

Non-Volatile SRAM MODULE 2Mbit (256K x 8-Bit), 32Pin-DIP, 5V
Part No. HMN2568D

GENERAL DESCRIPTION

The HMN2568D Nonvolatile SRAM is a 2,097,152-bit static RAM organized as 262,144 bytes by 8 bits.

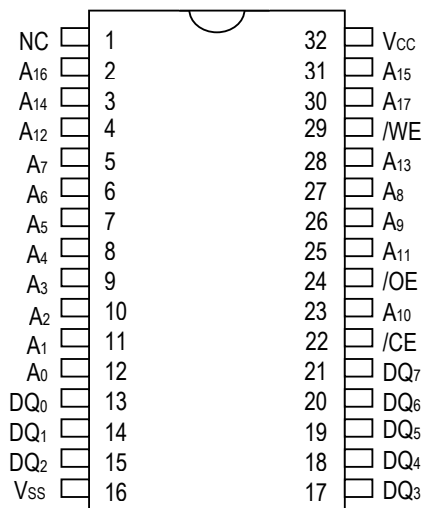

The HMN2568D has a self-contained lithium energy source provide reliable non-volatility coupled with the unlimited write cycles of standard SRAM and integral control circuitry which constantly monitors the single 5V supply for an out-of-tolerance condition. When such a condition occurs, the lithium energy source is automatically switched on to sustain the memory until after V_{CC} returns valid and write protection is unconditionally enabled to prevent garbled data. In addition the SRAM is unconditionally write-protected to prevent an inadvertent write operation. At this time the integral energy source is switched on to sustain the memory until after V_{CC} returns valid.

The HMN2568D uses extremely low standby current CMOS SRAM's, coupled with small lithium coin cells to provide non-volatility without long write-cycle times and the write-cycle limitations associated with EEPROM.

FEATURES

- ◆ Access time : 70, 85, 120, 150 ns
- ◆ High-density design : 2Mbit Design
- ◆ Battery internally isolated until power is applied
- ◆ Industry-standard 32-pin 256K x 8 pinout
- ◆ Unlimited write cycles
- ◆ Data retention in the absence of V_{CC}
- ◆ 10-years minimum data retention in absence of power
- ◆ Automatic write-protection during power-up/power-down cycles
- ◆ Data is automatically protected during power loss
- ◆ Conventional SRAM operation; unlimited write cycles

MARKING

FUNCTIONAL DESCRIPTION

The HMN2568D executes a read cycle whenever /WE is inactive(high) and /CE is active(low). The address specified by the address inputs(A₀-A₁₇) defines which of the 262,144 bytes of data is accessed. Valid data will be available to the eight data output drivers within t_{ACC} (access time) after the last address input signal is stable.

When power is valid, the HMN2568D operates as a standard CMOS SRAM. During power-down and power-up cycles, the HMN2568D acts as a nonvolatile memory, automatically protecting and preserving the memory contents.

The HMN2568D is in the write mode whenever the /WE and /CE signals are in the active (low) state after address inputs are stable. The later occurring falling edge of /CE or /WE will determine the start of the write cycle. The write cycle is terminated by the earlier rising edge of /CE or /WE. All address inputs must be kept valid throughout the write cycle. /WE must return to the high state for a minimum recovery time (t_{WR}) before another cycle can be initiated. The /OE control signal should be kept inactive (high) during write cycles to avoid bus contention. However, if the output bus been enabled (/CE and /OE active) then /WE will disable the outputs in t_{ODW} from its falling edge.

The HMN2568D provides full functional capability for V_{CC} greater than 4.5 V and write protects by 4.37 V nominal. Power-down/power-up control circuitry constantly monitors the V_{CC} supply for a power-fail-detect threshold V_{PFD}. When V_{CC} falls below the V_{PFD} threshold, the SRAM automatically write-protects the data. All inputs to the RAM become “don’t care” and all outputs are high impedance. As V_{CC} falls below approximately 3 V, the power switching circuit connects the lithium energy source to RAM to retain data. During power-up, when V_{CC} rises above approximately 3.0 volts, the power switching circuit connects external V_{CC} to the RAM and disconnects the lithium energy source. Normal RAM operation can resume after V_{CC} exceeds 4.5 volts.

NOTE: 1. A write ends at the earlier transition of /CE going high and /WE going high.

2. A write occurs during the overlap of allow /CE and a low /WE. A write begins at the later transition of /CE going low and /WE going low.

