 Rev 1.00
 April 2, 2007

The ISL97801 is a high-power LED backlight driver with an integrated 36V FET designed to drive up to 8 high-power LEDs in series. The PWM converter runs from an internally generated 1MHz clock. With efficiencies over 90% the regulator provides tight control of LED current and may be configured in either boost or buck topologies, allowing from 3 to 8 series diodes to be driven from wide input voltages.

LED light level may be controlled either by:

1. LED DC bias current set via the LEVEL pin, or
2. External low frequency PWM control via the ENABLE/PWM pin.

In both control modes optional over temperature thermal protection of the LED reduces the LED DC bias current above an adjustable set temperature, protecting the LED from thermal damage. An optional fault monitor drives an external FET between the input supply and inductor, providing short circuit current protection for the LED and inductor as well as load dump protection for automotive applications. For low cost applications the pass transistor may be omitted and the fault pin bypassed.

The ISL97801 is packaged in a 20 Ld 4mm x 4mm QFN package and is specified for operation over the -40°C to +105°C temperature range.

Ordering Information

PART NUMBER (Note)	PART MARKING	TAPE & REEL/ QTY	PACKAGE (Pb-free)	PKG. DWG. #
ISL97801ARZ	978 01ARZ	-	20 Ld 4x4 QFN	L20.4x4C
ISL97801ARZ-TK	978 01ARZ	13"/ 1,000	20 Ld 4x4 QFN	L20.4x4C
ISL97801ARZ-T	978 01ARZ	13"/ 6,000	20 Ld 4x4 QFN	L20.4x4C

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Features

- Drives 3-8 high-power LEDs in series, up to 32V
- 2.7V to 16V input voltage range
- Boost or Buck configurable switch
- 3A integrated FET
- Automotive load dump protection
- Light output temperature compensation
- LED over-temperature protection
- LED disconnect
- PWM/analog light level control
- Small, 20 Ld 4mm x 4mm QFN package
- Pb-free plus anneal available (RoHS compliant)

Applications

- Display backlighting
 - Automotive
 - LCD monitor
 - Notebook displays
- LED accent lighting
- Automotive lighting

Pinout

Absolute Maximum Ratings ($T_A = +25^\circ\text{C}$)

Maximum pin voltage, all pins except below 6.5V	
V_{IN} , SWS1, SWS2, EN/PWM	18V
VBAT, FAULT, FB	24V
VHI - SWS1, SWS2	6.5V
SWD1, SWD2, OVP	34V
Continuous Output Current	1A

Thermal Information

Thermal Resistance	θ_{JA} ($^\circ\text{C}/\text{W}$) / θ_{JC} ($^\circ\text{C}/\text{W}$)
QFN-20 Package (Notes 1, 2)	39 / 2.5
Maximum Junction Temperature	+135 $^\circ\text{C}$
Storage Temperature	-65 $^\circ\text{C}$ to +150 $^\circ\text{C}$

Operating Conditions

Temperature Range -40 $^\circ\text{C}$ to +105 $^\circ\text{C}$

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typical values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore: $T_J = T_C = T_A$

Operating continuously at a junction temperature of +135 $^\circ\text{C}$ will shorten the life of the device while the thermal shutdown may trigger at a higher temperature than +135 $^\circ\text{C}$ since it is a typical number.

NOTE:

- θ_{JA} is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
- For θ_{JC} , the "case temp" location is the center of the exposed metal pad on the package underside.

Electrical Specifications $V_{BAT} = V_{IN} = 12\text{V}$, $V_{DC} = 5\text{V}$, $T_A = -40^\circ\text{C}$ to +105 $^\circ\text{C}$ unless otherwise specified.

