

# FPD85308

## Panel Timing Controller

### General Description

The FPD85308 Panel Timing Controller is an integrated FPD-Link based TFT-LCD timing controller. It resides on the flat panel display and provides the interface signal routing and timing control between graphics or video controllers and a TFT-LCD system. FPD-Link is a low power, low electromagnetic interference interface used between this controller and the host system.

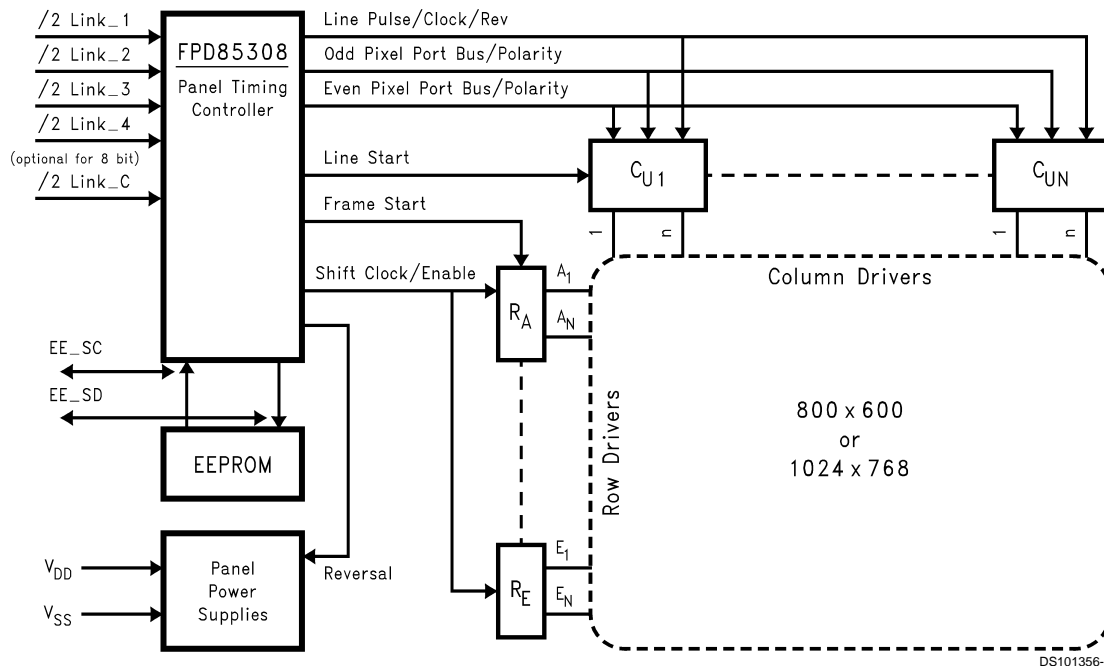

The FPD85308 chip links the panel's system interface to the LCD display via a ten wire LVDS data bus. The data is then routed to the source and gate display drivers. Both XGA and SVGA resolutions are supported.

The FPD85308 is programmable via an optional external serial EEPROM. Reserved space in the EEPROM is available for display identification information. The system can access the EEPROM to read the display identification data or program initialization values used by the FPD85308.

### Features

- FPD-Link System Interface utilizes Low Voltage Differential Signaling (LVDS).
- Supports Graphics Controllers with Spread Spectrum interfaces for lower EMI
- System programmable via EEPROM
- Suitable for notebook and monitor applications
- 8-bit or 6-bit system interface
- XGA or SVGA capable
- Supports single or dual port column drivers
- Programmable outputs provide customized control for standard or in-house column drivers and row drivers
- Programmable slew rate controlled outputs on CD interface for reduced EMI
- Polarity pin reduces CD data bus switching
- CMOS circuitry operates from a 3.3V supply

### System Diagram

### Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage ( $V_{DD}$ )	4.0V
DC Input Voltage ( $V_{IN}$ )	-0.3V to $V_{DD}$ +0.3V
DC Output Voltage ( $V_{OUT}$ )	-0.3V to $V_{DD}$ +0.3V
Storage Temperature Range ( $T_{STG}$ )	-65°C to +150°C
Lead Temperature ( $T_L$ ) (Soldering 10 sec.)	260°C
ESD Rating: ( $C_{ZAP} = 120$ pF, $R_{ZAP} = 1500\Omega$ ) MM = 200V, HBM = 2000V	

### Operating Conditions

	Min	Max	Units
Supply Voltage ( $V_{DD}$ )	3.0	3.6	V
Operating Temp. Range ( $T_A$ )	0	70	°C
Supply Noise Voltage ( $V_{CC}$ )		100	mV <sub>PP</sub>

**Note 1:** "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. They are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" specifies conditions of device operation.

