Table of Contents

Chapter 1

Overview

1.1 Features & Pin Assignments	1-1
1.2 Block Diagram	1-2
1.3 Package Dimension	1-3
1.4 Pin Function	1-5
1.5 Port Structure	1-6
1.6 Electrical Characteristics	1-10

Chapter 2

Function Description

2.1 Register	2-1
2.2 Memory Map	2-6
2.3 TCALL Vector Area	2-7
2.4 Zero-Page Peripheral Registers	2-8

Chapter 3

I/O PORT

3.1 Port R0	3-1
3.2 Port R1	3-2
3.3 Port R2	3-2

Chapter 4

Peripheral Hardware

4.1 Clock Generating Circuit	4-1
4.2 Timer	4-10

Table of Contents

Chapter 5

Interrupt

5.1 Interrupt Source	5-1
5.2 Interrupt Control Register	5-3
5.3 Interrupt Accept Mode	5-4
5.4 Interrupt Processing Sequence	5-7
5.5 Software Interrupt	5-8
5.6 Multiple Interrupt	5-9
5.7 Key Scan Input Processing	5-11

Chapter 6

Standby Function

6.1 Stop Mode	6-1
6.2 Standby Mode Release	6-3
6.3 Release Operation of Standby Mode	6-5

Chapter 7

Reset Function

7.1 External $\overline{\text{RESET}}$	7-1
7.2 Power On Reset	7-1
7.3 Low Voltage Detection Mode	7-4

<p>$\overline{\text{TEST}}$</p>		<p>High level</p>

1.6 Electrical Characteristics

1.6.1 Absolute Maximum Ratings (Ta = 25 °C)

PARAMETER	SYMBOL	RATINGS	UNIT
Supply Voltage	VDD	-0.3 ~ +7.0	V
Input Voltage	VI	-0.3 ~ VDD + 0.3	V
Output Voltage	VO	-0.3 ~ VDD + 0.3	V
Operating Temperature	Topr	0 ~ 70	°C
Storage Temperature	Tstg	-65 ~ 150	°C
Power Dissipation	PD	700	mW

1.6.2 Recommended Operating Ranges

PARAMETER	SYMBOL	CONDITION	MIN.	TYP.	MAX.	UNIT
Supply Voltage	VDD1	fXin = 1MHz fXin = 2MHz	2.0		4.0	V
	VDD2	fXin = 4MHz	2.2		4.0	V
Oscillation Frequency	fXin		1.0	2.0	4.0	MHz
Operating Temperature	Topr		0		70	°C

Chapter 1. Overview

1.6.3 DC Characteristics (VDD = 2.0~4.0, Vss = 0V, Ta = 0°C ~ 70°C)

Parameter	Symbol	Condition		Specification			Unit	
				min	typ	max		
high level input voltage	V _{IH1}	R11, R12, R14, RESETB		0.8V _{DD}		V _{DD}	V	
	V _{IH2}	R0, R1(Except R11,R12,R14) , R2		0.7V _{DD}		V _{DD}	V	
low level input voltage	V _{IL1}	R11, R12, R14, RESETB		0		0.2V _{DD}	V	
	V _{IL2}	R0, R1(Except R11,R12,R14) , R2		0		0.3V _{DD}	V	
high level input leakage current	I _{IH}	R0,R1,R2,RESETB	V _{IH} =V _{DD}			1	uA	
low level input leakage current	I _{IL}	R0,R1,R2,RESETB (without pull-up)	V _{IL} =0V			-1	uA	
high level output voltage	V _{OH1}	R0	I _{OH} =-0.5mA	V _{DD} -0.4			V	
	V _{OH2}	R1(ExceptR17),R2	I _{OH} =-1mA	V _{DD} -0.4			V	
	V _{OH3}	R17	I _{OH} =-8mA	V _{DD} -0.9			V	
	V _{OH5}	OSC	I _{OH} =-200uA	V _{DD} -0.9			V	
low level output voltage	V _{OL1}	R0	I _{OL} =1mA			0.4	V	
	V _{OL2}	R1, R2	I _{OL} =5mA			0.8	V	
	V _{OL5}	OSC	I _{OL} =200uA			0.8	V	
high level output leakage current	I _{OHL}	R0, R1, R2	V _{OH} =V _{DD}			1	uA	
low level output leakage current	I _{OLL}	R0, R1, R2	V _{OL} =0V			-1	uA	
high level output current	I _{OH}	REMOUT	V _{OH} =2V	-30	-12	-5	mA	
low level output current	I _{OL}	REMOUT	V _{OL} =1V	0.5	-	3	mA	
input pull-up current	IP1	RESETB	V _{DD} =3V	15	30	60	uA	
	IP2	R0, R1, R2	V _{DD} =3V	10	20	40	uA	
POWER SUPPLY CURRENT	I _{DD}	operating current	f _{XIN} =4MHz	V _{DD} =4V		4	10	mA
				V _{DD} =2.2V		2.4	6	mA
		f _{XIN} =2MHz	V _{DD} =4V		2.4	6	mA	
			V _{DD} =2V		1.2	3	mA	
	I _{STOP}	stop mode current	oscillator stop	V _{DD} =4V	---	3	10	uA
				V _{DD} =2V	---	2	8	uA
RAM retention supply voltage	V _{RET}			0.7			V

CHAPTER 2. FUNCTION DESCRIPTION

2.1 REGISTERS

Chapter 2. Function Description

2.1.1 A register

- 8bit Accumulator.
- In the case of 16-bit operation, compose the lower 8-bit of A, upper 8bit in Y (16-bit Accumulator)
- In the case of multiplication instruction, execute as a multiplier register. After multiplication operation, the lower 8-bit of the result enters. (Y*A ;æ YA)
- In the case of division instruction, execute as the lower 8-bit of dividend. After division operation, quotient enters.

2.1.2 X register

- General-purpose 8-bit register
- In the case of index addressing mode within direct page(RAM area), execute as index register.
- In the case of division instruction, execute as register.

2.1.3 Y register

- General-purpose 8-bit register
- In the case of index addressing mode, execute as index register
- In the case of 16-bit operation instruction, execute as the upper 8-bit of YA (16-bit accumulator).
- In the case of multiplication instruction, execute as a multiplicand register. After multiplication operation, the upper 8-bit of the result enters.
- In the case of division instruction, execute as the upper 8-bit of dividend. After division operation, remains enters.
- Can be used as loop counter of conditional branch command. (e.g.DBNE Y, rel)

2.1.4 Stack Pointer

- In the cases of subroutine call, Interrupt and PUSH, POP, RETI, RET instruction, stack data on RAM or in the case of returning, assign the storage location having stacked data.
- Stack area is constrained within 1-page (00H-FFH). The SP is post-decremented when a subroutine call or a push instruction is executed, or when an interrupt is accepted; and the SP is pre-incremented when a return or a pop instruction is executed.
- SP should be initialized as follows
ex) LDX #0FEH : 0FEH ;æ X reg.
TXSP : X reg. ;æ SP
- The behaviors of stack pointer according to each instruction are the following.

2.1.4.1 Interrupt

2.1.4.2 RETI(Return from interrupt)

2.1.4.3 Subroutine call

2.1.4.4 RET(Return from subroutine)

Chapter 2. Function Description

2.1.4.5 PUSH A(X, Y, PSW)

2.1.4.6 POP A(X, Y, PSW)

2.1.5 PC (Program Counter)

- Program counter is a 16-bit counter consisted of 8-bit register PCH and PCL.
- Addressing space is 64K bytes.

2.1.6 PSW (Program Status Word)

- PSW is an 8-bit register.
- Consisted of the flags showing the post state of operation and the flags determining the CPU operation, initialized as 00H in reset state.

2.1.7 Flag register.

2.1.7.1 Carry flag (C)

- After operation, set when there is a carry from bit7 of ALU or there is not a borrow.
- Set by SETC and clear by CLRC.
- Executable as 1-bit accumulator.
- Branch condition flag of BCS, BCC.

