

# ICL7106/ICL7107

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

### General Description

The Maxim ICL7106/ICL7107 are monolithic analog-to-digital converters (ADCs). They have very high input impedances and require no external display drive circuitry. On-board active components include polarity and digit drivers, segment decoders, voltage reference and a clock circuit. The ICL7106 will directly drive a nonmultiplexed liquid crystal display (LCD), whereas the ICL7107 will directly drive a common anode light emitting diode (LED) display.

Versatility and accuracy are inherent features of these converters. The dual-slope conversion technique automatically rejects interference signals common in industrial environments. The true differential input and reference are particularly useful when making ratiometric measurements (ohms or bridge transducers). Maxim has added a zero-integrator phase to the ICL7106 and ICL7107, eliminating overrange hangover and hysteresis effects. Finally, these devices offer high accuracy by lowering rollover error to less than one count and zero reading drift to less than 1 $\mu$ V/°C.

These devices are used in a wide range of digital panel meter applications. Most applications, however, involve the measurement and display of analog data.

### Applications

Pressure	Temperature	Speed
Voltage	Conductance	Material
Resistance	Current	Thickness

### Typical Operating Circuit

The "Maxim Advantage" signifies an upgraded quality level. At no additional cost we offer a second-source device that is subject to the following: guaranteed performance over temperature along with tighter test specifications on many key parameters; and device enhancement, when needed, that result in improved performance without changing the functionality.

**For pricing, delivery, and ordering information, please contact Maxim Direct at 1-888-629-4642, or visit Maxim's website at [www.maximintegrated.com](http://www.maximintegrated.com).**

### Features

- ◆ Improved 2nd Source (see Page 3 for "Maxim Advantage")
- ◆ Guaranteed First Reading Recovery from Overrange
- ◆ On-Board Display Drive Capability—No External Circuitry Required  
LCD—ICL7106  
LED—ICL7107
- ◆ High-Impedance CMOS Differential Inputs
- ◆ Low Noise (< 15 $\mu$ Vp-p) without Hysteresis or Overrange Hangover
- ◆ Clock and Reference On-Chip
- ◆ True Differential Reference and Input
- ◆ True Polarity Indication for Precision Null Applications
- ◆ Monolithic CMOS Design

### Order Information

PART	TEMP RANGE	PIN-PACKAGE
ICL7106CPL+	0°C to +70°C	40 PDIP
ICL7106CQH+	0°C to +70°C	44 PLCC
ICL7107CPL+	0°C to +70°C	40 PDIP
ICL7107CQH+	0°C to +70°C	44 PLCC

+Denotes a lead(Pb)-free/RoHS-compliant package.

### Pin Configurations

Pin Configurations continued at end of data sheet

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

Figure 1. Maxim ICL7106 Typical Operating Circuit

Figure 2. Maxim ICL7107 Typical Operating Circuit

### Analog Section

Figure 3 shows the Block Diagram of the Analog Section for the ICL7136. Each measurement cycle is divided into four phases:

1. Auto-Zero (A-Z)
2. Signal Integrate (INT)
3. Reference De-Integrate (DI)
4. Zero Integrator (ZI)

### Auto-Zero Phase

Three events occur during auto-zero. The inputs, IN-HI and IN-LO, are disconnected from the pins and internally shorted to analog common. The reference capacitor is charged to the reference voltage. And lastly, a feedback loop is closed around the system to charge the auto-zero capacitor  $C_{AZ}$  to compensate for offset voltages in the comparator, buffer amplifier and integrator. The inherent noise of the system determines the A-Z accuracy.

### Signal Integrate Phase

The internal input high (IN-HI) and input low (IN-LO) are connected to the external pins, the internal short is removed and the auto-zero loop is opened. The converter then integrates the differential voltage between IN-HI and IN-LO for a fixed time. This differential voltage can be within a wide common-mode range (within one volt of either supply). If, however, the input signal has no return with respect to the converter power supply, IN-LO can be tied to analog common to establish the correct common-mode voltage. The polarity of the integrated signal is determined at the end of this phase.

### Reference De-Integrate

IN-HI is connected across the previously charged reference capacitor and IN-LO is internally connected to analog common. Circuitry within the chip ensures that the capacitor will be connected with the correct polarity to cause the integrator output to return to zero. The input signal determines the time required for the output to return to zero. The digital reading displayed is:

$$1000 \times \frac{V_{IN}}{V_{REF}}$$

### Zero Integrator Phase

Input low is shorted to analog COMMON and the reference capacitor is charged to the reference voltage. A feedback loop is closed around the system to input high, causing the integrator output to return to zero. This phase normally lasts between 11 and 140 clock pulses but is extended to 740 clock pulses after a "heavy" over-range conversion.

