

1 CHANNEL SYNCHRONOUS PWM CONTROL IC

GENERAL DESCRIPTION

The **FP5137** is a synchronous buck switching regulator control IC for DC-DC applications field. The **FP5137** includes a totem-pole high/low side stage for driving NMOS, high precision reference (1.25V) for comparing output voltage with feedback amplifier, an internal **200KHz** oscillator and programmable soft start function.

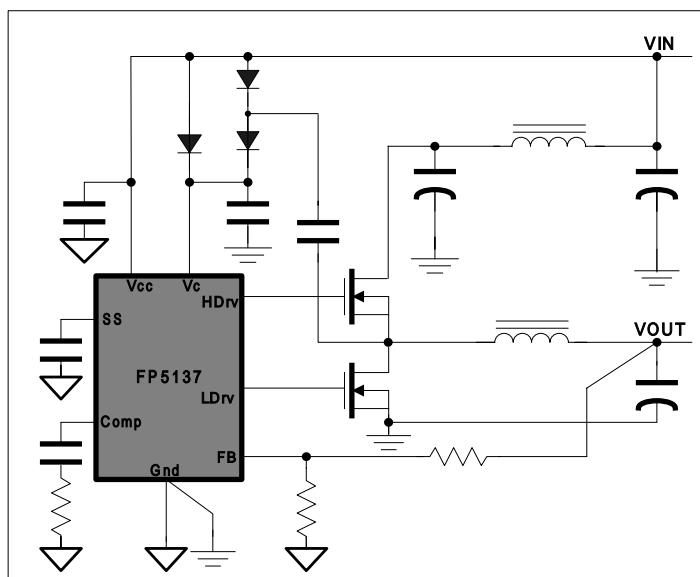

FEATURES

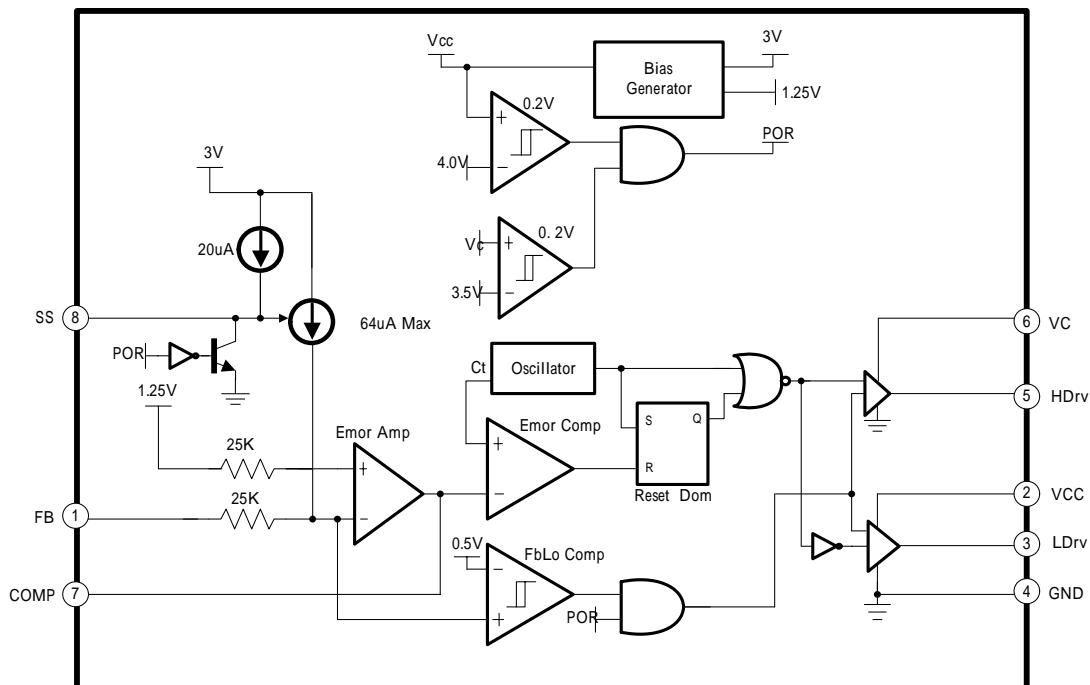

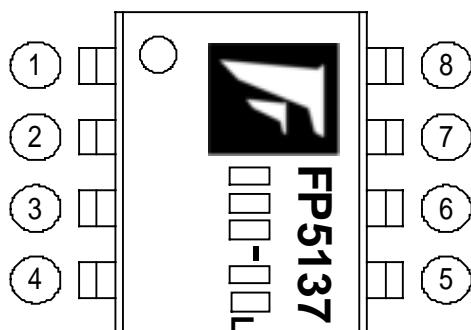

- Feedback Reference Voltage: 1.25V (2%)
- Peak Output Source/Drive Capability: 500mA
- Internal 200KHz Oscillator
- Programmable Soft Start function (SS)
- Short Circuit Protection function(SCP)
- Internal UVLO function
- Package: PDIP8/SOP8

SOP8

PDIP8

TYPICAL APPLICATION

- VGA Card
- High Efficiency DC-DC Converter
- Battery Charger

DETAILED DESCRIPTION

Voltage reference

A 3.0V regulator operating from VCC is used to power the internal circuitry of the **FP5137**. An internal resistive divider provides **1.25V** reference for the error amplifier, Soft-start (**typ. 1.5V**) and SCP (**typ. 0.5V**) circuits.

Error amplifier

The error amplifier compares a sample of the dc-dc converter output voltage to the **1.25V** reference and generates an error signal for the error comparator. Output voltage of dc-dc converter is setting with the resistor divider using the following expression (see figure 7):