2.1.7.2 Zero flag (Z)

- After operation also including 16-bit operation, set if the result is 0.
- Branch condition flag of BEQ, BNE.

2.1.7.3 Interrupt enable flag (I)

- Master enable flag of interrupt except for RST (reset).
- Set and cleared by EI, DI

2.1.7.4 Half carry flag (H)

- After operation, set when there is a carry from bit3 of ALU or there is not a borrow from bit4 of ALU.
- Can not be set by any instruction.
- Cleared by CLRV instruction like V flag.

2.1.7.5 Break flag (B)

- Set by BRK (S/W interrupt) instruction to distinguish BRK and TCALL instruction having the same vector address.

2.1.7.6 G flag (G)

- Set and cleared by SETG, CLRG instruction.
- Assign direct page (0-page, 1-page).
- Addressable directly to RAM 1-page by SETG. and to RAM 0-page by CLRG.

2.1.7.7 Overflow flag (V)

- After operation, set when overflow or underflow occurs.
- In the case of BIT instruction, bit6 memory location is transferred to V-flag.
- Cleared by CLRV instruction, but not set by any instruction.
- Branch condition flag of BVS, BVC.

2.1.7.8 Negative flag (N)

- Set whenever the result of a data transfer or operation is negative (bit7 is set to 1).
- In the case of BIT instruction, bit7 of memory location is transferred to N-flag
- N-flag is not affected by CLR or SET instruction.
- Branch condition flag of BPL, BMI.

<i>STANDBY FUNCTION</i>	6
<i>RESET FUNCTION</i>	7
<i>APPENDIX A.</i>	8
<i>APPENDIX B.</i>	9

CHAPTER 3. I/O PORTS

The GMS810series has 21 I/O ports which are PORT0(8 I/O), PORT1 (8 I/O) and PORT2 (8 I/O). Each port contains data direction register which controls I/O and data register which stores port data.

3.1 PORT R0

3.1.1 PORT R0 Registers

REGISTER	SYMBOL	R/W	RESET VALUE	ADDRESS
R0 I/O Data Direction Register	R0DD	W	00H	00C1H
R0 Data Register	R0	R/W	Undefined	00C0H

Table 3.1 Port R0 Registers

3.1.2 I/O Data Direction Register (R0DD)

bit	7	6	5	4	3	2	1	0	
R0DD	R0DD7	R0DD6	R0DD5	R0DD4	R0DD3	R0DD2	R0DD1	R0DD0	<00C1H>
initial value	0	0	0	0	0	0	0	0	
R/W	W	W	W	W	W	W	W	W	

R0 I/O Data Direction Register(R0DD) is 8-bit register, and can assign input state or output state to each bit. If R0DD is $\bar{1}$, port R0 is in the output state, and if $\bar{0}$, it is in the input state. R0DD is write-only register. Since R0DD is initialized as $\bar{0}$ in reset state, the whole port R0 becomes input state.

3.1.1 Data Register(R0)

bit	7	6	5	4	3	2	1	0	
R0	R07	R06	R05	R04	R03	R02	R01	R00	<00C0H>
initial value	X	X	X	X	X	X	X	X	
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	

PORT0 data register (R0) is 8-bit register to store data of port R0. When set as the output state by R0DD, and data is written in R0, data is outputted into R0 pin. When set as the input state, input state of pin is read. The initial value of R0 is unknown in reset state.

Chapter 3. I/O PORT

3.2 PORT R1

PIN NAME	PORT SELECTION	FUNCTION SELECTION
R10	R10(I/O)	
R11/INT1	R11(I/O)	INT1 (INPUT)
R12/INT2	R12(I/O)	INT2 (INPUT)
R13	R13(I/O)	
R14/ \overline{EC}	R14(I/O)	\overline{EC} (INPUT)
R15/T2	R15(I/O)	T2 (OUTPUT)
R16/T1	R16(I/O)	T1 (OUTPUT)
R17/T0	R17(I/O)	T0 (OUTPUT)

Fig 3.1 Pin Function of port R1

3.2.1 PORT R1 Register

REGISTER	SYMBOL	R/W	RESET VALUE	ADDRESS
R1 I/O Data Direction Register	R1DD	W	00H	00C3H
R1 Data Register	R1	R/W	Undefined	00C2H
R1 Port Mode Register	PMR1	W	00H	00C9H
R1 Port Open drain Assign Register	R10DC	W	00H	00CEH

Table 3.1 Port R1 Registers

3.2.2 I/O Data Direction Register (R1DD)

bit	7	6	5	4	3	2	1	0	
R1DD	R1DD7	R1DD6	R1DD5	R1DD4	R1DD3	R1DD2	R1DD1	R1DD0	<00C3H>
initial value	0	0	0	0	0	0	0	0	
R/W	W	W	W	W	W	W	W	W	

R1 Data Direction Register(R1DD) is 8-bit register, and can assign input state or output state to each bit. If R1DD is $i\bar{E}1j\bar{E}$, port R1 is in the output state, and if $i\bar{E}0j\bar{E}$, it is in the input state. R1DD is write-only register. Since R1DD is initialized as $i\bar{E}00Hj\bar{E}$ in reset state, the whole port R1 becomes input state.

3.2.3 Data Register(R1)

R1 Data Register(R1) is 8-bit register to store data of port R1. When set as the output state by R1DD, and data is written in R1, data is output into R1 pin. The initial value of R1 is unknown in reset state.

bit	7	6	5	4	3	2	1	0	
R1	R17	R16	R15	R14	R13	R12	R11	R10	<00C2H>
initial value	X	X	X	X	X	X	X	X	
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	

3.2.4 Port R1 Open drain Assign Register (R1ODC)

bit	7	6	5	4	3	2	1	0	
R1ODC	R17OD	R16OD	R15OD	R14OD	R13OD	R12OD	R11OD	R10OD	<00DEH>
initial value	0	0	0	0	0	0	0	0	
R/W	W	W	W	W	W	W	W	W	

Port R1 Open Drain Assign Register(R1ODC) is 8bit register, and can assign R1 port as open drain output port each bit, if corresponding port is selected as output. If R1ODC is selected as $\bar{1}$, port R1 is open drain output, and if selected as 0 , it is push-pull output. R1ODC is write-only register and initialized as $000H$ in reset state.

Chapter 3. I/O PORT

3.2.5 Port R1 Mode Register (PMR1)

bit	7	6	5	4	3	2	1	0	
PMR1	T0S	T1S	T2S	ECS	-	INT2S	INT1S	-	<00C9H>
initial value	0	0	0	0	0	0	0	0	
R/W	W	W	W	W	W	W	W	W	

R1 Port Mode Register (PMR1) is 8-bit register, and can assign the selection mode for each bit. When set as $\bar{1}$, corresponding bit of PMR1 acts as port R1 selection mode, and when set as $\bar{1}$, it becomes function selection mode.

BIT NAME	PMR1	Selection Mode	Remarks
T0S	0	R17 Sel (I/O)	-
	1	T0 Sel (Output)	Output Port of Timer0
T1S	0	R16 Sel (I/O)	-

INT1S	0	R11 Sel (I/O)	-
	1	INT1 Sel (Input)	-
-	0		
	1		

Table 3.3 Selection Mode of PMR1

PMR1 is write-only register and initialized as $\bar{0}$ in reset state. Therefore, becomes Port selection mode. Port R1 can be I/O port by manipulating each R1DD bit, if corresponding PMR1 bit is selected as $\bar{1}$.