### Differential Reference

The reference voltage can be generated anywhere within the power supply voltage of the converter. The main source of common-mode error is a rollover voltage. This is caused by the reference capacitor losing or gaining charge to stray capacitance on its nodes. The reference capacitor can gain charge (increase voltage) if there is a large common-mode voltage. This happens during de-integration of a positive signal. In contrast, the reference capacitor will lose charge (decrease voltage) when de-integrating a negative input signal. Rollover error is caused by this difference in reference for positive or negative input voltages. This error can be held to less than half a count for the worst-case condition by selecting a reference capacitor that is large enough in comparison to the stray capacitance. (See component value selection.)

### Differential Input

Differential voltages anywhere within the common-mode range of the input amplifier can be accepted by the input (specifically from 1V below the positive supply to 1.5V above the negative supply). The system has a CMRR of 86dB (typ) in this range. Care must be exercised, however, to ensure that the integrator output does not saturate, since the integrator follows the common-mode voltage. A large positive common-mode voltage with a near full-scale negative differential input voltage is a worst-case condition. When most of the integrator output swing has been used up by the positive common-mode voltage, the negative input signal drives the integrator more positive. The integrator swing can be reduced to less than the recommended 2V full-scale swing with no loss of accuracy in these critical

# ICL7106/ICL7107

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

Figure 3. Analog Section of ICL7106/ICL7107

Figure 4. Using an External Reference

applications. The integrator output can swing within 0.3V of either supply without loss of linearity.

### Analog Common

The primary purpose of this pin is to set the common-mode voltage for battery operation. This is useful when using the ICL7106, or for any system where the input signals are floating with respect to the power supply. A voltage of approximately 2.8V less than the positive supply is set by this pin. The analog common has some of the attributes of a reference voltage. If the total supply voltage is large enough to cause the zener to regulate ( $> 7V$ ), the common voltage will have a low output impedance (approximately  $15\Omega$ ), a temperature coefficient of typically  $80\text{ppm}/^\circ\text{C}$ , and a low voltage coefficient ( $.001\%$ ).

The internal heating of the ICL7107 by the LED display drivers degrades the stability of Analog Common. The power dissipated by the LED display drivers changes with the displayed count, thereby changing the temperature of the die, which in turn results in a small change in the Analog Common voltage. This combination of variable power dissipation, thermal resistance, and temperature coefficient causes a  $25\text{--}80\mu\text{V}$  increase in noise near full scale. Another effect of LED display driver power dissipation can be seen at the transition between a full scale reading and an overload condition. Overload is a low power dissipation condition since the three least significant digits are blanked in overload. On the other hand, a near full scale reading such as 1999 has many segments turned on and is a high power dissipation condition. The difference in power dissipation between overload and full scale may cause a ICL7107 with a negative temperature coefficient reference to cycle between overload and a near full scale display as the die alternately heats and cools. An ICL7107 with a positive TC reference will exhibit hysteresis under these conditions: once put into overload by a voltage just barely more than full scale, the voltage must be reduced by several counts before the ICL7107 will come out of overload.

None of the above problems are encountered when using an external reference. The ICL7106, with its low power dissipation, has none of these problems with either an external reference or when using Analog Common as a reference.

During auto-zero and reference integrate the internal input low is connected to Analog Common. If IN-LO is different from analog-common, a common-mode voltage exists in the system and is taken care of by the excellent CMRR of the converter. In some applications, however, IN-LO will be set at a fixed known voltage (e.g., power supply common). Whenever possible analog common should be tied to the same point, thus removing the common-mode voltage from the converter. The same holds true for the reference voltage. If convenient, REF-LO should be connected to analog common. This will remove the common-mode voltage from the reference system.

Analog Common is internally tied to an N-channel FET that can sink 30mA or more of current. This will hold the Analog Common voltage 2.8V below the positive supply (when a source is trying to pull the common line positive). There is only  $10\mu\text{A}$  of source current, however, so COMMON may easily be tied to a more negative voltage, thus overriding the internal reference.

### Test

Two functions are performed by the test pin. The first is using this pin as the negative supply for externally generated segment drivers or any other annunciators the user may want to include on the LCD. This pin is coupled to the internally generated digital supply through a  $500\Omega$  resistor. This application is illustrated in Figures 5 & 6.

A lamp test is the second function. All segments will be turned on and the display should read  $-1888$ , when TEST is pulled high ( $V+$ ).

**Caution:** In the lamp test mode, the segments have a constant dc voltage (no square wave). This can burn the LCD if left in this mode for several minutes.

