Added the operation frequency of AD converted to 16 MHz max. 7. Added the operation frequency of SPI to 16 MHz max. 8. Modified some values of the Electrical characteristics table particularly RPU1, RPU2, RPU3. 9. Modified the single key control method for Port A. 10. Added UART baud rate setting in the Code Option. 11. Added ADPCM encoder / decoder in Section 2.4, Elan Software support. 12. Modified the current consumption in Idle mode (Idd4) with LCD enabled. 13. Modified the operation temperature range: -10°C to +70°C 14. Added the LCD code option and the circuit design method : 1/3 bias small current setting. 15. Removed Bit 2 (DLNPU) and Bit 0 (DLNDC) of DCRDE (R36h). 	2006/05/23

1 General Description

The **EPD3331** is an 8-bit RISC MCU embedded with the following features:

- 10-bit SAR A/D converter with touch screen controller
- Analog front end, 32 × 64 LCD driver
- Two 8-bit timers and one 16-bit general timer with capture and event counter functions
- Embedded large size user RAM and program/data memory
- Watchdog timer, SPI, UART, and four melody timers
- PWM or current D/A
- IR generator

The **EPD3331** is ideally suitable for educational learning tools application that requires high performance and low cost solution.

The MCU core is ELAN's second generation RISC (RISC II) based IC. The core is specifically designed as a low power and portable device. It supports Fast, Slow, and Idle mode, as well as Sleep mode for low power consumption application.

IMPORTANT NOTES

- *Do not use Register BSR (05h) Bit 7 ~ Bit 5.*
- *Do not use Register BSR1 (07h) Bit 7 ~ Bit 5.*
- *Do not use Special Register (04h).*
- *Do not use Special Register (1Bh).*
- *Do not use Special Register (1Ch).*
- *Do not use Special Register (1Fh).*
- *Do not use Special Register (2Ah).*
- *Do not use Special Register (32h).*
- *Do not use Special Register (33h).*
- *Do not use Special Register (39h).*
- *Do not use Special Register (4Fh).*
- *Do not use LCD RAM Page 00 (40h~4Fh).*
- *Do not use LCD RAM Page 01 (40h~4Fh).*
- *Do not use LCD RAM Page 02 (40h~4Fh).*
- *Do not use LCD RAM Page 03 (40h~4Fh).*
- *Do not use LCD RAM Page 04 (40h~4Fh).*
- *Do not use LCD RAM Page 05 (40h~4Fh).*
- *Do not use Port B.3~4.*
- *Do not use Port C.0~1.*
- *Do not use Port D.0~3.*
- *Do not use JDNZ and JINZ at FSR1 (09h) special register.*
- *Do not use Register TABPTRH (0Dh) Bit 6.*
- *Do not use "MOV A,r" with PUSH, POP to avoid affecting S_Z.*

1.1 Applications

- Educational Learning Tools
- Kids PDA, Kids computer
- Electronics book
- Dictionary, Data Bank

2 Features

2.1 MCU Features

- 8 bit RISC MCU
- 8×8 multiplier with controllable signed or unsigned operation
- Operating voltage and speed: 16~11 MHz @ 2.9V~3.6V, 10 MHz @ 2.2V~3.6V
- One Instruction cycle time = 2 × System clock time
- Program ROM addressing: 64K words max.
- Data ROM addressing: 512K words max.
- 28 bytes un-banked RAM including special registers and common registers
- 32×128 bytes banked RAM
- RAM stack has a maximum of 128 levels
- Look-up Table function is fast and highly efficient when implemented with Repeat instruction
- Register-to-Register move instruction
- Compare and Branch in one instruction (2 cycles)
- Single Repeat function (256 repeat times max.)
- Decimal Add and Sub instruction
- Full range Call and Jump capability (2 cycles)

2.2 Peripheral

- One input port (Port A) and 32 general I/O pins (Port B.7~5, Port B.2~0, Port C.7~2, Port D.7~4, Port G ~ Port H)
- 4-channel Melody/Speech Synthesizer
- 32 COM × 64 SEG LCD driver embedded or supplied with 96 segments for external LCD driver that is compatible with EM65168 which has 48 COM × (96+32) SEG.
- 16-bit timer (Timer 0) with capture and event counter functions

- 8-bit timer (Timer 1) with wake-up function
- 8-bit timer (Timer 2) as beat counter for Melody function
- 8-bit IR generator
- 8-bit PWM or a current D/A for melody and speech application
- 8-bit Watchdog Timer
- 10 bits resolution SAR A/D converter with 4 channels general analog input and 2 channels for touch panel application
- Key I/O function with 112 keys maximum
- SPI (Serial Peripheral Interface)
- UART (Universal Asynchronous Receiver and Transmitter)

2.3 Internal Specification

- Watchdog Timer with on-chip RC oscillator
- MCU mode: Sleep Mode, Idle Mode, Slow Mode, and Fast Mode
- Supports RC oscillation and crystal oscillation for system clock
- PLL is turned on at Fast mode, and controlled by the PEN bit when the MCU is in Slow mode and Idle mode
- MCU Wake-up function includes input wake up, Timer 1 wake up, touch panel wake up, SPI wake up, and A/D wake up
- MCU interrupt function includes Input port interrupt, touch panel interrupt, Capture interrupt, speech timer interrupt, Timer interrupt (Timers 0~2), A/D interrupt, SPI interrupt and UART interrupt
- MCU reset function includes power-on reset, RSTB pin reset, and Watchdog timer reset

2.4 ELAN Software Support (Option)

- Hand writing recognition
- LCD display
- 4-channel Melody or 3-channel Melody + 1-channel Speech
- ADPCM decoder
- ADPCM encoder

5 Pin Description

5.1 MCU System Pins (9 Pins)

Name	I/O/P Type	Description
AVDD VSS	P	Analog positive power supply ranging from 2.2V ~ 3.6V. Connect to VSS through the capacitors (0.1µF).
VDD VSS	P	Digital positive power supply ranging from 2.2V~3.6V. Connect to VSS through the capacitors (0.1µF)
RSTB	I	System reset input with built-in pull-up resistor (100KΩ Typ.) Low: RESET asserted High: RESET released
TEST	I	Normally connects to VSS. Reserved for testing use
OSCI/RC OSCO	I O	RC or Crystal selection by Code Option 32768 Hz oscillator pins: Connect to VSS through a capacitor (20pF) RC oscillator connector pin: Connect to VDD through a resistor (2MΩ)
PLLC	I	PLL capacitor connector pin: Connect to VSS through a capacitor (0.047µF)
VREX	I/O	External or internal reference voltage for A/D converter: Connects to VSS through a capacitor (0.1µF)

5.2 Embedded LCD Pins (94 Pins)

Name	I/O/P Type	Description
COM0~COM31/ SEG80~SEG111	O	LCD common/segment signal output pin Multiplexed: Common and segment pin
SEG0~SEG47	O	LCD segment signal output pin (SEG0~SEG15 are shared with key strobe)
CL	I/O	Display clock input/output pin
FR	I/O	LCD frame signal input/output pin
Vx	-	Clamping circuit output voltage. Ext. C (0.1µF) to VSS
Vout	-	Charge pump output voltage. Ext. C (0.22µF) to VSS
VR	-	V0 voltage adjusting pin
V0~V4	O	LCD bias pin. Ext. C (0.1µF) to VSS
C1+, C1-, C2+, C2-	-	Charge pump capacitor (0.1µF) 2 times pumping (charge pump capacitor C1:0.1µF) 3 times pumping (charge pump capacitor C1 & C2:0.1µF)

5.3 I/O Ports (40 Pins)

Name	I/O/P Type	Description
Port A	I	General Input port for special functions, i.e., Wake-up and Interrupt Bit 7: ON key input Bits 6~0: Key matrix input pins
Port B (7~5, 2~0)	I/O	General Input/Output port
	I	Bit 7: UART Rx pin
	O	Bit 6: UART Tx pin
	I	Bit 5: Event counter/Capture input pin
	O	Bit 2: IR output pin
	O	Bit 1: PWM or Current D/A output pin
	O	Bit 0: PWM output pin
Port C (7~2)	I/O	General Input/Output port
	O	Bit 7: Touch screen X direction negative pin
	O	Bit 6: Touch screen Y direction negative pin
	I	Bit 5: Touch screen X direction positive pin & A/D input Channel 3
	I	Bit 4: Touch screen Y direction positive pin & A/D input Channel 4
	I	Bit 3: A/D input Channel 5
	I	Bit 2: A/D input Channel 6
Port D (7~4)	I/O	General Input/Output port
	I	Bit 7: Serial data input pin
	O	Bit 6: Serial data output pin
	I/O	Bit 5: Serial clock Input/Output pin
	I	Bit 4: /Slave Select pin
Port G	I/O	General Input/Output port
	O	SEG 55~48: LCD segment signal output pins
Port H	I/O	General Input/Output port
	O	SEG 63~56: LCD segment signal output pins

7 Functional Description

7.1 Reset Function

A reset can be caused by:

- Power-on voltage detector reset and power-on reset
- WDT timeout
- RSTB pin pull low

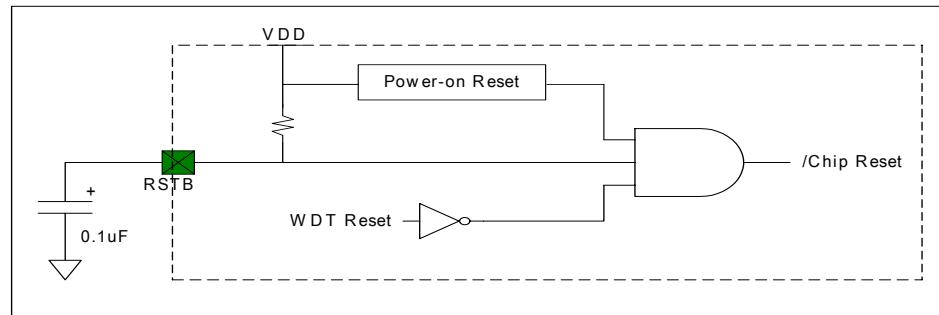

Figure 7-1 On-chip Reset Circuit

7.1.1 Power-up and Reset Timing

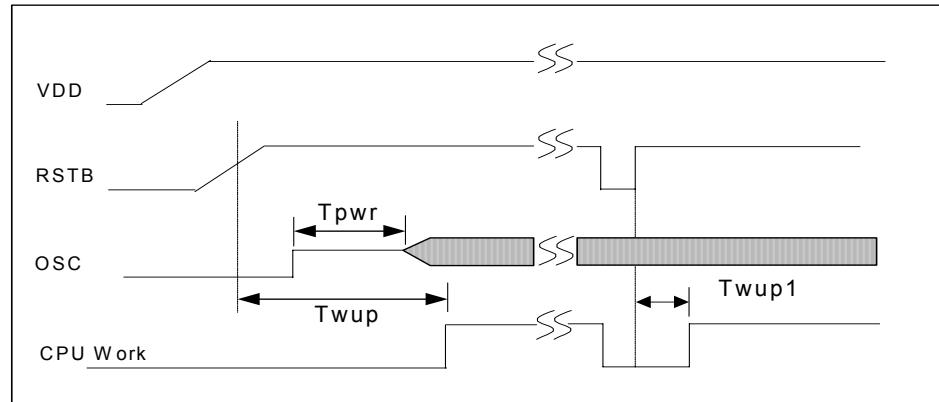

Figure 7-2 Power-up and Reset Timing

Symbol	Characteristics	Min.	Typ.	Max.	Unit
Tpwr	Oscillator start up time	100	226	300	ms
Twup	CPU warm up time	260	340	550	ms
Twup1	CPU reset time	18	22	44	ms

■ Status (R0Fh)

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
/TO	/PD	SGE	SLE	OV	Z	DC	C

Bit 0 (C): Carry flag or inverse of Borrow flag (B)

When in SUB operation, borrow flag is indicated by the inverse of carry bit (B = /C)

Bit 1 (DC): Auxiliary carry flag

Bit 2 (Z): Zero flag

Bit 3 (OV): Overflow flag. Use in signed operation when Bit 6 carry into or borrow from a signed bit (Bit 7).