3.3 PORT R2

3.3.1 PORT R2 Registers

REGISTERS	SYMBOL	R/W	RESET VALUE	ADDRESS
R2 I/O Data Direction Register	R2DD	W	00H	00C5H
R2 Data Register	R2	R/W	Undefined	00C4H

Table 3.3 Port R2 Registers

3.3.2 I/O Data Direction Register (R2DD)

bit	7	6	5	4	3	2	1	0	
R2DD	R2DD7	R2DD6	R2DD5	R2DD4	R2DD3	R2DD2	R2DD1	R2DD0	<00C5H>
initial value	0	0	0	0	0	0	0	0	
R/W	W	W	W	W	W	W	W	W	

R2 Data Direction Register(R2DD) is 8-bit register, and can assign input state or output state to each bit. If R2DD is $\bar{1}$, port R2 is in the output state, and if $\bar{0}$, it is in the input state.

R2DD is write-only register. Since R2DD is initialized as $\bar{00H}$ in reset state, the whole port R2 becomes input state.

3.3.3 Data Register (R2)

bit	7	6	5	4	3	2	1	0	
R2	R27	R26	R25	R24	R23	R22	R21	R20	<00C4H>
initial value	X	X	X	X	X	X	X	X	
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	

R2 Data Register(R2) is 8-bit register to store data of port R2.

When set as the output state by R2DD, and data is written in R2, data is output into R2 pin. When set as input state, input state of pin is read.

The initial value of R2 is unknown in reset state.

CHAPTER 4. PERIPHERAL HARDWARE

4.1 CLOCK GENERATING CIRCUIT

Clock generating circuit consists of Clock Pulse Generator(C.P.G), Prescaler, Basic Interval Timer(B.I.T) and Watch Dog Timer.

The clock applied to the Xin pin divided by two is used as the internal system clock.

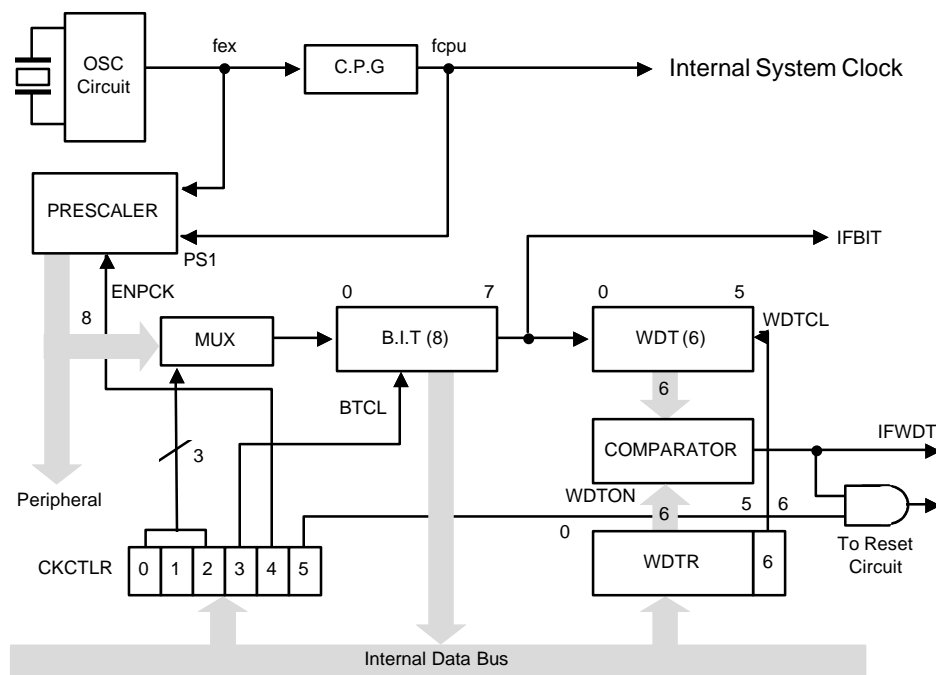

Fig. 4.1 Block diagram of clock generating circuit

Chapter 4. Peripheral Hardware

4.1.1 Oscillation Circuit

Oscillation circuit is designed to be used either with a ceramic resonator or crystal oscillator. Fig. 4.2-(a) shows circuit diagrams using a crystal (or ceramic) oscillator. As shown in the diagram, oscillation circuits can be constructed by connecting an oscillator between Xout and Xin. Clock from oscillation circuit makes CPU clock via clock pulse generator, and then enters prescaler to make peripheral hardware clock. alternately, the oscillator may be driven from an external source as shown is Fig. 4.2-(b). In the Standby(STOP) mode, oscillation stop, Xout state goes to $\bar{1}$ (HIGH), Xin state goes to $\bar{0}$ (LOW), and built-in feed back resistor is disabled.

(a) External Crystal (Ceramic) oscillator circuit

	TDK	CCR4.0MC3	Cin=Cout=open	2.2 ~ 4.0V

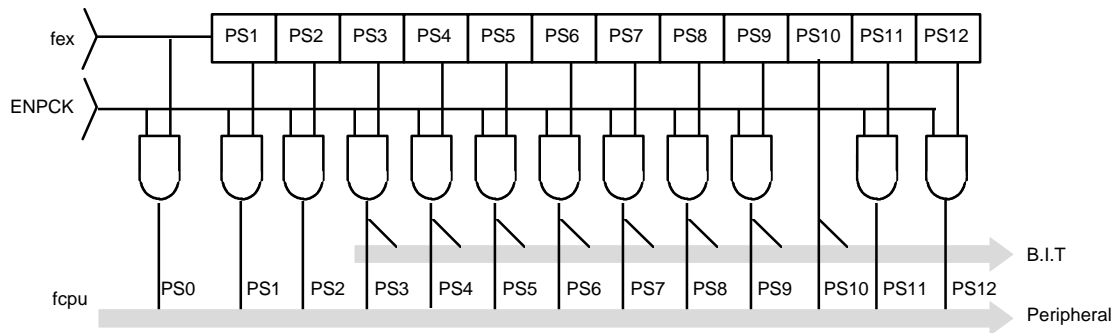

$\bar{0}$ MC type is building in load capacitor.CCR type is chip type.

4.1.2 Prescaler

Prescaler consists of 12-bit binary counter. The clock supplied from oscillation circuit is input to prescaler (fex). The divided output from each bit of prescaler is provided to peripheral hardware.

4.1.3 Peripheral hardware clock control

Clock to peripheral hardware can be stopped by bit4 (ENPCK) of CKCTLR Register. ENPCK is set to 1 in reset state.

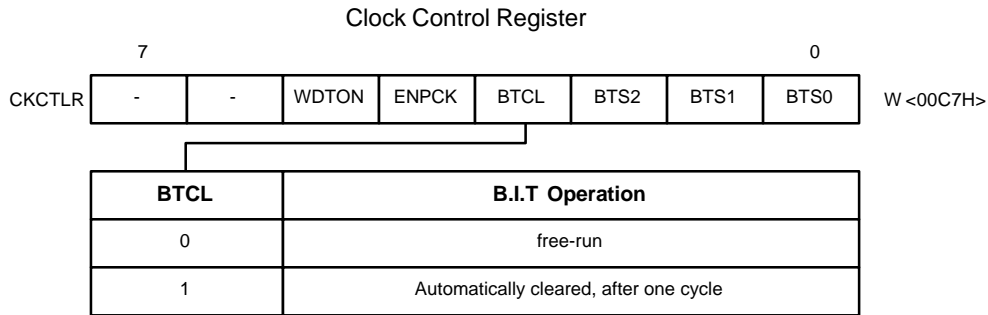

fex(MHz)		PS0	PS1	PS2	PS3	PS4	PS5	PS6	PS7	PS8	PS9	PS10	PS11	PS12

Fig. 4.3 Block diagram of Prescaler

4.1.4.1 Control of B.I.T

If bit3(BTCL) of CKCTLR is set to 1, B.I.T is cleared, and then, after one machine cycle, BTCL becomes 0, and B.I.T starts counting. BTCL is set to 0 in reset state.

4.1.4.2 Input Clock Selection of Basic Interval Timer

The input clock of B.I.T can be selected from the prescaler within a range of 2us to 256us by clock input selection bits(BTS2~BTS0). (at fex = 4MHz).

In reset state, or power on reset, BTS2=1, BTS1=1, BTS0=1 to secure the longest oscillation stabilization time.