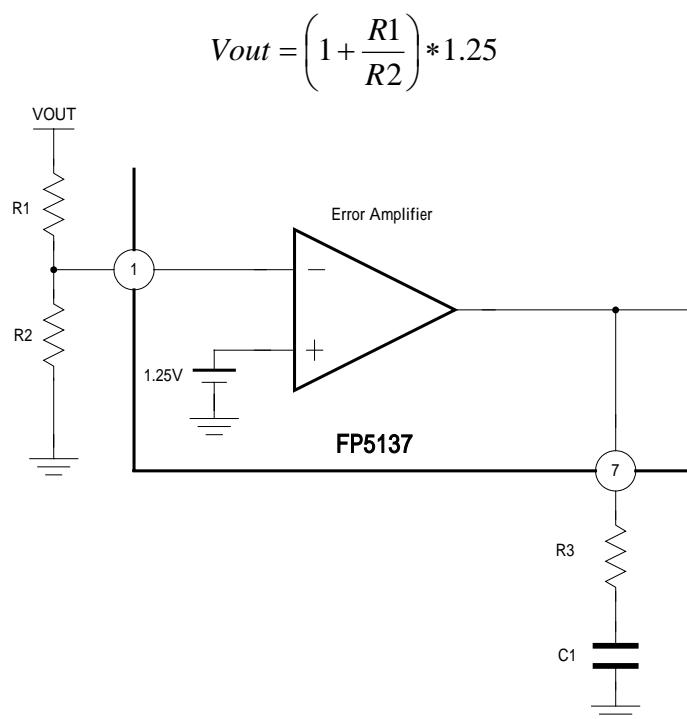

Figure 7. Error Amplifier with Feedback resistance divider

Oscillator

The fixed frequency generates from an internal RC oscillator, and the typical value is **200KHz**.

Under voltage lockout (UVLO)

FP5137 has a different under voltage lockout point for VCC (**typ. 4.2V**) and VC (**typ. 3.3V**).

The converter is normal operation when supply voltage rises above the point of lockout; otherwise the output drivers of **FP5137** are off.

Soft Start

When the VCC and VC of **FP5137** are ready, the power on reset (POR) signal is enable. The internal current source (**typ. 20 μ A**) will charge the external capacitor connected soft-start pin and another internal current source (**max. 64 μ A**) will control feedback voltage of error amplifier and enable output driver for soft-start function. The soft-start timing can be decided by following expression:

$$tss = 75 * C_{ss}(ms)$$

FP5137 should be shutdown whenever it is forced a voltage under **0.5V** at soft-start pin.

Short-circuit protection

FP5137 should be shutdown immediately whenever output voltage under **0.6V**, the mean is hard to maintain the output voltage during maximum duty cycle under short-circuit, and the PWM output are off until short circuit problem is release.