Bit 4 (SLE): Computation result is less than or equal to zero (Negative value) after a signed arithmetic. It is only affected by a HEX arithmetic instruction.

Bit 5 (SGE): Computation result is greater than or equal to zero (Positive value) after a signed arithmetic. It is only affected by a HEX arithmetic instruction.

NOTE

1. When OV=1 after a signed arithmetic, you can check the SGE and SLE bits to determine whether an overflow (carry into a signed bit) or underflow (borrow from a signed bit) occurs.

OV=1 and SGE=1 → overflow occurs

OV=1 and SLE=1 → underflow occurs

2. When overflow occurs, you should clear the MSB of the Accumulator in order to get the correct value.

Example 1 ADD a positive value to another positive value, and ACC signed bit will be affected.

```
MOV ACC, #60h ; Signed number +60h.  
ADD ACC, #70h ; +60h ADD WITH +70h.
```

After instruction: ACC = 0D0h

SGE=1, means the result is greater than or equal to 0 (positive value)

OV=1, means the result is carried into a signed bit (Bit 7), overflow occurs.

Correct the signed bit: ACC = 50h (Clear the signed bit)

The actual result= +80h (OV=1) + 50h = +0D0h

Example 2 SUB a positive value from a negative value, and ACC signed bit will be affected.

```
MOV ACC, #50h ; Signed number +50h.  
SUB ACC, #90h ; +50h SUB from -70h (Signed number of 90h)
```

After instruction: ACC = 40h

SLE=1, means the result is less than or equal to 0 (negative value)

OV=1, means the result is borrowed from a signed bit (Bit 7), underflow occurs.

Correct the signed bit: ACC = 0C0h (Set the signed bit)

The actual result = -80h (OV=1) + 0C0h (signed number of 0C0h) = 40h

Bit 6 (/PD): Reset to “0” when entering Sleep mode.

Set to “1” by “WDTC” instruction, during power-on reset, or during a Reset pin low condition.

Bit 7 (/TO): Reset to “0” during WDT time out reset.

Set to “1” by “WDTC” instruction, when entering Sleep Mode, during power-on reset, or during a Reset pin low condition.

When a reset occurs, the special function register will be reset to its initial value except for the /TO and /PD bits of the Status register.

Bit 7 (/TO)	Bit 6 (/PD)	Event
0	0	WDT time-out reset from Sleep mode
0	1	WDT time-out reset (not Sleep mode)
1	0	Reserved
1	1	Power-on or RSTB pin low condition

“c” = value depending on the condition

¹ Not a physical register

² Bit 0 (MS0) of RE (CPUCON) is reloaded from “INIM” bit of code option when the MCU is reset

³ If it is a power-on reset or RSTB pin is at low condition, the /TO bit and /PD bit of RF (Status) are set to “1”. If it is a WDT time out reset, the /TO bit is cleared and /PD bit is unchanged.

7.2 Oscillator System

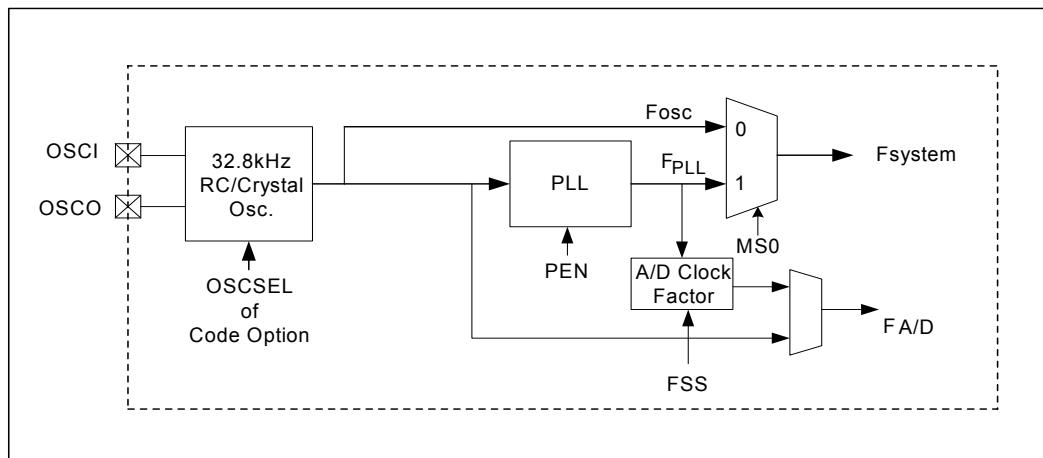

Figure 7-3 Oscillator System Function Block Diagram

7.2.1 32.768kHz Crystal or 32.8kHz RC

For the 32.8kHz RC oscillator, connect a 2MΩ pull-up resistor to OSCI pin and the OSCO pin should be floating.

For the 32.768kHz Crystal oscillator, connect the crystal between OSCI and OSCO pins. Then connect the OSCI and OSCO pins to ground through a 20pF capacitor.

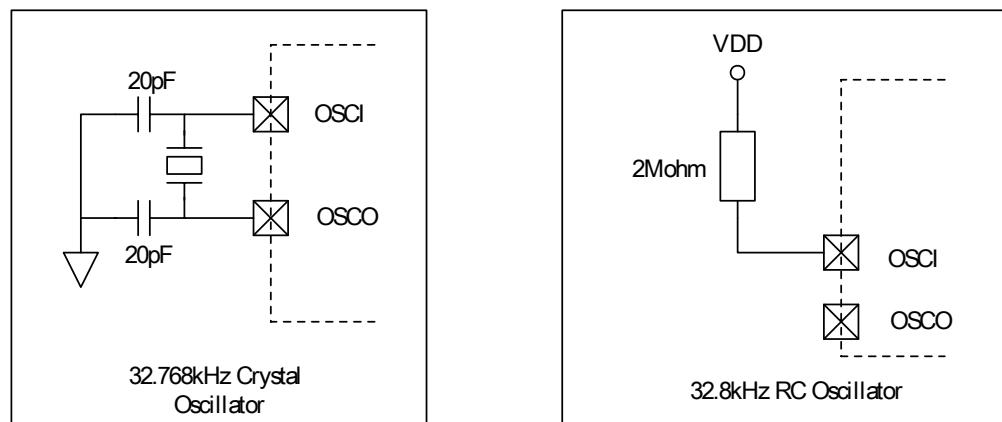

Figure 7-4 Crystal and RC Oscillator Circuit Diagram

7.2.2 Phase-Locked Loop (PLL)

- **PLLF (R3Ch):** Store the actual PLL frequency value. It is used to check whether the PLL frequency is stable or not.

$$F_{actual} = 2 \times PLLF \times F_{OSC}$$

- **PFS (R20h): Target PLL frequency select register.** System clock can be fine tuned from 0.983MHz to 16MHz. The initial value of the PFS register after a chip reset is set at “20h” (FPLL=2.097 MHz)

$$F_{target} = 2 \times PFS \times F_{OSC}$$

61	3.998	153	10.027
76	4.981	255	16.712

¹ PFS=0~14 are not available.

² When UART is enabled, the system clock should be at 9.83MHz (PFS=150) or 14.745 MHz (PFS=225).

The table is based on 32.768kHz oscillator frequency.

The maximum range of PLL is 983kHz ~ 16.712MHz.

Sleep Mode: When MS1 bit is set to '0' and "SLEP" instruction is executed, the MCU will enter into Sleep mode.

Idle Mode When MS1 bit is set to '1' and "SLEP" instruction is executed, the MCU will enter into Idle mode.

Slow Mode: When MS0 bit is set to '0', the MCU will enter into Slow mode.

Fast Mode: When MS0 bit is set to '1', the MCU will enter into Fast mode.

PLL enable: It is only effective when the MCU is in Idle mode or Slow mode.

NOTE

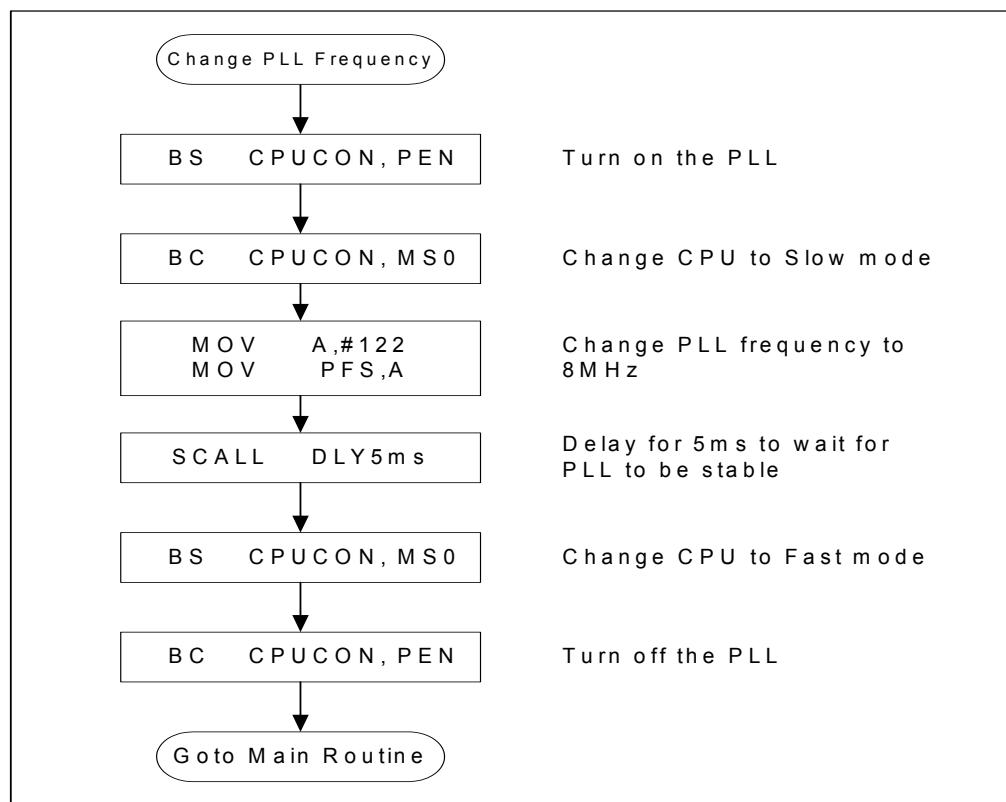

1. Switch from Slow mode to Fast mode at Time=0 ms
2. The System clock will switch to FPLL after 8 oscillation clocks, and the system clock will then increase to about hundreds of kHz.
3. The PLL frequency will be stable ($\pm 5\%$) at Time=Ts (2ms~5ms).