B.I.T can generate the wide range of basic interval time interrupt request(IFBIT) by selecting prescaler output.

Interrupt interval can be selected to 8 kinds of interval time as shown in Table. 4.1.

Chapter 4. Peripheral Hardware

Table 4.1 Standby release time according to BTS

4.1.4.3 Reading Basic Interval Timer

By reading of the Basic Interval Timer Register(BITR), we can read counter value of B.I.T. Because B.I.T can be cleared or read, the spending time up to maximum 65.5ms can be available. B.I.T is read-only register. If B.I.T register is written, then CKCTLR register with same address is written.

Basic Interval Timer Register

		7						0	
BITR	BIT7	BIT6	BIT5	BIT4	BIT3	BIT2	BIT1	BIT0	R <00C7H>

4.1.5 Watch Dog Timer

Watch Dog Timer(WDT) consists of 6-bit binary counter, 6-bit comparator, and Watch Dog Timer Register (WDTR).

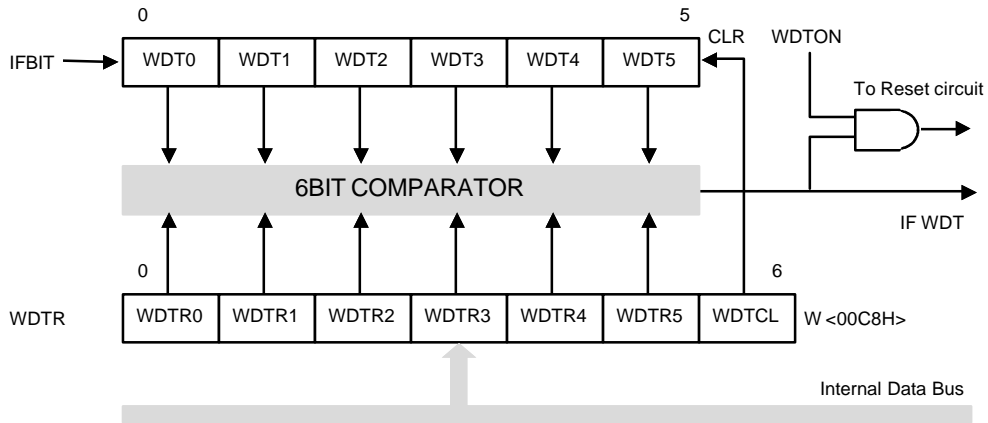

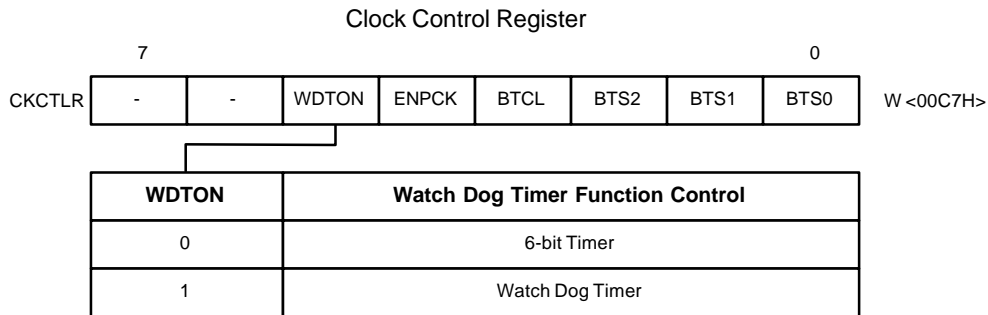

Fig. 4.5 Block diagram of Watch Dog Timer

4.1.5.1 Control of WDT

Watch Dog Timer can be used 6-bit general Timer or specific Watch dog timer by setting bit5(WDTON) of Clock Control Register(CKCTLR).

Chapter 4. Peripheral Hardware

By assigning bit6(WDTCL) of WDTR, 6-bit counter can be cleared

(Caution) : after WDTCL = 1, timer maximum error is one cycle of IFBIT.

4.1.5.2 WDT Interrupt Interval

WDT Interrupt(IFWDT) interval is determined by the interrupt IFBIT interval of Basic Interval Timer and the value of WDT Register.

$$\text{Interval of IFWDT} = (\text{IFBIT interval}) * (\text{WDTR value})$$

Interval of IFWDT : 512us i 1 = 512us (MIN>)
: 65,536us i 63 = 4,128,768us (MAX>)

As IFBIT (Basic Interval Timer Interrupt Request) is used for input clock of WDT, Input clock cycle is possible from 512us to 65,536us by BTS. (at fex = 4MHz)

*At Hardware reset time ,WDT starts automatically. Therefore, the user must select the CKCTRL,WDTR before WDT overflow.
(Reset WDTR value = 0Fh,15
interval of WDT = 65,536 i 15 = 983040 uS (about 1second))

BTS2	BTS1	BTS0	Input clock of WDT	Max. Interval of WDT output (*note1)
0	0	0	512 μ s	32,756 μ s
0	0	1	1,024 μ s	64,512 μ s
0	1	0	2,048 μ s	129,024 μ s
0	1	1	4,096 μ s	258,048 μ s
1	0	0	8,192 μ s	516,096 μ s
1	0	1	16,384 μ s	1,032,192 μ s
1	1	0	32,768 μ s	2,064,384 μ s
1	1	1	65,536 μ s	4,128,768 μ s

*note1) When WDTR Register value is 63(3FH)

Caution : Do not use 0000 for WDTR Register value.
Device come into the reset state by WDT

Chapter 4. Peripheral Hardware

4.2 TIMER

4.2.1 Timer operation mode

Timer consists of 16bit binary counter Timer0(T0), 8bit binary Timer1(T1), Timer2(T2), Timer Data Register, Timer Mode Register (TM01, TM0, TM1, TM2) and control circuit. Timer Data Register Consists of Timer0 High-MSB Data Register(T0HMD), Timer0 High-LSB Data Register(T0HLD), Timer0 Low-MSB Data Register(T0LMD), Timer0 Low-LSB Data Register(T0LLD), Timer1 High Data Register(T1HD), Timer1 Low Data Register(T1LD), Timer2 Data Register(T2DR).

Any of the PS0~PS5, PS11 and external event input \overline{EC} can be selected as clock source for T0. Any of the PS0~PS3, PS7~PS10 can be selected as clock T1. Any of the PS5~PS12 can be selected as clock source for T2.

4.2.3 Timer0, Timer1

TIMER0 and TIMER1 have an up-counter. When value of the up-counter reaches the content of Timer Data Register(TDR), the up-counter is cleared to 0, and interrupt(IFT0, IFT1) is occurred at the next clock

Fig. 4. 10 Operatiion of Timer0

For Timer0, the internal clock(PS) and the external clock(\overline{EC}) can be selected as counter clock. But Timer1 and Timer2 use only internal clock. As internal clock. Timer0 can be used as internal-timer which period is determined by Timer Data Register(TDR). Chosen as external clock, Timer0 executes as event-counter. The counter execution of Timer0 and Timer1 is controlled by T0CN, T0ST, CAP0, T1CN, T1ST, of Timer Mode Register TM0 and TM1. T0CN, T1CN are used to stop and start Timer0 and Timer1 without clearing the counter. T0ST, T1ST is used to clear the counter. For clearing and starting the counter, T0ST or T1ST should be temporarily set to 0 and then set to 1. T0CN, T1CN, T0ST and T1ST should be set to 1, when Timer counting-up. Controlling of CAP0 enables Timer0 as input capture. By programming of CAP0 to 1, the period of signal from INT2 can be measured and then, event counter value for INT2 can be read.