Output transistor and boost voltage V_C

FP5137 uses two NMOS and their turn-on VGS voltage near 4.5V, the source voltage of high side NMOS is near VIN, and it is necessary to supply a boost voltage higher than VIN for high side NMOS gate drive, the following figure explains the relation of MOS gate to source voltage. Application circuits can use different method to solve the boost power supply VC for high side driver. (**Recommend boost voltage VC is sum of VIN and VGS**)

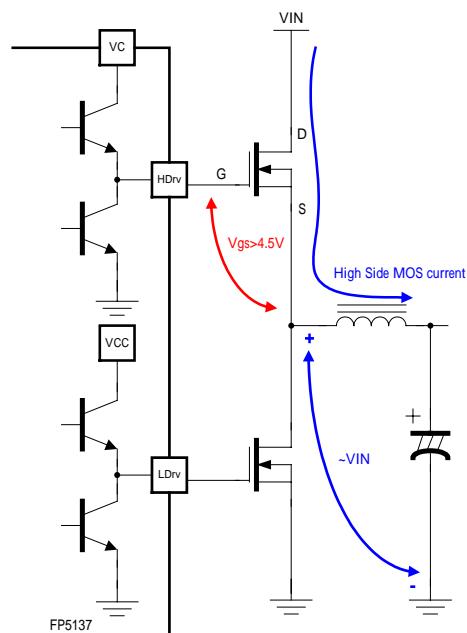

Figure 8. IC Output Stage with NMOS

BASIC APPLICATION NOTE (Dual Power Supply)

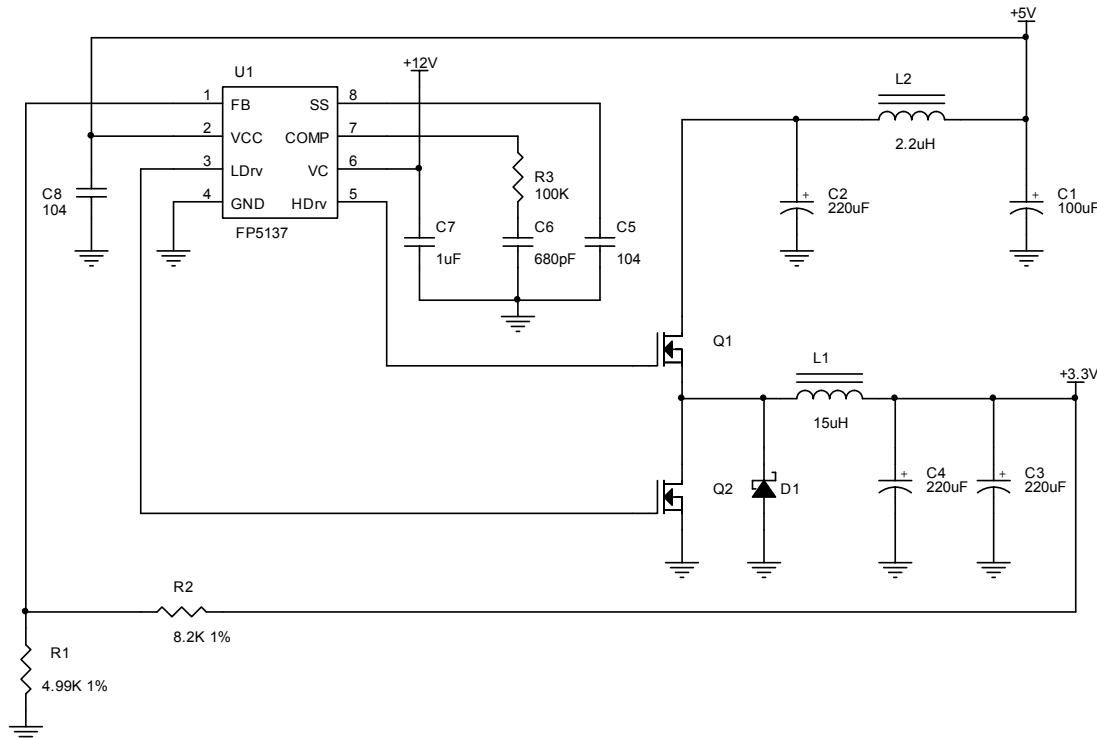

Figure 9. FP5137 DC/DC Converter circuit using dual power supply

Application Description

This is a simple application circuit using dual power supply (+5V and +12V), the converting voltage is from +5V to +3.3V, and +12V connects with VC pin makes sure the high side NMOS can be turn-on.