7.5 Interrupt

When an interrupt occurs, the **GLINT** bit of the CPUCON register is reset to '0', which disables all interrupts, including Level 1 ~ Level 5. Setting this bit to '1' will enable all un-mask interrupts.

Interrupt Level	Interrupt Source	Start Address	Remark
—	Reset	0x00000	—
Level 1	Input Port	0x00002	PAINT, PIRQB
Level 2	Capture	0x00004	CPIF
Level 3	Speech Timer	0x00006	SPHTI
Level 4	Timers 0~2	0x00008	TMR0I, TMR1I, TMR2I

7.5.1 Input Port A Interrupt

1. Port A Interrupt (Falling edge trigger): Port A is used as external interrupt/wake-up input.
2. Touch Panel Interrupt (Level trigger): When Port C.7~Port C.4 (X+, X-, Y+ & Y-) are connected to touch panel input pins and the touch panel is touched, PIRQB interrupt occurs.

■ Code Example:

```

;==Input Port And Touch Panel Interrupt
INPTINT:
    S0CALL  PUSH
    JBC    ADCON,PIRQB,toTPINT
    TEST   PAINTSTA

7.5.2 Capture Input Interrupt

The Capture function is used to capture an input event at rising to falling edge, falling to rising edge, rising to rising edge, or falling to falling edge. When every event input edge is detected, a Capture interrupt occurs.

■ **Code Example:**

<code>; === Capture Input Interrupt</code>	<code>; ---Capture input interrupt</code>
<code>CAPINT:</code>	<code>toCAPINT:</code>
<code> S0CALL PUSH</code>	<code> BS INTSTA,CPIF</code>
<code> JBS INTSTA,CPIF,toCAPINT</code>	<code> :</code>
<code> SJMP POP</code>	<code> SJMP POP</code>

7.5.3 Speech Timer Interrupt

Speech Timer is an 11-bit timer for time counting. When the counting value of the Speech Timer underflows, an interrupt occurs and the SPHTRL value will be reloaded to counting value.

■ **Code Example:**

<code>; === Speech Timer Interrupt</code>	<code>; --- To speech timer interrupt</code>
<code>SPHINT:</code>	<code>toSPHINT:</code>
<code> S0CALL PUSH</code>	<code> BC SPHTCON,SPHTI</code>
<code> JBS PHTCON,SPHTI,toSPHINT</code>	<code> :</code>
<code> SJMP POP</code>	<code> SJMP POP</code>

7.5.4 Timer 0, Timer 1, and Timer 2 Interrupts

1. Timer 0 Interrupt: Timer 0 is a 16-bit timer for general time counting. When the counting value is larger than TRL0H : TRL0L value, a Timer 0 interrupt occurs.
2. Timer 1 Interrupt: Timer 1 is an 8 bit-timer for time counting and wake-up function. When the counting value of Timer 1 underflows, an interrupt occurs and the TRL1 value will be reloaded to counting value.
3. Timer 2 Interrupt: Timer 2 is an 8-bit timer for time counting. When the counting value of Timer 2 underflows, an interrupt occurs and the TRL2 value will be reloaded to counting value.

■ **Code Example:**

<code>; === Timer-0,1,2 Interrupt</code>	<code>; --- Timer 0 Interrupt</code>
<code>TIMERINT:</code>	<code>toTM0INT:</code>
<code> S0CALL PUSH</code>	<code> BC INTSTA,TMR0I</code>

	<code> SJMP POP</code>
	<code>; --- Timer 2 Interrupt</code>
	<code>toTM2INT:</code>
	<code> BC INTSTA,TMR2I</code>
	<code> :</code>
	<code> SJMP POP</code>

7.5.5 Peripheral Interrupt

1. A/D (Analog to Digital converter) Interrupt: A/D is used to convert analog input signal to digital output bits. When the conversion is completed, an A/D interrupt occurs.
2. UERRI Interrupt: UART receiving error interrupt
3. UTXI Interrupt: UART transfer buffer empty interrupt
4. URXI Interrupt: UART receiver buffer full interrupt
5. SRBFI Interrupt: SPI read buffer full interrupt

■ Code Example:

```

; === Peripheral Interrupt

7.10 Special Registers Description

■ STKPTR (R06h)

The stack level starts from the bottom going up (in a decreasing order), starting from OFFh of Bank 31.

Stack is located at Bank 30 and 31 from Address FFh~80h. Initial top position of stack pointer is located at 00h.

Bits 0~6 of STKPTR are used as address pointer from 80h~FFh, Bit 7=1 is used to select Bank 31, Bit 7=0 is used to select Bank 30.

Each INT/CALL will stack two bytes address, total capacity is 128 levels.

■ PCL, PCM (R02h, R03h): Program Counter Register

Bit 15	...	Bit 8	Bit 7	...	Bit 0
	PCM				PCL

Generates up to 64K×16 on-chip ROM addresses at the relative programming instruction codes.

“S0CALL” loads the low 12 bits of the PC (4K×16 ROM).

“SCALL” or “SJUMP” loads the low 13 bits of the PC (8K×16 ROM).

“LCALL” or “LJUMP” loads the full 16 bits of the PC (64K×16 ROM).

“ADD R2, A” or “ADC R2, A” allows a relative address to be added to the current PC. The carry bit of R2 will automatically carry into PCM.

■ Code Example:

```
START: MOV    A,entry
        MOV    number,a ;number <- entry
        LCALL Indirect_JUMP
AAA:   .....
        .....

Indirect_JUMP:
        MOV    A,number
        ADD    A,ACC      ; A<- 2*A
        ADD    PCL,A      ; PCL<- PCL+A

        LJMP   Function_Address_2 ;number=1
        LJMP   Function_Address_3 ;number=2

-	LCD_ID	FSR1_ID	FSR0_ID	-	LCDPE	FSR1PE	FSR0PE

Bit 0 (FSR0PE): Enable FSR0 post increase/decrease function, FSR0 will *NOT* carry into or borrow from BSR.

Bit 1 (FSR1PE): Enable FSR1 post increase/decrease function, FSR1 will carry into or borrow from BSR1.

Bit 4 (FSR0_ID): Setting to 1 means auto increase, resetting to 0 means auto decrease of FSR0.

Bit 5 (FSR1_ID): Setting to 1 means auto increase, resetting to 0 means auto decrease of FSR1.

◊ Indirect Addressing Pointer 0

- **BSR (R05h):** is determining which bank is active (working bank) among the 32 banks (Bank 0 ~ Bank 31).
- **FSR0 (R01h):** is an address register for INDF0. User can select up to 256 bytes (Address: 00 ~ OFFh).
- **INDF0 (R00h):** is not a physically implemented register.

◊ Indirect Addressing Pointer 1

- **BSR1 (R07h):** is a bank register for INDF1. Cannot determine the working bank for the general register.
- **FSR1 (R09h):** is an address register for INDF1. User can select up to 128 bytes (Address: 80 ~ OFFh); Bit 7 of FSR1 is fixed to 1.
- **INDF1 (R08h)** is not a physically implemented register.

■ Code Example:

```
;Data transform Bank0 to Bank1:
    MOV      A,#00110011B      ;Enable FSR0 & FSR1 post increase
    MOV      POST_ID,A
    BANK    #0                  ;BSR = 0 working bank
    MOV      A,#1
    MOV      BSR1,A             ;BSR1 = 1 is Bank 1
    MOV      A,#80H
    MOV      FSR0,A              ;FSR0 = 80H
    CLR      FSR1                ;FSR1 = 80H
    MOV      A,#80H
    RPT      ACC
    MOVRP   INDF1,INDF0          ;Move 80H ~ OFFH data to Bank 1
    :
```

8 Peripheral

8.1 Timer 0 (16-bit Timer with Capture and Event Counter Functions)

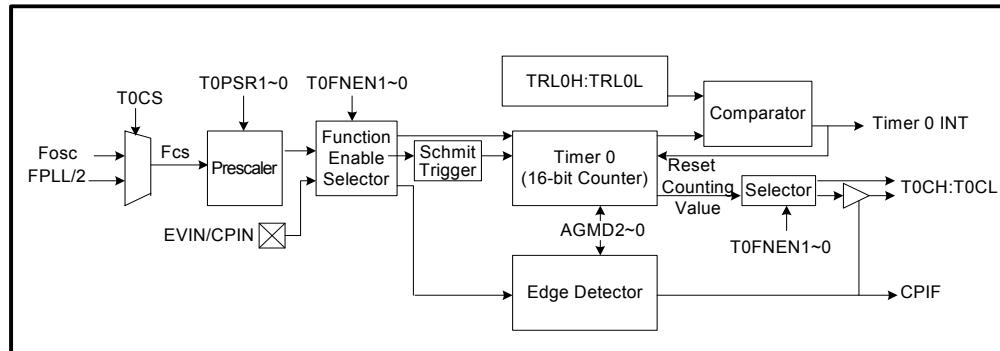

Figure 8-1 Timer 0 Function Block Diagram

8.1.1 Timer 0 Mode

In this mode, Timer 0 is used as a general-purpose 16-bit up counter offering an interrupt for your application.

A prescaler is also available for the timer. The T0PSR2~T0PSR0 bits of the TR01CON register determine the prescaler ratio and generate different clock rates for the timer clock source. Counter value will be incremented by one (counting up) according to the timer clock source and stored into the T0CH: T0CL register. The clock source (Fcs) is selected from Fosc or $F_{PLL}/2$ by T0CS and pre-scaled by T0PSR1~0. When the counting value is larger than TRL0H: TRL0L value, Timer 0 interrupt will occur, and the counter value will automatically reset to zero.

$$T = \frac{1}{F_{cs}} \times \text{Prescaler} \times (TRL0H : TRL0L + 1)$$

■ Timer 0 Frequency:

Clock Source	Fper / 2	TRL0H:TRL0L	Prescaler	Timer 0 Freq.
Fosc (32.768kHz)	-	FFFFh	1:64	128Hz
Fpll (8MHz)	4MHz	00FFh	1:1	15.6kHz
Fpll (16MHz)	8MHz	00FFh	1:1	31.2kHz

8.1.2 Capture Mode: CPIN (Port B.5) Pin

Capture is a function that captures the Timer 0 value when an event occurs on CPIN pin.

The counter value is captured at: 1st rising edge, 2nd falling edge, etc.; 1st falling edge, 2nd rising edge, etc.; every rising edge or every falling edge selected by AGMD2~0 bit of the SFCR register. When an event edge is detected from the CPIN input pin, the interrupt flag CPIF is set. If a new event edge is detected before the old value in T0CH: T0CL register is read, the old captured value will be lost.

The CPIN pin should be configured in capture function input by setting T0FNEN1~0 bits of TR2CON register.

$$T = \frac{1}{F_{CS}} \times \text{Prescaler} \times [(T0CH : T0CL)_{\text{NEW}} - (T0CH : T0CL)_{\text{OLD}}]$$

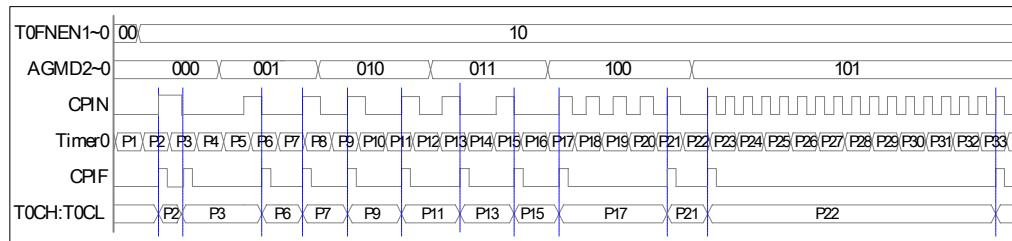

Figure 8-2 Capture Mode Example Timing Diagram

8.1.3 Event Counter Mode: EVIN (Port B.5) Pin

Event counter is a function wherein the 16-bit counter value increments by one when an event occurs on EVIN pin at every rising edge or every falling edge selected by AGMD2~0 bit of the SFCR register. In other words, the Timer 0 clock source is from an external event (EVIN pin).

The EVIN pin should be configured in event counting function input by setting the T0FNEN1~0 bits of the TR2CON register. The counting value of Timer 0 will be stored in T0CH: T0CL registers.

8.2 Timer 1 (8 Bits)

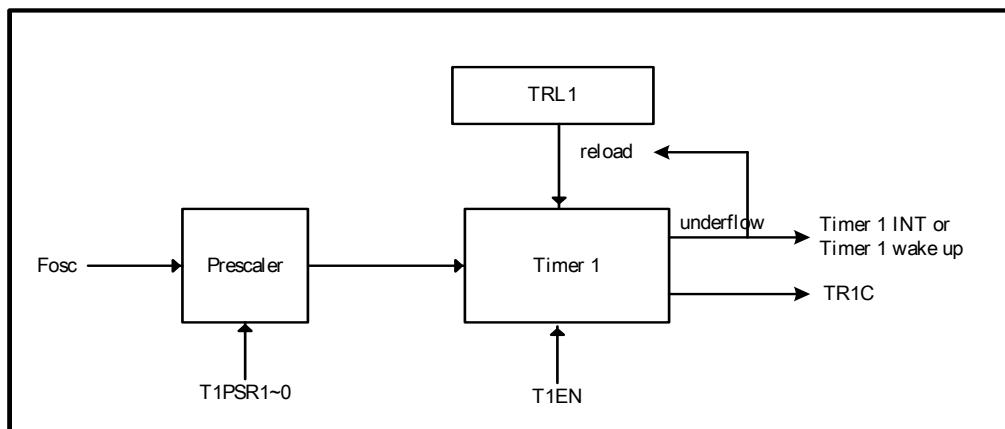

Figure 8-4 Timer 1 Function Block Diagram

Timer 1 is a general-purpose 8-bit down counter for applications requiring time counting. There are interrupt and wake up function available for user's application. The clock source is from the oscillator clock.

There is also a prescaler for the timer. The **T1PSR1~T1PSR0** bits of the TR01CON register determine the prescaler ratio and generate different clock rates for the timer clock source. Setting **T1WKEN** bit of the TR01CON register to '1' will enable the Timer 1 underflow wake-up function in Idle Mode.

Counting value will be decremented by one (count down) according to the real timer clock source. When the counter underflows, the timer interrupt is triggered if the global interrupt and Timer 1 interrupt are both enabled. At the same time, the TRL1 value will automatically reload into the 8 bits counter.

$$T = \frac{1}{F_{osc}} \times \text{Prescaler} \times (TRL1 + 1)$$

The Timer 1 frequency range is from 0.5Hz (TRL1 = 0FFh, prescaler = 1:256) to 8.192kHz (TRL1 = 0h, prescaler = 1:4). The clock source is from the oscillator clock (Fosc).

8.2.1 Timer 1 Registers Description

8.4 IR Generator: IROT (Port B.2) Pin

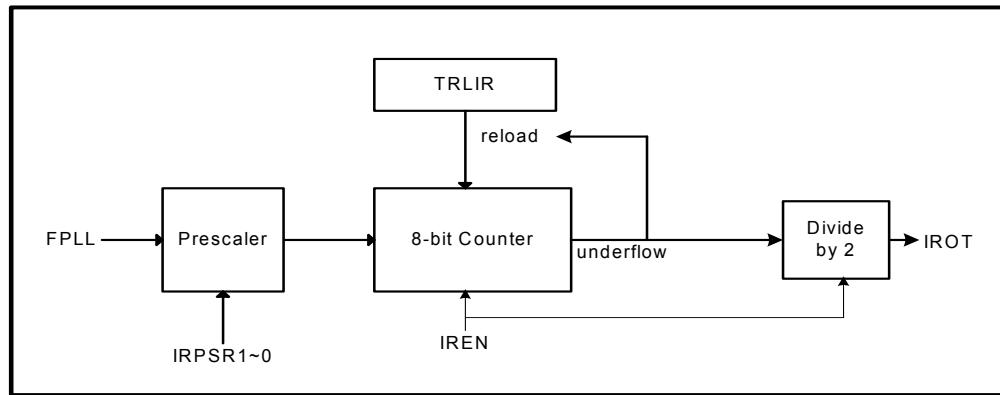

Figure 8-6 IR Generator Function Block Diagram

The IR function is enabled by IREN bit and output on the IROT (Port B.2) pin by a general-purpose 8-bit down counter. When IREN is low, the T-flip-flop should be initialized, as IROT equals zero. The clock source is from the PLL clock. The IRPSR1 ~ IRPSR0 bits of the TR2CON register determine the prescaler ratio and generate different clock rates for the timer clock source. The counting value will be decremented by one (counting down) according to the clock source. When the counter value underflows, the IR reload register value will be reloaded into the counter.

8.5 Watchdog Timer (WDT)

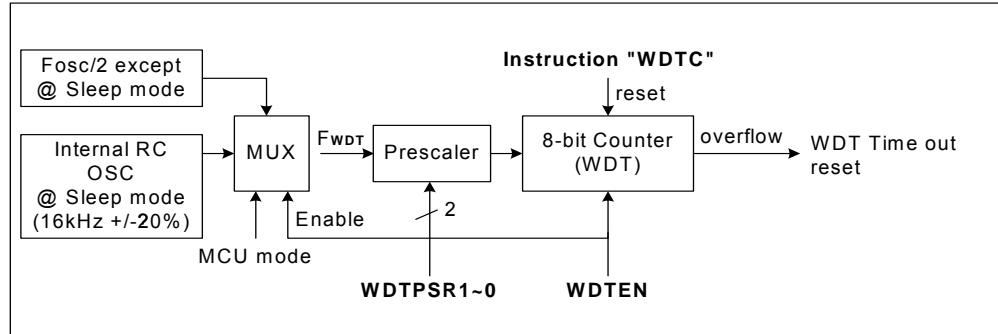

Figure 8-7 Watchdog Timer Function Block Diagram

The watchdog timer (WDT) clock source is from the on-chip RC oscillator (16kHz \pm 20%, MCU in Sleep mode) or $F_{osc}/2$ (MCU in Fast, Slow or Idle mode). The WDT will keep on running even when the oscillator has been turned off (i.e., in Sleep Mode). WDT time-out will cause the MCU to reset (if WDT is enabled). To prevent a reset from occurring, you should clear the WDT value by using the “WDTC” instruction before WDT time-out. The WDTEN bit must be set to ‘1’ (Enable) as the WDT function is disabled by default. A prescaler that generates different clock rates for the WDT clock source is also available. The prescaler ratio is defined by WDTPSR1 ~ WDTPSR0.

$$T = \frac{1}{F_{WDT}} \times \text{Prescaler} \times (WDT + 1)$$

The WDT time out range is 64ms (prescaler = 1:4) to 2.048 second (prescaler = 1:128).

8.6 Universal Asynchronous Receiver Transmitter (UART)

- RS232C compatible
