## 1.5 ProxFusion® Sensitivity

The measurement circuitry uses a temperature stable internal sample capacitor ( $C_S$ ) and internal regulated voltage ( $V_{REG}$ ). Internal regulation provides for more accurate measurements over temperature variation. The size  $C_S$  can be decreased to increase sensitivity on the capacitive channels of the IQS621.

$$Sensitivity \propto \frac{1}{C_S}$$

The Automatic Tuning Implementation (ATI) is a sophisticated technology implemented on the ProxFusion® series devices. It allows for optimal performance of the devices for a wide range of sense electrode capacitances, without modification or addition of external components. The ATI functionality ensures that sensor sensitivity is not affected by external influences such as temperature, parasitic capacitance and ground reference changes.

The ATI process adjusts three values (Coarse multiplier, Fine multiplier, Compensation) using two parameters (ATI base and ATI target) as inputs. A 10-bit compensation value ensures that an accurate target is reached. The base value influences the overall sensitivity of the channel and establishes a base count from where the ATI algorithm starts executing. A rough estimation of sensitivity can be calculated as:

$$Sensitivity \propto \frac{Target}{Base}$$

As seen from this equation, the sensitivity can be increased by either increasing the Target value or decreasing the Base value. A lower base value will typically result in lower multipliers and more compensation would be required. It should, however, be noted that a higher sensitivity will yield a higher noise susceptibility. Refer to Appendix B: Hall ATI for more information on Hall ATI.

## 4.5 Sensor data output and flags

The following registers can be monitored by the master to detect ALS related events.

- a) The **ALS EVENT (bit 2)** in the **Global events (0x11)** register are dedicated to ALS related events. This bit will toggle when any change in ALS flags occurs and is automatically cleared after reading the registers.

## 5 Hall-effect sensing

### 5.1 Introduction to Hall-effect sensing

The IQS621 has two internal Hall-effect sensing plates (on chip). No external sensing hardware is required for Hall-effect sensing.

The Hall-effect measurement is essentially a current measurement of the induced current through the Hall-effect-sensor plates produced by the magnetic field passing perpendicular through each plate.

Advanced digital signal processing is performed to provide sensible output data.

- Two threshold levels are provided (proximity & touch).
- Hall-effect output is linearized by inverting signals.
- North/South field direction indication provided.
- Differential Hall-effect sensing:
  - Removes common mode disturbances
  - North-South field indication

### 5.2 Channel specifications

Channels 5 and 6 are dedicated to Hall-effect sensing. Channel 5 performs the positive direction measurements and channel 6 will handle all measurements in the negative direction. These two channels are used in conjunction to acquire differential Hall-effect data and will always be used as input data to the Hall-effect UI's.

There is a dedicated Hall-effect user interface:

- a) Hall-effect switch UI

## 6 Temperature monitoring

### 6.1 Introduction to temperature monitoring

The IQS621 provides temperature monitoring capabilities which can be used for temperature change detection in order to ensure the integrity of other sensing technology. The use of the temperature sensor is primarily to reseed other sensor channels to account for sudden changes in environmental conditions.

The IQS621 uses a linearly proportional to absolute temperature sensor for temperature data. The temperature output data is given by,

$$T = \frac{a \cdot 2^{19}}{b \cdot CH_2} + c$$

Where  $a$ ,  $b$  and  $c$  are constants that can be determined to provide a required output data as a function of device temperature. Additionally, the channel setup must be calculated during a testing process.

**Table 6.1 Temperature calibration setting registers and ranges**

Parameter		IQS621		
Name	Description	Register	Range	
$a$	<i>Multiplier</i>	0xC2	Higher nibble	1 – 16
$b$	<i>Divider</i>		Lower nibble	1 – 16
$c$	<i>Offset</i>	0xC3		0 – 255

### 6.2 Channel specifications

The IQS621 requires only external passive components to do temperature monitoring (no additional circuitry/components required). The temperature UI will be executed using data from channel 2.

### 6.3 Hardware configuration

No additional hardware required. Temperature monitoring is realized on-chip.