Pin Descriptions

PIN	NAME	DESCRIPTION
1	VDC	Internally regulated 5V supply, tracks V_{IN} for input voltages less than 5V. LDO output can also be biased with external supply if V_{IN} is <5.5V. A minimum of 3.3 μ F decoupling capacitor is needed in this pin.
2	VHI	Power FET gate drive supply. Can be biased with external supply if V_{in} is <5.5V
3	OVP	Overvoltage monitor input; tie to VOUT for normal operation
4	SWD1	NMOS power FET drain
5	SWD2	NMOS power FET drain
6	BUCK/BOOSTN	Tie to GND for BOOST operation and to VDC for Buck operation
7	LEVEL	Sets LED bias current level; $V_{FB}(\text{nominal}) = V_{LEVEL}/5$
8	TEMP	Temperature reference, tie to GND to disable temperature compensation
9	FB	LED current feedback
10	TMAX	Maximum LED temperature set point; if TEMP voltage exceeds TMAX, FB set point will be reduced
11	SWS2	NMOS power FET source
12	SWS1	NMOS power FET source
13	EN/PWM	Chip enable and light modulation PWM dimming input
14	MODE	Digital Input; tie to GND to set FB reference to 400mV, tie to VDC to control FB reference with LEVEL input
15	ENL	LED load isolation MOS gate driver
16	VBAT	Input supply monitor
17	NC	Leave floating (internally connected)
18	GND	Ground return and FB ground reference
19	FAULT	Gate drive of fault protection FET. Driven low under fault conditions
20	VIN	Input supply

