![GAMMA MICROELECTRONICS]

Description

The GM6603 series of positive adjustable and fixed regulators are designed to provide 3.0A output with low dropout voltage performance.

On-chip trimming adjusts the reference voltage to 2.0%. Put them to work in post regulators or microprocessor power supplies where low voltage operation and fast transient response are required.

Device includes over-current protection and thermal shutdown protection as well.

Pin-to-pin compatible with the LT1085 family of regulators, the GM6603's are available in TO-252, TO-220 and surface-mount TO-263 packages.

Features

- ◆ Adjustable or Fixed Output
- ◆ Output Current of 3.0A
- ◆ Dropout Voltage (typical) 1.3V @ 3.0A
- ◆ Typical Line Regulation 0.015%
- ◆ Typical Load Regulation 0.05%
- ◆ Fast Transient Response
- ◆ Current Limit Protection
- ◆ Thermal Shutdown Protection

## Application

Microprocessor Supply

Post Regulators for Switching Supplies

Telecommunication Systems

**Printer Supplies**

Motherboards

TYPICAL APPLICATION CIRCUITS

(Adjustable Version)

(Fixed Version)

$$V_{OUT} = V_{REF} \times (1 + \frac{R2}{R1}) + I_{ADJ} \times R2$$

Notes:
1. C1 needed if device is far from filter capacitors
2. C2 minimum value required for stability

◆ APPLICATION INFORMATION

The GM6603 series linear regulators provide fixed and adjustable output voltages at currents up to 3.0A. These regulators are protected against overcurrent conditions and include thermal shutdown protection. The GM6603's have a composite PNP-PN output transistor and require an output capacitor for stability.

A detailed procedure for selecting this capacitor follows.

Stability Considerations

The output compensation capacitor helps to determine three main characteristics of a linear regulator's performance: start-up delay, load transient response, and loop stability. The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is preferred, as a film or ceramic capacitor with almost zero ESR can cause instability. An aluminum electrolytic capacitor is the least expensive type, but when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary widely. For optimum performance over the full operating temperature range, a tantalum capacitor is best. A 22µF tantalum capacitor will work fine in most applications, but with high current regulators such as the GM6603 higher capacitance values will improve the transient response and stability. Most applications for the GM6603's involve large changes in load current, so the output capacitor must supply instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$V = I \times ESD$$

In microprocessor applications an output capacitor network of several tantalum and ceramic capacitors in parallel is commonly used. This reduces overall ESR and minimizes the instantaneous output voltage drop under transient load conditions. The output capacitor network should be placed as close to the load as possible for
Protection Diodes

When large external capacitors are used with most linear regulator it is wise to add protection diodes. If the input voltage of the regulator is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of capacitor, output voltage and rate at which V_{IN} drops.

FIGURE 1 [(a),(b)]. Protection Diode Scheme for Large Output Capacitors

(a) Fixed Version
(b) Adjustable Version

In the GM6603 linear regulators, the discharge path is through a large junction, and protection diodes are normally not needed. However, if the regulator is used with large output capacitance values and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown above in Figure 1.

Output Voltage Sensing

The GM6603 series are three terminal regulators, so they cannot provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the GM6603 should be connected as shown in Figure 2.

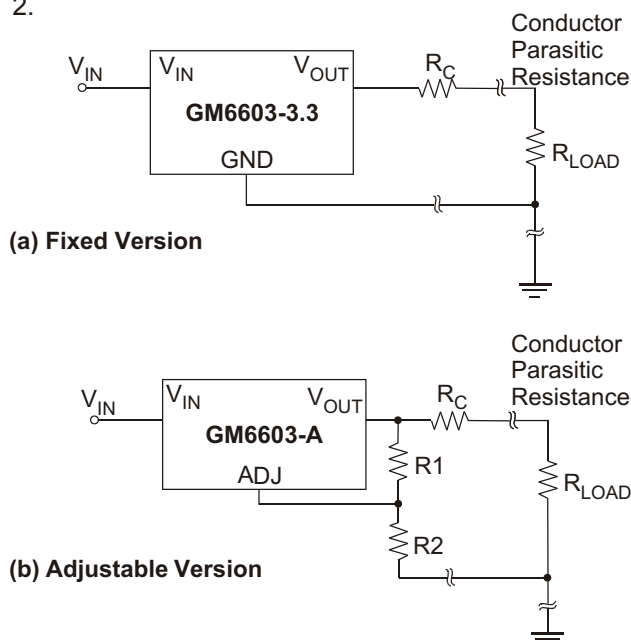

(a) Fixed Version

(b) Adjustable Version

FIGURE 2 [(a),(b)] **Conductor Parasitic Resistance Effects are Minimized by this Grounding Scheme For Fixed and Adjustable Output Regulators**

Calculating Power Dissipation and Heat Sink Requirements

The GM6603 series precision linear regulators include thermal shutdown and current limit circuitry to protect the devices. However, high power regulators normally operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to be sure that you use and adequate heat sink. The case is connected to V_{OUT} on the GM6603, so electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators like the GM6603.

The thermal characteristics of an IC depend four factors:
1. Maximum Ambient Temperature T_A (°C)
2. Power Dissipation P_D (Watts)
3. Maximum Junction Temperature T_J (°C)
4. Thermal Resistance Junction to ambient R_{JA} (°C/W)

These relationship of these four factors is expressed by equation (1):

$$T_J = T_A + P_D \; X \; R_{JA}$$

Maximum ambient temperature and power dissipation are determined by the design while the maximum junction temperature and thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is expressed by equation (2):

$$P_{D(max)} = \{V_{IN(max)} - V_{OUT(min)}\} \, I_{OUT(max)} + V_{IN(max)} I_Q$$

where:
$V_{IN(max)}$ is the maximum input voltage,
$V_{OUT(min)}$ is the minimum output voltage,
$I_{OUT(max)}$ is the maximum output current
I_Q is the maximum quiescent current at $I_{OUT(max)}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC into the air. Each material in the heat flow path between the IC and the environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine R_{JA}, the total thermal resistance between the junction and the air. This is expressed by equation (3):

$$R_{JA} = R_{JC} + R_{CS} + R_{SA}$$

Where all of the following are in °C/W:
R_{JC} is thermal resistance of junction to case,
R_{CS} is thermal resistance of case to heat sink,
R_{SA} is thermal resistance of heat sink to ambient air

The value for R_{JA} is calculated using equation (3) and the result can be substituted in equation (1). The value for R_{JC} is 3.5°C/W for a given package type based on an average die size. For a high current regulator such as the GM6603 the majority of the heat is generated in the power transistor section.
