	N/A	No toggle	0
	Embedded Erase Algorithm	0	Toggle	0	1	Toggle	0
Erase Suspend Mode	Reading within Erase Suspended Sector	1	No Toggle	0	N/A	Toggle	1
	Reading within Non-Erase Suspended Sector	Data	Data	Data	Data	Data	1
	Erase-Suspend Program	DQ7#	Toggle	0	N/A	N/A	0

Table 10. Status Register Bits

DQ	Name	Logic Level	Definition
7	DATA# Polling	'1'	Erase Complete or erase Sector in Erase suspend
		'0'	Erase On-Going
		DQ7	Program Complete or data of non-erase Sector during Erase Suspend
		DQ7#	Program On-Going
6	Toggle Bit	'-1-0-1-0-1-0-1-'	Erase or Program On-going
		DQ6	Read during Erase Suspend
		'-1-1-1-1-1-1-1-'	Erase Complete
5	Time Out Bit	'1'	Program or Erase Error
		'0'	Program or Erase On-going
3	Erase Time Out Bit	'1'	Erase operation start
		'0'	Erase timeout period on-going
2	Toggle Bit	'-1-0-1-0-1-0-1-'	Chip Erase, Erase or Erase suspend on currently addressed Sector. (When DQ5=1, Erase Error due to currently addressed Sector. Program during Erase Suspend on-going at current address
		DQ2	Erase Suspend read on non Erase Suspend Sector

Notes:

1. DQ7 DATA# Polling: indicates the P/E status check during Program or Erase, and on completion before checking bits DQ5 for Program or Erase Success.
2. DQ6 Toggle Bit: remains at constant level when P/E operations are complete or erase suspend is acknowledged. Successive reads output complementary data on DQ6 while programming or Erase operation are on-going.
3. DQ5 Time Out Bit: set to "1" if failure in programming or erase.
4. DQ3 Sector Erase Command Timeout Bit: Operation has started. Only possible command is Erase suspend (ES).
5. DQ2 Toggle Bit: indicates the Erase status and allows identification of the erased Sector.

			BGA	1.1	1.2	
C_{IN2}	Control Pin Capacitance	$V_{IN} = 0$	TSOP	7.5	9	pF
			BGA	1.0	1.3	

Note: Test conditions are Temperature = $25^{\circ}C$ and $f = 1.0$ MHz.

AC Characteristics

Figure 4. AC Waveforms for Chip/Sector Erase Operations Timings

Notes:

- SA=Sector Address (for sector erase), VA=Valid Address for reading status, D_{OUT}=true data at read address.
- V_{CC} shown only to illustrate t_{VCS} measurement references. It cannot occur as shown during a valid command sequence.

Figure 5. Program Operation Timings

Notes:

1. PA=Program Address, PD=Program Data, D_{OUT} is the true data at the program address.
2. V_{CC} shown in order to illustrate t_{VCS} measurement references. It cannot occur as shown during a valid command sequence.

Figure 6. AC Waveforms for /DATA Polling During Embedded Algorithm Operations

Notes:

1. VA=Valid Address for reading Data# Polling status data.
2. This diagram shows the first status cycle after the command sequence, the last status read cycle and the array data read cycle.

Figure 7. AC Waveforms for Toggle Bit During Embedded Algorithm Operations

Figure 8. Alternate CE# Controlled Write Operation Timings

Notes:

PA = address of the memory location to be programmed.

PD = data to be programmed at byte address.

VA = Valid Address for reading program or erase status

D_{OUT} = array data read at VA

Shown above are the last two cycles of the program or erase command sequence and the last status read cycle

Reset# shown to illustrate t_{RH} measurement references. It cannot occur as shown during a valid command sequence.

Figure 9. DQ2 vs. DQ6

Table 17. Temporary Sector Unprotect

Parameter Std	Description	Test Setup	Speed	Unit
			-70	
t_{VIDR}	V_{ID} Rise and Fall Time	Min	500	ns
t_{RSP}	RESET# Setup Time for Temporary Sector Unprotect	Min	4	μ s

Note: t_{RSP} is Not 100% tested.