Functional Block Diagram

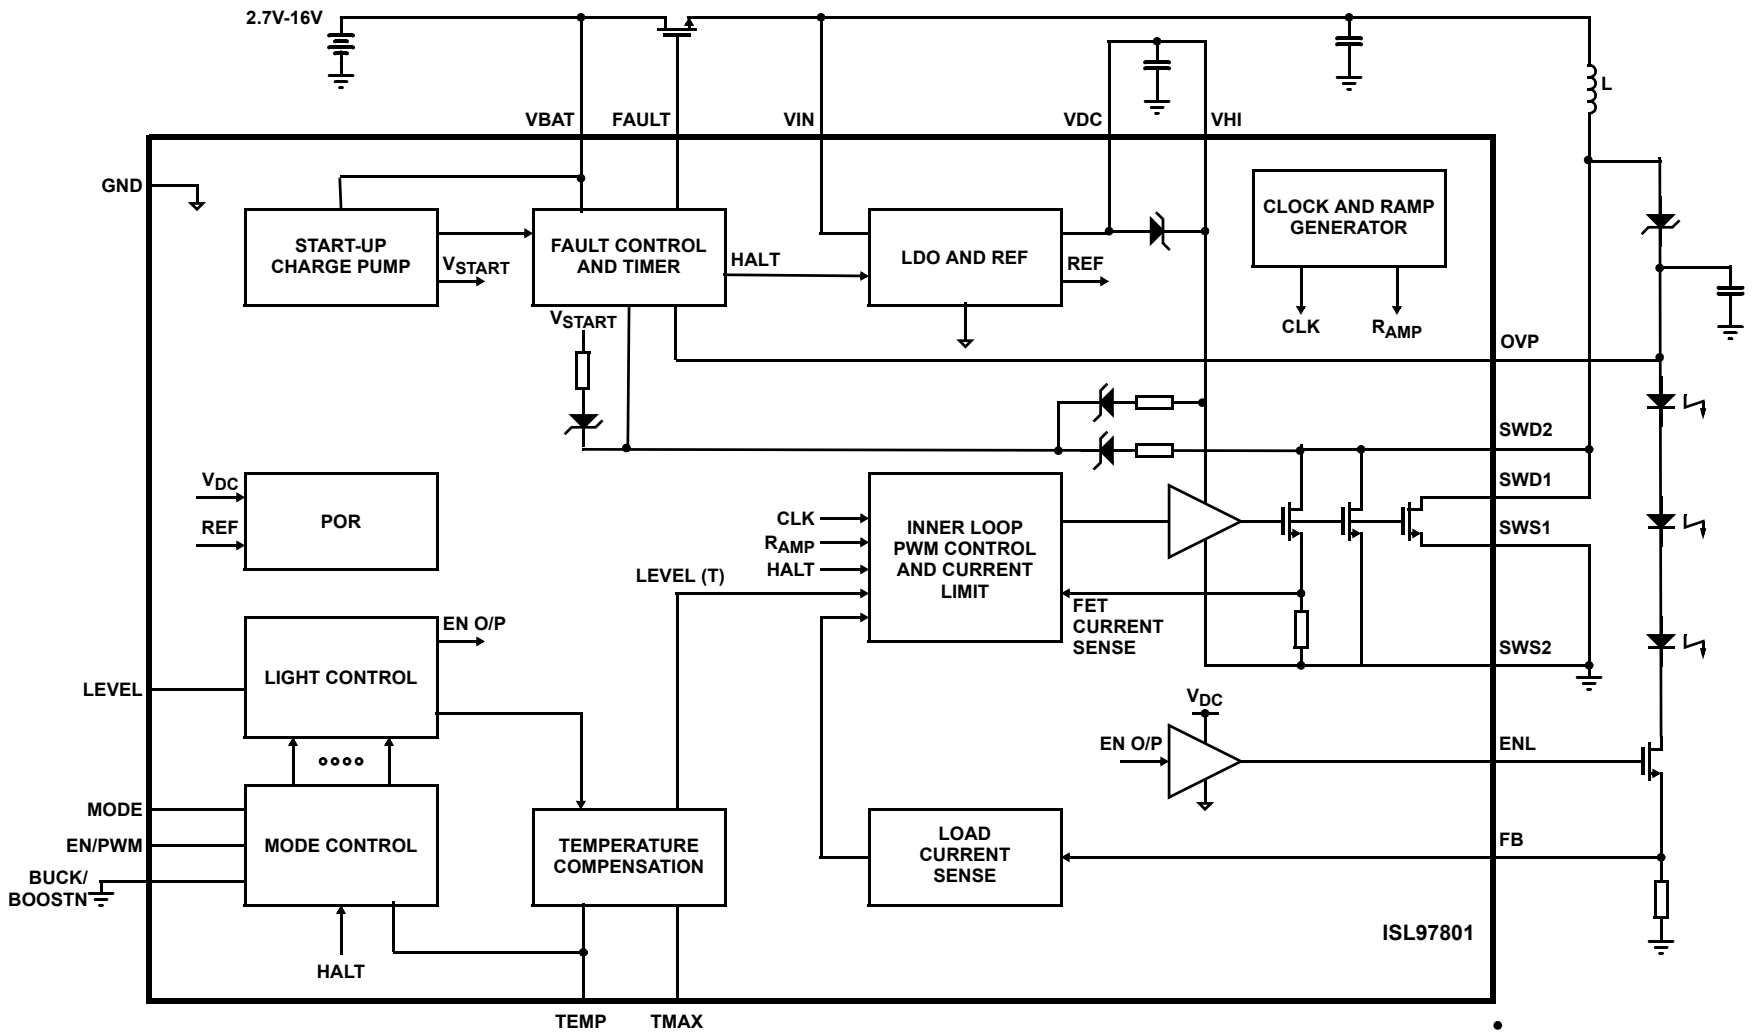

FIGURE 28. ISL97801 BLOCK DIAGRAM

Theory of Operation

General Description

The ISL97801 is a flexible, highly integrated high-power LED driver consisting of a PWM switching controller and integrated 36V NDMOS power FET. The device can drive up to 8 series high-power LED's at currents up to 1A at 16V input or 5 LEDs at current up to 350mA at 2.7V input. The control loop can be configured as either as a boost or buck regulator with the configuration of the buck/boost pin, providing an output voltage above or below the input supply voltage, depending on the number of stacked LED's. The controller operates from 2.7V to 16V depending on the numbers of LEDs and current required and can be powered by a single lithium ion battery, 5V or 12V regulated supplies or automotive electrical systems. LED current is sensed through a low value resistor in series with the LED. A thermistor can be used to implement a thermal protection scheme to limit the maximum LED temperature to a preset desirable level.

Switching Regulator

The ISL97801 employs a current mode PWM control scheme with a nominal switching frequency of 1MHz. This provides fast transient response and enables the use of low profile inductors and compact multilayer ceramic capacitors. Settling time is optimized by the use of a simple control loop without an error amplifier, relying instead on intrinsic gain within the direct summing path. Due to the lower loop gain, offset must be accounted for when setting up initial LED bias current. Refer to the applications section of the datasheet for further information. Figure 28 shows a block diagram of the system.

Application Configurations

Operating Modes

The ISL97801 can operate as either a buck or boost regulator. Hardwire BUCK/BOOSTN to GND for boost mode or to VDC for buck mode. In buck mode the power NDMOS drive circuit is "floated" (boot-strapped) allowing the NDMOS gate to be driven above VIN to fully enhance the power NDMOS. An internal Schottky diode between VDC (5V) and VHI reduces external component count. Use a ceramic capacitor of at least 50nF between VHI and SWS1/2 to bootstrap VHI.

LED Load Connection

ISL97801 includes an auto-sensing FB level shift circuit that enables the LED load to be connected to either GND or VIN. An internal sense circuit monitors the FB pin voltage. When the level exceeds VDC/2, the feedback reference voltage is switched from GND to VIN. Refer to the application section of the datasheet for typical application schematics.

