

HIGH FREQUENCY SYNCHRONOUS PWM BUCK CONTROLLER

Features

- Internal 600kHz Oscillator
- Operates with Single 5V or 12V Supply
- Programmable Over Current Protection
- Hiccup Current Limit Using MOSFET $R_{DS(on)}$ sensing
- Precision Reference Voltage (0.6V)
- Programmable Soft-Start
- Pre-Bias Start-up
- Thermal Protection
- 10-Lead MLPD Package

Applications

- Embedded Telecom Systems
- Distributed Point of Load Power Architectures
- Computing Peripheral Voltage Regulator
- Graphics Card
- General DC/DC Converters

Description

The IR3624 is a PWM controller designed for high performance synchronous Buck DC/DC applications. The IR3624 drives a pair of external N-MOSFETs using a fixed 600kHz switching frequency allowing the use of small external components. The output voltage can be precisely regulated using the internal 0.6V reference voltage for low voltage applications. Protection such as Pre-Bias startup, hiccup current limit and thermal shutdown are provided to give required system level security in the event of fault conditions.

ABSOLUTE MAXIMUM RATINGS

(Voltages referenced to GND)

- Vcc Supply Voltage -0.5V to 16V
- Vc Supply Voltage -0.5V to 30V
- Storage Temperature Range -65°C To 150°C
- Operating Junction Temperature Range -40°C To 150°C
- ESD Classification JEDEC, JESD22-A114
- Moisture Sensitivity Level JEDEC Level 1 @ 260°C

Caution: Stresses above those listed in “Absolute Maximum Rating” may cause permanent damage to the device. These are stress ratings only and function of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to “Absolute Maximum Rating” conditions for extended periods may affect device reliability.

Package Information

10-Lead MLPD, 3x3mm

$$\theta_{JA} = 33^{\circ} \text{ C/W} *$$

$$\theta_{JC} = 2.1^{\circ} \text{ C/W}$$

*Exposed pad on underside is connected to a copper pad through vias for 4-layer PCB board design

Block Diagram

Pin Description

Pin	Name	Description
1	Vcc	This pin provides power for the internal blocks of the IC as well as powers the low side driver. A minimum of 0.1uF, high frequency capacitor must be connected from this pin to power ground.
2	LDrv	Output driver for low side MOSFET
3	PGnd	Power Ground. This pin serves as a separate ground for the MOSFET drivers and should be connected to the system's power ground plane.
4	HDrv	Output driver for high side MOSFET
5	Vc	This pin powers the high side driver and must be connected to a voltage higher than bus voltage. A minimum of 0.1uF, high frequency capacitor must be connected from this pin to power ground.
6	Fb	Inverting input to the error amplifier. This pin is connected directly to the output of the regulator via resistor divider to set the output voltage and provide feedback to the error amplifier.
7	Comp	Output of error amplifier. An external resistor and capacitor network is typically connected from this pin to ground to provide loop compensation.
8	Gnd	Signal ground for internal reference and control circuitry.
9	SS/SD	Soft start / shutdown. This pin provides user programmable soft-start function. Connect an external capacitor from this pin to ground to set the start up time of the output voltage. The converter can be shutdown by pulling this pin below 0.3V.
10	OCSet	Current limit set point. A resistor from this pin to drain of low side MOSFET will set the current limit threshold.

TYPICAL OPERATING CHARACTERISTICS

Circuit Description

THEORY OF OPERATION

Introduction

The IR3624 is a voltage mode PWM synchronous controller and operates with a fixed 600kHz switching frequency, allowing the use of small external components. The output voltage is set by feedback pin (Fb) and the internal reference voltage (0.6V). These are two inputs to error amplifier. The error signal between these two inputs is compared to a fixed frequency linear sawtooth ramp and generates fixed frequency pulses of variable duty-cycle (D) which drives N-channel external MOSFETs.

The timing of the IC is controlled by an internal oscillator circuit that uses on-chip capacitor to set the switching frequency.