## 7 Device clock, power management and mode operation

### 7.1 Device main oscillator

The IQS621 has a **16MHz** main oscillator (default enabled) to clock all system functionality.

An option exists to reduce the main oscillator to 8MHz. This will result in all system timings, charge transfers and sample rates to be slower by half of the default implementations.

To set this option this:

- As a software setting – Set the System\_settings: bit4 = 1, via an I<sup>2</sup>C command.
- As a permanent setting – Set the OTP option in OTP Bank 0: bit2 = 1, using Azoteq USBProg program.

### 7.2 Device modes

The IQS621 supports the following modes of operation;

- **Normal mode** (Fixed report rate)
- **Low power mode** (Reduced report rate, no UI execution)
- **Ultra-low power mode** (Only channel 0 is sensed for a prox)
- **Halt mode** (Suspended/disabled)

*Note: Auto modes must be disabled to enter or exit halt mode.*

The device will automatically switch between the different operating modes by default. However, this Auto mode feature may be disabled by setting the DSBL\_AUTO\_MODE bit (Power\_mode\_settings 0xD2: bit5) to confine device operation to a specific power mode. The POWER\_MODE bits (Power\_mode\_settings 0xD2: bit4-3) can then be used to specify the desired mode of operation.

#### 7.2.1 Normal mode

Normal mode is the fully active sensing mode to function at a fixed report rate specified in the Normal mode report rate (0xD3) register. This 8-bit value is adjustable from 0ms – 255ms in intervals of 1ms.

*Note: The device's low power oscillator has an accuracy as specified in section 9.*

#### 7.2.2 Low power mode

Low power mode is a reduced sensing mode where all channels are sensed but at a reduced oscillator speed. The sample rate can be specified in the Low Power mode report rate (0xD4) register. The 8-bit value is adjustable from 0ms – 255ms in intervals of 1ms. Reduced report rates also reduce the current consumed by the sensor.

*Note: The device's low power oscillator has an accuracy as specified in section 9.*

#### 7.2.3 Ultra-low power mode

Ultra-low power mode is a reduced sensing mode where only channel 0 is sensed and no other channels or UI code are executed. Set the EN\_ULP\_MDE bit (Power\_mode\_settings: bit6) to enable use of the ultra-low power mode. The sample rate can be specified in the Low Power mode report rate (0xD5) register. The 8-bit value is adjustable from 0ms – 4sec in intervals of 16ms.

Wake up will occur on prox detection on channel 0.

#### 7.2.4 Halt mode

Halt mode will suspend all sensing and will place the device in a dormant or sleep state. The device requires an I<sup>2</sup>C command from a master to explicitly change the power mode out of the halt state before any sensor functionality can continue.

#### 7.2.5 Mode time

The mode time is specified in the Auto mode timer (0xD6) register. The 8-bit value is adjustable from 0ms – 2 min in intervals of 500ms.

---

### 7.3 System reset

The IQS621 device monitor's system resets and events.

- a) Every device power-on and reset event will set the Show Reset bit (System flags 0x10: bit7) and the master should explicitly clear this bit by writing it active to acknowledge a valid reset.
- b) The system events will also be indicated with the Global events register's SYS\_EVENT bit (Global events 0x11: bit4) if any system event occur such as a reset. This event will continuously trigger until the reset has been acknowledged.

## 8 Communication

### 8.1 I<sup>2</sup>C module specification

The device supports a standard two wire I<sup>2</sup>C interface with the addition of an RDY (ready interrupt) line. The communications interface of the IQS621 supports the following:

- *Fast-mode (Fm)* standard I<sup>2</sup>C up to 400kHz.
- Streaming data as well as event mode.
- The master may address the device at any time. If the IQS621 is not in a communication window, the device will return an ACK after which clock stretching may be induced until a communication window is entered. Additional communication checks are included in the main loop in order to reduce the average clock stretching time.
- The provided interrupt line (RDY) is an open-drain active low implementation and indicates a communication window.

### 8.2 I<sup>2</sup>C Read

To read from the device a *current address read* can be performed. This assumes that the address-command is already setup as desired.

