6. FUNCTIONAL DESCRIPTIONS

6.1. Memories

GPLB62P100UA1 contains 2560-byte SRAM, 1536-byte LCD RAM and works with 1M bytes OTP ROM.

6.2. Operating States

There are three operation modes involved in GPLB62P100UA1: standby, halt and operating. The following table shows the differences between these modes.

	Operating	Halt	Standby
CPU	ON	OFF	OFF
32768Hz Oscillator	ON	ON	OFF
LCD Driver	ON	ON/OFF	OFF

6.2.1. Operating Mode

In operating state, all functions (CPU, 32768Hz oscillator, timer/counter, LCD driver...) are activated.

6.2.2. Standby Mode

Turn off 32768Hz oscillator and write "07H" to P_CLK_CPU_Ctrl Register (\$3006) to activate standby mode. The standby mode is a mode that the device is placed in its lowest current consumption state. In standby mode, all functions are turned off; in addition, RAM and I/Os will remain in their previous states.

6.2.3. Halt Mode

Write "07H" to P_CLK_CPU_Ctrl Register (\$3006) but still keeps 32768Hz oscillator running to enter halt mode. In halt mode, CPU clock halts and waits for an event (e.g. key press, timer overflow) to wake up. The 32768Hz related functions, such as timer/counter and LCD driver, may remain active in the halt mode.

The following figure is the GPLB62P100UA1 state diagram:

GPLB62P100UA1 State Diagram

6.3. Speech and Melody, and DAC

The GPLB62P100UA1 uses a high performance SPU voice engine to archive 8-channel voice with ADPCM/PCM code. The SPU also supports automatic zero-crossing concatenating function. A hardware multiplier is also embedded in this SPU for software use. The fixed addresses of RAM area \$0000 - \$009F is designed as address pointers and a data buffer for the 8-channel speech/melody generation. Moreover, one 14-bit software channel with noise filter is also supported. There is one 14-bit DAC with push-pull amplifier for direct audio output.

6.4. Hardware PWMIO

Hardware PWMIO supports 4 LED outputs with brightness control of 256 levels. The clock source of PWMIO is selective by user's request.

6.5. LCD Controller/Driver

GPLB62P100UA1 has a built-in LCD driver and support monochrome and 4-gray-level LCD control. The LCD driver can support up to 32COM * 74SEG, and it also can cascade external LCD SEG driver that can extend LCD resolution up to 32COM * 192SEG with gray level or up to 32COM * 384SEG with mono level. Programmers are able to define the LCD configuration by setting up the LCD Control Register. Once the LCD configuration is completed, the desired pattern can be displayed by filling the LCD buffer with proper data. The LCD driver can also operate in halt mode by keeping 32768Hz oscillator running. The LCD driver in GPLB62P100UA1 supports 1/2 - 1/32 duty and 1/3 - 1/7 bias.

6.6. LCD Voltage Generator

To achieve highly integrated circuit and save external components, GPLB62P100UA1 has built-in charge-pump circuit to generate LCD's bias voltages VLCD, V4, V3, V2 and V1. The level of VLCD can be adjusted by software. It is suggested that VLCD must be higher than VDD_IO or abnormal operation will occur.

6.7. LCD Sprite Function

The GPLB62P100UA1 also supports special functions such as PIP, data shift, and write back, etc. User can implement sprite function easily.

6.8. USB Device Function

The GPLB62P100UA1 provides the device function which is compatible with USB 2.0 full-speed standard. A USB transceiver is also built-in.

6.9. Low Voltage Detection

The GPLB62P100UA1 equips an 8-level (software programmable) low voltage detector to detect low voltage events. Users can turn on the low voltage detection that monitors VDD_REGIN periodically to check whether it is lower than the given value. In addition, if LV NMI is enabled, an NMI will be issued to notify CPU if power voltage drops below the given value. Also, the voltage detector will generate a system reset if power supply voltage drops too low.