The IR3624 operates with single input voltage from 4.5V to 12V allowing an extended operating input voltage range.

The current limit is programmable and uses on-resistance of the low-side MOSFET, eliminating the need for external current sense resistor.

Under-Voltage Lockout

The under-voltage lockout circuit monitors the two input supplies (V_{cc} and V_c) and assures that the MOSFET driver outputs remain in the off state whenever the supply voltage drops below set thresholds. Lockout occurs if V_c or V_{cc} fall below 3.3V and 4.2V respectively. Normal operation resumes once V_c and V_{cc} rise above the set values.

Thermal Shutdown

Temperature sensing is provided inside IR3624. The trip threshold is typically set to 145°C. When trip threshold is exceeded, thermal shutdown turns off both MOSFETs. Thermal shutdown is not latched and automatic restart is initiated when the sensed temperature drops within the operating range. There is a 20°C hysteresis in the thermal shutdown threshold.

Shutdown

The output can be shutdown by pulling the soft-start pin below 0.3V. This can be easily done by using an external small signal transistor. During shutdown both MOSFET drivers will be turned off. Normal operation will resume by cycling soft start pin.

Error Amplifier

The IR3624 is a voltage mode controller. The error amplifier is of transconductance type. The amplifier is capable of operating with Type III compensation control scheme using low ESR output capacitance.

Pre-Bias Startup

IR3624 is able to start up into pre-charged output, which prevents oscillation and disturbances of the output voltage.

The output starts in asynchronous fashion and keeps the synchronous MOSFET off until the first gate signal for control MOSFET is generated. Figure 4 shows a typical Pre-Bias condition at start up.

Depends on system configuration, specific amount of output capacitors may be required to prevent discharging the output voltage.

Fig. 4: Pre-Bias start up

Soft-Start

The IR3624 has programmable soft-start to control the output voltage rise and limit the inrush current during start-up.

To ensure correct start-up, the soft-start sequence initiates when V_{cc} and V_c rise above their threshold and generate the Power On Ready (POR) signal. The soft-start function operates by sourcing current to charge an external capacitor to about 3V.

Initially, the soft-start function clamps the output of error amplifier by injecting a current (40uA) into the Fb pin and generates a voltage about 0.96V (40uA x 24K) across the negative input of error amplifier (see figure 5).

The magnitude of the injected current is inversely proportional to the voltage at the soft-start pin. As the soft-start voltage ramps up, the injected current decreases linearly and so does the voltage at negative input of error amplifier.

When the soft-start capacitor is around 1V, the voltage at the positive input of the error amplifier is approximately 0.6V.

The output of error amplifier will start increasing and generating the first PWM signal. As the soft-start capacitor voltage continues to go up, the current flowing into the Fb pin will keep decreasing.

The feedback voltage increases linearly as the soft start voltage ramps up. When soft-start voltage is around 2V the output voltage is reached the steady state and the injected current is zero.

Figure 6 shows the theoretical operational waveforms during soft-start.

The output voltage start-up time is the time period when soft-start capacitor voltage increases from 1V to 2V.

The start-up time will be dependent on the size of the external soft-start capacitor and can be estimate by:

$$20\mu A * \frac{T_{start}}{C_{ss}} = 2V - 1V$$

For a given start-up time, the soft-start capacitor (nF) can be estimated as:

$$C_{SS} \cong 20\mu A * T_{start}(ms) \quad --(1)$$

Fig. 5: Soft-Start circuit for IR3624

Fig. 6: Theoretical operation waveforms during soft-start

Over-Current Protection

The over current protection is performed by sensing current through the $R_{DS(on)}$ of low side MOSFET. This method enhances the converter's efficiency and reduce cost by eliminating a current sense resistor. As shown in figure 7, an external resistor (R_{SET}) is connected between OCSet pin and the drain of low side MOSFET (Q2) which sets the current limit set point.

