

# KH207

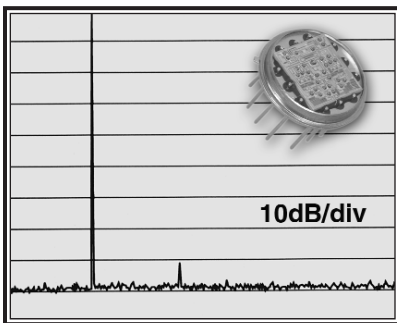

## Low Distortion Wideband Op Amp

### Features

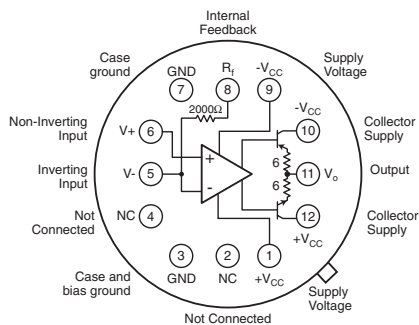

- -80/-85dBc 2nd/3rd HD at 20MHz
- -3dB bandwidth of 170MHz
- 0.1% settling in 22ns
- Complete overdrive protection
- 2400V/μs slew rate
- 3MΩ input resistance
- Output may be current limited
- Direct replacement for CLC207

### Applications

- Fast, precision A/D conversion
- Automatic test equipment
- Input/output amplifiers
- Photodiode, CCD preamps
- High-speed modems, radios
- Line drivers

Bottom View

Pin 8 provides access to a 2000Ω feedback resistor which can be connected to the output or left open if an external feedback resistor is desired.

### General Description

The KH207 is a wideband, low distortion operational amplifier designed specifically for applications requiring both high speed and wide dynamic range. Utilizing a proprietary current feedback architecture, the KH207 offers performance far superior to that of conventional voltage feedback op amps.

The most attractive feature of the KH207 is its extremely low distortion: -80/-85dBc 2nd/3rd harmonics at 20MHz ( $2V_{pp}$ ,  $R_L = 200\Omega$ ). The KH207 also provides -3dB bandwidth of 170MHz at a gain of +20, settles to 0.1% in 22ns and slews at a rate of 2400V/μs. The combination of these features positions the KH207 as the right choice for high speed applications requiring exceptional signal purity.

High speed, high resolution A/D and D/A converter systems requiring low distortion operation will find the KH207 an excellent choice. Wide dynamic range systems such as radar and communication receivers will find that the KH207's low harmonic distortion and low noise make it an attractive high speed solution.

The addition of the KH207 to the KH205/206 Series of high speed operational amplifiers broadens the selection of features available from which to choose. The KH205 offers low power operation, the KH206 offers higher drive operation, and the KH207 offers operation with extremely low distortion, all of which are pin compatible and overdrive protected.

The KH207 is constructed using thin film resistor/bipolar transistor technology, and is available in the following versions:

KH207AI	-25°C to +85°C	12-pin TO-8 can
KH207AK	-55°C to +125°C	12-pin TO-8 can, features burn-in & hermetic testing
KH207AM	-55°C to +125°C	12-pin TO-8 can, environmentally screened and electrically tested to MIL-STD-883
KH207HXC	-55°C to +125°C	SMD#: 5962-9097701HXC
KH207HXA	-55°C to +125°C	SMD#: 5962-9097701HXA

### Typical Performance

Parameter	Gain Setting						Units
	+7	+20	+50	-1	-20	-50	
-3dB bandwidth	220	170	80	220	130	80	MHz
rise time	1.7	2.2	4.7	1.7	2.9	4.7	ns
slew rate	2.4	2.4	2.4	2.4	2.4	2.4	V/ns
settling time (to 0.1%)	22	22	20	21	20	19	ns

## KH207 Electrical Characteristics ( $A_v = +20V$ , $V_{CC} = \pm 15V$ , $R_L = 200\Omega$ , $R_f = 2k\Omega$ ; unless specified)

Min/max ratings are based on product characterization and simulation. Individual parameters are tested as noted. Outgoing quality levels are determined from tested parameters.

