## APPLICATION INFORMATION

### (1) Voltage Gain

The closed loop voltage gain is determined by  $R_1$ ,  $R_2$

$$G_V = 20 \log \frac{R_1 + R_2}{R_2} \text{ (dB)}$$

$$= 20 \log \frac{20\text{k}\Omega + 400\Omega}{400\Omega} = 34\text{(dB)}$$

Fig. 1

### (2) Amplifier with gain < 34dB

$$G_V = 20 \log \frac{R_1 + R_2 + R_3}{R_2 + R_3} \text{ (dB)}$$

When  $R_3 = 220\Omega$   
 $G_V \approx 30\text{(dB)}$   
 is given.

## Muting

### (1) Audio muting

This IC is possible to make audio muting operation by using  $\text{MUTE}$  pin muting terminal.

In Fig.3, the equivalent circuit in the muting circuit section is shown.

By means of reducing the voltage of  $\text{MUTE}$  pin down to 2.8V or less in Fig.3,  $Q_1$  is turned ON and the base voltage of  $Q_2$  in the differential circuit fabricated with  $Q_2$  and  $Q_3$ .

Therefore, with the voltage reduction of  $\text{MUTE}$  pin, the input circuits of dummy of input terminal and that in the dotted line operate and cut-off the input signal.

After muting, the bias circuit continues its operation and the power supply current of quiescent time.

$\text{NF}$  pin, the capacitor terminal for reducing the pop noise can reduce the pop noise through making the time constant longer by means of inserting the capacitor externally.

In the case this terminal is not used, short  $\text{NF}$  pin with  $\text{MUTE}$  pin.

The voltage of  $\text{MUTE}$  pin set up to 4V or more.

### (2) IC internal muting at $V_{CC}$ OFF

When  $V_{CC}=8V$  or less at  $V_{CC}$  off, the detection circuit at  $V_{CC}$  off is operated. And the base voltage of  $Q_1$  is reduced and the muting operation is mode.