The internal current source develops a voltage across R_{SET} . When the low side MOSFET is turned on, the inductor current flows through the Q2 and results a voltage which is given by:

$$V_{OCSet} = (I_{OCSet} * R_{OCSet}) - (R_{DS(on)} * I_L) \quad --(2)$$

Fig. 7: Connection of over current sensing resistor

The critical inductor current can be calculated by setting:

$$V_{OCSet} = (I_{OCSet} * R_{OCSet}) - (R_{DS(on)} * I_L) = 0$$

$$I_{SET} = I_{L(critical)} = \frac{R_{OCSet} * I_{OCSet}}{R_{DS(on)}} \quad --(3)$$

An over current is detected if the OCSet pin goes below ground. This trips the OCP comparator and cycles the soft start function in hiccup mode.

The hiccup is performed by charging and discharging the soft-start capacitor in certain slope rate. As shown in figure 8 a 3uA current source is used to discharge the soft-start capacitor.

The OCP comparator resets after every soft start cycles, the converter stays in this mode until the overload or short circuit is removed. The converter will automatically recover.

Fig. 8: 3uA current source for discharging soft-start capacitor during hiccup

The OCP circuit starts sampling current when the low gate drive is about 3V. The OCSet pin is internally clamped during deadtime to prevent false triggering, figure 9 shows the OCSet pin during one switching cycle. As it is shown there is about 150ns delay to mask the deadtime, since this node contains switching noises, this delay also functions as a filter.

Fig. 9: OCset pin during normal condition
Ch1: Inductor point, Ch2:Ldrv, Ch3:OCSet

The value of R_{SET} should be checked in an actual circuit to ensure that the over current protection circuit activates as expected. The IR3624 current limit is designed primarily as disaster preventing, "no blow up" circuit, and doesn't operate as a precision current regulator.

Application Information

Design Example:

The following example is a typical application for IR3624. The application circuit is shown in page17.

$$V_{in} = 12V, (13.2V, \max)$$

$$V_o = 1.8V$$

$$I_o = 6A$$

$$\Delta V_o \leq 30mV$$

$$F_s = 600kHz$$

Output Voltage Programming

Output voltage is programmed by reference voltage and external voltage divider. The Fb pin is the inverting input of the error amplifier, which is internally referenced to 0.6V. The divider is ratioed to provide 0.6V at the Fb pin when the output is at its desired value. The output voltage is defined by using the following equation:

$$V_o = V_{ref} * \left(1 + \frac{R_8}{R_9}\right) \quad --(4)$$

When an external resistor divider is connected to the output as shown in figure 10.

Fig. 10: Typical application of the IR3624 for programming the output voltage

Equation (4) can be rewritten as:

$$R_9 = R_8 * \left(\frac{V_{ref}}{V_o - V_{ref}}\right) \quad --(5)$$

For the calculated values of R_8 and R_9 see feedback compensation section.

Soft-Start Programming

The soft-start timing can be programmed by selecting the soft-start capacitance value. The start-up time of the converter can be calculated by using:

$$C_{SS} \cong 20\mu A * T_{start} \quad --(1)$$

Where T_{start} is the desired start-up time (ms)

For a start-up time of 5ms, the soft-start capacitor will be 0.1uF. Choose a ceramic capacitor at 0.1uF.

Vc supply for single input voltage

To drive the high side switch, it is necessary to supply a gate voltage at least 4V greater than the bus voltage. This is achieved by using a charge pump configuration as shown in figure 11. This method is simple and inexpensive. The operation of the circuit is as follows: when the lower MOSFET is turned on, the capacitor (C1) is pulled down to ground and charges, up to V_{BUS} value, through the diode (D1). The bus voltage will be added to this voltage when upper MOSFET turns on in next cycle, and providing supply voltage (V_c) through diode (D2). V_c is approximately:

$$V_c \cong 2 * V_{bus} - (V_{D1} + V_{D2}) \quad --(6)$$

Capacitors in the range of 0.1uF is generally adequate for most applications. The diodes must be a fast recovery device to minimize the amount of charge fed back from the charge pump capacitor into V_{BUS} . The diodes need to be able to block the full power rail voltage, which is seen when the high side MOSFET is switched on. For low voltage application, schottky diodes can be used to minimize forward drop across the diodes at start up.