**Figure 8.1 Current Address Read**

If the address-command must first be specified, then a *random read* must be performed. In this case, a WRITE is initially performed to setup the address-command, and then a repeated start is used to initiate the READ section.

**Figure 8.2 Random Read**

### 8.3 I<sup>2</sup>C Write

To write settings to the device a *Data Write* is performed. Here the Address-Command is always required, followed by the relevant data bytes to write to the device.

**Figure 8.3 I<sup>2</sup>C Data Write**

## 8.4 Stop-bit disable option

The IQS621 offer:

- an additional [I<sup>2</sup>C settings](#) register (0xD9) specifically added for stop-bit disable functionality,
- as well as a [RDY timeout period](#) register (0xD8) in order to set the required timeout period for termination of any communication windows (RDY = Low) if no I<sup>2</sup>C activity is present on SDA and SCL pins.

Customers using a MCU with a binary serial-encoder peripheral which is not fully I<sup>2</sup>C compatible (but provide some crude serial communication functions) can use this option to configure the IQS621 so that any auto generated stop command from the serial peripheral can be ignored by the IQS621 I<sup>2</sup>C hardware. This will restrict the IQS621 from immediately exiting a communication window during event mode (reduced communication only for events) until all required communication has been completed and a stop command can correctly be transmitted. Please refer to the figures below for serial data transmission examples.

Please note:

1. Stop-bit disable and enable must be performed at the beginning and end of a communication window. The first and last I<sup>2</sup>C register to be written to ensure no unwanted communication window termination.
2. Leaving the Stop-bit disabled will result in successful reading of registers but will not execute any commands written over I<sup>2</sup>C in a communication window being terminated after a RDY timeout and with no IQS recognised stop command.
3. The default RDY timeout period for IQS621 is purposefully long (10.24ms) for slow responding MCU hardware architectures. Please set this register according to your requirements/preference.

- a) Default address:       **0x44** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_0 (**0000b**)
- b) Sub-address:         **0x45** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_1 (**0001b**)
- c) Sub-address:         **0x46** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_2 (**0010b**)

- e) Sub-address:         **0x4C** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_4 (**1000b**)
- f) Sub-address:         **0x4D** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_5 (**1001b**)

- h) Sub-address:         **0x4F** = DEFAULT\_ADDR (**0x44**)    **OR**   SUB\_ADDR\_7 (**1011b**)

## 8.6 Additional OTP options

All one-time-programmable device options are located in OTP bank 0.