The output voltage determines from the following formula:

$$V_{out} = \left(1 + \frac{R2}{R1}\right) * V_{REF} = \left(1 + \frac{8.2K}{4.99K}\right) * 1.25 = 3.30V$$

The soft-start time determines from the following formula:

$$T_{ss} = 75 * C5 = 75 * 0.1(ms) = 7.5ms$$

BASIC APPLICATION NOTE (Single Power Supply)

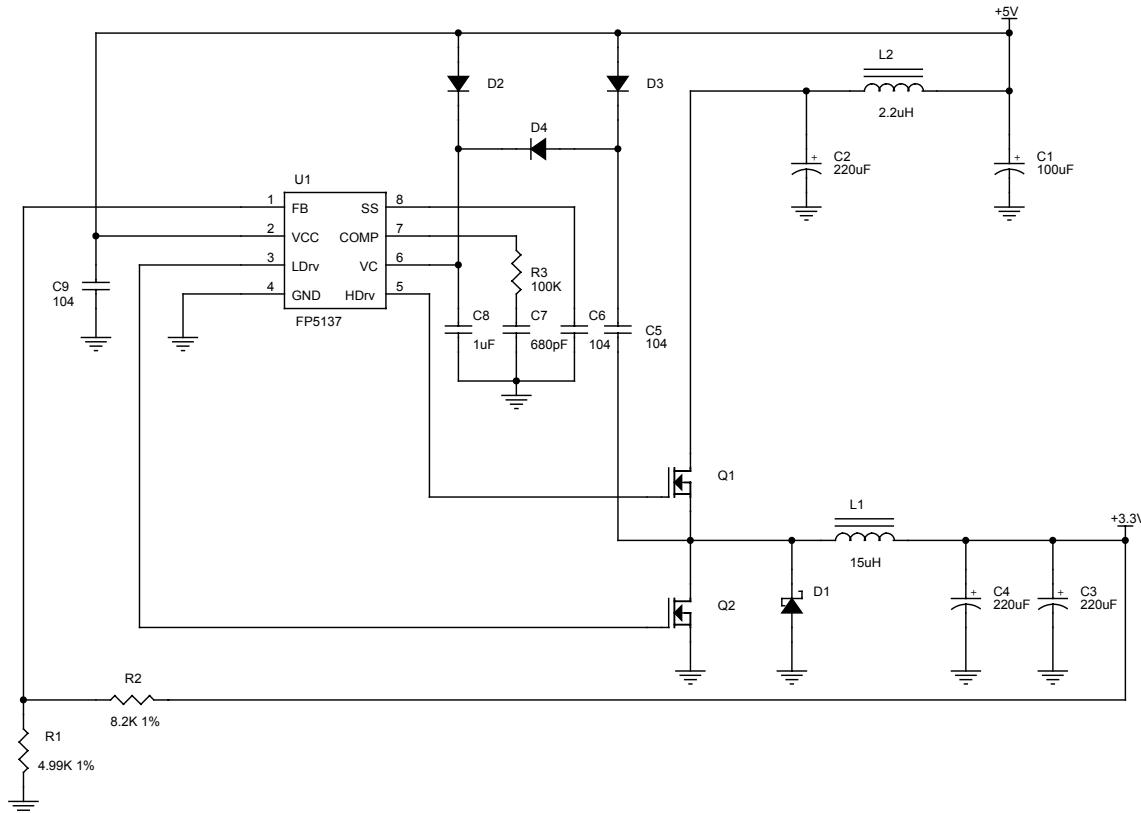

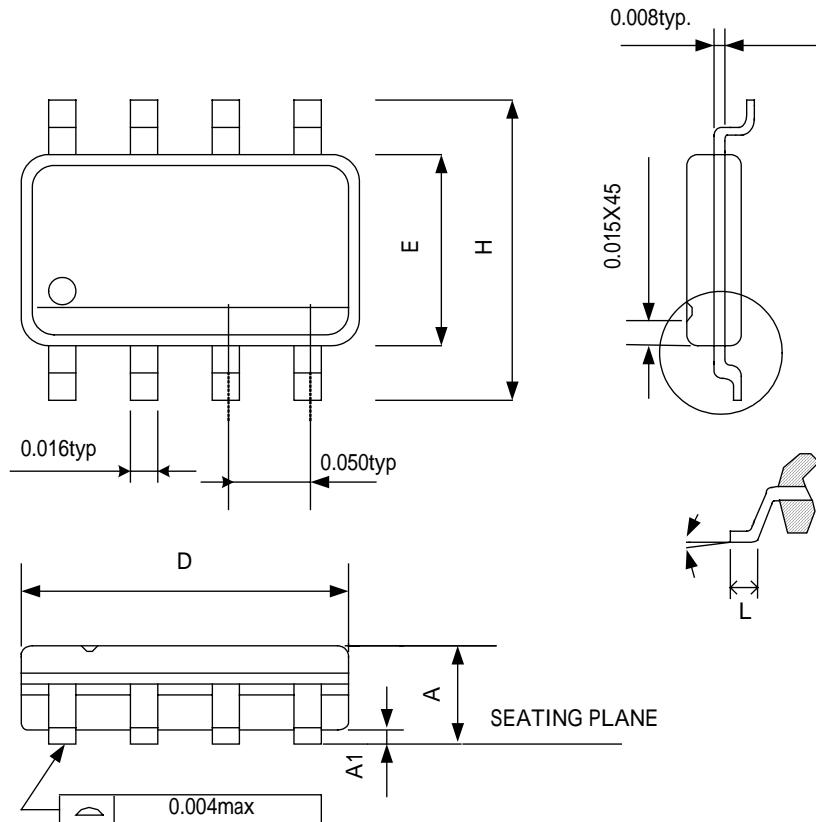