Fig. 11: Charge pump circuit to generate V_c voltage

Input Capacitor Selection

The input filter capacitor should be selected based on how much ripple the supply can tolerate on the DC input line. The ripple current generated during the on time of upper MOSFET should be provided by input capacitor. The RMS value of this ripple is expressed by:

$$I_{RMS} = I_o * \sqrt{D * (1 - D)} \quad --(7)$$

Where: $D = \frac{V_o}{V_{in}}$

D is the Duty Cycle

I_{RMS} is the RMS value of the input capacitor current.

I_o is the output current.

For $I_o = 6A$ and $D = 0.13$, the $I_{RMS} = 2.0A$.

Ceramic capacitors are recommended due to their peak current capabilities, they also feature low ESR and ESL at higher frequency which enhance better efficiency,

Use one 10uF, 25V ceramic capacitor from Panasonic.

Inductor Selection

The inductor is selected based on output power, operating frequency and efficiency requirements. Low inductor value causes large ripple current, resulting in the smaller size, faster response to a load transient but poor efficiency and high output noise. Generally, the selection of inductor value can be reduced to desired maximum ripple current in the inductor (ΔI). The optimum point is usually found between 20% and 50% ripple of the output current.

For the buck converter, the inductor value for desired operating ripple current can be determined using the following relation:

$$V_{in} - V_o = L * \frac{\Delta I}{\Delta t}; \quad \Delta t = D * \frac{1}{F_s}$$

$$L = (V_{in} - V_o) * \frac{V_o}{V_{in} * \Delta I * F_s} \quad --(8)$$

Where:

V_{in} = Maximum input voltage

V_o = Output Voltage

ΔI = Inductor ripple current

F_s = Switching frequency

Δt = Turn on time

D = Duty cycle

If $\Delta I \approx 50\%(I_o)$, then the output inductor will be:

$$L = 0.82\mu H$$

The ACT STS703 series provides a range of inductors in different values, low profile suitable for large currents.

Output Capacitor Selection

The voltage ripple and transient requirements determines the output capacitors types and values. The criteria is normally based on the value of the Effective Series Resistance (ESR). However the actual capacitance value and the Equivalent Series Inductance (ESL) are other contributing components, these components can be described as:

$$\Delta V_o = \Delta V_{o(ESR)} + \Delta V_{o(ESL)} + \Delta V_{o(C)}$$

$$\Delta V_{o(ESR)} = \Delta I_L * ESR \quad --(9)$$

$$\Delta V_{o(ESL)} = \left(\frac{V_{in}}{L}\right) * ESL$$

$$\Delta V_{o(C)} = \frac{\Delta I_L}{8 * C_o * F_s}$$

$$\Delta V_o = \text{Output voltage ripple}$$

$$\Delta I_L = \text{Inductor ripple current}$$

Since the output capacitor has major role in overall performance of converter and determine the result of transient response, selection of capacitor is critical. The IR3624 can perform well with all types of capacitors.

As a rule the capacitor must have low enough ESR to meet output ripple and load transient requirements, yet have high enough ESR to satisfy stability requirements.

The goal for this design is to meet the voltage ripple requirement in smallest possible capacitor size. Therefore ceramic capacitor is selected due to low ESR and small size. Two of the Panasonic ECJ2FB0J226M (22uF, 6.3V, X5R and EIA 0805 case size) is a good choice.

In the case of tantalum or low ESR electrolytic capacitors, the ESR dominates the output voltage ripple, equation (9) can be used to calculate the required ESR for the specific voltage ripple.

Power MOSFET Selection

The IR3624 uses two N-Channel MOSFETs. The selections criteria to meet power transfer requirements is based on maximum drain-source voltage (V_{DSS}), gate-source drive voltage (V_{GS}), maximum output current, On-resistance $R_{DS(on)}$ and thermal management.

