

32-Channel High Voltage Sample and Hold Amplifier Array

Features

- ▶ 32 independent high voltage amplifiers
- ▶ 300V operating voltage
- ▶ 295V output voltage
- ▶ 2.2V/ μ s typical output slew rate
- ▶ Adjustable output current source limit
- ▶ Adjustable output current sink limit
- ▶ Internal closed loop gain of 72V/V
- ▶ 12M Ω feedback impedance
- ▶ Layout ideal for die applications

Applications

- ▶ MEMS (microelectromechanical systems) driver
- ▶ Piezoelectric transducer driver
- ▶ Optical crosspoint switches (using MEMS technology)

General Description

The Supertex HV257 is a 32-channel, high voltage, sample and hold amplifier array integrated circuit. It operates on a single high voltage supply, up to 300V, and two low voltage supplies, V_{DD} and V_{NN} .

All 32 sample and hold circuits share a common analog input, V_{SIG} . The individual sample and hold circuits are selected by a 5 to 32 logic decoder. The sampled voltage on the holding capacitor is buffered by a low voltage amplifier and amplified by a high voltage amplifier with a closed loop gain of 72V/V. The internal closed loop gain is set for an input voltage range of 0 to 4.096V. The input voltage can be up to 5.0V, but the output will saturate. The maximum output voltage swing is 5.0V below the V_{PP} high voltage supply. The outputs can drive capacitive loads of up to 3000pF.

The maximum output source and sink current can be adjusted by using two external resistors. An external R_{SOURCE} resistor controls the maximum sourcing current, and an external R_{SINK} resistor controls the maximum sinking current. The current limit is approximately 12.5V divided by the external resistor value. The setting is common for all 32 outputs. A low voltage silicon junction diode is made available to help monitor the die temperature.

Typical Application Circuit

Ordering Information

Part Number	Package Option	Packing
HV257FG-G	100-Lead MQFP	66/Tray

-G denotes a lead (Pb)-free / RoHS compliant package

Absolute Maximum Ratings

Parameter	Value
V_{PP} , High voltage supply	310V
AV_{DD} , Analog low voltage positive supply	8.0V
DV_{DD} , Digital low voltage positive supply	8.0V
AV_{NN} , Analog low voltage negative supply	-7.0V
DV_{NN} , Digital low voltage negative supply	-7.0V
Logic input voltage	-0.5V to DV_{DD}
V_{SIG} , Analog input signal	0V to 6.0V
Storage temperature range	-65°C to 150°C
Maximum junction temperature	150°C

Absolute Maximum Ratings are those values beyond which damage to the device may occur. Functional operation under these conditions is not implied. Continuous operation of the device at the absolute rating level may affect device reliability. All voltages are referenced to device ground.

Power Up/Down Issues

External Diode Protection

The device can be damaged due to improper power up / down sequence. To prevent damage, please follow the acceptable power up / down sequences, and add two external diodes as shown in the diagram on the right. The first diode is a high voltage diode across VPP and VDD, where the anode of the diode is connected to VDD and the cathode of the diode is connected to VPP. Any low current, high voltage diode, such as a 1N4004, will be adequate. The second diode is a Schottky diode across VNN and DGND, where the anode of the Schottky diode is connected to VNN, and the cathode is connected to DGND. Any low current Schottky diode such as a 1N5817 will be adequate.

Acceptable Power Up Sequences

The HV257 can be powered up with any of the following sequences listed below.

- 1) VPP 2) VNN 3) VDD 4) Inputs and Anode
- 1) VNN 2) VDD 3) VPP 4) Inputs and Anode
- 1) VDD & VNN 2) Inputs 3) VPP 4) Anode

Acceptable Power Down Sequences

The HV257 can be powered down with any of the following sequences listed below.

- 1) Inputs and Anode 2) VDD 3) VNN 4) VPP
- 1) Inputs and Anode 2) VPP 3) VDD 4) VNN
- 1) Anode 2) VPP 3) Inputs 4) VNN & VDD

External Diode Protection Connection

Suggested Power Up/Down Sequence

The HV257 needs all power supplies to be fully up and all channels refreshed with $V_{SIG} = 0V$ to force all high voltage outputs to 0V. Before that time, the high voltage outputs may have temporary voltage excursions above or below GND level depending on selected power up sequence. To minimize the excursions:

1. The VDD and VNN power supplies should be applied at the same time (or within a few nanoseconds).
2. All channels should be continuously refreshed with $V_{SIG} = 0V$, just before, and while the VPP is ramping up. Suggested VPP ramp up speed should be 10msec or longer and ramp down to be 1msec or longer.

Recommended Power Up/Down Timing

HV_{OUT} Level at Power Up

Power Up Sequence

RSINK / RSOURCE

The VDD_BYP, VDD_BYP, and VNN_BYP pins are internal, high impedance current, mirror gate nodes, brought out to maintain stable opamp biasing currents in noisy power supply environments. 0.1 μ F/25V bypass capacitors, added from VPP_BYP pin to VPP, from VDD_BYP pin to VDD, and from

VNN_BYP to VNN, will force the high impedance gate nodes to follow fluctuation of power lines. The expected voltages at the VDD_BYP, and VNN_BYP pins are typically 1.5 volts from their respectful power supply. The expected voltage at VPP_BYP is typically 3V below VPP.

Ground Isolation (AGND/DGND Isolation)

It is important that the AGND pin is connected to a clean ground. The hold capacitors are internally connected to the AGND, and any ground noise will directly couple to the high voltage outputs (with a gain of 72). The analog and digital

ground traces on the PCB should be physically separated to reduce digital switching noise degrading the signal to noise performance.

Typical Characteristics