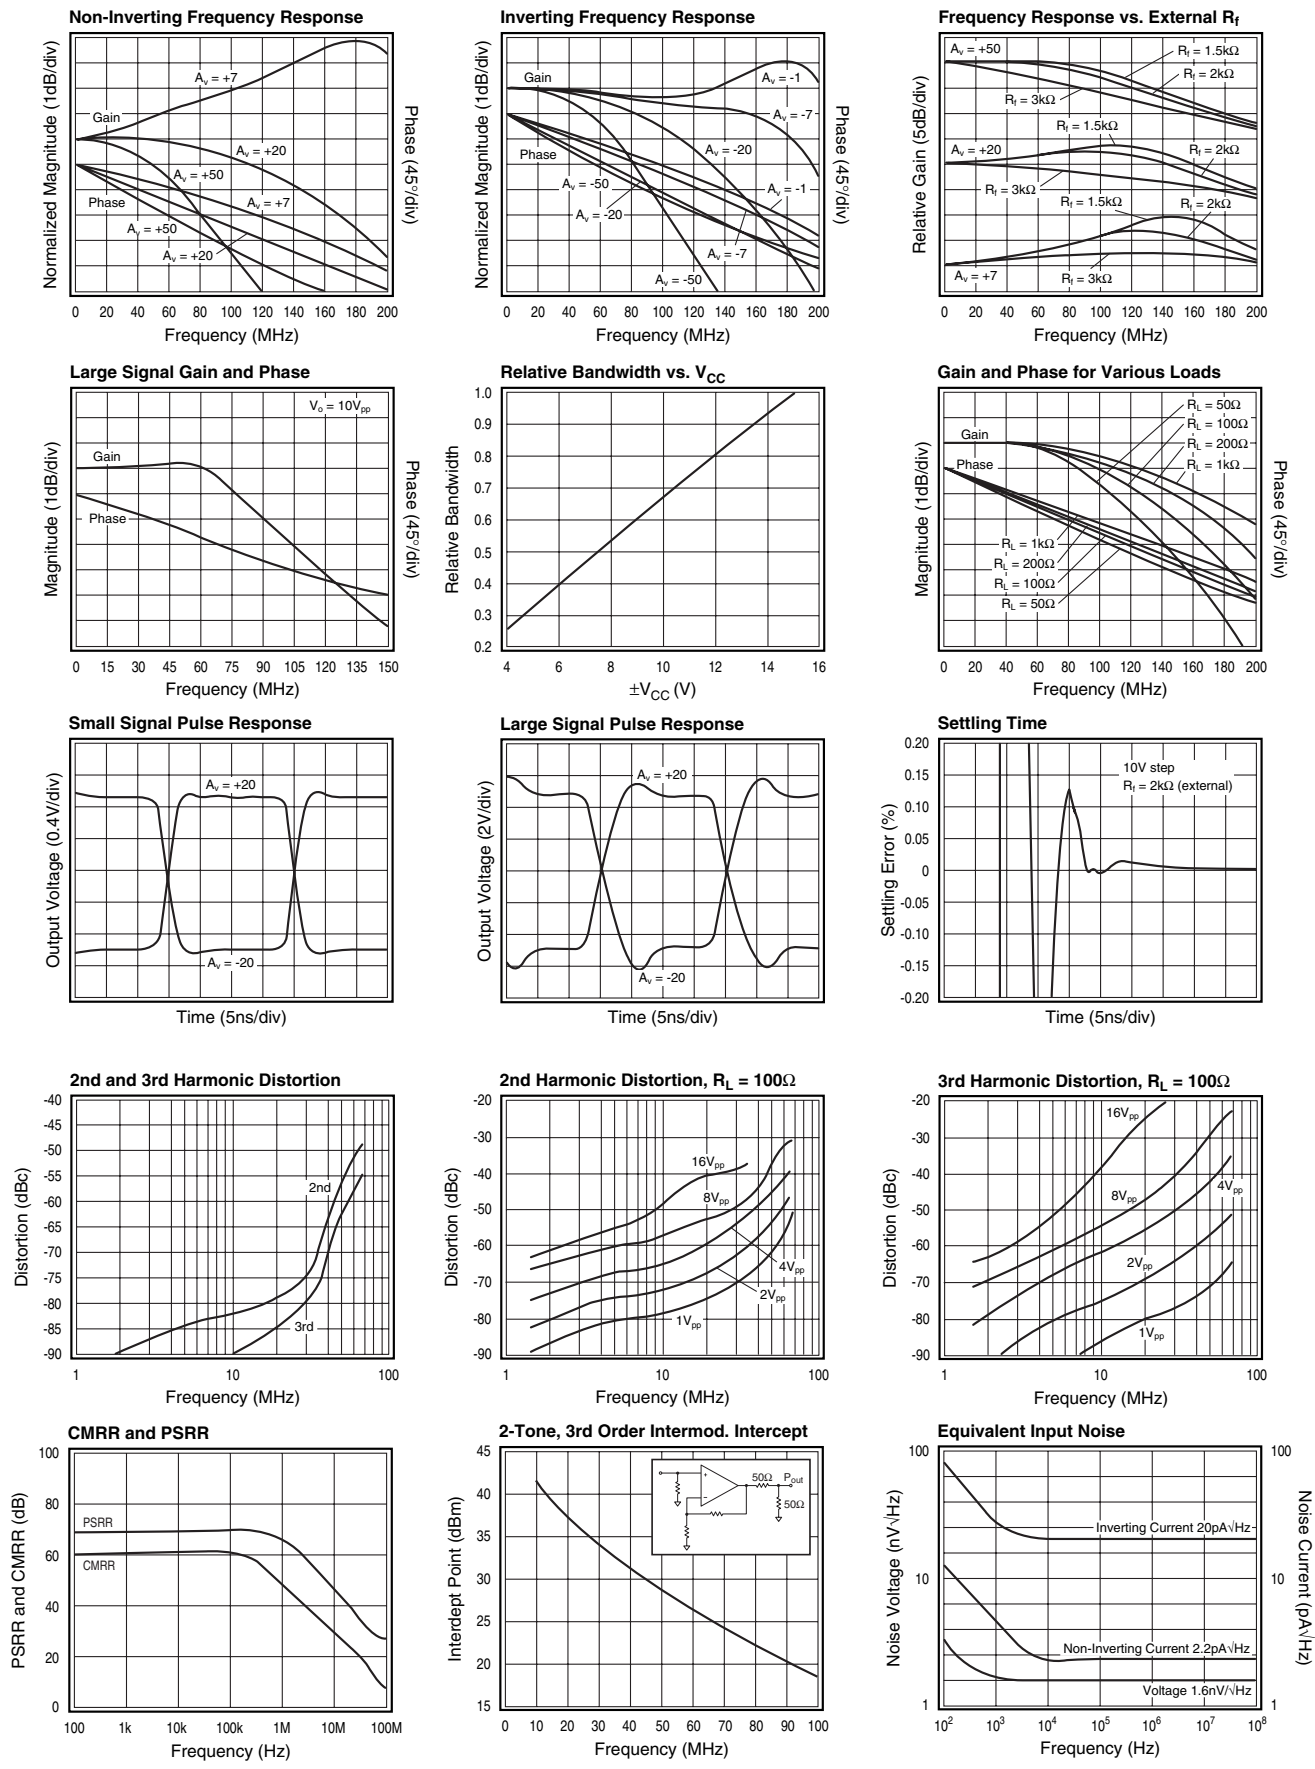

### Absolute Maximum Ratings

$V_{CC}$	±20V
$I_o$	±150mA
common mode input voltage, $V_o$	$ V_{CC}  > 15V \pm(29 -  V_{CC} )V$ $ V_{CC}  \leq 15V \pm( V_{CC}  - 1)V$
differential input voltage	±3V
thermal resistance	(see thermal model)
junction temperature	+175°C
operating temperature	AI: -25°C to +85°C AK/AM/HXC/HXA: -55°C to +125°C
storage temperature	-65°C to +150°C
lead temperature (soldering 10s)	+300°C

### Recommended Operating Conditions

$V_{CC}$	±5V to ±15V
$I_o$	±100mA
common mode input voltage	±(  $V_{CC}$   - 5)V
gain range	+7 to +50, -1 to -50
<b>note 1:</b>	* AI/AK/AM/HXC/HXA 100% tested at +25°C † AK/AM/HXC/HXA 100% tested at +25°C and sample tested at -55°C and +125°C
	† AI sample tested at +25°C
<b>note 2:</b>	Settling time specifications require the use of an external feedback resistor (2kΩ).

