Green-Mode PWM Controller with Frequency Swapping and Integrated Protections

Rev. 00a

General Description

The LD7536S is built-in with several functions, protection and EMI-improved solution in a tiny package. It takes less components counts or circuit space, especially ideal for those total solutions of low cost.

The implemented functions include low startup current, green-mode power-saving operation, leading-edge blanking of the current sensing and internal slope compensation. It also features more protections like OLP (Over Load Protection) and OVP (Over Voltage Protection) to prevent circuit damage occurred under abnormal conditions.

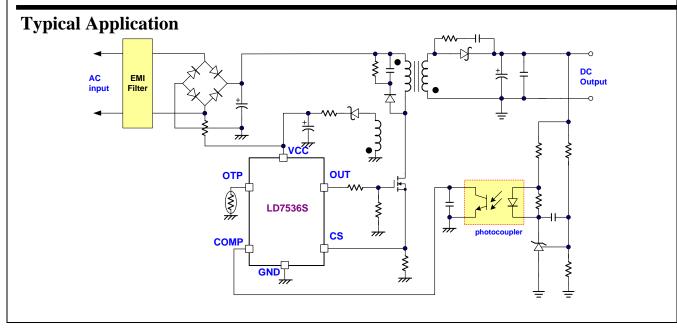

Furthermore, the Frequency Swapping function is to reduce the noise level and thus helps the power circuit designers to easily deal with the EMI filter design by spending minimum amount of component cost and developing time.

Features

- High-Voltage CMOS Process with Excellent ESD protection
- Very Low Startup Current (<20μA)
- Current Mode Control
- Green Mode Control
- UVLO (Under Voltage Lockout)
- LEB (Leading-Edge Blanking) on CS Pin
- Internal Frequency Swapping
- Internal Slope Compensation
- OVP (Over Voltage Protection) on Vcc Pin
- OTP (Over Temperature Protection) through a NTC
- OLP (Over Load Protection)
- 300mA Driving Capability

Applications

- Switching AC/DC Adaptor and Battery Charger
- Open Frame Switching Power Supply

Ordering Information

Part number	Package	Top Mark	Shipping
LD7536S GL	SOT-26	YWP/36S	3000 /tape & reel
LD7536S GN	DIP-8	LD7536SGN	3600 /tube /Carton

The LD7536S is Green Packaged.

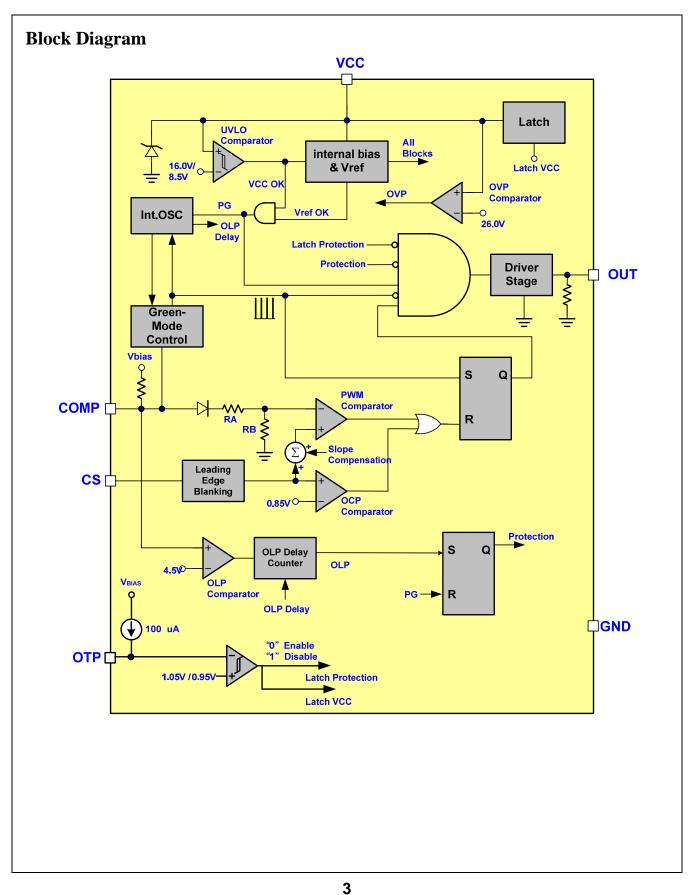

Protection Mode

Switching Freq.	VCC OVP	OLP	OTP Pin
65kHz	Auto recovery	Auto recovery/ 65ms	Latch