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

Figure 5A. Fixed Decimal Point Drivers

Figure 5B. Fixed Decimal Point Drivers

Figure 6. Exclusive "OR" Gate for Decimal Point Drive

### Digital Section

The digital section for the ICL7106 and ICL7107 is illustrated in Figures 8 and 9. In Figure 8, an internal digital ground is generated from a 6V zener diode and a large P-channel source follower. This supply is made stiff to absorb the large capacitive currents when the back plane (BP) voltage is switched. The BP frequency is calculated by dividing the clock frequency by 800. For example, with a clock frequency of 48kHz (3 readings per second), the backplane will be a 60Hz square wave with a nominal amplitude of 5V. The segments are driven at the same frequency and amplitude. Note that these are out-of-phase when the segment is ON and in-phase when OFF. Negligible dc voltage exists across the segments in either case.

The ICL7107 is identical to the ICL7106 except that the backplane and drivers have been replaced by N-channel segment drivers. The ICL7107 is designed to drive common anode LED's with a typical segment current of 8mA. Pin 19 (thousands digit output) sinks current from two LED segments, and has a 16mA drive capability.

The polarity indication is "on" for negative analog inputs, for both the ICL7106 and ICL7107. If desired IN-HI and IN-LO can be reversed giving a "on" for positive analog inputs.

### System Timing

The clocking circuitry for the ICL7106 and ICL7107 is illustrated in Figure 7. Three approaches can be used:

1. A crystal between pins 39 and 40.
2. An external oscillator connected to pin 40.
3. An RC oscillator using all three pins.

The decade counters are driven by the clock frequency divided by four. This frequency is then further divided to form the four convert-cycle phases, namely: signal integrate (1000 counts), reference de-integrate (0 to 2000 counts), auto-zero (260 to 2989 counts) and zero integrator (11 to 740).

The signal integration should be a multiple of 60Hz to achieve a maximum rejection of 60Hz pickup. Oscillator frequencies of 30kHz, 40kHz, 48kHz, 60kHz, 80kHz, 120kHz, 240kHz, etc., should be selected. Similarly, for 50Hz rejection, oscillator frequencies of 200kHz, 100kHz, 66<sup>2</sup>/<sub>3</sub>kHz, 50kHz, 40kHz, etc., are appropriate. Note that 40kHz (2.5 readings/second) will reject both 50 and 60Hz (also 400 and 440Hz).

Auto-zero receives the unused portion of reference deintegrate for signals less than full-scale. A complete measurement cycle is 4,000 counts (16,000 clock pulses), independent of input voltage. As an example, an oscillator frequency of 48kHz would be used to obtain three readings per second.

### Component Value Selection

#### Auto-Zero Capacitor

The noise of the system is influenced by the auto-zero capacitor. For the 2V scale, a 0.047 $\mu$ F capacitor is adequate. A capacitor size of 0.47 $\mu$ F is recommended for 200mV full scale where low noise operation is very important. Due to the ZI phase of Maxim's ICL7106/7, noise can be reduced by using a larger auto-zero capacitor without causing hysteresis or overrange hangover problems seen in other manufacturers' ICL7106/7 which do not have the ZI phase.

#### Reference Capacitor

For most applications, a 0.1 $\mu$ F capacitor is acceptable. However, a large value is needed to prevent rollover error where a large common-mode voltage exists (i.e., the REF-LO pin is not at analog common) and a 200mV scale is used. Generally, the roll over error will be held half a count by using a 1.0 $\mu$ F capacitor.

#### Integrating Capacitor

To ensure that the integrator will not saturate (at approximately 0.3V from either supply), an appropriate integrating capacitor must be selected. A nominal  $\pm$ 2V full-scale integrator swing is acceptable for the ICL7106 or ICL7107 when the analog common is used as a reference. A nominal  $\pm$ 3.5 to 4 volt swing is acceptable for the ICL7107 with a  $\pm$ 5V supply and analog common tied to supply ground. The nominal values for  $C_{INT}$  is 0.22 $\mu$ F for three readings per second. (48kHz clock). These values should be changed in inverse proportion to maintain the same output swing if different oscillator frequencies are used.

The integrating capacitor must have low dielectric absorption to minimize linearity errors. Polypropylene capacitors are recommended for this application.

#### Integrating Resistor

The integrator and the buffer amplifier both have a class A output stage with 100 $\mu$ A of quiescent current. 20 $\mu$ A of drive current can be supplied with negligible non-linearity. This resistor should be large enough to maintain the amplifiers in the linear region over the entire input voltage range. The resistor value, however, should be low enough that undue leakage requirements are not placed on the PC boards. For a 200mV scale, a 47K $\Omega$  resistor is recommended; (2V scale/470K $\Omega$ ).