FIGURE 29. FB REFERENCE AUTO SWITCH

Start-up

To maximize external PWM switching speed, the ISL97801 does not include an internal soft-start circuit. When VDC exceeds the power on reset threshold, switching is delayed for 1ms (T_{DELAY}) allowing the output capacitor to charge through the inductor. If soft-start control is required, a suitable application circuit is shown in Figure 30.

FIGURE 30. EXTERNAL SOFT-START CIRCUIT

Light Level Control

Two light control schemes are provided:

1. An external PWM signal via the EN/PWM pin, providing low frequency PWM dimming.
2. Bias current level adjustment via the LEVEL input or fixed internal bias.

PWM Dimming

LED color temperature varies with bias current. In backlighting applications PWM dimming offers better control of color temperature because current through the LED's is kept constant. A 5V gate driver (ENL) synchronized to EN/PWM can be used to control an external N-Ch FET and disconnect the LED stack during the PWM off period. The switch prevents discharge of the output capacitor by the LED load, maintaining a constant bias independent of PWM duty cycle. Operation at 1kHz PWM rate is shown in Figure 31 and Figure 32. The load disconnect switch improves PWM dynamic range, linearity and color temperature control. To further improve the linearity of

PWM dimming, an internal timer delays system shutdown via EN/PWM for 50ms.

FIGURE 31. OPERATION WITH ENL CONTROLLED FET

FIGURE 32. OPERATION WITH NO ENL CONTROLLED FET

Bias Current Dimming

Current in the LED load is determined by the value of the feedback resistor and the target feedback regulation voltage:

$$I_{LED} = \frac{V_{FB}}{R_{SENSE}} \quad (\text{EQ. 1})$$

With MODE tied to VDC, voltage across the feedback resistor is set by V_{LEVEL} :

$$V_{FB} = \frac{V_{LEVEL}}{5} \quad (\text{EQ. 2})$$

The value of V_{FB} should be limited to between 50mV and 450mV for linear operation. For minimum light output, V_{FB} may be set below 50mV. With MODE tied to GND, voltage across the feedback resistor is set at ~400mV via an internal reference. In either operating mode, if LED temperature control is enabled the value of V_{FB} will be reduced when maximum LED temperature is exceeded.

Input Overvoltage

For automotive applications, an external high voltage NFET driven by the FAULT pin disconnects the device from the input supply in response to voltage spikes on the input supply. During start-up an internal charge pump drives the FAULT pin above the input voltage, ensuring the NFET is fully enhanced and powering up the device. In normal operation the switching node of the boost regulator or the floating supply of the buck regulator is used to pump FAULT above V_{IN} . On detection of an overvoltage, the FAULT pin is discharged to GND. The gate to source voltage of the NDMOS is internally limited to $\pm 15V$ to prevent voltage stress.

Fault Protection

The external NFET is also used as a fault protection switch, disconnecting the input supply if a fault occurs for more than 50ms. The system monitors feedback voltage regulation, output overvoltage and input overvoltage. For applications not requiring input voltage or fault protection, connect VBAT and V_{IN} directly together. All faults except input supply overvoltage latch the ISL97801 into an off state that can be cleared by either power cycling the input supply or the EN/PWM pin. Connecting the TMAX pin to VDC disables the fault latch function (LED over temperature control is also disabled).

Output Overvoltage Protection (OVP)

If the FB pin is shorted to ground or an LED fails open circuit, output voltage in BOOST mode can increase to potentially damaging voltages. An optional overvoltage protection circuit can be enabled by connection of the OVP pin to the output voltage. The device will stop switching if the output voltage exceeds OVPH and re-start when the output voltage falls below OVPL. During sustained OVP fault conditions, V_{OUT} will saw-tooth between the upper and lower threshold voltages at a frequency determined by the magnitude of current available to discharge the output capacitor and the value of output capacitor used.

The OVP threshold can be set to a lower value by using an external zener diode and resistor, as shown in Figure 33. R_1 should be adjusted to minimize offset in the FB voltage due to FB pin input current. A value of 100 Ω is recommended.

FIGURE 33. EXTERNAL OVP CIRCUIT

Over Temperature Shutdown

An internal sense circuit disables PWM switching if the die temperature exceeds +135°C. Switching is re-enabled when the temperature falls below +100°C.