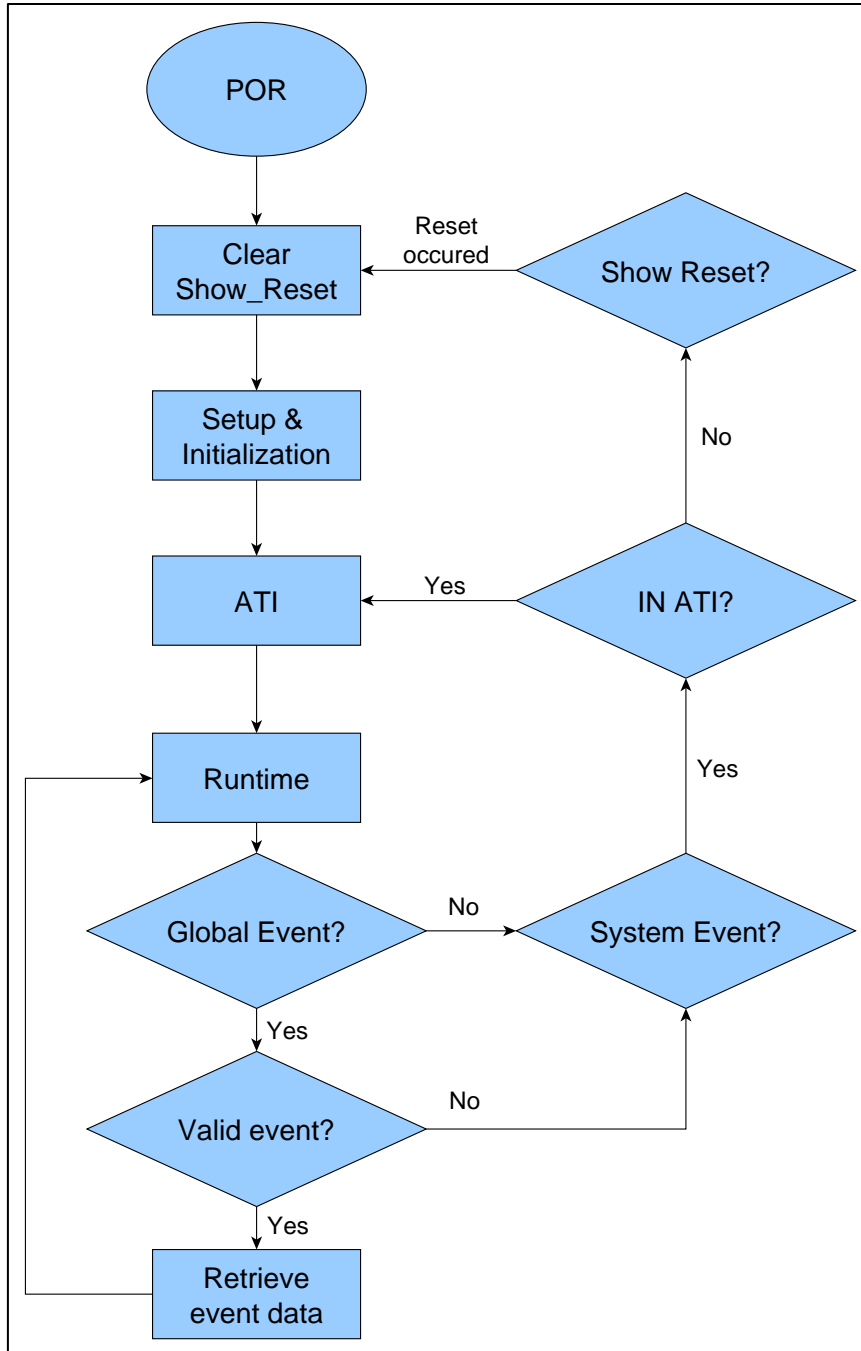

OTP Bank0

  - 1: Communication continues as setup regardless of ATI state.
- Bit4-5: Internal use
  - Do not configure
- Bit 2: Main Clock frequency selection

## 8.7 Recommended communication and runtime flow diagram

The following is a basic master program flow diagram to communicate and handle the device. It addresses possible device events such as output events, ATI and system events (resets).

**Figure 8.6 Master command structure and runtime event handling flow diagram**

It is recommended that the master verifies the status of the System\_Flags0 bits to identify events and resets. Detecting either one of these should prompt the master to the next steps of handling the IQS621.

Streaming mode communication is used for detail sensor evaluation during prototyping and/or development phases.

Event mode communication is recommended for runtime use of the IQS621. This reduce the communication on the I<sup>2</sup>C bus and report only triggered events.

## 10.10 ALS specifications

### 10.10.1 Human eye response Lux calculation

The spectral response of the human eye does not match that of typical silicone based light sensors. The human eye perceives a peak response in the “green” colour band centred at around 550nm. However, silicone based sensors has a maximum response to ambient light typically in the infrared band. To translate the sensor measurement to correlate with the human eye’s natural perceived ambient light sensitivity a dynamic mathematical function is applied.

The follow parameter values are defined for explanatory purposes:

- ***a* → ALS multiplier:**
  - A dynamic multiplier value calculated as in the table below for the specific ALS setup and current ALS value output.
- ***b* → ALS (raw) to Lux divider:**
  - 8-bit value loaded from OTP Bank 2 into register 0x82. This calibration value is determined during IC calibration.
- ***c* → ALS IR compensation divider:**
  - For IQS621 a 6-bit value is loaded from OTP Bank 0 (bit 5 & 4) and OTP Bank 3 (bit3 - 0) into register 0x83.
  - This calibration value is determined during IC calibration and can be increased to an 8-bit value if calibration requires a higher value.