### DC Electrical Characteristics $T_A = 0^\circ\text{C}$ to $70^\circ\text{C}$ , $V_{DD} = 3.3\text{V} \pm 0.3\text{V}$ (unless otherwise specified)

Symbol	Parameter	Conditions	Min	Max	Units
$V_{OH}$	Minimum High Level Output Voltage	$V_{DD} = 3.0\text{V}$ , $I_{OH} = -8$ mA	2.4		V
$V_{OL}$	Maximum Low Level Output Voltage	$V_{DD} = 3.0\text{V}$ , $I_{OL} = 8$ mA		0.4	V
$V_{IH}$	Minimum High Level Input Voltage		2.0		V
$V_{IL}$	Maximum Low Level Input Voltage			0.8	V
$I_{IN}$	Input Current	$V_{IN} = V_{DD}$		10	$\mu\text{A}$
$I_{OZ}$	Maximum TRI-STATE Output Leakage Current	$V_{IN} = V_{DD}$ , $V_{IN} = V_{SS}$		10	$\mu\text{A}$
$I_{DD}$	Average Supply Current	$f = 65$ MHz, $C_{LOAD} = 50$ pF		312	mA
$V_{THH}$	Differential Input High Threshold	Common Mode Voltage = +1.2V		+100	mV
$V_{THL}$	Differential Input Low Threshold	Common Mode Voltage = +1.2V	-100		mV

### Device Specifications $T_A = 0^\circ\text{C}$ to $70^\circ\text{C}$ , $V_{DD} = 3.3\text{V}$ (unless otherwise specified)

Symbol	Parameter	Conditions	Min	Max	Units
RPLLS	Receiver Phase Lock Loop Set Time			10	ms
RCCS	RxIN Channel-to-Channel Skew (Note 2)			700	ps

**Note 2:** This limit assumes a maximum cable skew of 350 ps. Actual automated test equipment limit is 400 ps due to tester accuracy.

**FPD85308 Default Timing**

DS101356-22

Vertical Backporch = 35  
 Lines/Frame = ~825  
 Pixels/Line = ~1200  
 Horizontal Backporch = ~100  
 Displayed pixels/line = 1024  
 (Valid data during ENAB High time)  
 Displayed lines/frames = 768  
 Frequency = 65 MHz (or less)

**Block Diagram**

DS101356-3

## Functional Description

### FPD-LINK Receiver

The LVDS based FPD-Link Receiver receives inputs video data and control timing. Four LVDS channels plus clock provide 24-bit color. Three LVDS channels can be used for 18-bit color.

The video data is regenerated to a parallel data stream and routed to the 8 to 6 Bit Translator. The General Purpose Outputs (GPOs) continue outputting the programmed control sequence at a reduced frame rate. RSTZ initialized the chip with the default register values. EEPROM configuration data is loaded if EEPROM is detected. (EEPROM address 80H = "00").

### Spread Spectrum Support

The FPD-Link receiver supports graphics controllers with Spread Spectrum interfaces for reducing EMI. The Spread Spectrum method supported is Center Spread. A maximum of 2% Center Spread at a modulation frequency of 200 KHz is supported.

### 8 to 6 Bit Translator

8-bit data is reduced to a 6-bit data path via a time multiplexed dithering technique or a simple truncation of the LSBs. This function is enabled via the Input Control Register bits 4 and 3. See *Table 2* Input Format Control register.

### Data Alignment

This function delays and aligns data to match the CD/panel architecture. Programmable selections in the Output Format Control Register bits 0 and 1 provide support for various LCD panel architectures. See *Figures 12, 13, 14, 15, 16* for additional explanation.

### Dual Bus, Single Port CD Interface

When interfacing two busses to a bank of single port column drivers, the RGB data must be aligned/delayed with respect to the size of the column drivers being used. The CD Size register is programmed to support single port column drivers of up to 384 outputs (128 pixels).