# KH207 Typical Performance Characteristics ( $T_A = +25^\circ\text{C}$ , $A_V = +20$ , $V_{CC} = \pm 15\text{V}$ , $R_f = 20\Omega$ , $R_L = 200\Omega$ ; unless specified)

**Current Feedback Amplifiers**

Some of the key features of current feedback technology are:

- Independence of AC bandwidth and voltage gain
- Adjustable frequency response with feedback resistor
- High slew rate
- Fast settling

Current feedback operation can be described using a simple equation. The voltage gain for a non-inverting or inverting current feedback amplifier is approximated by Equation 1.

$$\frac{V_o}{V_{in}} = \frac{A_v}{1 + \frac{R_f}{Z(j\omega)}} \quad \text{Equation 1}$$

where:

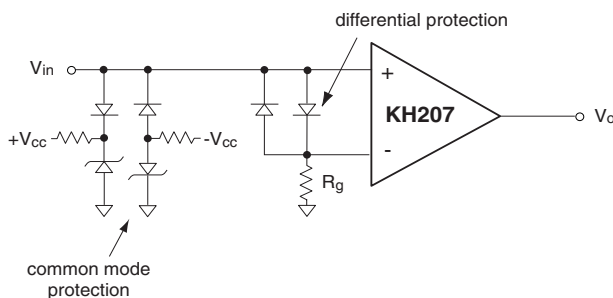

- $A_v$  is the closed loop DC voltage gain
- $R_f$  is the feedback resistor
- $Z(j\omega)$  is the CLC205's open loop transimpedance gain
- $\frac{Z(j\omega)}{R_f}$  is the loop gain

The denominator of Equation 1 is approximately equal to 1 at low frequencies. Near the -3dB corner frequency, the interaction between  $R_f$  and  $Z(j\omega)$  dominates the circuit performance. The value of the feedback resistor has a large affect on the circuits performance. Increasing  $R_f$  has the following affects:

- Decreases loop gain
- Decreases bandwidth
- Reduces gain peaking
- Lowers pulse response overshoot
- Affects frequency response phase linearity

**Overdrive Protection**

Unlike most other high-speed op amps, the KH207 is not damaged by saturation caused by overdriving input signals (where  $V_{in} \times \text{gain} > \text{max. } V_o$ ). The KH207 self limits the current at the inverting input when the output is saturated (see the inverting input current self limit specification); this ensures that the amplifier will not be damaged due to excessive internal currents during overdrive. For protection against input signals which would exceed either the maximum differential or common mode input voltage, the diode clamp circuits below may be used.

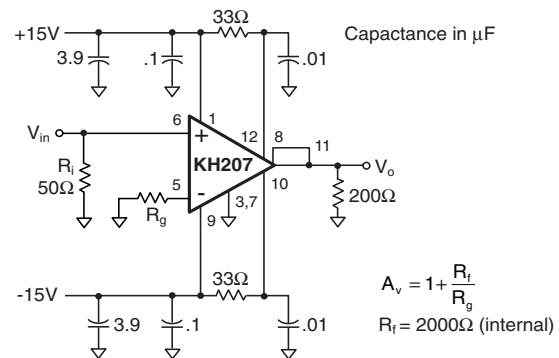

**Figure 1: Diode Clamp Circuits for Common Mode and Differential Mode Protection**

**Short Circuit Protection**

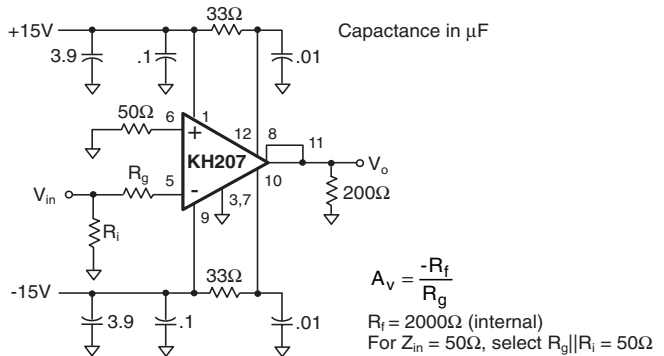

Damage caused by short circuits at the output may be prevented by limiting the output current to safe levels. The most simple current limit circuit calls for placing resistors between the output stage collector supplies and the output stage collectors (pins 12 and 10). The value of this resistor is determined by:

$$R_C = \frac{V_C}{I_l} - R_l$$

where  $I_l$  is the desired limit current and  $R_l$  is the minimum expected load resistance ( $0\Omega$  for a short to ground). Bypass capacitors of  $0.01\mu\text{F}$  on should be used on the collectors as in Figures 2 and 3.

**Figure 2: Recommended Non-Inverting Gain Circuit**

**Figure 3: Recommended Inverting Gain Circuit**

A more sophisticated current limit circuit which provides a limit current independent of  $R_l$  is shown in Figure 4 on page 5.

With the component values indicated, current limiting occurs at 50mA. For other values of current limit ( $I_l$ ), select  $R_C$  to equal  $V_{be}/I_l$ . Where  $V_{be}$  is the base to emitter voltage drop of Q3 (or Q4) at a current of  $[2V_{CC} - 1.4] / R_x$ , where  $R_x \leq [(2V_{CC} - 1.4) / I_l] B_{min}$ .

Also,  $B_{min}$  is the minimum beta of Q1 (or Q2) at a current of  $I_l$ . Since the limit current depends on  $V_{be}$ , which is temperature dependent, the limit current is likewise temperature dependent.

Figure 4: Active Current Limit Circuit (50mA)

**Controlling Bandwidth and Passband Response**

In most applications, a feedback resistor value of 2kΩ will provide optimum performance; nonetheless, some applications may require a resistor of some other value. The response versus  $R_f$  plot on the previous page shows how decreasing  $R_f$  will increase bandwidth (and frequency response peaking, which may lead to instability). Conversely, large values of feedback resistance tend to roll off the response.

The best settling time performance requires the use of an external feedback resistor (use of the internal resistor results in a 0.1% to 0.2% settling tail). The settling performance may be improved slightly by adding a capacitance of 0.4pF in parallel with the feedback resistor (settling time specifications reflect performance with an external feedback resistor but with no external capacitance).

**Thermal Model**

**Noise Analysis**

Approximate noise figure can be determined for the KH207 using the **Equivalent Input Noise** plot on page 3 and the equations shown below.

$$kT = 4.00 \times 10^{-21} \text{ Joules at } 290^\circ\text{K}$$

$V_n$  is spot noise voltage (V/√Hz)

$i_n$  is non-inverting spot noise current (A/√Hz)

$i_i$  is inverting spot noise current (A/√Hz)

$$F = 10 \log \left[ 1 + \frac{R_s}{R_n} + \frac{R_s}{4kT} \cdot \left( i_n^2 + \frac{V_n^2}{R_p^2} + \frac{R_f^2 i_i^2}{R_p^2 A_v^2} \right) \right]$$

where  $R_p = \frac{R_s R_n}{R_s + R_n}$ ;  $A_v = \frac{R_f}{R_g} + 1$

Figure 5: Noise Figure Diagram and Equations (Noise Figure is for the Network Inside this Box.)

**Driving Cables and Capacitive Loads**

When driving cables, double termination is used to prevent reflections. For capacitive load applications, a small series resistor at the output of the KH207 will improve stability and settling performance.

**Transmission Line Matching**

One method for matching the characteristic impedance ( $Z_0$ ) of a transmission line or cable is to place the appropriate resistor at the input or output of the amplifier. Figure 6 shows typical inverting and non-inverting circuit configurations for matching transmission lines.

Figure 6: Transmission Line Matching

Non-inverting gain applications:

- Connect  $R_g$  directly to ground.
- Make  $R_1$ ,  $R_2$ ,  $R_6$ , and  $R_7$  equal to  $Z_0$ .
- Use  $R_3$  to isolate the amplifier from reactive loading caused by the transmission line, or by parasitics.

$$P_{\text{circuit}} = [(+V_{CC}) - (-V_{CC})]^2 / 1.77k\Omega$$

$$P_{\text{xxx}} = [(\pm V_{CC}) - V_{\text{out}} - (I_{\text{col}})(R_{\text{col}} + 6)] (I_{\text{col}}) \text{ (% duty cycle)}$$

(For positive  $V_o$  and  $V_{CC}$ , this is the power in the npn output stage.)