Figure 10. FP5137 DC/DC Converter circuit using single power supply

Application Description

This application circuit is same as dual power supply but VC pin uses a charge-pump circuit with D2~D4 and C5, C8.

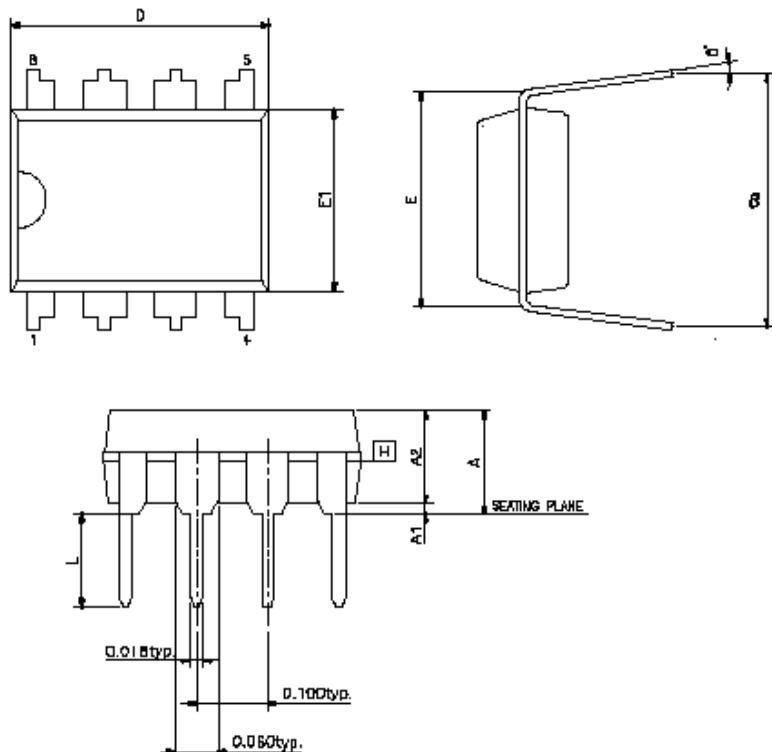

The C5 capacitor would charge near +5V through D3 when +5V power supply is turn-on, the voltage of VC is a sum of C5 voltage and $V_{IN} - V_{DIODE}$ voltage, is higher than Q1 source terminal during Q1 turns on.