The MOSFET must have a maximum operating voltage (V_{DSS}) exceeding the maximum input voltage (V_{in}).

The gate drive requirement is almost the same for both MOSFETs. Logic-level transistor can be used and caution should be taken with devices at very low V_{GS} to prevent undesired turn-on of the complementary MOSFET, which results a shoot-through current.

The total power dissipation for MOSFETs includes conduction and switching losses. For the Buck converter the average inductor current is equal to the DC load current. The conduction loss is defined as:

$$P_{cond} = (\text{upper switch}) = I_{load}^2 * R_{ds(on)} * D * \mathcal{G}$$

$$P_{cond} = (\text{lower switch}) = I_{load}^2 * R_{ds(on)} * (1-D) * \mathcal{G}$$

$$\mathcal{G} = R_{ds(on)} \text{ temperature dependency}$$

The $R_{DS(on)}$ temperature dependency should be considered for the worst case operation. This is typically given in the MOSFET data sheet. Ensure that the conduction losses and switching losses do not exceed the package ratings or violate the overall thermal budget.

For this design, IRF8910 is a good choice. The device provides two N-MOSFETs in a compact SO-8 package.

The IRF8910 has the following data:

$$V_{ds} = 20V, I_a = 10A$$

$$R_{ds(on)} = 13.4m\Omega @ V_{gs} = 10V$$

The conduction losses will be: $P_{con} = 0.724W$

The switching loss is more difficult to calculate, even though the switching transition is well understood. The reason is the effect of the parasitic components and switching times during the switching procedures such as turn-on / turn-off delays and rise and fall times. The control MOSFET contributes to the majority of the

switching losses in synchronous Buck converter. The synchronous MOSFET turns on under zero voltage conditions, therefore, the turn on losses for synchronous MOSFET can be neglected. With a linear approximation, the total switching loss can be expressed as:

$$P_{sw} = \frac{V_{ds(off)}}{2} * \frac{t_r + t_f}{T} * I_{load} \quad \dots (10)$$

Where:

$V_{ds(off)}$ = Drain to source voltage at the off time

t_r = Rise time

t_f = Fall time

T = Switching period

I_{load} = Load current

The switching time waveforms is shown in figure12.

Fig. 12: switching time waveforms

From IRF8910 data sheet:

$$tr = 10ns$$

$$tf = 4.1ns$$

These values are taken under a certain condition test. For more details please refer to the IRF8910 data sheet.

By using equation (10), we can calculate the switching losses. $P_{sw} = 0.37W$

Feedback Compensation

The IR3624 is a voltage mode controller; the control loop is a single voltage feedback path including error amplifier and error comparator. To achieve fast transient response and accurate output regulation, a compensation circuit is necessary. The goal of the compensation network is to provide a closed loop transfer function with the highest 0dB crossing frequency and adequate phase margin (greater than 45°).

The output LC filter introduces a double pole, –40dB/decade gain slope above its corner resonant frequency, and a total phase lag of 180° (see figure 13). The resonant frequency of the LC filter expressed as follows:

$$F_{LC} = \frac{1}{2 * \pi * \sqrt{L_o * C_o}} \quad \text{--- (11)}$$

Figure 13 shows gain and phase of the LC filter. Since we already have 180° phase shift just from the output filter, the system risks being unstable.

Fig. 13: Gain and Phase of LC filter

The IR3624's error amplifier is a differential-input transconductance amplifier. The output is available for DC gain control or AC phase compensation.

The error amplifier can be compensated either in type II or typeIII compensation. When it is used in typeIII compensation the transconductance properties of the error amplifier become evident and can be used to cancel one of the output filter poles. This will be accomplished with a series RC circuit from Comp pin to ground as shown in figure 14.

This method requires that the output capacitor should have enough ESR to satisfy stability requirements. In general the output capacitor's ESR generates a zero typically at 5kHz to 50kHz which is essential for an acceptable phase margin.