### Dual Bus, Dual Port CD Interface

When interfacing with dual port column drivers, data is simply output with odd and even data on separate outputs.

### Single Bus, Single Port CD Interface

The single bus, single port column driver interface provides support of existing SVGA systems. All data is output on a single bus. The second bus can be turned off when using this configuration.

### Output Formatting

The output formatting function provides several capabilities to reduce noise EMI and to generate customized timing. These capabilities are selectable/programmable via the Output Format Control, Output Enable/Polarity Control, and Output Drive Control Registers. See *Table 2* for specific bit definitions.

### Data Bus Skewing

This function aligns the two output channels in either a non-skewed data format (simultaneous switching) or a skewed data format. The skewed format delays the even channel data and control by  $\frac{1}{2}$  clock. This reduces the

number of outputs which switch simultaneously. See *Figures 12, 13, 14, 15, 16*. Data Bus Skewing is enabled by setting bit 2 in the Output Format Control register.

### Programmable Slew Rates

Programmable edge rates allow the Data, Polarity, Start Pulse, and Clock outputs to be adjusted for better impedance matching for noise and EMI reduction. Bits [7:6] of the Output Enable/Polarity Control Register control OSP and ESP outputs. The Output Drive Control register control the OCLK, ECLK, ORGB/OPOL, ERGB/EPOL outputs.

### Polarity Generation

When enabled, a polarity indication (OPOL, EPOL) is output for each data bus. When in the dual bus output configuration, if the number of transitions from pixel to pixel exceed 18 bits from a total of 36 bits, the data is then inverted and a polarity indication corresponding to that bus is set active. In the single bus (ORGB bus) applications such as SVGA, when the number of pixel to pixel transitions exceed 9 bits from a total of 18 bits, the data is inverted and the OPOL is set active. This feature requires the use of a CD with a polarity input. In SKEWED dual output data bus applications, OPOL and EPOL are aligned with their respective buses and should be used as the Polarity generation input to the CD which supports dual bus/Polarity generation. In Non-Skewed dual output bus applications, OPOL is aligned with both data buses and should be used as the Polarity Generation input to the CD. The polarity function is enabled by setting bit 6 of the Output Format Control register (EEPROM address D2). The OCLK and ECLK polarity is also programmable. Inversion and TRI-STATE control of OCLK and ECLK is provided by bits [3:0] of the Output Enable/Polarity Control Register. The ERGB/ESP/EPOL and ORGB/OSP/OPAL outputs can be disabled (TRI-STATE) using bits [5:4] of the Output Enable/Polarity Control register.

### Programmable Positioning of CD Start Pulse

The position of the CD Start Pulse is programmable. This allows use with column drivers having non-standard start pulse timing. The CD Start Pulse position is determined by bits [3:0] of the Output Format Control Register (EEPROM address D3).

### Data Blanking

Data, Polarity, Start Pulse and Clock can be blanked (forced to "0") during horizontal and/or vertical blanking periods. GPO [8] is programmed to correspond to display periods. When GPO [8] is low, outputs are forced to "0". This reduces amount of switching over the frame time thus reducing power. See GPO programming procedure in *APPENDIX A: GPO Programming Examples*.

### Line Inversion

When enabled (Bit 3 of the Output Format Register), the polarity of the output data is determined by GPO [0]. Bit 4 defines the relationship between GPO [0] and the output data. Bit 5 provides a variation of this where the Odd and Even data is of different polarity. This could be used in a system with CDs on both top and bottom of the panel in which dot inversion is desired.

## Functional Description (Continued)

### White Data

The White Data function generates all “1” data beginning at line 769 and continuing until the beginning of the next frame. This function is controlled via D6 Register Bit 7.

### Timing Control

The Timing Control function generates control to column drivers, row drivers, and power supply. The programmable GPOs provide for CD latch pulse, REV, and gate driver control generation. The GPOs allow the user to generate control anywhere within the frame data. Standard gate driver interface or custom gate interfaces can be implemented with the nine GPOs. Note that GPO [8] must be used for output blanking control.