The IQS621’s ALS multiplier (parameter *a*) is calculated as specified in the following table.

**Table 10.18 ALS multiplier calculation**

Inputs					Output
ALS value (0x16: bit3-0)	Coarse multiplier (0x75: bit5-4)	Fine multiplier (0x75: bit3-0)	Charge frequency divider (0x70: bit5-4)	CS size (0x70: bit2)	ALS multiplier <i>a</i>
0	0	MULTIPLIER_CALIBRATION	3	0	1
1	0	MULTIPLIER_CALIBRATION	2	0	2
2	0	MULTIPLIER_CALIBRATION	1	0	4
3	0	MULTIPLIER_CALIBRATION	0	0	8
4	0	MULTIPLIER_CALIBRATION	1	1	16
5	0	MULTIPLIER_CALIBRATION	0	1	32
6	0	(MULTIPLIER_CALIBRATION+1)*2-1	0	1	64
7	0	(MULTIPLIER_CALIBRATION+1)*4-1	0	1	128
8	1	(MULTIPLIER_CALIBRATION+1)*4-1	0	1	384
9	2	(MULTIPLIER_CALIBRATION+1)*4-1	0	1	1152
10	3	(MULTIPLIER_CALIBRATION+1)*4-1	0	1	3456

All the calculations performed on chip are simplified for fixed-point arithmetic. The ALS Lux output is calculated by the following equation:

$$ALS \cong \frac{a}{b} \left( \frac{2^{21}}{c \cdot CH_4} - \frac{2^{21}}{c \cdot CH_3} \right)$$

ALS in units of Lux (as perceived by a human eye) is calculated using the measurement of channels 3 (IR-component) & 4 (ALS-component) as well as the three compensation parameters *a*, *b* & *c* as defined above. The output of this function is a 16-bit integer available in the **ALS UI output** register (0x17-0x18).

## Appendix B: Hall ATI

Azoteq’s ProxFusion® Hall technology has ATI Functionality; which ensures stable sensor sensitivity. The ATI functionality is similar to the ATI functionality found in ProxSense® technology. The difference is that the Hall ATI requires two channels for a single plate.

Using two channels ensures that the ATI can still be used in the presence of the magnet. The two channels are the inverse of each other, this means that the one channel will sense North and the other South. The two channels being inverted allows the capability of calculating a reference value which will always be the same regardless of the presence of a magnet.

### 13.1.1 Hall reference value:

The equation used to calculate the reference value, per plate:

$$Ref_n = \frac{1}{2 \cdot \left( \frac{1}{P_n} + \frac{1}{P'_n} \right)}$$

### 13.1.2 ATI parameters:

**Channel 5/6**

<p><b>Multipliers</b></p> <p>Coarse : <input type="text" value="1"/> Fine : <input type="text" value="10"/></p>	<p><b>Compensation</b></p> <p><input type="text" value="100"/></p>	<p><b>ATI Target x32</b></p> <p><input type="text" value="16"/> <input type="text" value="512"/></p>

 Semi-Partial ATI (only coarse multipliers are fixed)

**Auto ATI Base Value**

The ATI process adjusts three values (Coarse multiplier, Fine multiplier, Compensation) using two parameters per plate (ATI base and ATI target). The ATI process is used to ensure that the sensor’s sensitivity is not severely affected by external influences (Temperature, voltage supply change, etc.).

### 13.1.3 Coarse and Fine multipliers:

In the ATI process the compensation is set to 0 and the coarse and fine multipliers are adjusted such that the counts of the reference value (*Ref*) are roughly the same as the ATI Base value. This means that if the base value is increased, the coarse and fine multipliers should also increase and vice versa.

### 13.1.4 ATI-Compensation:

After the coarse and fine multipliers are adjusted, the compensation is adjusted till the reference value (*Ref*) reaches the ATI target. A higher target means more compensation and therefore more sensitivity on the sensor.

The ATI process ensures that long term temperature changes, or bulk magnetic interference (e.g. the accidental placement of another magnet too close to the setup), do not affect the sensor’s ability to detect the intended magnetic change.