The ESR zero of the output capacitor expressed as follows:

$$F_{ESR} = \frac{1}{2 * \pi * ESR * C_o} \quad \text{--- (12)}$$

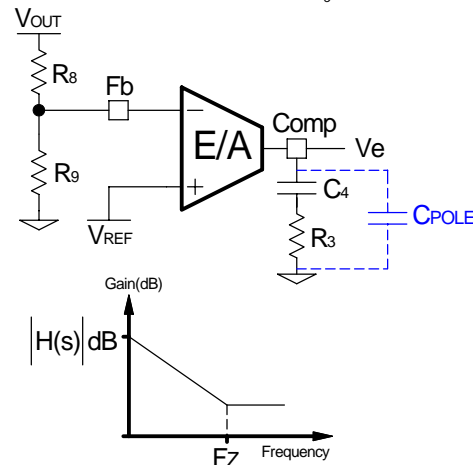

Fig. 14: TypeIII compensation network and its asymptotic gain plot

The transfer function (Ve/Vo) is given by:

$$H(s) = \left(g_m * \frac{R_9}{R_9 + R_8} \right) * \frac{1 + sR_3C_4}{sC_4} \quad \text{--- (13)}$$

The (s) indicates that the transfer function varies as a function of frequency. This configuration introduces a gain and zero, expressed by:

$$[H(s)] = \left(g_m * \frac{R_9}{R_9 + R_8} \right) * R_3 \quad \text{--- (14)}$$

$$F_z = \frac{1}{2\pi * R_3 * C_4} \quad \text{--- (15)}$$

The gain is determined by the voltage divider and error amplifier's transconductance gain.

First select the desired zero-crossover frequency (Fo):

$$F_o > F_{ESR} \text{ and } F_o \leq (1/5 \sim 1/10) * F_s$$

Use the following equation to calculate R4:

$$R_3 = \frac{V_{osc} * F_o * F_{ESR} * (R_8 + R_9)}{V_{in} * F_{LC}^2 * R_9 * g_m} \quad \text{--- (15)}$$

Where:

V_{in} = Maximum Input Voltage

V_{osc} = Oscillator Ramp Voltage

F_o = Crossover Frequency

F_{ESR} = Zero Frequency of the Output Capacitor

F_{LC} = Resonant Frequency of the Output Filter

R_8 and R_9 = Feedback Resistor Dividers

g_m = Error Amplifier Transconductance

To cancel one of the LC filter poles, place the zero before the LC filter resonant frequency pole:

$$F_z = 75\%F_{LC}$$

$$F_z = 0.75 * \frac{1}{2\pi\sqrt{L_o * C_o}} \quad \text{--- (16)}$$

Using equations (15) and (16) to calculate C9. One more capacitor is sometimes added in parallel with C4 and R3. This introduces one more pole which is mainly used to suppress the switching noise.

The additional pole is given by:

$$F_p = \frac{1}{2\pi * R_3 * \frac{C_4 * C_{POLE}}{C_4 + C_{POLE}}}$$

The pole sets to one half of switching frequency which results in the capacitor C_{POLE}:

$$C_{POLE} = \frac{1}{\pi * R_3 * F_s - \frac{1}{C_4}} \cong \frac{1}{\pi * R_3 * F_s}$$

For $F_p \ll \frac{F_s}{2}$

For a general solution for unconditionally stability for any type of output capacitors, in a wide range of ESR values we should implement local feedback with a compensation network (typeIII). The typically used compensation network for voltage-mode controller is shown in figure 15.

In such configuration, the transfer function is given by:

$$\frac{V_e}{V_o} = \frac{1 - g_m Z_f}{1 + g_m Z_{IN}}$$

The error amplifier gain is independent of the transconductance under the following condition:

$$g_m * Z_f \gg 1 \text{ and } g_m * Z_{in} \gg 1 \quad \text{--- (17)}$$

By replacing Z_{in} and Z_f according to figure 15, the transfer function can be expressed as:

$$H(s) = \frac{1}{sR_8(C_4 + C_3)} * \frac{(1 + sR_3C_4) * [1 + sC_7(R_8 + R_{10})]}{\left[1 + sR_3\left(\frac{C_4 * C_3}{C_4 + C_3}\right)\right] * (1 + sR_{10}C_7)}$$