6.10. Watchdog Timer (WDT)

An on-chip watchdog timer is also available in the GPLB62P100UA1. The WDT is designed to recover the system from unexpected operations. In some cases, if WDT is not cleared within one second, the WDT will generate a system reset to restart system. If WDT is enabled, the WDT should be cleared periodically to avoid accidental reset. The WDT can be cleared through software programming. Note that the WDT only works when 32768Hz clock is activated.

6.11. SPI Controller

Two Serial Peripheral Interface (SPI) controllers are built-in to enable synchronous serial communication with master/slave peripherals. There are four control signals on SPI including SPICSN, SPICLK (SCK), SPIRX (SDI), and SPITX (SDO). The four signals of SPI1 are shared with PB4, PB5, PB6 and PB7. The four signals of SPI2 are shared with PB0, PB1, PB2 and PB3. While SPI module is enabled by corresponding control bit, these four pins cannot be used as GPIOs and any setting on corresponding GPIO control register will have no effect. Four types of operating modes are supported as follows:

Master Mode, Polarity = 0, Phase=0

Master Mode, Polarity = 0, Phase=1

Master Mode, Polarity = 1, Phase=0

Master Mode, Polarity = 1, Phase=1

8.1. 2,368 Dots LCD Driver, 74 Segments x 32 Commons, 3-battery Application, Internal 3.3V Regulator Enabled, ROSC24M XTAL32K Selected, PB[4:7] Connected to 3.3V SPI Flash using Internal 3.3V Regulator Power - (1)