3. Either t_{WR1} or t_{WR2} must be met.

4. Either t_{DH1} or t_{DH2} must be met.

5. If /CE goes low simultaneously with /WE going low or after /WE going low, the outputs remain in high-impedance state.

POWER-DOWN/POWER-UP CYCLE ($T_A = T_{OPR}$, $V_{CC} = 5V$)

| PARAMETER | SYMBOL | CONDITIONS | MIN | TYP. | MAX | UNIT |

TIMING WAVEFORM

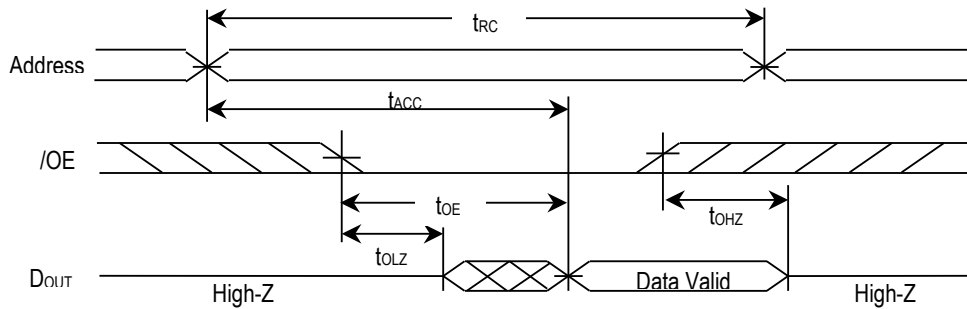

- Read Cycle (Address Access)*1,2

- Read Cycle No.2 (/CE Access)*1,3,4

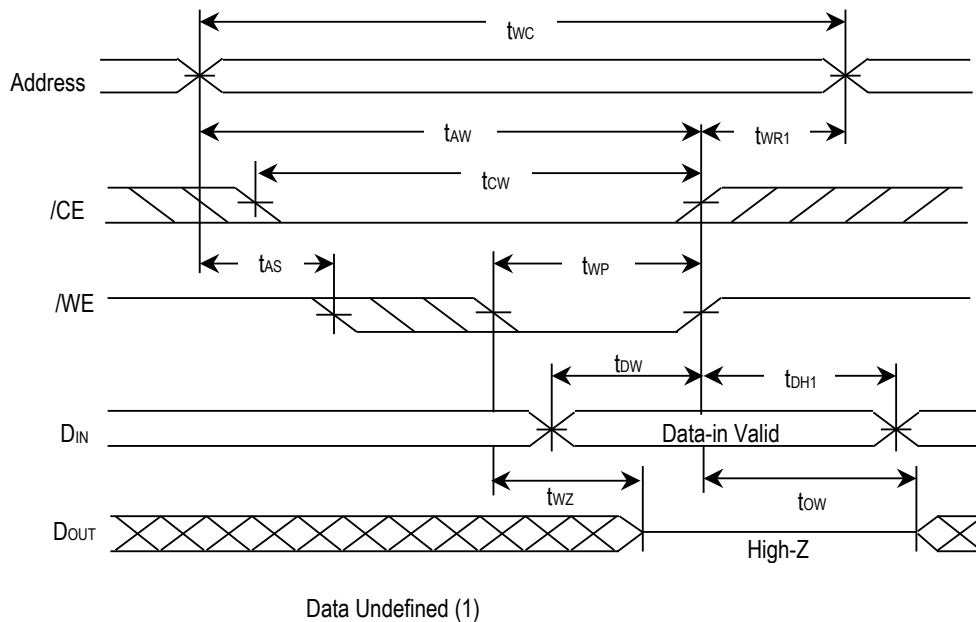

- Read Cycle No.3 (/OE Access)^{*1,5}

- NOTES:**
1. /WE is held high for a read cycle.
 2. Device is continuously selected: /CE = /OE = V_{IL} .
 3. Address is valid prior to or coincident with /CE transition low.
 4. /OE = V_{IL} .
 5. Device is continuously selected: /CE = V_{IL} .

- WRITE CYCLE NO.1 (/WE-CONTROLLED)^{*1,2,3}

- WRITE CYCLE NO.2 (/CE-CONTROLLED)*1,2,3,4,5

- NOTE:**
1. \overline{CE} or \overline{WE} must be high during address transition.
 2. Because I/O may be active (\overline{OE} low) during this period, data input signals of opposite polarity to the outputs must not be applied.
 3. If \overline{OE} is high, the I/O pins remain in a state of high impedance.
 4. Either t_{WR1} or t_{WR2} must be met.
 5. Either t_{DH1} or t_{DH2} must be met.