(For negative  $V_o$  and  $V_{CC}$ , this is the power in the pnp output stage.)

$\theta_{ca} = 65^\circ\text{C/W}$  in still air without a heatsink.  
 $35^\circ\text{C/W}$  in still air without a Thermalloy 2268.  
 $15^\circ\text{C/W}$  in 300ft/min air with a Thermalloy 2268 (Thermalloy 2240 works equally well.)

$I_{\text{col}} = V_{\text{out}}/R_{\text{load}}$  or 3mA, whichever is greater. (Include feedback R in  $R_{\text{load}}$ .)

$R_{\text{col}}$  is a resistor (33Ω recommended) between the xxx collector and  $\pm V_{CC}$ .

$T_j(\text{pnp}) = P_{\text{pnp}}(100 + \theta_{ca}) + (P_{\text{cir}} + P_{\text{nnp}})\theta_{ca} + T_a$ , similar for  $T_j(\text{nnp})$ .

$T_j(\text{cir}) = P_{\text{cir}}(17.5 + \theta_{ca}) + (P_{\text{pnp}} + P_{\text{nnp}})\theta_{ca} + T_a$ .

Inverting gain applications:

- Connect  $R_3$  directly to ground.
- Make the resistors  $R_4$ ,  $R_6$ , and  $R_7$  equal to  $Z_o$ .
- Make  $R_5 \parallel R_g = Z_o$ .

The input and output matching resistors attenuate the signal by a factor of 2, therefore additional gain is needed. Use  $C_6$  to match the output transmission line over a greater frequency range.  $C_6$  compensates for the increase of the amplifier's output impedance with frequency.

### Dynamic Range (Intermods)

For RF applications, the KH207 specifies a third order intercept of 26dBm at 60MHz and  $P_o = 10$ dBm. A **2-Tone, 3rd Order IMD Intercept** plot is found in the **Typical Performance Characteristics** section. The output power level is taken at the load. Third-order harmonic distortion is calculated with the formula:

$$HD\ 3^{rd} = 2 \cdot (IP3_o - P_o)$$

where:

- $IP3_o$  = third-order output intercept, dBm at the load.
- $P_o$  = output power level, dBm at the load.
- $HD\ 3^{rd}$  = third-order distortion from the fundamental, -dBc.
- dBm is the power in mW, at the load, expressed in dB.

Realized third-order output distortion is highly dependent upon the external circuit. Some of the common external circuit choices that improve 3<sup>rd</sup> order distortion are:

- short and equal return paths from the load to the supplies.
- de-coupling capacitors of the correct value.
- higher load resistance.
- a lower ratio of the output swing to the power supply voltage.

### Printed Circuit Layout

As with any high frequency device, a good PCB layout will enhance the performance of the KH207. Good ground plane construction and power supply bypassing close to the package are critical to achieving full performance. In the non-inverting configuration, the amplifier is sensitive to stray capacitance to ground at the inverting input. Hence, the inverting node connections should be small with minimal stray capacitance to the ground plane or other nodes. Shunt capacitance across the feedback resistor should not be used to compensate for this effect.

General layout and supply bypassing play major roles in high frequency performance. Follow the steps below as a basis for high frequency layout:

- Include 6.8 $\mu$ F tantalum and 0.1 $\mu$ F ceramic capacitors on both supplies.
- Place the 6.8 $\mu$ F capacitors within 0.75 inches of the power pins.
- Place the 0.1 $\mu$ F capacitors less than 0.1 inches from the power pins.
- Remove the ground plane under and around the part, especially near the input and output pins to reduce parasitic capacitance.
- Minimize all trace lengths to reduce series inductances.
- Use flush-mount printed circuit board pins for prototyping, never use high profile DIP sockets.

An evaluation PC board (part number 730009) for the KH207 is available to aid in device testing.
