**64Kx36-Bit Synchronous Burst SRAM**

**FEATURES**

- Synchronous Operation.
- On-Chip Address Counter.
- Write Self-Timed Cycle.
- On-Chip Address and Control Registers.
- $V_{DD} = 3.3V + 0.3V / -0.165V$  Power Supply.
- $V_{DDQ}$  Supply Voltage  $3.3V + 0.3V / -0.165V$  for 3.3V I/O or  $2.5V + 0.4V / -0.125V$  for 2.5V I/O.
- 5V Tolerant Inputs except I/O Pins.
- Byte Writable Function.
- Global Write Enable Controls a full bus-width write.
- Power Down State via ZZ Signal.
- Asynchronous Output Enable Control.
- $\overline{ADSP}$ ,  $\overline{ADSC}$ ,  $\overline{ADV}$  Burst Control Pins.
- LBO Pin allows a choice of either a interleaved burst or a linear burst.
- Three Chip Enables for simple depth expansion with No Data Contention.
- TTL-Level Three-State Output.
- 100-TQFP-1420A

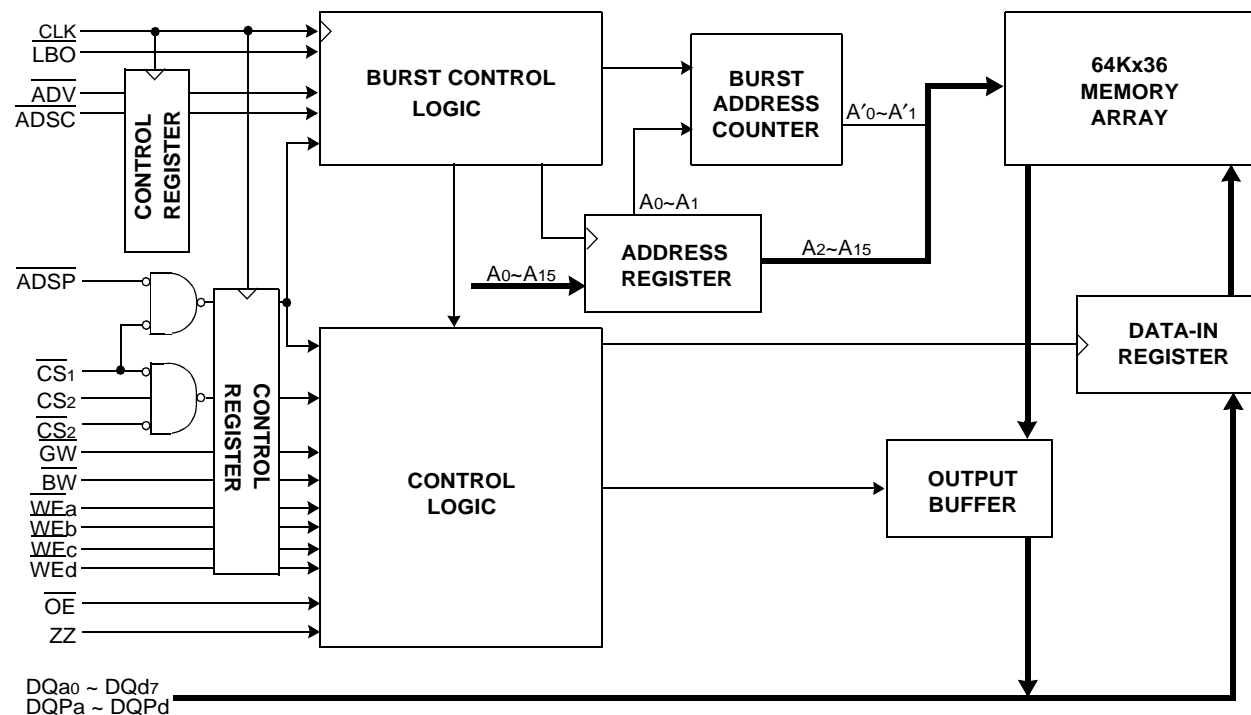

**GENERAL DESCRIPTION**

The KM736V687A is 2,359,296 bits Synchronous Static Random Access Memory designed to support zero wait state performance for advanced Pentium/Power PC based system. And with  $\overline{CS1}$  high,  $\overline{ADSP}$  is blocked to control signals. It can be organized as 64K words of 36 bits. And it integrates address and control registers, a 2-bit burst address counter and high output drive circuitry onto a single integrated circuit for reduced components counts implementation of high performance cache RAM applications. Write cycles are internally self-timed and synchronous. The self-timed write feature eliminates complex off chip write pulse shaping logic, simplifying the cache design and further reducing the component count. Burst cycle can be initiated with either the address status processor ( $\overline{ADSP}$ ) or address status cache controller ( $\overline{ADSC}$ ) inputs. Subsequent burst addresses are generated internally in the system's burst sequence and are controlled by the burst address advance ( $\overline{ADV}$ ) input. ZZ pin controls Power Down State and reduces Stand-by current regardless of CLK. The KM736V687A is implemented with SAMSUNG's high performance CMOS technology and is available in a 100pin TQFP package. Multiple power and ground pins are utilized to minimize ground bounce.

**FUNCTION DESCRIPTION**

The KM736V687A is a synchronous SRAM designed to support the burst address accessing sequence of the Pentium and Power PC based microprocessor. All inputs (with the exception of OE, LBO and ZZ) are sampled on rising clock edges. The start and duration of the burst access is controlled by ADSC, ADSP and ADV and chip select pins.

When ZZ is pulled high, the SRAM will enter a Power Down State. At this time, internal state of the SRAM is preserved. When ZZ returns to low, the SRAM normally operates after 2cycles of wake up time. ZZ pin is pulled down internally.