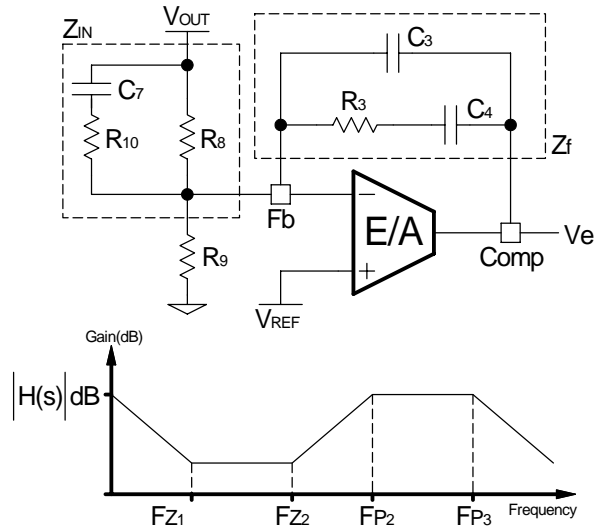

Fig.15: Compensation network with local feedback and its asymptotic gain plot

As known, transconductance amplifier has high impedance (current source) output, therefore, consider should be taken when loading the error amplifier output. It may exceed its source/sink output current capability, so that the amplifier will not be able to swing its output voltage over the necessary range.

The compensation network has three poles and two zeros and they are expressed as follows:

$$F_{P1} = 0$$

$$F_{P2} = \frac{1}{2\pi * R_{10} * C_7}$$

$$F_{P3} = \frac{1}{2\pi * R_3 * \left(\frac{C_4 * C_3}{C_4 + C_3}\right)} \cong \frac{1}{2\pi * R_3 * C_3}$$

$$F_{Z1} = \frac{1}{2\pi * R_3 * C_4}$$

$$F_{Z2} = \frac{1}{2\pi * C_7 * (R_8 + R_{10})} \cong \frac{1}{2\pi * C_7 * R_8}$$

Cross over frequency is expressed as:

$$F_o = R_3 * C_7 * \frac{V_{in}}{V_{osc}} * \frac{1}{2\pi * L_o * C_o}$$

Based on the frequency of the zero generated by output capacitor and its ESR versus crossover frequency, the compensation type can be different. The table below shows the compensation types and location of crossover frequency.

Compensator type	F_{ESR} vs. F_o	Output capacitor
TypeII(PI)	$F_{LC} < F_{ESR} < F_o < F_{s/2}$	Electrolytic, Tantalum
TypeIII(PID) Method A	$F_{LC} < F_o < F_{ESR} < F_{s/2}$	Tantalum, ceramic
TypeIII(PID) Method B	$F_{LC} < F_o < F_{s/2} < F_{ESR}$	Ceramic

Table1- The compensation type and location of F_{ESR} versus F_o

The details of these compensation types are discussed in application note AN-1043 which can be downloaded from IR Web-Site.

For this design we have:

$V_{in} = 13.2V$
 $V_o = 1.8V$
 $V_{osc} = 1.25V$
 $V_{ref} = 0.6V$
 $g_m = 1000\mu m$
 $L_o = 0.82\mu H$
 $C_o = 2 \times 22\mu F$, ESR=1.5mOhm
 $F_s = 600kHz$

These result to:

$F_{LC} = 26.5kHz$
 $F_{ESR} = 2.4MHz$
 $F_{s/2} = 300kHz$

Select crossover frequency:

$$F_o < F_{ESR} \text{ and } F_o \leq (1/5 \sim 1/10) * F_s$$

Fo=60kHz

Since: $F_{LC} < F_o < F_{s/2} < F_{ESR}$, typeIII method B is selected to place the poles and zeros.