Internal 5V LDO

An internal LDO between VIN and VDC regulates VDC to 5V, to power control and gate drive circuits when VIN exceeds 5.1V. In normal operation decouple VDC with at least 3.3µF. In applications where the input supply is less than 5.5V, VDC should be tied directly to VIN.

LED Temperature Control

LED lifetime reduces dramatically with elevated temperature. An over temperature control circuit utilizing the thermistor voltage at TEMP reduces the LED bias current when VTEMP exceeds the threshold voltage on TMAX. To minimize noise injection use a potential divider between VDC and GND to set the voltage on TMAX, as shown in Figure 34. The value of TMAX for a specific threshold temperature is determined by the choice of thermistor temperature coefficient. Disable the function by connecting the TMAX pin to VDC and TEMP pin to GND.

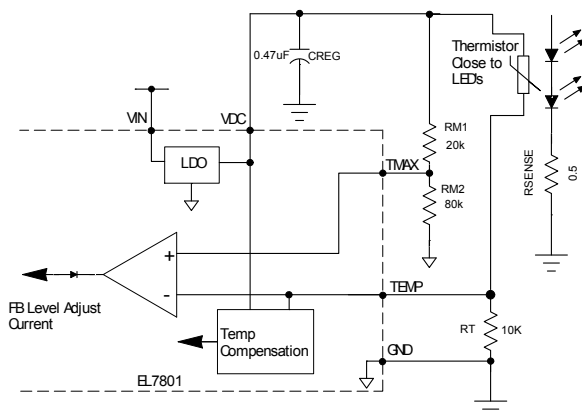

FIGURE 34. OVER-TEMPERATURE CIRCUIT

Component Selection

Input Capacitor

Switching regulators require input capacitors to deliver peak charging current and to reduce the impedance of the input supply. This reduces interaction between the regulator and input supply, improving system stability. The high switching frequency of the loop causes almost all ripple current to flow in the input capacitor, which must be rated accordingly.

Considerably more input current ripple is generated in buck mode than boost mode. In buck mode input current is alternately switched between I_{OUT} and zero. The rms current flow in the input capacitor is given by:

$$I_{CAPRMS} = I_{OUT} \cdot \sqrt{D - D^2} \quad (\text{EQ. 3})$$

Where: D = Duty Cycle

The input current is maximum for D = 0.5 and when I_{OUT} approaches current limit (2.4A) giving a value of around 1.2A.

A capacitor with low internal series resistance should be chosen to minimize heating effects and improve system efficiency, such as X5R or X7R ceramic capacitors, which offer small size and a lower value of temperature and voltage coefficient compared to other ceramic caps.

In boost mode input current flows continuously into the inductor, with an AC ripple component proportional to the rate of inductor charging only and smaller value input capacitors may be used. It is recommended that an input capacitor of at least 10µF be used. Ensure the voltage rating of the input capacitor is suitable to handle the full supply range.

In automotive applications the input capacitor can be protected from exposure to high voltages present during fault conditions (load dump) by connecting it downstream of the fault protection switch, as shown in Figures 39 and 40.

Inductor

Careful selection of inductor value will optimise circuit operation. Inductor type and value influence many key parameters, including ripple current, current limit, efficiency, transient performance and stability. Internal slope compensation has been optimised for inductor values between 4.7µH and 10µH. Ensure the inductor current rating is capable of handling the current limit value in the configuration used (2.4A for buck, 3.5A for boost). If an inductor core is chosen with too low a current rating, saturation in the core will cause the effective inductor value to fall, leading to an increase in peak to average current level, poor efficiency and overheating in the core.

Rectifier Diode

A high speed rectifier diode is necessary to prevent excessive voltage overshoot, especially in the boost configuration. Low forward voltage and reverse leakage current will minimize losses, making Schottky diodes the preferred choice. Similarly to the inductor, a diode with a suitable current rating to handle current limit in the configuration must be used.

Output Capacitor

The output capacitor acts to smooth the output voltage and in the boost configuration supplies load current directly during the conduction phase of the power switch. Ripple voltage consists of two components, the first due to charging and discharging of the capacitor; the second due to IR drop across the ESR of the capacitor by inductor ripple current.