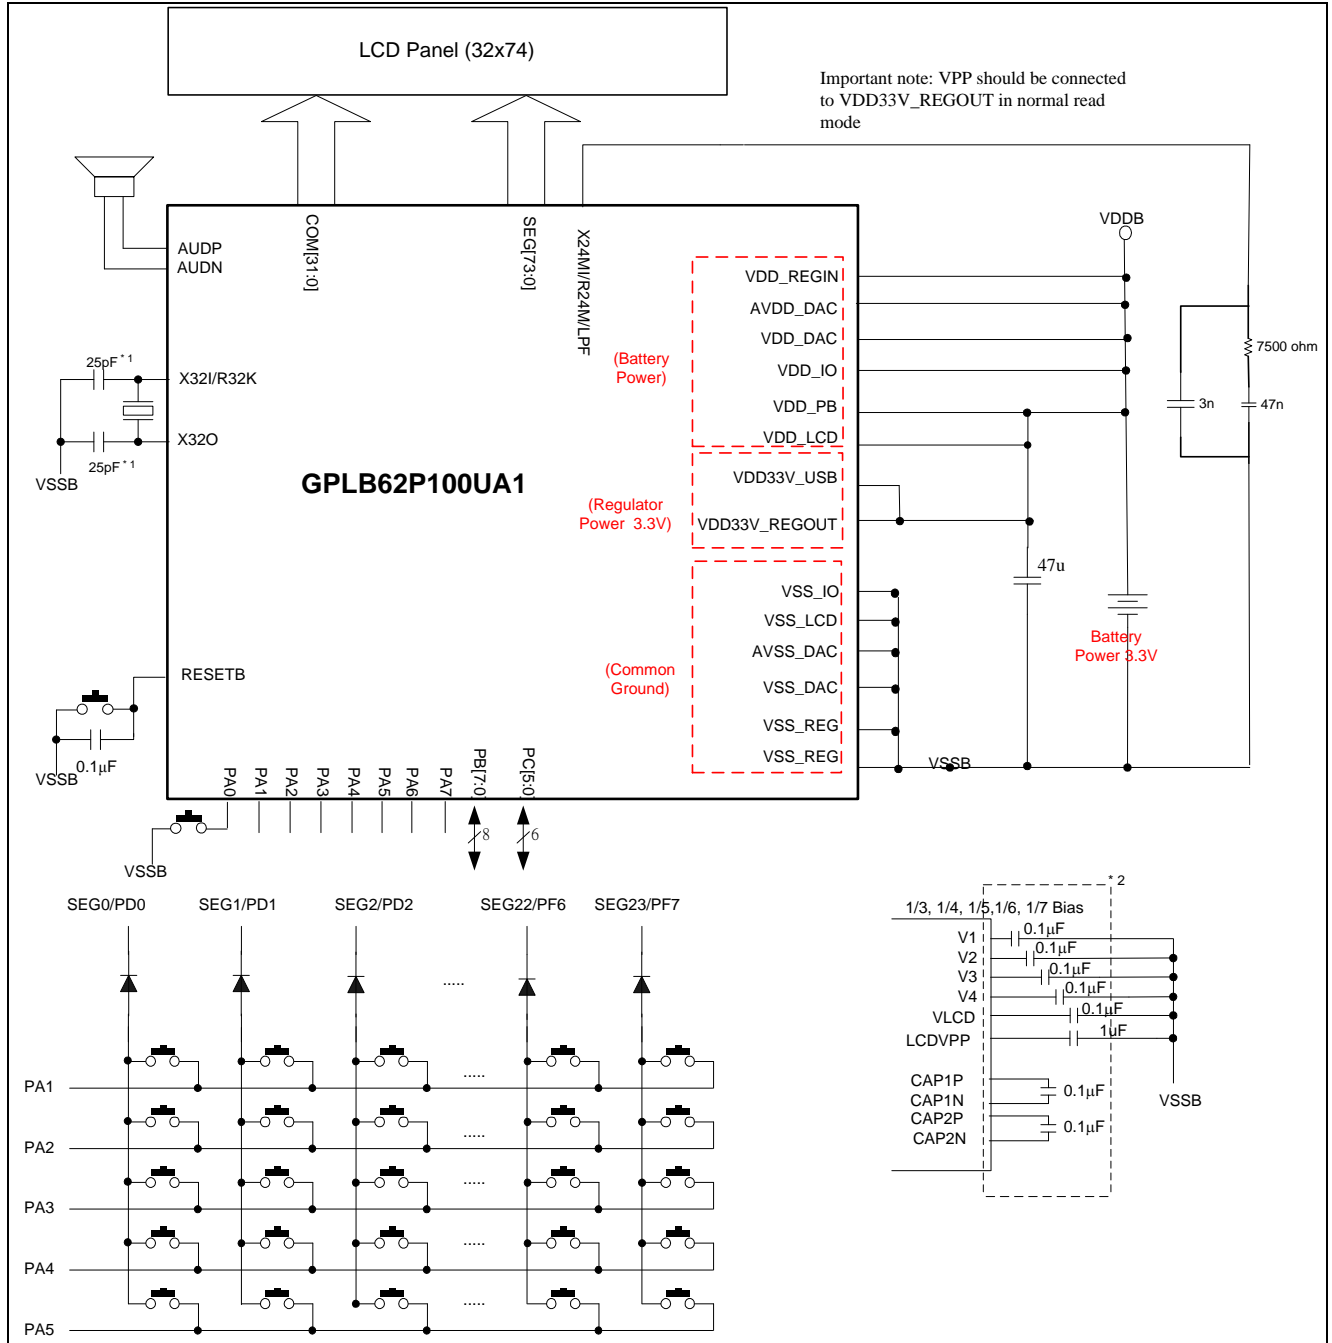

Note*1: These capacitor values are for design guidance only. The recommended 32K XTAL features are ESR=11.2~60K and CL1=CL2 =26~36pF (including PCB parasitic loading, for example, user should apply additional 20~30pF on X32I and X32O if PCB parasitic loading is 6pF).

Note*2: These capacitor values are for design guidance only. The ratio of LCDVPP capacitance to CAP1N/CAP1P/CAP2N/CAP2P capacitance is recommended to be 10:1. Generally, capacitance of VLCD and V1~V4 is 0.1uF and cannot be larger than capacitance of LCDVPP. In a large LCD panel, the followings are recommended: 1uF capacitance for VLCD and V1~V4, 2.2uF capacitance for LCDVPP and 0.22uF capacitance for CAP1P/CAP1N/CAP2P/CAP2N.

Note*3: This capacitor can be removed if this node is immune from noise.