- Mode selectable (7/8/9-bit) with/without parity bit
- Baud rate selectable
- Error detect function
- Interrupt available for Tx buffer empty, Rx buffer full, and receiver error
- TXD and RXD port inverse output control

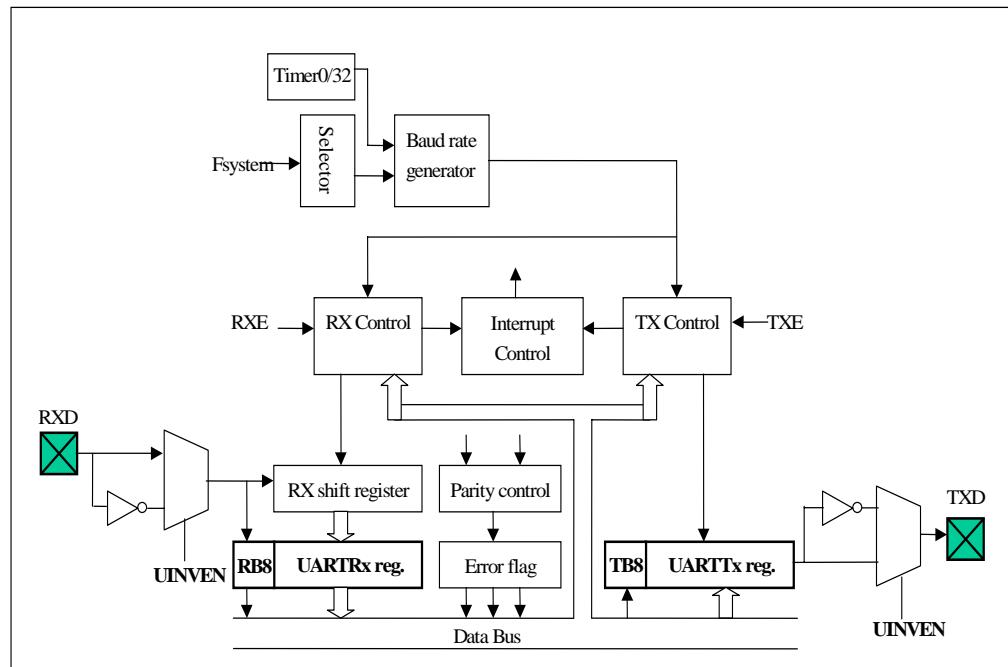

Figure 8-8 UART Function Block Diagram

In Universal Asynchronous Receiver Transmitter (UART), each transmitted or received character is individually synchronized by framing it with a start bit and stop bit.

Full duplex data transfer is possible because the UART has independent transmit and receive sections. Double buffering in both sections enables the UART to be programmed for continuous data transfer.

The figure below shows the general format of one character sent or received. The communication channel is normally held in the marked state (high). Character transmission or reception starts with a transition to the space state (low).

The first bit transmitted or received is the start bit (low). It is followed by the data bits, in which the least significant bit (LSB) comes first. The data bits are followed by the parity bit. If present, then the stop bit or bits (high) confirm the end of the frame.

In receiving, the UART synchronizes on the falling edge of the start bit. When two or more "0's" are detected during three sampling, it is recognized as a normal start bit and receiving operation starts.

8.6.1 Data Format in UART

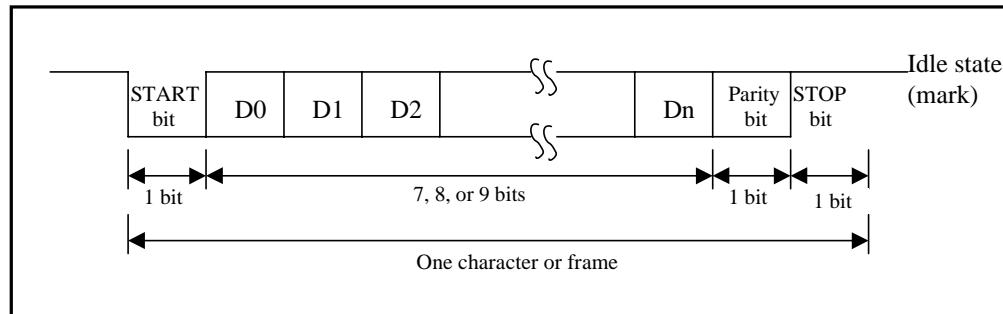

Figure 8-9 UART Data Format Diagram

8.6.2 UART Modes

There are three modes in UART. Mode 1 (7 bits data) and Mode 2 (8 bits data) allow the addition of a parity bit. The parity bit addition is not available in Mode 3. The figure below shows the data format in each mode.

	UMODE	PRE	1	2	3	4	5	6	7	8	9	10	11
Mode 1	0	0	0	START	7 bits DATA	STOP							
	0	0	1	START	7 bits DATA	Parity	STOP						
Mode 2	0	1	0	START	8 bits DATA	STOP							
	0	1	1	START	8 bits DATA	Parity	STOP						
Mode 3	1	0	X	START	9 bits DATA	STOP							

Figure 8-10 UART Modes Data Format

8.6.3 UART Transmit Data

In transmitting serial data, the UART operates as follows:

- Set the **TXE** bit of the UARTCON register to enable UART transmission function.
- Write data into the UARTRX register, and the **TBE** bit of the UARTCON register will be set by hardware. Then start transmitting.
- Serially transmitted data are transmitted in the following order from the TXD pin:
 - Start bit: one "0" bit is output
 - Transmit data: 7, 8, or 9 bits data are output from LSB to MSB
 - Parity bit: one parity bit (odd or even selectable) is output
 - Stop bit: one "1" bit (stop bit) is output
 - Mark state: output "1" continues until the start bit of the next transmit data
- After transmitting the stop bit, the UART generates a **UTXI** interrupt (if enabled)

8.6.4 UART Receive Data

1. Sets the **RXE** bit of the **UARTCON** register to enable the UART receiving function.
2. The UART monitors the RXD pin and synchronizes internally when it detects a start bit.
3. Received data is shifted into the **UARTRX** register in LSB to MSB sequence.
4. The parity bit and the stop bit are received. After one character is received, the UART generates a **URXI** interrupt (if enabled). And the **URBF** bit of the **UARTSTA** register is set to '1'.
5. The UART performs the following checks:
 - a) Parity check: The number of "1" in the receive data must match with the even or odd parity setting of the **EVEN** bit in the **UARTSTA** register.
 - b) Frame check: The start bit must be "0" and the stop bit must be "1."
 - c) Overrun check: the **URBF** bit of the **UARTCON** register must be cleared (i.e., the **UARTRX** register should be read out) before the next received data are loaded into the **UARTRX** register.

If any of the above checks failed, the **UERRI** interrupt will be generated (if enabled). And the error flag is indicated in **PRERR**, **OVERR** or **FMERR** bit. The error flag should be cleared by software, otherwise, a **UERRI** interrupt will occur when the next byte is received.

6. Read the received data from the **UARTRX** register. The **URBF** bit will be cleared by hardware.

8.6.5 UART Baud Rate Generator

- The baud rate generator comprises of a circuit that generates a clock pulse which determines the transfer speed of the transmitted/received data in the UART.
- The input clock of the baud rate generator is derived from the system clock divided by 64 or from Timer 0 divided by 32.
- The system clock should be at 9.830 MHz (PFS = 150) or 14.745MHz (PFS=225) when UART is enabled.
- The BRATE2 ~ BRATE0 bits of the **UARTCON** register can determine the desired baud rate.

8.7 A/D Converter

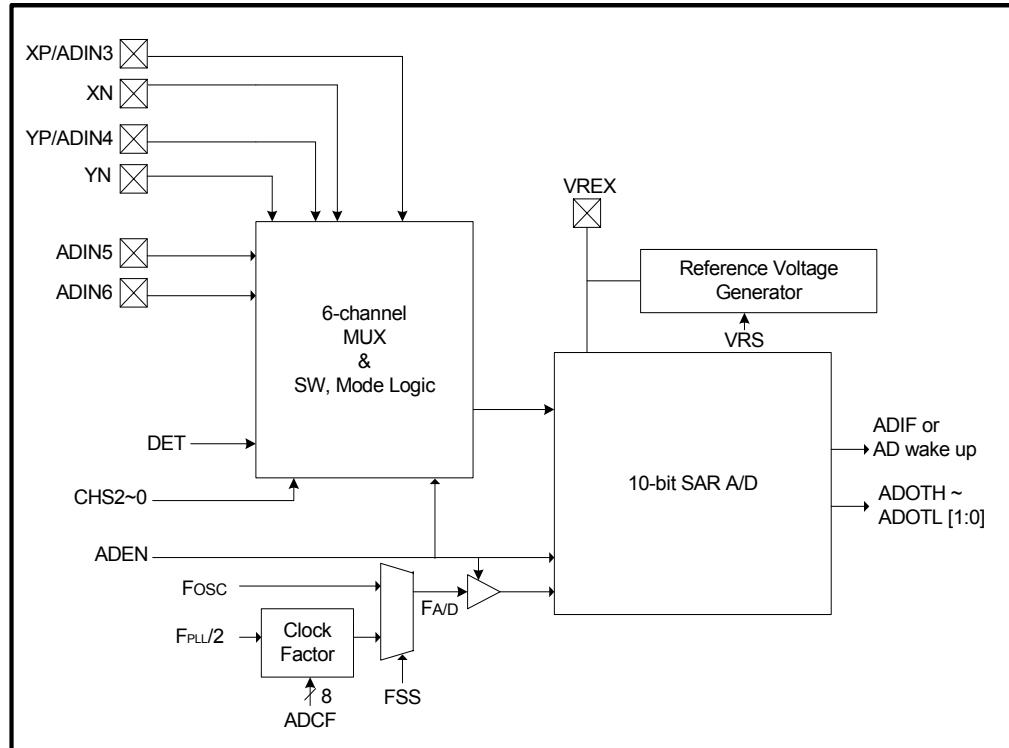

Figure 8-15 A/D Converter Function Block Diagram

Where:

VREX: Reference voltage I/O pin
 When VRS=1; it is input pin
 When VRS=0, it is output pin

XN (Port C.7): X negative position input

YN (Port C.6): Y negative position input

XP/ADIN3 (Port C.5): X positive position input or A/D input Channel 3

YP/ADIN4 (Port C.4): Y positive position input or A/D input Channel 4

ADIN5 (Port C.3): A/D converter input Channel 5

ADIN6 (Port C.2): A/D converter input Channel 6

This A/D has 6 channels and 10-bit resolution. When the MCU is in Slow or Fast mode and ADEN=1, A/D conversion runs immediately. The two channels; XP and YP have low resistance switches for driving the touch screens. The other 4 channels are for general application.

The A/D converter operation for touch panel application is as follows:

Step 1: Pen down detection

If the touch panel is not tapped, the PIRQB is high. When the touch panel is tapped, the PIRQB is low and PIRQB interrupt occurs (if INT is enabled).

Step 2: Measure the X position

If the PIRQB remains low and steady for awhile, the DET bit is cleared, then the PIRQB returns to high and the X position is measured.

Step 3: Measure the Y position

Y position is measured immediately after Step 2.