Chapter 4. Peripheral Hardware

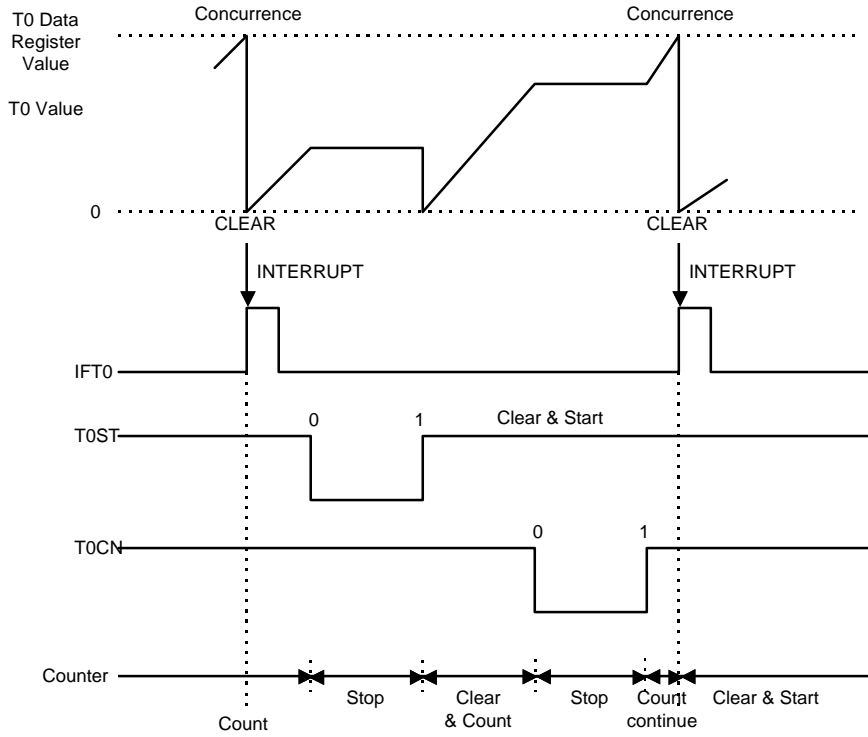

Fig. 4. 11. Start/Stop operation of Timer0

Fig. 4. 12. Input capture operation of Timer0

During counting-up, value of counter can be read. Timer execution is stopped by the reset signal ($\overline{\text{RESET}} = \text{1}$)

(Note) in the process of reading 16-bit Timer Data, first read the upper 8-bit data. Then read the lower 8-bit data, and read the upper 8-bit data again. If the earlier read upper 8-bit data are matched with the later read upper 8-bit data, read 16-bit data are correct. If not, caution should be taken in the selection of upper 8-bit data.

Example)

1) Upper	8-bit	Read	0A	0A
2) Lower	8-bit	Read	FF	01
3) Upper	8-bit	Read	0B	0B
			16	16
			0AFF	0B01

4.2.3.1 Single/Modulo-N Mode

Timer0 (Timer1) can select initial (T0INIT, T1INIT of TM0, TM1) output level of Timer Output port. If initial level is 0 , Low-Data Register value of Timer Data Register is transferred to comparator and T0OUT(T1OUT) is to be 0 , if initial level is 1 , High -Data Register is transferred and to be 1 . Single Mode can be set by Mode Select bit(T0MOD, T1MOD) of Timer Mode Register (TM0, TM1) to 0 . When used as Single Mode, Timer counts up and compares with value of Data Register. If the result is same, Time Out interrupt occurs and level of Timer Output port toggle, then counter stops as reset state. When used as Modulo-N Mode, T0MOD(T1MOD) should be set 1 . Counter counts up until the value of Data Register and occurs Time-out interrupt. The level of Timer Output port toggle and repeats process of counting the value which is selected in Data Register. During Modulo-N Mode, If interrupt select bit(TOIFS, T1IFS) of Mode Register is 0 , Interrupt occurs on every Time-out. If it is 1 , Interrupt occurs every second time-out.
 (*note. Timer Output is toggled whenever time out happen)

Chapter 4. Peripheral Hardware

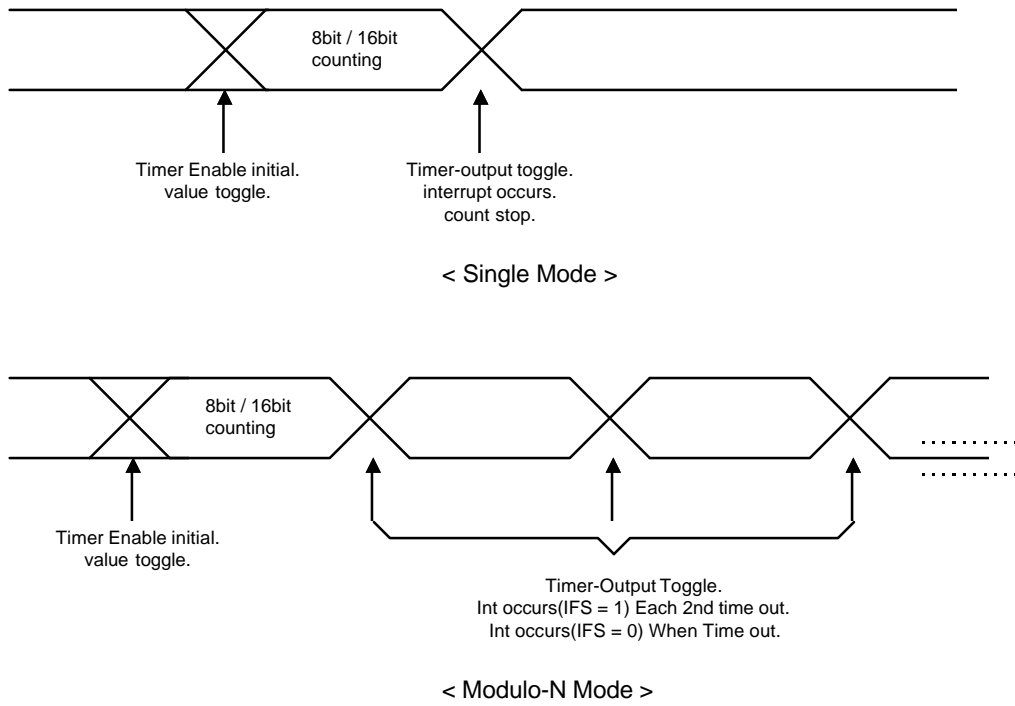

Fig. 4. 13 Operation Diagram for Single/Modulo-N Mode

4.2.4 Timer2

Timer2 operates as a up-counter. The content of T2DR are compared with the contents of up-counter. If a match is found. Timer2 interrupt (IFT2) is generated and the up-counter is cleared to 0. Therefore, Timer2 executes as a interval timer. Interrupt period is determined by the count source clock for the Timer2 and content of T2DR.

When T2ST is set to 1, count value of Timer 2 is cleared and starts counting-up. For clearing and starting the Timer2. T2ST have to set to 1 after set to 0. In order to write a value directly into the T2DR, T2ST should be set to 0. Count value of Timer2 can be read at any time.

<i>FUNCTION DESCRIPTION</i>	2
<i>I/O PORT</i>	3
<i>PERIPHERAL HARDWARE</i>	4
<i>INTERRUPT</i>	5
<i>STANDBY FUNCTION</i>	6
<i>RESET FUNCTION</i>	7
<i>APPENDIX A.</i>	8
<i>APPENDIX B.</i>	9

CHAPTER 5. INTERRUPT

The GMS810 Series contains 8 interrupt sources; 3 externals and 5 internals. Nested interrupt services with priority control is also possible. Software interrupt is non-maskable interrupt, the others are all maskable interrupts.

- 8 interrupt source (2Ext, 3Timer, BIT, WDT and Key Scan)
- 8 interrupt vector
- Nested interrupt control is possible
- Programmable interrupt mode
 - Hardware accept mode
 - Software selection accept mode
- Read and write of interrupt request flag are possible.
- In interrupt accept, request flag is automatically cleared.