Figure 10. Temporary Sector Unprotect Timing Diagram

Figure 11. Sector Protect/Unprotect Timing Diagram

Notes:

1. Use standard microprocessor timings for this device for read and write cycles.
2. For Sector Protect, use $A6=0, A1=1, A0=0$. For Sector Unprotect, use $A6=1, A1=1, A0=0$.

Figure 12. 48L TSOP 12mm x 20mm package outline

SYMBOL	DIMENSION IN MM		
	MIN.	NOR	MAX
A	---	---	1.20
A1	0.05	---	0.15
A2	0.95	1.00	1.05
D	19.80	20.00	20.20
D1	18.30	18.40	18.50
E	11.9	12.00	12.10
e	---	0.50	---
b	0.17	0.22	0.27
L	0.5	0.60	0.70
L1	---	0.25	---
R	0.08	---	0.20
θ	0°	3°	5°

Note : 1. Coplanarity: 0.1 mm

2. Max. allowable mold flash is 0.15 mm
at the pkg ends, 0.25 mm between leads.

Figure 13. 48L TFBGA 6mm x 8mm package outline

SYMBOL	DIMENSION IN MM		
	MIN.	NOR	MAX
A	---	---	1.30
A1	0.23	0.29	0.35
A2	0.84	0.91	0.95
D	7.90	8.00	8.10
E	5.90	6.00	6.10
D1	---	5.60	---
E1	---	4.00	---
e	---	0.80	---
b	0.35	0.40	0.45

Note : 1. Coplanarity: 0.1 mm

Technical drawing of a microchip package showing top, side, and detail views with dimensions and labels.

Top View:

- Overall width: 4.00 ± 0.10
- Overall height: 6.00 ± 0.10
- Label: A1 LAND PAD CORNER
- Label: A1 BALL PAD CORNER
- Pin grid dimensions: 0.50 (pitch), (0.50) (offset), (1.25) (offset), 0.50 (pitch).
- Pin grid columns: 6, 5, 4, 3, 2, 1
- Pin grid rows: A, B, C, D, E, F, G, H, J, K, L

Side View:

- Lead height: 0.08 C
- Lead thickness: 0.20 ± 0.05
- Lead width: 0.63 ± 0.10
- Ball diameter: $\phi 0.30 \pm 0.05$

Note : Controlling dimensions are in millimeters (mm).

Absolute Maximum Ratings

Parameter		Value	Unit
Storage Temperature		-65 to +150	°C
Output Short Circuit Current ¹		200	mA
Voltage with Respect to Ground	A9, OE#, Reset# ²	-0.5 to +11.5	V
	All other pins ³	-0.5 to $V_{CC}+0.5$	V
	V_{CC}	-0.5 to +4.0	V

Notes:

1. No more than one output shorted at a time. Duration of the short circuit should not be greater than one second.
2. Minimum DC input voltage on A9, OE#, RESET# pins is -0.5V. During voltage transitions, A9, OE#, RESET# pins may undershoot V_{SS} to -1.0V for periods of up to 50ns and to -2.0V for periods of up to 20ns. See figure below. Maximum DC input voltage on A9, OE#, and RESET# is 11.5V which may overshoot to 12.5V for periods up to 20ns.
3. Minimum DC voltage on input or I/O pins is -0.5V. During voltage transitions, inputs may undershoot V_{SS} to -1.0V for periods of up to 50ns and to -2.0V for periods of up to 20ns. See figure below. Maximum DC voltage on output and I/O pins is $V_{CC} + 0.5V$. During voltage transitions, outputs may overshoot to $V_{CC} + 1.5V$ for periods up to 20ns. See figure below.
4. Stresses above the values so mentioned above may cause permanent damage to the device. These values are for a stress rating only and do not imply that the device should be operated at conditions up to or above these values. Exposure of the device to the maximum rating values for extended periods of time may adversely affect the device reliability.

Recommended Operating Ranges¹

Parameter	Value	Unit
Ambient Operating Temperature Industrial Devices	-40 to 85	°C
Operating Supply Voltage V_{CC}	Full Voltage Range: 2.7 to 3.6V	V

Notes:

1. Recommended Operating Ranges define those limits between which the functionality of the device is guaranteed.

Maximum Negative Overshoot
Waveform

Maximum Positive Overshoot
Waveform