#### Oscillator Components

A 100K $\Omega$  resistor is recommended for all ranges of frequency. By using the equation  $f = 0.45/RC$ , the capacitor value can be calculated. For 48kHz clock, (3 readings/second), the oscillator capacitor plus stray capacitance should equal 100pF.

### Reference Voltage

An analog input voltage of  $V_{IN}$  equal to 2 ( $V_{REF}$ ) is required to generate full scale output of 2000 counts. Thus, for 2V and 200mV scales,  $V_{REF}$  should equal 1V and 100mV respectively. However, there will exist a scale factor other than unity between the input voltage and the digital reading in many applications where the A/D is connected to a transducer.

As an example, the designer may like to have a full scale reading in a weighing system when the voltage from the transducer is 0.682V. The designer should use the input voltage directly and select  $V_{REF}$  at 0.341V instead of dividing the input down to 200mV. Suitable values of the capacitor and integrating resistor would be 0.22 $\mu$ F and 120K $\Omega$ . This provides for a slightly quieter system and also avoids a divider network on the input. The ICL7107 can accept input signals up to  $\pm$ 3.5V with  $\pm$ 5V supplies. Another advantage of this system occurs when the digital reading of zero is desired for  $V_{IN} \neq$  zero. Examples are temperature and weighing systems with variable tare. By connecting the voltage transducer between  $V_{IN}$  positive and common, and the variable (or fixed) offset voltage between common and  $V_{IN}$  negative, the offset reading can be conveniently generated.

### ICL7107 Power Supplies

The ICL7107 is designed to operate from  $\pm$ 5V supplies. However, when a negative supply is not available it can be generated from a clock output with two diodes, two capacitors, and an inexpensive IC. Refer to Figure 10. Alternatively a -5V supply can be generated using Maxim's ICL7660 and two capacitors.

A negative supply is not required in selected applications. The conditions to use a single +5V supply are:

- ◆ An external reference is used.
- ◆ The signal is less than  $\pm$ 1.5V.
- ◆ The input signal can be referenced to the center of the common-mode range of the converter.

See Figure 18.

Figure 10. Generating Negative Supply from +5V

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

### Applications Information

Heat is generated within the ICL7107 IC package due to the sinking of LED display current. Fluctuating chip temperature can cause a display to change reading if the internal voltage reference is used. By reducing the power being dissipated such variations can be reduced. The ICL7107 power dissipation is reduced by reducing the LED common anode voltage. The curve tracer illustration showing the relationship between the output current and the output voltage for typical ICL7107 is seen in Figure 11. Note that the typical ICL7107 output is 3.2V (point A), since the typical LED has 1.8V across it (8mA drive current) and its common anode is connected to +5V. Maximum power dissipation is:

$$8.1\text{mA} \times 3.2\text{V} \times 24 \text{ segments} = 622\text{mW}$$

Once the ICL7107 output voltage is above 2V, the LED current is essentially constant as output voltage increases. Point B illustrates that reducing the output voltage by 0.7V results in 7.7mA of LED current, (only 5% reduction). The maximum power dissipation is a reduction of 26% as calculated by:

$$7.7\text{mA} \times 2.5\text{V} \times 24 \text{ segments} = 462\text{mW}$$

As illustrated in Figure 12, reduced power dissipation is easy to obtain. This can be accomplished by placing either a 5.1Ω resistor or a 1 amp diode in series with the display (but not in series with the ICL7107). Point C of Figure 18 illustrates that a resistor will reduce the ICL7107 output voltage when all 24 segments are "On". The output voltage will increase when segments are turned "Off". On the other hand, the diode will result in a relatively steady output voltage, around Point B. The resistor not only reduces the change in power dissipation as the display changes, but also limits the maximum power dissipation. This is due to the fact that as fewer segments are "On", each "On" output drops more voltage and current. The resistor circuit will change about 230mW when changing from the best case of six segments, a "111" display, to worst-case of a "1888" display. If the resistor is removed, the power dissipation change will be 470mW. The resistor, therefore, will reduce the effect of display dissipation on reference voltage drift by about 50%.

As more segments are turned off, the change in LED brightness caused by the resistor is almost unnoticeable. A diode may be used instead of the resistor if it is important to maintain a steady level of display brightness.

## 3<sup>1</sup>/<sub>2</sub> Digit A/D Converters

### Typical Applications

Figure 19. Thermocouple Thermometer. This circuit operates with approximately 50mV reference, so the 50.4 $\mu$ V/ $^{\circ}$ C output of a Type J thermocouple results in 1 count/ $^{\circ}$ C.

### Pin Configurations (continued)

### Chip Information

PROCESS: BiCMOS

### Package Information

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.