Interrupt hardware consists of Interrupt Mode Register(MOD), Interrupt Enable Register High (IENH), Interrupt Enable Register Low(IENL), Interrupt Request Register High(IRQH), Interrupt Request Register Low(IRQL) and priority circuit. Interrupt function block diagram is shown in Fig. 5.1

5.1 INTERRUPT SOURCE

Each interrupt vector is independent and has its own priority. Software interrupt(BRK) is also available. Interrupt source classification is shown in Table 5.1

Chapter 5. Interrupt

Fig. 5.1 Interrupt Source

	Mask	Priority	Interrupt Source	INT Vector H	INT Vector L
Hardware Interrupt	Non-maskable	-	RST ($\overline{\text{RESET}}$ PIN)	FFFF	FFFE
	Maskable	0	KSCNR (Key Scan)	FFFB	FFFA
		1	INT1R(External Interrupt 1)	FFF9	FFF8
		2	INT2R(External Interrupt 2)	FFF7	FFF6
		3	T0R (Timer0)	FFF3	FFF2
		4	T1R (Timer1)	FFF1	FFF0

		6	WDTR (Watch Dog Timer)	FFE9	FFE8
7	BITR (Basic Interval Timer)	FFE7	FFE6		
Software Interrupt	-	-	BRK Instruction	FFDF	FFDE

Table 5.1 Interrupt Source

5.2 INTERRUPT CONTROL REGISTER

I flag of PSW is a interrupt mask enable flag. When I flag = 0, all interrupts become disable. When I flag = 1, interrupts can be selectively enabled and disabled by contents of corresponding Interrupt Enable Register.

When interrupt is occurred, interrupt request flag is set, and Interrupt request is detected at the edge of interrupt signal. The accepted interrupt request flag is automatically cleared during interrupt cycle process. The interrupt request flag maintains 1 until the interrupt is accepted or is cleared in program.

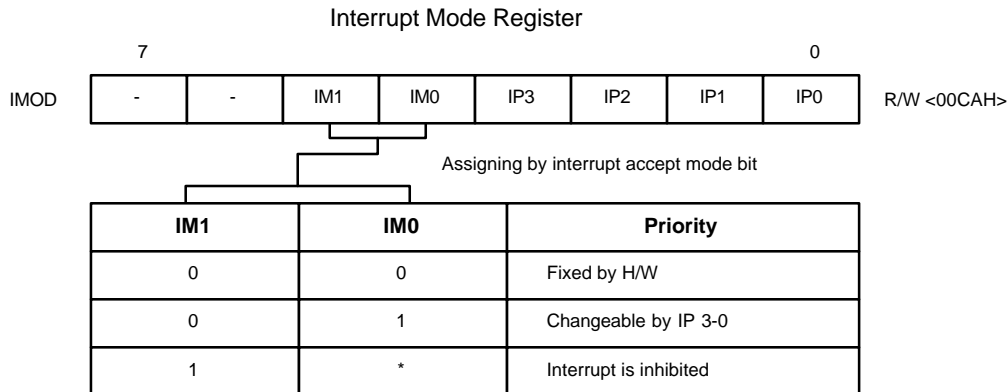

In reset state, interrupt request flag register(IRQH, IRQL) is cleared to 0. It is possible to read the state of interrupt register and to mainpulate the contents of register and to generate interrupt. (Refer to software interrupt).

Chapter 5. Interrupt

5.3 INTERRUPT ACCEPT MODE

The interrupt priority order is determined by bit(IM1, IM0) of IMOD register.

5.3.1 Selection of interrupt by IP3 - IP0

The condition allow for accepting interrupt is set state of the interrupt mask enable flag and the interrupt enable bit must be $\bar{E}1\bar{E}$.

IP3	IP2	IP1	IP0	Selection interrupt
0	0	0	1	KSCNR (Key Scan)
0	0	1	0	INT1R (External interrupt 1)
0	0	1	1	INT2R (External interrupt 2)
0	1	0	0	Reserved
0	1	0	1	T0R (Timer 0)
0	1	1	0	T1R (Timer 1)
0	1	1	1	T2R (Timer 2)
1	0	0	0	Reserved
1	0	0	1	Reserved
1	0	1	0	WDTR (Watch Dog Timer)
1	0	1	1	BITR (Basic Interval Timer)
1	1	0	0	Reserved

Table 5.2 Interrupt Selection by IP3 - IP0

*In Reset state, these IP3 - IP0 registers become all $\bar{E}0\bar{E}$.

5.3.2 Interrupt Timing

Fig. 5.2 Interrupt Enable Accept Timing

- Interrupt Request sampling time
 - Maximum 12 machine cycle (When execute DIV instruction)
 - Minimum 0 machine cycle
- Interrupt preprocess step is 8 machine cycle
- Interrupt overhead
 - Maximum $1 + 12 + 8 = 21$ machine cycle
 - Minimum $1 + 0 + 8 = 9$ machine cycle

5.3.3 The valid timing after executing Interrupt control instructions

I flag is valid just after executing of EI/DI on the contrary.
 Interrupt Enable register is valid one instruction after controlling interrupt Enable Register.

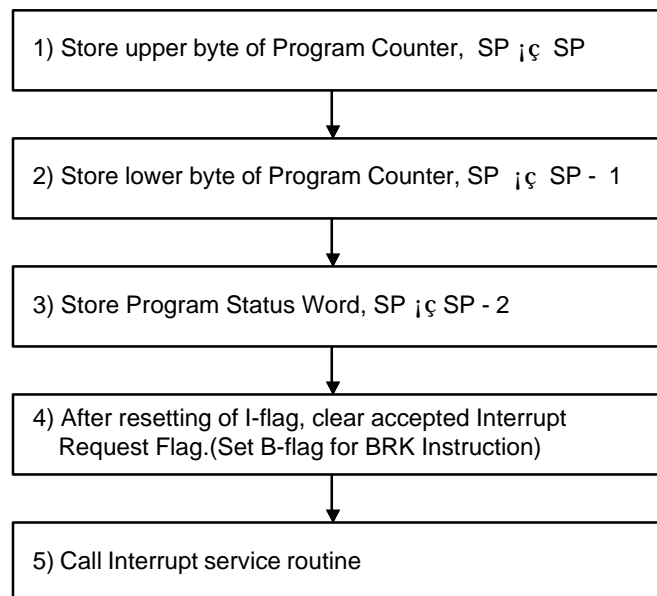

5.4 INTERRUPT PROCESSING SEQUENCE

When an interrupt is accepted, the on-going process is stopped and the interrupt service routine is executed. After the interrupt service routine is completed it is necessary to restore everything to the state before the interrupt occurred.

As soon as an interrupt is accepted, the content of the program counter and PSW are saved in the stack area.

At the same time, the content of the vector address corresponding to the accepted interrupt, which is in the interrupt vector table, enters into the program counter and interrupt service is executed. In order to execute the interrupt service routine, it is necessary to write the jump addresses in the vector table (FFEOH-FFFFH) corresponding to each interrupt

Interrupt Processing Step

Fig. 5. 3 Interrupt Processing Step Timing

- *1 ISR : Interrupt Service Routine
- *2 LVA : Low Vector Address
- *3 HVA : High Vector Address

5.1 SOFTWARE INTERRUPT

5.5.1 Interrupt by Break(BRK) Instruction

Software interrupt is available just by writing `Break(BRK)` instruction. The values of PC and PSW is stacked by BRK instruction and then B flag of PSW is set and I flag is reset.

Chapter 5. Interrupt

Interrupt vector of BRK instruction is shared by vector of Table Call(TCALL0). When both instruction of BRK and TCALL0 are used, as shown in Fig. 5.4 each processing routine is judged by contents of B flag. There is no instruction to reset directly B flag.