Step 4: Back to Step 1

8.8 Key I/O

The 7-pin key input (Port A.0~6) and 16-pin key strobe (shared with LCD SEG0~15) can achieve a maximum of 112-key matrix.

8.8.1 Automatic Key Scan or Software Key Scan

Interrupt is enabled when in automatic key scan (**SCAN=1**). Wake-up is also enabled when key input falling edge is detected under automatic key scan mode (**SCAN=1**).

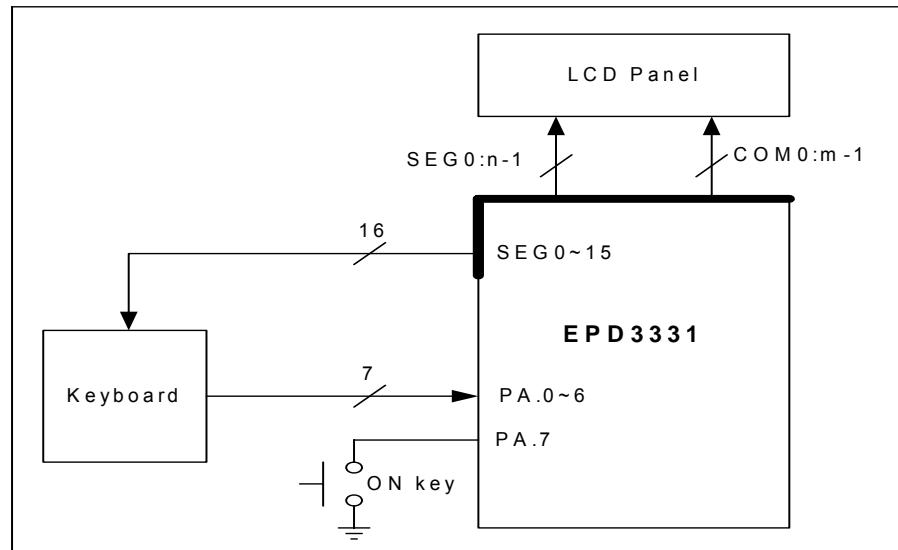

Figure 8-18 Keyboard Function Block Diagram

As shown in the above figure, it is taken into consideration that the Key strobe output has resistance R_{ON} , as well as each key, has resistance K_{ON} and capacitance C . Since a prolonged strobe output makes an LCD display confusing, strobe output should be as short as possible. So R_{IN} (pull-up resistance) should be low enough for the capacitance to be charged quickly. But R_{IN} should be high enough for V_{IN} to be ascertained in "L" level ($R_{IN} \gg R_{ON} + K_{ON}$). Hence, the value of R_{IN} should be flexible.

The following are the "Key input process":

1. Output the strobe signal
2. Pull up the input port by lowest resistance (R1 and R2 enabled): Capacitance is charged quickly.
3. Pull up the input port by highest resistance (only R2 is enabled).
4. Read the key
5. Disable the pulled-up resistance
6. Stop the strobe signal

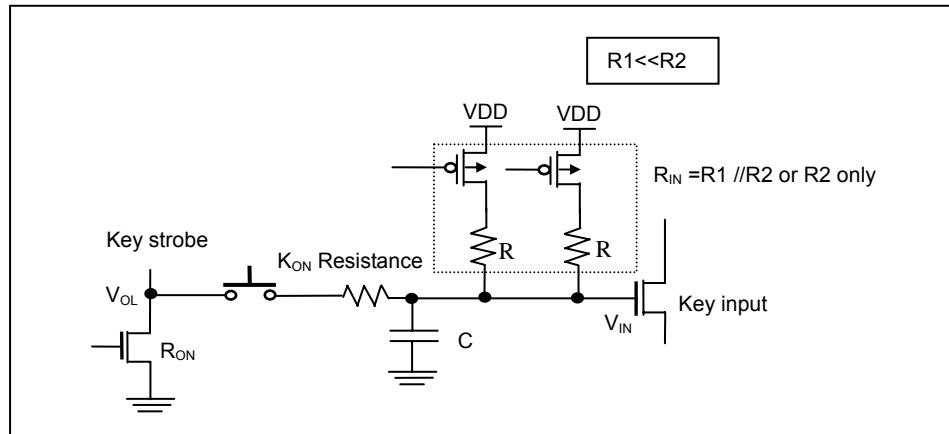

Figure 8-19 Key Circuit Diagram

The detailed function is summarized in the following table:

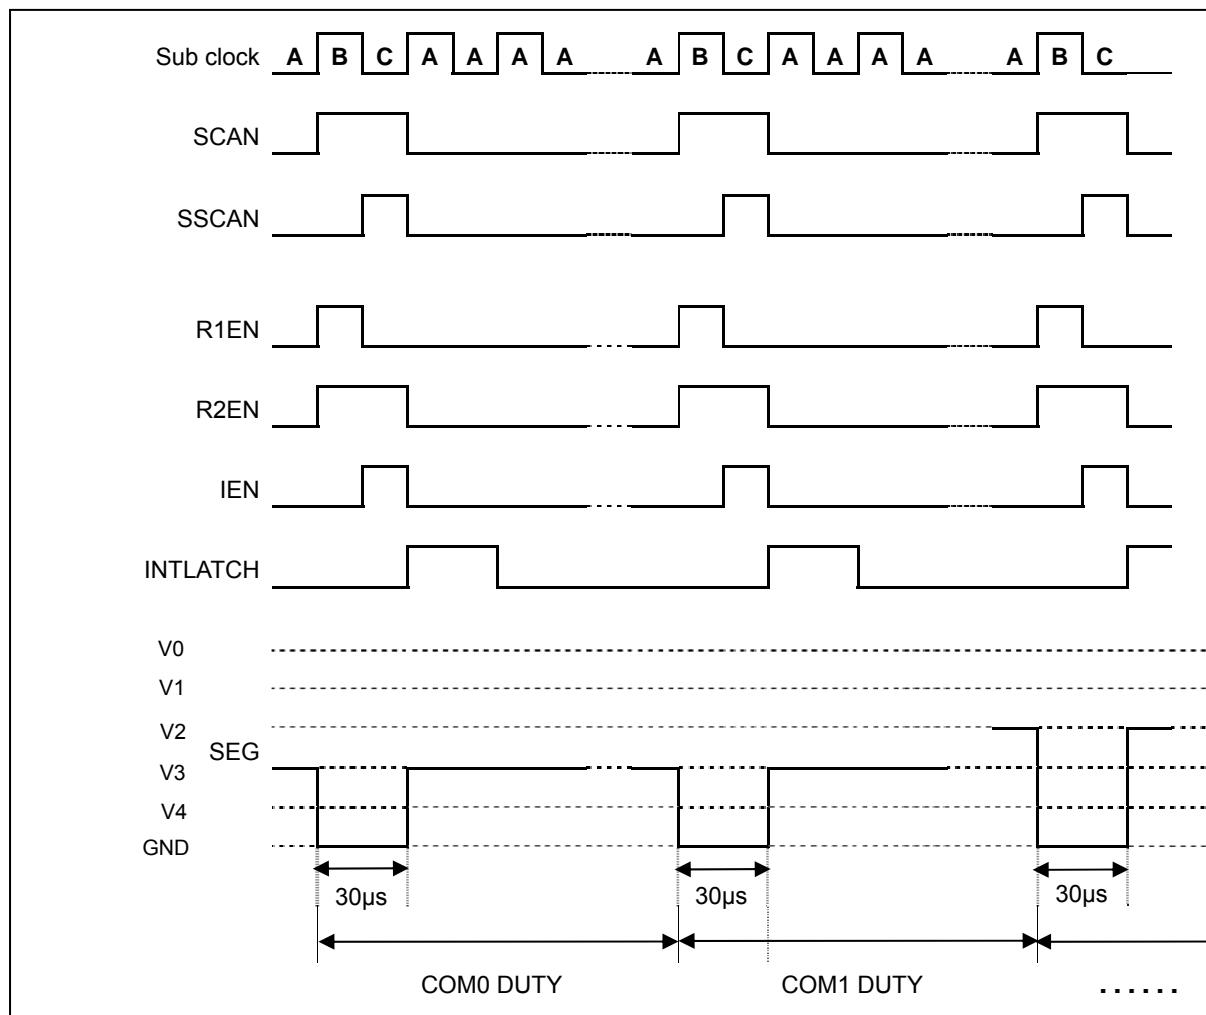

Figure 8-20 Automatic Key Scan Timing Diagram (SCAN = 1)

The Key strobe pin shares with the LCD segment pin in the CPU with embedded LCD driver model.

When a pin is shared with an LCD segment, the strobe output should be as short as possible to avoid a confusing LCD display.

There are two ways to output a strobe signal:

■ Automatic Key Scan

The LCD waveform has a 30µs low pulse at the beginning of every common duty signal when the **SCAN** bit of the STBCON register is set. The strobe timing is as shown in the following figure (Figure 8-21).

When in automatic key scan mode, the PAINT or Port A wake-up must be enabled. During Key scan, wake-up and interrupt will occur if key input pin (Port A) falling edge is detected.

■ Software Key Scan

Segment is switched to strobe signal temporally by setting the **BitST** bit of the STBCON register to “1” and the **SCAN** bit to “0”.

Setup the **STB3~STB0** bits of the STBCON register to select which pin will be the strobes.

In this mode you can set **All** bits of the STBCON register to let Segments 0~15 to be kept at GND level.

In **Idle Mode**, during automatic key scanning, if PA.0~7 pin falling edge is detected (when IEN=1), wake-up will occur. Then the CPU runs and interrupt occurs (if enabled).

In **Slow Mode** or **Fast Mode**, both automatic key scan and software key scan will be used.

Automatic key scan is used to check **whether any key is pressed**. If a key is pressed, PA.0~7 pin falling edge will be detected, then an **interrupt occurs**.

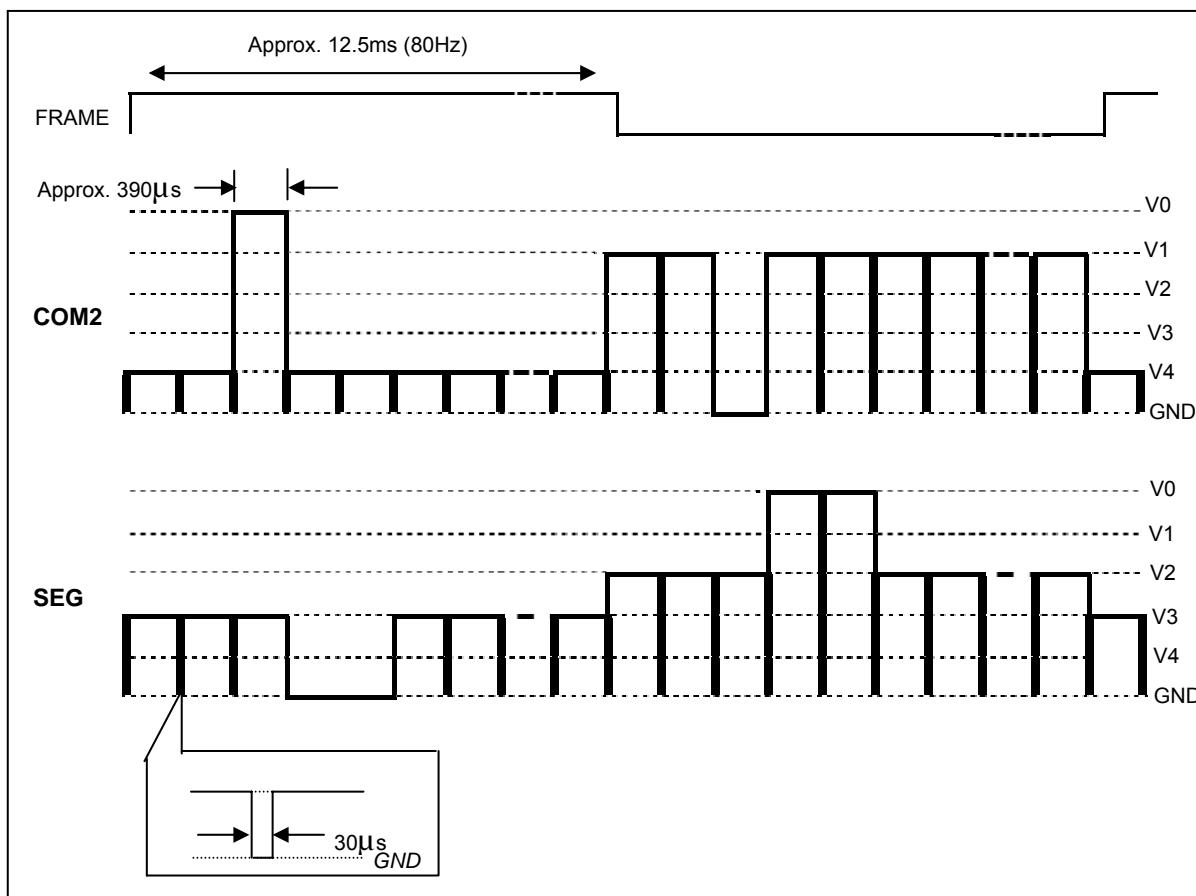

Figure 8-21 Automatic Strobe Signal (SCAN = 1)

Software key scan checks which key is pressed.

The key strobe pin function is as shown in the following table:

8.9 LCD Driver

The **EPD3331** provides direct driven LCD. It supports multiplex drive for 64SEG×32COM or up to 96 segments with external COM driver. It is also able to use pads as an LCD driver pin or as input/output port. The duty ratio is selected by the LCDCONC register. An LCD RAM for direct correspondence is available with LCD Pixel. Charge pump can pump 2 or 3 times of Vx. The LCD contrast has 32 adjustable levels and the LCD bias is selectable. The maximum LCD operating voltage can be determined by external resistor Ra and Rb. Furthermore, multiple frame frequencies are provided to reduce power consumption.

This embedded LCD driver contains power supply circuits and generates waveforms for display drive.

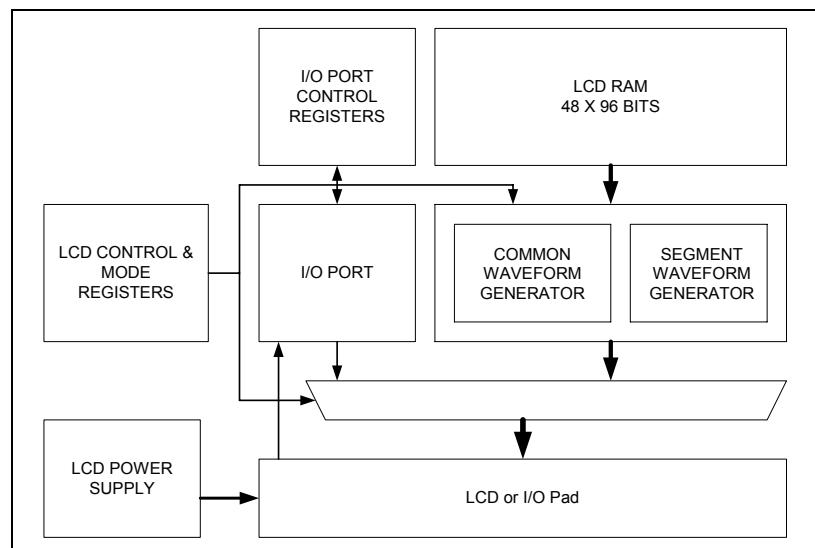

Figure 8-22 Function Block Diagram

The internal power supply circuits generate the voltage levels that drive the liquid crystal driver circuits at low-power consumption and with least required components. Also available are voltage converter (V/C) circuits, voltage regulator (V/R) circuits, and voltage follower (V/F) circuits.

The internal power supply circuit is shown in the following figure.

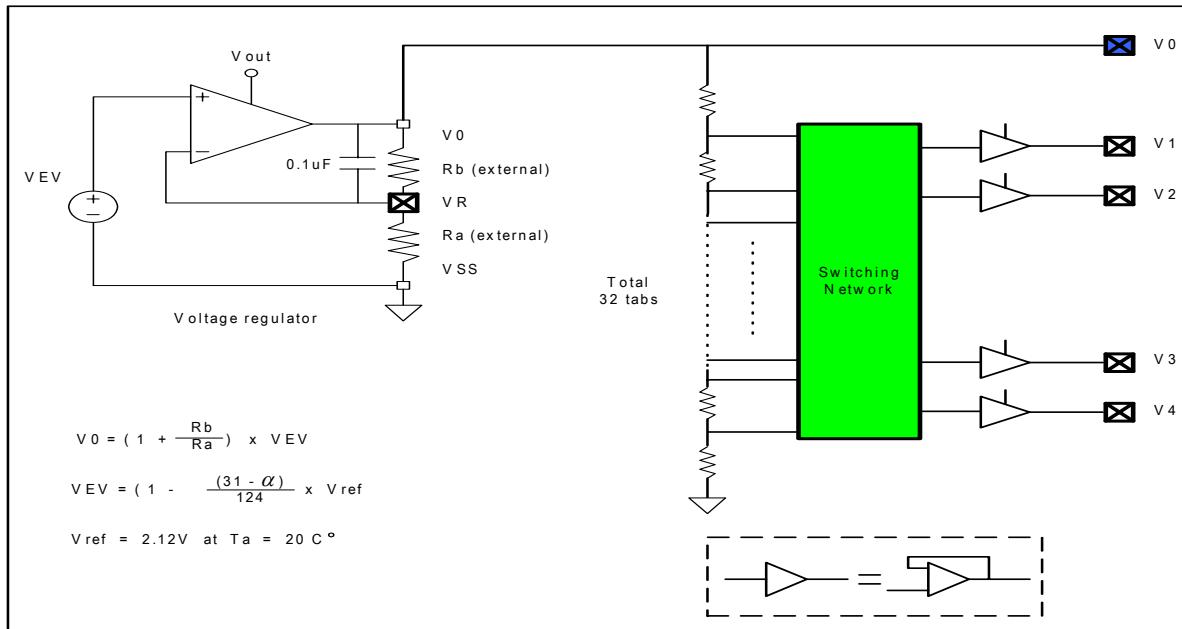

Figure 8-23 Internal Power Supply Circuit

1/6.5	0.845*V0	0.690*V0	0.310*V0	0.155*V0

The built-in voltage converter (boost circuit), generates twice or triple boosted voltage output to VOUT pin. And VOUT provides the operating voltage for the operational-amplifier circuits. The external capacitors must be connected as shown in the figure at right.

Different duty ratio requires different bias level. For optimum bias level, B_L can be calculated from the following equation:

$$B_L = \frac{1}{\sqrt{\text{Duty ratio} + 1}}$$

Setting to the optimum bias level will have a better result on contrast and view angle.

8.10 Serial Peripheral Interface (SPI)

- Operation in either Master mode or Slave mode
- Three-wire or 4-wire full duplex synchronous communication
- Programmable Shift Register Length (24/16/8 bits)
- Programmable communication bit rates
- Programmable clock polarity
- Programmable shift direction
- Programmable sample phase
- Interrupt flag available for the read buffer full
- Up to 4 MHz (system clock at 16 MHz) bit frequency

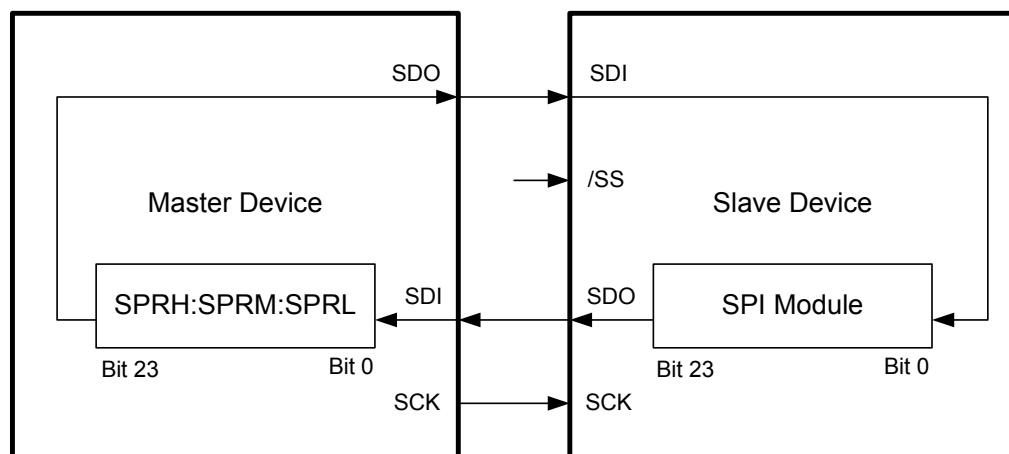

Figure 8-26a Single SPI Master/Slave Communication

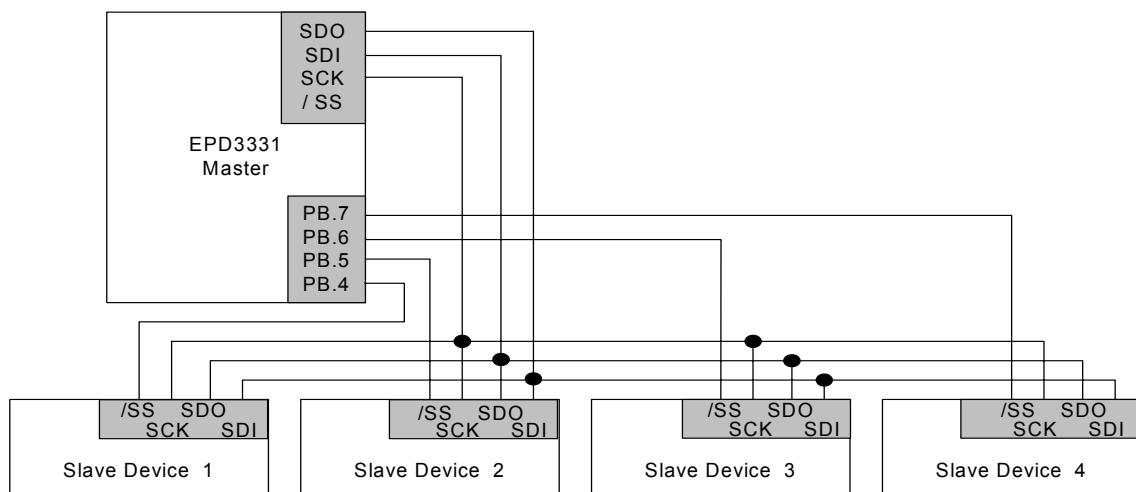

Figure 8-26b SPI Configuration Example of Single-Master and Multi-Slaves

The MCU communicates with other devices through an SPI module. If the MCU is defined as the master controller, it sends clock through the SCK pin. An 8-bit data is transmitted and received at the same time. If the MCU, however, is defined as a slave, its SCK pin could be programmed as an input pin. Data will continue to be shifted at selected clock rate and selected edge.