The following design rules will give a crossover frequency approximately one-tenth of the switching frequency. The higher the band width, the potentially faster the load transient response. The DC gain will be large enough to provide high DC-regulation accuracy (typically -5dB to -12dB). The phase margin should be greater than 45° for overall stability.

Desired Phase Margin: $\theta_{max} = \frac{\pi}{3}$

$$F_{Z2} = F_o * \sqrt{\frac{1 - \sin\theta}{1 + \sin\theta}}$$

$$F_{Z2} = 16kHz$$

$$F_{P2} = F_o * \sqrt{\frac{1 + \sin\theta}{1 - \sin\theta}}$$

$$F_{P2} = 224kHz$$

Select: $F_{Z1} = 0.5 * F_{Z2}$ and $F_{P3} = 0.5 * F_s$

$$R_3 \geq \frac{2}{g_m}; R_3 \geq 2K\Omega; \text{ Select: } R_3 = 5K\Omega$$

Calculate C_4, C_3 and C_7 :

$$C_4 = \frac{1}{2\pi * F_{Z1} * R_3}; C_4 = 3.96nF, \text{ Select: } C_4 = 3.9nF$$

$$C_3 = \frac{1}{2\pi * F_{P3} * R_3}; C_3 = 106pF, \text{ Select: } C_3 = 100pF$$

$$C_7 = \frac{2\pi * F_o * L_o * C_o * V_{osc}}{R_3 * V_{in}}; C_{10} = 0.26nF,$$

Select: $C_7 = 0.33nF$

Calculate R_{10}, R_8 and R_9 :

$$R_{10} = \frac{1}{2\pi * C_7 * F_{P2}}; R_{10} = 2.1K\Omega, \text{ Select: } R_{10} = 2K\Omega$$

$$R_8 = \frac{1}{2\pi * C_7 * F_{Z2}} - R_{10}; R_8 = 28K\Omega, \text{ Select: } R_8 = 28K\Omega$$

$$R_9 = \frac{V_{ref}}{V_o - V_{ref}} * R_8; R_9 = 14K\Omega, \text{ Select: } R_9 = 14K\Omega$$

Programming the Current-Limit

The Current-Limit threshold can be set by connecting a resistor (R_{SET}) from drain of low side MOSFET to the OCSet pin. The resistor can be calculated by using equation (3).

The $R_{DS(on)}$ has a positive temperature coefficient and it should be considered for the worse case operation. This resistor must be placed close to the IC, place a small ceramic capacitor from this pin to ground for noise rejection purposes.

$$I_{SET} = I_{L(critical)} = \frac{R_{OCSet} * I_{OCSet}}{R_{DS(on)}} \quad --(3)$$

$$R_{DS(on)} = 13.4m\Omega * 1.5 = 20.1m\Omega$$

$$I_{SET} \cong I_{o(LIM)} = 6A * 1.5 = 9A$$

(50% over nominal output current)

$$R_{OCSet} = R_7 = 9K\Omega$$

Layout Consideration

The layout is very important when designing high frequency switching converters. Layout will affect noise pickup and can cause a good design to perform with less than expected results.

Start to place the power components, make all the connection in the top layer with wide, copper filled areas.

The inductor, output capacitor and the MOSFET should be close to each other as possible. This helps to reduce the EMI radiated by the power traces due to the high switching currents through them. Place input capacitor directly to the drain of the high-side MOSFET, to reduce the ESR replace the single input capacitor with two parallel units.

The feedback part of the system should be kept away from the inductor and other noise sources.

The critical bypass components such as capacitors for Vcc and Vc should be close to respective pins. It is important to place the feedback components include feedback resistors and compensation components close to Fb and Comp pins.

In multilayer PCB use one layer as power ground plane and have a control circuit ground (analog ground), to which all signals are referenced. The goal is to localize the high current path to a separate loop that does not interfere with the more sensitive analog control function. These two grounds must be connected together on the PC board layout at a single point.

The MLPD is thermal enhanced package, based on thermal performance it is recommended to use 4-layers PCB. To effectively remove heat from the device the exposed pad should be connected to ground plane using vias.