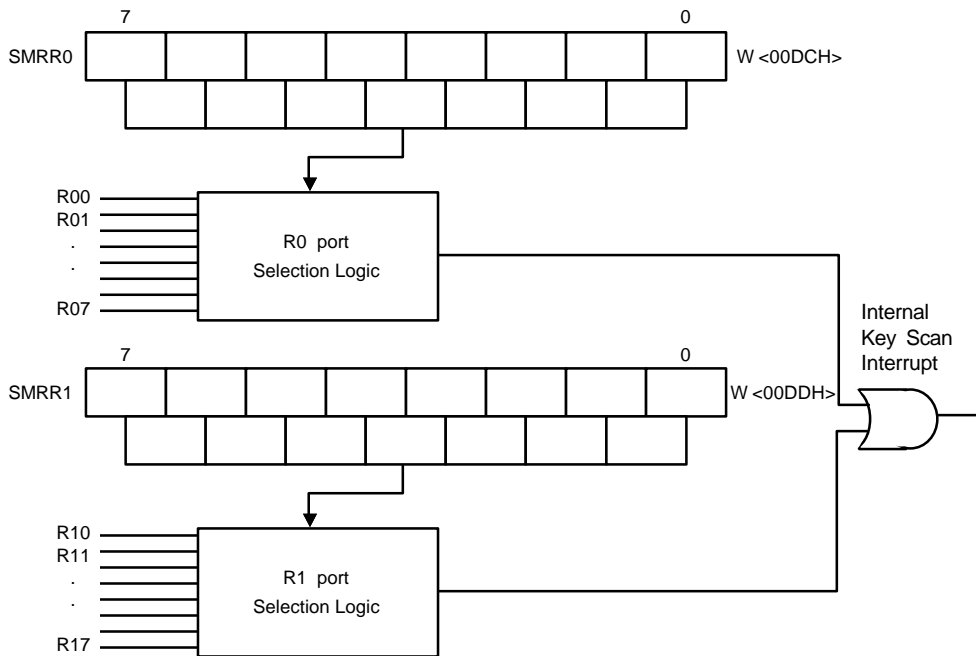

Fig. 5.4 Execution of BRK or TCALL0

5.6 MULTIPLE INTERRUPT

If there is an interrupt, Interrupt Mask Enable Flag is automatically cleared before entering the Interrupt Service Routine. After then, no interrupt is accepted. If EI instruction is executed, interrupt mask enable bit becomes 1, and each enable bit can accept interrupt request. When two or more interrupts are generated simultaneously, the highest priority interrupt set by Interrupt Mode Register is accepted.

5.7 Key Scan Input Processing

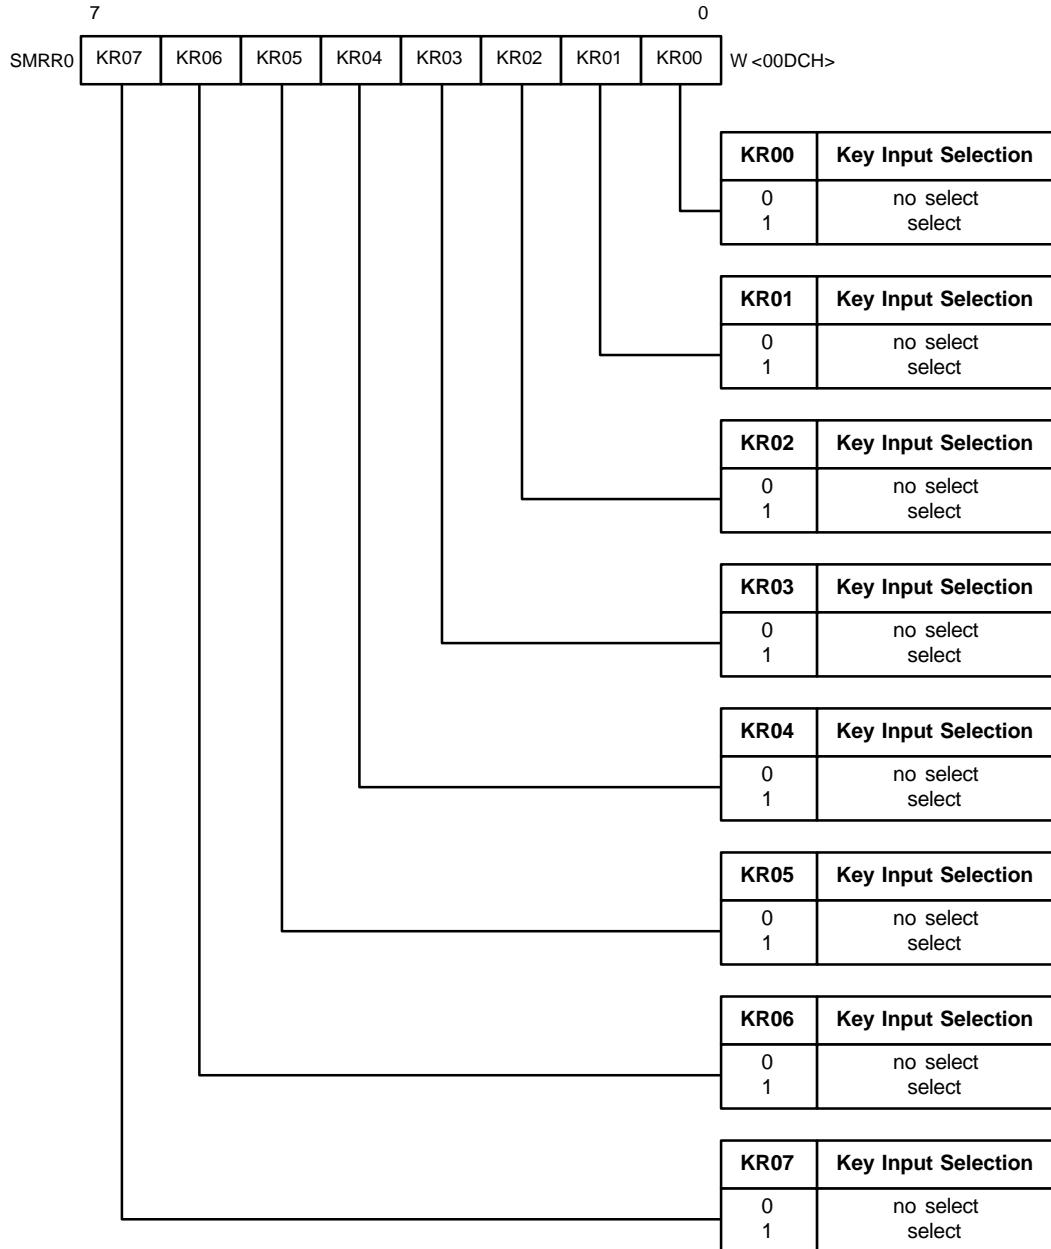

Key Scan Interrupt is generated by detecting low Input from each Input pin (R0, R1) or standby(SLEEP, STOP) release signal. Key Scan ports are all 16bit which are controlled by Stand-by Mode Release Register (SMRR0, SMRR1). Key Input is considered as Interrupt, therefore, KSCNE bit of IEHN should be set for correct interrupt executing, SLEEP mode and STOP mode, the rest of executing is the same as that of external Interrupt. Each SMRR Register bit is allowed for each port(for Bit=0, no Key Input, for Bit=1, Key Input available). At reset, SMRR becomes 000H . So, there is no Key Input source.

<i>APPENDIX A.</i>	8
<i>APPENDIX B.</i>	9

CHAPTER 6. STANDBY FUNCTION

To save power consumption, there is STOP modes. In this modes, the execution of program stops.

6.1 STOP MODE

STOP mode can be entered by STOP instruction during program. In STOP mode, oscillator is stopped to make all clocks stop, which leads to less power consumption. All registers and RAM data are preserved. ;NOP; instruction should be follows STOP instruction for rising precharge time of Data Bus line.

ex) STOP : STOP instructiion excution
NOP : NOP instruction

Chapter6. Standby Function

Fig. 6.1 Block Diagram of Standby Circuit

Fig. 6.2 ENPCK and Basic Interval Timer Clock

6.2 STANDBY MODE RELEASE

6.2.1 STOP Mode Release

Release of STANDBY mode is executed by $\overline{\text{RESET}}$ input and Interrupt signal. Register value is defined when Reset. When there is a release signal of STOP mode (Interrupt, RESET input), the instruction execution starts after stabilization oscillation time is set by value of BTS2~BTS0 and set ENPCK to 1.