Five registers provide the timing definition for each GPO. The Horizontal Start register defines the output pixel number for which the GPO output goes active. The Horizontal duration register determines how many clocks the output will remain active during the line. The Vertical Start register defines at what line # the output becomes active, and the Vertical duration register defines how many lines the output remains active. Each output has a control register (bit 0) which defines the GPO polarity (active high or low). Another bit in the control register (bit 1) enables the “toggle” mode. This mode is useful in REV generation when alternating polarity is required from line to line. Frame to Frame polarity changes are made by programming an odd # in the vertical duration register when in “toggle” mode. Please note that ODD Frame size inputs are not supported in “toggle mode” function.

Two of the General Purpose Outputs have additional capabilities. GPO [8] controls output blanking and must be used for this purpose. If output blanking is not desired, this register must be programmed to always be active. White data generation (all “1” data) at the end of each frame is generated when D6 register bit 7 is set. When this bit is set, white data is output after line #768 if GPO [8] is active. GPO [0] is capable of performing line inversion on the output data. Bits [5:3] of the Output Format Control register provides control for this function.

See *APPENDIX A: GPO Programming Examples*.

### SERIAL EEPROM INTERFACE

The Serial EEPROM Interface controls the FPD85308 initialization. If the EEPROM is not present (EESD and EESC are pulled high), or if EEPROM address 80H is not “00”, the internal default values are used to initialize all programmable functions of the FPD85308.

At power-up, the FPD85308 configures the internal programmable registers with data from the EEPROM. After the FPD85308 is initialized, the EEPROM can be accessed by the system in which display configuration and manufacturing information can be obtained. The EEPROM can be programmed “in system” providing quick evaluation of different display timing.

External access to the EEPROM must be preceded by applying a “1” to pin TEST [2] in order to interrupt the FPD85308 download.

The FPD85308 initialization data begins at EEPROM address 80H. The first 128 bytes (0-7F) are reserved for display identification data.

A power-up delay can be programmed using bits [6:5] of the Input Format Control Register. This delays outputting (driv-

ing) of the data and control for up to 5 frame times after reset. The TEST [2] pin must be low for a power-up delay to occur.

### VERTICAL/HORIZONTAL REFERENCE GENERATOR

This block provides Vertical and Horizontal Reference points for the Timing Control Function. VSYNC, HSYNC and ENAB along with programmable control from the input control register bits 0 and 1 (FIX HORIZONTAL and FIX VERTICAL) are used to determine when the video from the host is valid. Three input modes are supported. See *Table 1*.

#### Fixed Vertical, Fixed Horizontal

The horizontal timing is fixed and determined by the Horizontal Backporch register. The vertical timing is also fixed and determined by the Vertical Backporch register. ENAB is ignored and is not necessary.

#### Fixed Vertical, ENAB Controlled Horizontal

The horizontal timing is controlled by the ENAB timing. The vertical timing is fixed and determined by the Vertical Backporch register and HSYNC input.

#### ENAB Only

In ENAB Only timing, VSYNC and HSYNC are ignored. All timing is derived from the ENAB signal.

**Functional Description** (Continued)**TABLE 1. Input Mode Definition**

<b>INPUT FORMAT FIXED VERTICAL, FIXED HORIZONTAL determined by the INPUT CONTROL REGISTER bits [1:0]</b>	<b>HORIZONTAL DATA START</b>	<b>VERTICAL DATA START</b>
FIXED VERTICAL, FIXED HORIZONTAL (FIX VERTICAL = 1, FIX HORIZONTAL = 1)	Programmable from HSYNC Falling Edge (# INPUT CLKS)	Programmable from VSYNC Falling Edge (# HSYNC PERIODS)
FIXED VERTICAL, FIXED HORIZONTAL ENABLE (FIXED VERTICAL = 1, FIXED HORIZONTAL = 0)	Data Valid during ENAB high. HSYNC input required for FIXED VERTICAL operation.	Programmable from VSYNC Falling Edge (# HSYNC PERIODS)
ENAB ONLY (FIXED VERTICAL = 0, FIXED HORIZONTAL = 0)	Data Valid during ENAB High (HSYNC is IGNORED)	First ENAB after ENAB low for greater than one line time (VSYNC is IGNORED)

## Functional Description (Continued)

fault values are used. The following parameters are initialized at power up. Pullups must be used on EE\_SD and EE\_SC pins.