Read cycles are initiated with ADSP(or ADSC) using the new external address clocked into the on-chip address register when both GW and BW are high or when BW is low and WEa, WEb, WEc, and WEd are high. When ADSP is sampled low, the chip selects are sampled active, and the output buffer is enabled with OE. the data of cell array accessed by the current address are projected to the output pins.

Write cycles are also initiated with ADSP(or ADSC) and are differentiated into two kinds of operations; All byte write operation and individual byte write operation.

All byte write occurs by enabling GW(independent of BW and WEx.), and individual byte write is performed only when GW is high and BW is low. In KM736V687A, a 64Kx36 organization, WEa controls DQa0 ~ DQa7 and DQPa, WEb controls DQb0 ~ DQb7 and DQPb, WEc controls DQc0 ~ DQc7 and DQPc and WEd controls DQd0 ~ DQd7 and DQPd.

CS1 is used to enable the device and conditions internal use of ADSP and is sampled only when a new external address is loaded.

ADV is ignored at the clock edge when ADSP is asserted, but can be sampled on the subsequent clock edges. The address increases internally for the next access of the burst when ADV is sampled low.

Addresses are generated for the burst access as shown below, The starting point of the burst sequence is provided by the external address. The burst address counter wraps around to its initial state upon completion. The burst sequence is determined by the state of the LBO pin. When this pin is Low, linear burst sequence is selected. And this pin is High, Interleaved burst sequence is selected.

**BURST SEQUENCE TABLE**

(Interleaved Burst)

LBO PIN	HIGH	Case 1		Case 2		Case 3		Case 4	
		A1	A0	A1	A0	A1	A0	A1	A0
	First Address	0	0	0	1	1	0	1	1
	↓	0	1	0	0	1	1	1	0
	↓	1	0	1	1	0	0	0	1
	Fourth Address	1	1	1	0	0	1	0	0

(Linear Burst)

LBO PIN	LOW	Case 1		Case 2		Case 3		Case 4	
		A1	A0	A1	A0	A1	A0	A1	A0
	First Address	0	0	0	1	1	0	1	1
	↓	0	1	1	0	1	1	0	0
	↓	1	0	1	1	0	0	0	1
	Fourth Address	1	1	0	0	0	1	1	0

Note : 1. LBO pin must be tied to high or low, and floating state must not be allowed.

**ASYNCHRONOUS TRUTH TABLE**

(See Notes 1 and 2):

OPERATION	ZZ	OE	I/O STATUS
Sleep Mode	H	X	High-Z
Read	L	L	DQ
	L	H	High-Z
Write	L	X	Din, High-Z
Deselected	L	X	High-Z

**Notes**

1. X means "Don't Care".
2. ZZ pin is pulled down internally
3. For write cycles that following read cycles, the output buffers must be disabled with OE, otherwise data bus contention will occur.
4. Sleep Mode means power down state of which stand-by current does not depend on cycle time.
5. Deselected means power down state of which stand-by current depends on cycle time.