Table 6.1. Standby Mode Register

Release Signal	STOP
$\overline{\text{RESET}}$	0
KSCN (Key input)	0
INT1 - INT2	0

Table 6.2 Standby Mode Release

Release Factor	Release Method
$\overline{\text{RESET}}$ Pin	By $\overline{\text{RESET}}$ Pin = Low level, Standby mode is release and system is initialized
KSCN (Key input)	Standby mode is released by Low input of selected pin by Key Scan Input (SMRR0, SMRR1) In case of interrupt Mask Enable flag = 0, program executes just after standby instruction, if flag = 1, enters each interrupt service routine.
INT 1 pin INT 2 pin	When external interrupt (INT1, INT2) enable flag is $\overline{1}$, standby mode is released at the rising edge of each terminal. When Standby mode is released at interrupt. Mask Enable flag = 0, program executes from the next instruction of standby instruction. When 1, enters each interrupt service routine.

Chapter6. Standby Function

Fig. 6.3 Release Timing of Standby Mode

6.3 RELEASE OPERATION OF STANDBY MODE

After Standby mode is released, the operation begins according to content of related interrupt register just before Standby mode start(Fig. 6.3)

6.3.1 In Case of Interrupt Enable Flag(I) of PSW = 0

Release by only interrupt which interrupt enable flag = 1, and starts to execute from next to Standby instruction (STOP).

6.3.2 In Case of Interrupt Enable Flag(I) of PSW = 1

Released by only interrupt which each interrupt enable flag = 1, and jump to the relevant interrupt service routine.

Note) When STOP instruction is used, B.I.T should guarantee the stabilization oscillation time. Thus, just before entering STOP mode, clock of bit10(PS10) of Prescaler is selected or peripheral hardware clock control bit(ENPCK) to 1, Therefore the clock necessary for stabilization oscillation time should be input into B.I.T. otherwise, Standby mode is released by reset signal. In case of interrupt request flag and interrupt enable flag are both 1, Standby mode is not entered.

Fig. 6.5 Standby Mode Release Flow

Chapter6. Standby Function

Internal circuit	STOP Mode
Oscillator	Stop
Internal CPU clock	Stop
Register	Retained
RAM	Retained
I/O port	Retained
Prescaler	Stop
Basic Interval Timer	Stop
Watch Dog Timer	Stop
Timer	Stop
Address Bus, Data Bus	Retained

<i>STANDBY FUNCTION</i>	6
<i>RESET FUNCTION</i>	7
<i>APPENDIX A.</i>	8
<i>APPENDIX B.</i>	9

CHAPTER 7. RESET FUNCTION

7.1 EXTERNAL $\overline{\text{RESET}}$

The $\overline{\text{RESET}}$ pin should be held at low for at least 2 machine cycles with the power supply voltage within the operating voltage range and must be connected 0.1uF capacitor for stable system initialization.

The RESET pin contains a Schmitt trigger with an internal pull-up resistor.

Fig 7.0 $\overline{\text{RESET}}$ Pin connection.

7.2 POWER ON RESET

Power On Reset circuit automatically detects the rise of power voltage (the rising time should be within 50ms) the power voltage reaches a certain level, $\overline{\text{RESET}}$ terminal is maintained at $\overline{1}$ Level until a crystal ceramic oscillator oscillates stably. After power applies and starting of oscillation, this reset state is maintained for about oscillation cycle of 2^{19} (about 65.5ms : at 4MHz).

The execution of built-in Power On Reset circuit is as follows :

- (1) Latch the pulse from Power On Detection Pulse Generator circuit, and reset Prescaler, B.I.T and B.I.T Overflow detection circuit.
- (2) Once B.I.T Overflow detection circuit is reset. Then, Prescaler starts to count.
- (3) Prescaler output is inputted into B.I.T and PS10 of Prescaler output is automatically selected. If overflow of B.I.T is detected, Overflow detection circuit is set.
- (4) Reset circuit generates maximum period of reset pulse from Prescaler and B.I.T.

Chapter7. Reset Function

Fig. 7.1 Block Diagram of Power On Reset Circuit

Notice ; When Power On Reset, oscillator stabilization time doesn't include OSC. Start time.

Fig. 7.2 Oscillator stabilization diagram

Fig. 7.3 Reset Timing by Diagram

Chapter7. Reset Function

7.3 Low Voltage Detection Mode

7.3.1 Low voltage detection condition

An on board voltage comparator checks that V_{DD} is at the required level to ensure correct operation of the device. If V_{DD} is below a certain level, Low voltage detector forces the device into low voltage detection mode.

7.3.2 Low Voltage Detection Mode

There is no power consumption except stop current, stop mode release function is disabled. All I/O port is configured as input mode and Data memory is retained until voltage through external capacitor is worn out. In this mode, all port can be selected with Pull-up resistor by Mask option. If there is no information on the Mask option sheet ,the default pull up option (all port connect to pull-up resistor) is selected.

7.3.3 Release of Low Voltage Detection Mode

Reset signal result from new battery(normally 3V) wakes the low voltage detection mode and come into normal reset state. It depends on user whether to execute RAM clear routine or not.

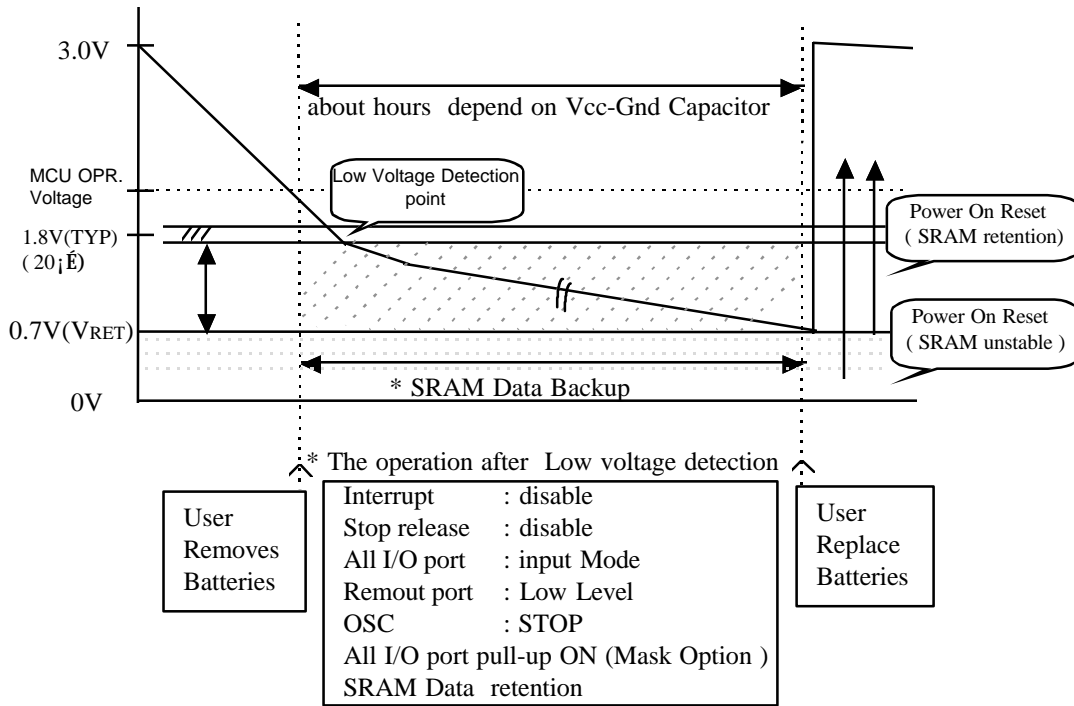

Fig 7.5 Low Voltage vs Temperature

*** SRAM BACK-UP after Low Voltage Detection.**