### PROGRAMMABLE REGISTERS

At power-up, data is read from an external EEPROM. If anything other than 00H is read back on the first EEPROM access (indicating EEPROM not present), the internal de-

**Note 20:** GPO resolution is video clock/2

**FIGURE 17. Standard or Custom Gate Driver Interface**

## Functional Description (Continued)

DS101356-10

**Note 21:** RSTZ transition Low-to-High occurs at the completion of the RPLLS delay or later as shown above.

**Note 22:** All outputs\* forced low in default timing of FPD85308 during power-up delay time.

**Note 23:** All outputs\*\* forced low in continuous download (every two frame) mode.

**Note 24:** All outputs\*\*\* generate the signal for default values in FPD85308 and unknown values when use the EEPROM values during power-up delay time. Then NS recommend to use the continuous download mode.

**Note 25:** EEPROM download occurs at first detected vertical blanking period.

**Note 26:** Active outputs depends on INPUT FORMAT register bits [5:6].

INPUT FORMAT [5:6]	VSYNC# at which outputs go active
00	Second VSYNC
01	Third VSYNC
10	Fourth VSYNC
11	Fifth VSYNC

**Note 27:** When configured in ENAB Only Mode (EOM), VSYNC signals are unused except for timing EEPROM DownLoad Sequences. When configured with default values in Fixed Vertical mode, the VSYNC signal is generated any time ENAB remains low for more than 2 horizontal periods.

During Power Up, before Reset has propagated, the EEPROM may receive spurious addressing that initiates a down load sequence, but the output data is often not captured for lack of timing alignment with VSYNC. In the case where EEPROM data is not captured during the initial (automatic) Reset or Power Up DownLoad sequence, Timing Controller outputs are indeterminate until the EEPROM data is successfully loaded, which always begins and is executed at the next VSYNC valid (low) cycle.

**Note 28:** During Power Up sequences, false RSTZ signals are possible due to instability of the power supply level, typically within the 10 ms of operation. To avoid this situation, implementation of the circuit in Figure 19, or other functional equivalent, is recommended, (Figure 19).

## APPENDIX A: GPO Programming Examples

The GPO control generation is based on the internal line count and pixel count shown in *Figure 9* and *Figure 10*. Two programmable registers (Vertical Start and Vertical Duration) control the vertical component of the control signal. This establishes at what line and for how many lines the control signal will be active. Likewise, two programmable registers (Horizontal Start and Horizontal Duration) control the horizontal component of the control signal. The Horizontal register values determine at what pixel count the signal goes active and for how many pixel counts the signal stays active during each line. The Vertical Component enables the signal for however many lines programmed for and the Horizontal Component generates pulses within that vertical time period.

Generally the following types of signals are generated:

1. DC (either 1 or 0)

2. A pulse every line
3. A pulse once a frame (either in pixels or lines)
4. Pulsed during active video (pulses are blanked during vertical blanking period of frame)

*Table 4* describes the programming requirements for general types of pulses generated.

The GPO's also have a "toggle mode". This provides the capability to generate a "REVERSAL" signal used in most LCD applications. Bit 1 of the Control register is set to a 1 to enable toggle mode operation. The GPO is programmed so that a rising edge is produced when the control signal is required to toggle. This generally occurs once each line. Also, the # of edges generated per frame is programmed to be an odd #. This ensures that the control signal will alternate polarity from frame to frame.

Examples of GPO programming to produce specific control signals are included in the following pages.

**TABLE 4. GPO Pulse Generation**

Vertical Start	Vertical Duration	Horizontal Start	Horizontal Duration	GPO Output
=don't care	=0	=0	=0	Stuck 0 (When Output Polarity = 0) Stuck 1 (When Output Polarity = 1) Polarity control is in GPO Control Register bit 0
=don't care	=0	#A	=0	Stuck 1 (When Output Polarity = 0) Stuck 0 (When Output Polarity = 1) Polarity control is in GPO Control Register bit 0
=don't care	=0	#A	#B (Note 29)	Pulse is generated every line beginning at ~#A 32 MHz clocks from start of output line and lasting for #B 32 MHz clocks
#A	#B	#C	=0	Pulse begins at line #A , clock #C and continues to line #(A+B) pixel #C (multi-line pulse)
#A	#B	#C	#D (Note 29)	Pulse generation begins at line A and continues for #B lines. Each pulse begins at ~pixel #C and lasts for D counts

**Note 29:** Pulses will occur every other line if Horizontal Duration is greater than a line time.

## APPENDIX A: GPO Programming Examples (Continued)

### GPO Programming Example #1:

Generate a control signal which transitions high at the end of each line, has a pulsewidth of 3  $\mu$ s, and remains low during the vertical blanking period. This control is used for the latch pulse to the column drivers.