In boost mode:

$$V_{\text{RIPPLE}} = \frac{I_o}{C_{\text{OUT}}} \times \frac{D}{f_s} + I_{\text{LPK}} \times \text{ESR} \quad (\text{EQ. 4})$$

where:

$$D = \frac{V_{\text{OUT}} - V_{\text{IN}}}{V_{\text{OUT}}} \quad (\text{EQ. 5})$$

and

$$I_{\text{LPK}} = \frac{I_o}{1-D} + \frac{(V_{\text{OUT}} - V_{\text{IN}})}{2 \times L} \times \frac{(1-D)}{f_s} \quad (\text{EQ. 6})$$

In buck mode:

$$V_{\text{RIPPLE}} = \frac{(V_{\text{IN}} - V_{\text{OUT}}) \times D}{2 \times f_s \times L} \times \left(\frac{D}{f_s \times C_{\text{OUT}}} + \text{ESR} \right) \quad (\text{EQ. 7})$$

where:

$$D = \frac{V_{\text{OUT}}}{V_{\text{IN}}} \quad (\text{EQ. 8})$$

For a low ESR ceramic capacitor, output ripple is dominated by the charging and discharging of the output capacitor. Care should be taken to ensure the voltage rating of the capacitor exceeds the maximum output voltage.

Compensation

The ISL97801 employs a direct summing control loop with current feedback. No error amplifier is used in the system. The arrangement provides fast transient response and makes use of the output capacitor to compensate the loop. The effect of the pole associated with the inductor is minimized by the current feedback. The number of LEDs, their DC bias current and the value of feedback resistor alter loop stability due to their effect on feedback factor which is heavily influenced by the small signal impedance of the LEDs. Generally, higher numbers of LEDs, lower bias levels and smaller values of feedback resistor will require smaller output capacitors to achieve loop stability. A combination of low ESR electrolytic and ceramic capacitors may be used to reduce implementation costs.

A Note about Ceramic Capacitors:

Many ceramic capacitors have strong voltage and temperature coefficients which reduces effective capacitance as the applied voltage or operating temperature is increased. Pay careful attention when selecting ceramic capacitor type. X5R and X7R families provide much better stability than Y5V, which should generally be avoided unless additional capacitance is added to compensate for the significant changes in value which occurs over voltage and temperature.

TABLE 5. CERAMIC CAPACITOR VARIABILITY

CAPACITOR TYPE	TYPICAL VOLTAGE VARIATION	TEMPERATURE VARIATION
X7R, 10V	-30% at 10V	-15% at +125°C
X5R, 25V	-50% at 25V	-9% at +85°C
Y5V, 6.3V	-90% at 6.3V	-65% at +85°C

Layout Considerations

PCB layout is very important for the converter to function properly. The following general guidelines should be followed:

- Separate the Power Ground and Signal Ground; connect them only at one point close to the GND pin.
- Maximize the Power Ground area as much as possible. It is essential to ensure the Power Ground return between Cin, Cout, and SWS1,2 as least obstructive as possible.
- Place the input capacitor close to VIN and SWS1,2 pins in boost mode-
- Make the following PC traces as short as possible:
 - from SWD1,2 to the inductor in boost mode
 - from SWS1,2 to the inductor in buck mode
 - from Cout to PGND
- Feedback signals levels are small to improve efficiency. Ensure the reference connection (GND or VIN) between the sense resistor and IC pin doesn't carry switching current.
- Place several via holes (thermal vias) under the chip to a backside ground plane to improve heat dissipation
- Maximize the copper area around the thermal vias to spread heat away from the chip.

Cost-Sensitive Applications

For cost-sensitive applications, the BOM can be reduced considerably by:

1. Removing temperature compensation
2. Removing the fault-protection switch
3. Removing the load isolation switch
4. Switching the FB into internal fixed bias mode (400mV across V_{FB})

In this configuration, light level may be controlled using the EN/PWM input to modulate the output current.

In the absence of the load isolation switch, LED bias current will vary with PWM duty cycle, due to the discharge of the output capacitor by the LED's during the PWM off time therefore low dimming frequencies can only be used in such application.

Automotive Applications

The LED load and ISL97801 may be protected against load dumps and other electrical faults in automotive supplies with a minor addition to the standard application schematic:

- A reverse transient automotive-rated protection power schottky must be added in series with the input supply
- A 500Ω current limit resistor must be inserted in series with the V_{BAT} pin
- The fault protection NFET must be specified to handle 100V VDS conditions.

The protection circuit is applicable to buck, boost, and supply-return load applications.

A small reduction in efficiency is caused by the drop in the power schottky.

Unless alternative transient protection is provided, minimum BOM automotive applications must include the circuit changes noted above.