Setup of the **TLS1 ~ TLS0** bits of the SPICON register can select the shift register length of the SPI and enable/disables the SPI function. Setting up the **BRS2 ~ BRS0** bits of the SPICON register can define the SPI mode (Master/Slave) and Bit Rate. When in Master mode, the clock source can be selected from the system clock or half of Timer 0 interval. When in Slave mode, the **ISS** pin can be enabled or disabled. Setting up the **DORD** bit of the SPICON register can determine the shift direction. Setting up the **EDS** bit of the SPICON register can select either rising edge or falling edge to latch the data.

Setting up the **SMP** bit of the SPISTA register can select the sample phase either at the middle or at the end of data output time.

■ Master Mode

In Master mode, the SCK pin functions as a clock output pin.

If a 24-bit shift register length is selected, SPRH, SPRM, and SPRL registers are the high, middle, and low bytes of the shift register respectively (likewise, if an 8-bit shift register length is selected, SPRL register is the content of the shift register). Data are written into SPRH, SPRM, and SPRL registers. After writing data into the SPRL register, the **SE** bit of the SPICON register is automatically set by hardware and starts shifting. After a shift buffer is empty, the **SE** bit is cleared by hardware and stops clock output from the **SCK** pin.

The receiver is active during SPI transfer. When the receiving buffer is full, the **RBF** flag will be set and an interrupt occurs (if enabled). During a read out of the shift register contents, and after the SPRL register has been read out, the hardware will automatically clear the **RBF** flag. If SPRL register has not been read out and **RBF** bit still remains set, data collision will occur during the next clock input.

■ Slave Mode

In Slave mode, the input clock is from the Master device. **SCK** pin is a clock input pin. The **SE** bit is not used to control the starting shift in this mode. It is used as a Transfer buffer empty status bit.

As with the Master Mode, you can also select the shift register length in Slave mode. Transfer data are written to SPRH, SPRM, SPRL registers. After writing data into the SPRL register, the **SE** bit of SPICON register is then set by hardware. However, the shifting start is controlled by the Master device clock input.

When the shift buffer is empty the **SE** bit will be cleared. At the same time, when the receive buffer is full, the **RBF** flag will be set and an interrupt occurs (if enabled). The received data are written in SPRH, SPRM, and SPRL registers. You should read them out before the next clock input. Otherwise, data collision will occur and the **DCOL** bit of the SPISTA register will be set.

8.10.1 SPI Pin Description

SDI (I): Serial Data Input pin. Receives data serially

SDO (O): Serial Data Output pin. Serially transmits data. In Slave mode, defined as high-impedance, if not selected.

SCK (I/O): Serial Clock input/output pin. When in Master mode, sends clock through the SCK pin. However, in Slave mode, SCK pin is programmed as an input pin.

/SS (I): /Slave Select pin. This pin becomes active when /SS function is enabled. (BRS=110), else /SS pin is a general purpose I/O.

Master device remains low for /SS pin to signify the slave(s) for transmit/receive data. Ignore the data on the SDI and SDO pins when /SS pin is high, since the SDO is no longer driven.

8.10.2 SPI Applicable Registers

■ **SPRH; SPRM; SPRL (R41h; R42h; R43h):** SPI shift buffer for 24/16/8 bits length.

The buffer will ignore any write until shifting is completed. If you select the 24 bits shift buffer, it will include the SPRH, SPRM, and SPRL. However, if 8 bits shift buffer is selected, only the SPRL register is included.

When writing data into the SPRL register, the **SE** bit of the SPICON register will be set by hardware and shifting starts. When the shift buffer is empty, and the receive buffer is full at the same time, the received data is shifted into SPRH, SPRM and SPRL registers. After the SPRL register has been read out, the hardware will automatically clear the **RBF** flag.

8.11 Melody/Speech Synthesizer

The EPD3331 MCU provides four channels for melody/speech function. Channels 1~3 are destined for melody channel, and Channel 4 can be either a melody or a speech channel as determined by SPHSB bit (Bit 2 of R44). Channels 1 ~ 4 are controlled by R45 ~ R4A of the corresponding control register Banks 0 ~ 3. Bits 0 ~ 2 of R44 are used to select the current control register bank.

8.11.1 Melody Function

The MCU melody function can effectively manage the instrument waveform address setting, instrument synthesis frequency control, and envelope control. It is embedded with four melody channels and with built-in large data ROM size for melody waveform data storage. To synthesize the instrument melody, you should write the starting address of the waveform to R45 ~ R47, setup the envelope value, and then enable the melody timer. The control registers are listed as follows:

- **ADDH, ADDM, ADDL (R47h ~ R45h): Address Registers** (Write-only registers)

These registers, i.e., ADDL, ADDM, and ADDH are treated as instrument waveform address. Each melody channel has its own waveform data address pointer that points to the waveform start address in the data ROM. The address values are written by the program and its total length is 24 bits.

- **ENV (R48h): Envelope Register**

The envelope register stores the envelope value for the current melody channel. The user's program should calculate the proper envelope value to obtain a suitable ADSR (Attack-Decay-Sustain-Release) for different instruments. The tone generator will automatically process the waveform data with the envelope and then synthesize the final instrument melody to the PWM or D/A converter mixer.