Horizontal time (clocks/line) = 1300 dot clocks

Vertical period (lines/frame) = 850 lines

Vertical control is active beginning at line 1 and remains active for 768 lines.

**GPO Vertical Start Register = 1**

**GPO Vertical Duration Register = 768d (300h)**

Positive pulse goes high each line at output clock 512 corresponding to when the last two pixels are output on OR, OG, OB, ER, EG, EB. Pulse remains high for 98 output clocks ( $98 \times 30.8 \text{ ns/clock} = 3.02 \mu\text{s}$ ). (Dual Bus output clock = 32.5 MHz for 65 MHz XGA video, 1024 pixels/line, 768 displayed lines/frame).

**Note:** 6 counts are added to the output start # because the GPO pixel count begins 6 clocks prior to the output data.

**GPO Horizontal Start Register = 518d (206h)**

**GPO Horizontal Duration Register = 98d (62h)**

The control pulses are positive (bit [0] = 0) and the toggle circuitry is disabled (bit1 [1] = 0).

**GPO Control Register = 0**

## APPENDIX A: GPO Programming Examples (Continued)

Horizontal time (clocks/line) = 1300 dot clocks

Vertical period (lines/frame) = 850 lines

### GPO Programming Example #2:

Generate a control signal which transitions low 20 output clocks after the beginning of each output line, has a pulse-width (low) of 12  $\mu$ s, and goes high during horizontal blanking. This control signal is used as an output enable for the gate drivers.

DS101356-24

Control is active beginning at line 2 and remains active for 768 lines.

**GPO Vertical Start Register = 2**

**GPO Vertical Duration Register = 768d (300h)**

Negative pulse goes low each line at output clock 20 corresponding to when the 39/40 pixels are output on OR, OG, OB, ER, EG, EB. Pulse remains low for 390 output clocks ( $390 \times 30.8 \text{ ns/clock} = 12 \mu\text{s}$ ). (Dual Bus output clock = 32.5 MHz for 65 MHz XGA video, 1024 pixels/line, 768 lines/frame).

**Note:** 6 counts are added to the output clock # because the GPO start count begins 6 clocks prior to the output data.

**GPO Horizontal Start Register = 26d (1ah)**

**GPO Horizontal Duration Register = 390d (186h)**

The control pulses are negative (bit [0] = 1) and the toggle circuitry is disabled (bit1 [1] = 0).

**GPO Control Register = 1**

## APPENDIX A: GPO Programming Examples (Continued)

Horizontal time (clocks/line) = 1300 dot clocks  
Vertical period (lines/frame) = 850 lines

### GPO Programming Example #3:

Generate a control signal which toggles during horizontal blanking and alternates polarity each frame. This control signal is used as the reversal signal.

Control is active beginning at line 1 and remains active for 769 lines.

(Odd number programmed in Duration Register causes control signal to alternate polarity each frame)

**GPO Vertical Start Register = 1**

**GPO Vertical Duration Register = 769d (301h)**

Positive going pulse causes output to toggle. Edge occurs 20 output clocks after end of each line ( $1024/2 + 20 = 532$ ). Pulse duration is not critical since the output will be in toggle mode. (Dual Bus output clock = 32.5 MHz for 65 MHz XGA video, 1024 pixels/line, 768 lines/frame).

**Note:** 6 counts are added to the output start # because the GPO pixel count begins 6 clocks prior to the output data.

**GPO Horizontal Start Register = 538 (238h)**

**GPO Horizontal Duration Register = 10d (0Ah)**

The control pulses are positive (bit [0] = 0) and the toggle circuitry is enabled (bit1 [1] = 1).

**GPO Control Register = 2**

(For a second control signal of opposite polarity, program another GPO Control Register with same count values with GPO Control Register = 3.)