The data written to the envelope register should be a 7-bit unsigned value and located at Bits 0~6 (the corresponding envelope value must be 0 to 127), which means the envelope resolution is of 128 steps. The reset initial value is “0.”

- **MTRL (R4Ah): Melody Timer Auto-reload Register**

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
MTRL7	MTRL6	MTRL5	MTRL4	MTRL3	MTRL2	MTRL1	MTRL0

Melody timer is an 11-bit down counter for melody applications. The frequency generated by the melody timer is determined by the value of 11-bit melody timer auto-reload register (including MTRL and MTRLH0~2 of MTCON). When the counter value underflows, the timer will auto-reload. To obtain the correct frequency, consult a frequency reference table and fetch the correct value for MTRL and MTRLH0~2 of MTCON.

- **MTCON (R49h): Melody Timer Control Register**

The MTCON is used to determine the three MSB's of the 11-bit auto-reload register and to enable/disable the melody timer of the current melody channel. Once the melody timer is enabled, it will fetch the waveform data (pointed to by the address registers) from the data ROM, process the data with the envelope, and then automatically feed the data to the DAC or PWM mixer. . The reset initial value of the MTCON is “xxxx 0000”.

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
-	-	-	-	MTEN	MTRLH2	MTRLH1	MTRLH0

Bits 0 ~ 2 (MTRLH0 ~ MTRLH2): Bits 8 ~10 of the melody timer auto-reload register

Bit 3 (MTEN): Melody Timer Enable Control Bit

MTEN	Melody Timer Enable or Disable
0	Melody Timer Disable
1	Melody Timer Enable

8.11.2 Speech Function

The 11-bit speech timer is shared with a melody timer (MT4) for Channel 4. The clock source for the speech timer is from $F_{PLL}/2$. When R44 [2:0] = “1xx,” the control register bank will change to speech channel. An interrupt function is available for your application. The control registers are listed as follows:

$$Sampling_rate = \frac{F_{PLL}/2}{SPHTRL[10:0]+1}$$

■ **SPHDR (R48h):** Speech Data Register

In speech function control, SPHDR acts as an output window to the PWM and D/A converter mixer. The program should write the synthesized data to SPHDR, and the data is fed into the mixer at the next speech timer underflow. For correct mixing operation, the value to be written to SPHDR must be an 8-bit signed data. The reset initial value is “0”.

■ **SPHTRL (R4Ah):** Low byte of Speech Timer Auto-reload Register

The Speech timer is an 11-bit down counter for speech applications. The frequency generated by the speech timer is determined by the value of the 11-bit auto-reload register, including SPHTRL and SPHTRLH0 ~ SPHTRLH2 of SPHTCON. When the counter value underflows, the timer interrupt will occur and auto-reload from the 11-bit auto-reload register.

■ **SPHTCON (R49h):** Speech Timer Control Register

SPHTCON is used to determine the three MSB of the 11-bit auto-reload register and enable/disable the speech timer. The reset initial value of SPHTCON is “xx00 0000”.

8.12 PWM / DAC Function

The EPD3331 is embedded with two choices of melody/speech outputs, i.e., PWM and D/A converter.

When the PWM function is enabled, the voice output uses PWM to drive the speaker directly. The 8-bit PWM function block diagram is shown in the figure below. The PWD register is double buffered for glitch free operation.

When Bit 7 of PWD is “1” and the PWM timer counter equals to PWM value (Bits 0 ~ 6 of PWD), the VO1 will transfer to low until the PWM timer is reset or overflowed. The VO2 is always kept at “0” in this case.

When the Bit 7 of PWD is “0” and the PWM timer counter equals to the inverse of Bits 0 ~ 6 of PWD, the VO2 will transfer to low until the PWM timer is reset or overflowed. The VO1 is always kept at “0” in this case.

$$T_{period} = \frac{128}{F_{PLL}} \times Prescaler; \quad T_{duty} = \frac{1}{F_{PLL}} \times Prescaler \times (PWD + 1)$$

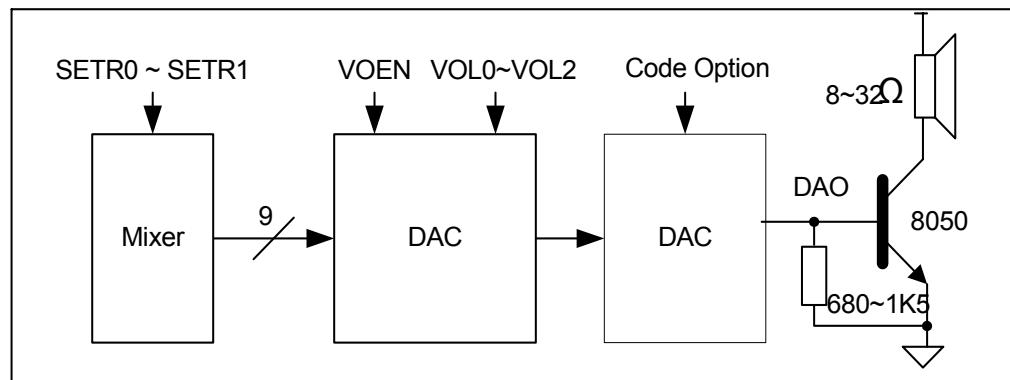

Figure 8-29 DAC Function Block Diagram

If both SPHSB and VOEN bits are set to “1” and SPHTEN bit is cleared to “0”, the data of the speech data register will output immediately through the D/A converter or PWM when the register changes.

111	8 (max.)

Bit 3 (PWMPSR): PWM Timer prescaler select bit

“0”: Prescaler 1:1

“1”: Prescaler 1:2

Bits 5 ~ 4 (SETR1 ~ SETR0): Set dynamic range

While mixing, the mixer accumulated result may have a large dynamic range (up to 11-bit), while DAC has only 9-bit resolution and PWM has only 8-bit. You can define a suitable output data range to prevent saturation condition from occurring.

SETR1~SETR0	Output Data fed to PWM / DAC
10	Take Bits 3~10 of mixer accumulation result for PWM Take Bits 2~10 of mixer accumulation result for DAC
01	Take Bits 2~9 of mixer accumulation result for PWM Take Bits 1~9 of mixer accumulation result for DAC
00 or 11	Take Bits 1~8 of mixer accumulation result for PWM Take Bits 0~8 of mixer accumulation result for DAC

Bit 7 (VOEN): Voice output control bit

“0”: DAC/PWM disabled

“1”: DAC/PWM enabled

¹ $TBRD i, r$:

$r \leftarrow ROM[(TABPTR)]$;
 $i=00$: TABPTR no change
 $i=01$: $TABPTR \leftarrow TABPTR+1$
 $i=10$: $TABPTR \leftarrow TABPTR-1$

² $TABPTR=(TABPTRH: TABPTRM: TABPTRL)$

Bit 0 = 0: Low byte of the pointed ROM data

Bit 0 = 1: High byte of the pointed ROM data

The maximum table look up space is internal 8Mbytes.

³ Carry bit of ADD PCL, A or ADD TABPTRL, A will automatically carry into PCM or TABPTRM.

The Instruction cycle for writing to the PC (program counter) takes 2 cycles.

⁴ When in SUB operation, borrow flag is indicated by the inverse of carry bit, i.e., $B = /C$.

⁵ The maximum jump range is 64K absolute address, which means it can only jump within the same 64K range.

⁶ S0CALL address ability is from 0x000 to 0xFFFF (4K space).