Pin Descriptions

SOT-26	DIP-8	NAME	FUNCTION	
1	8	GND	Ground	
2	7	COMP	Voltage feedback pin (same as the COMP pin in UC384X). Connect a photo-coupler to close the control loop and achieve the regulation.	
3	5	OTP Pull this pin below 0.95V to shutdown the controller into latch mode un resume power-on. Connecting this pin to ground with NTC will achieve protection. Keep this pin float to disable the latch protection.		
4	4	CS	Current sense pin, connect it to sense the MOSFET current	
5	2	VCC	Supply voltage pin	
6	1	OUT	Gate drive output to drive the external MOSFET	

Absolute Maximum Ratings

Supply Voltage VCC	-0.3V ~29V
COMP, RT, CS	-0.3V ~6V
OUT	-0.3V ~Vcc+0.3V
Maximum Junction Temperature	150°C
Operating Ambient Temperature	-20°C to 85°C
Operating Junction Temperature	-40°C to 125°C
Storage Temperature Range	-65°C to 150°C
Package Thermal Resistance (SOT-26, θ_{JA})	250°C/W
Package Thermal Resistance (DIP-8, θ_{JA})	100°C/W
Power Dissipation (SOT-26, at Ambient Temperature = 85°C)	250mW
Power Dissipation (DIP-8, at Ambient Temperature = 85°C)	650mW
Lead temperature (Soldering, 10sec)	260°C
ESD Voltage Protection, Human Body Model	2.5 KV
ESD Voltage Protection, Machine Model	250 V
Gate Output Current	300mA

Caution:

Stresses beyond the ratings specified in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

Application Information

Operation Overview

The LD7536S meets the green-power requirement and is intended for the use in those modern switching power suppliers and adaptors which demand higher power efficiency and power-saving. It integrates several functions to reduce the external components counts and the size. Its major features are described as below.

Under Voltage Lockout (UVLO)

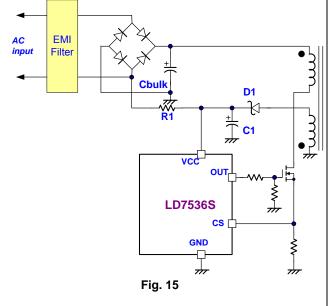

An UVLO comparator is implemented in it to detect the voltage on the VCC pin. It would assure the supply voltage enough to turn on the LD7536S PWM controller and further to drive the power MOSFET. As shown in Fig. 14, a hysteresis is built in to prevent the shutdown from the voltage dip during startup. The turn-on and turn-off threshold level are set at 16.0V and 8.5V, respectively.

Startup Current and Startup Circuit

The typical startup circuit to generate V_{CC} of the LD7536S is shown in Fig. 15. During startup transient, the V_{CC} is below UVLO threshold. Before it has sufficient voltage to develop OUT pulse to drive the power MOSFET, R1 will provide the startup current to charge the capacitor C1. Once V_{CC} obtains enough voltage to turn on the LD7536S and further to deliver the gate drive signal, it will enable the auxiliary winding of the transformer to provide supply

current. Fewer requirements for startup current will help to increase R1 value and then reduce power consumption on R1. By using CMOS process and the special circuit design, it takes only 20μ A for startup current maximum. If greater resistor of R1 is chosen, it will usually take more time to start up. To carefully select the value of R1 and C1 will optimize the power consumption and startup time.

Current Sensing and Leading-edge Blanking

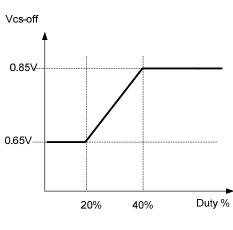

The typical current mode of PWM controller feedbacks both current signal and voltage signal to close the control loop and achieve regulation. The LD7536S detects the primary MOSFET current over CS pin for the peak current mode control and also for the pulse-by-pulse current limit.

In general, the power converter will provide more current when input voltage alters to high due to the signal propagation delay. This can be compensated through LD7536S. It's controlled by varying the current limit with the duty cycles in corresponding to Vcs_off,. As shown in Fig.16, Vcs_off (corresponding to current limit) is in direct proportion to duty ratio in a certain segment and is fixed at high or low if duty ratio is respectively over or below

threshold values. As a result, the current limit will be lowered at high-line inputs. This compensation control mechanism is developed with patents pending by Leadtrend Technology.

The maximum voltage threshold of the current sensing pin is set at 0.85V for low-line input. Thus the MOSFET peak current can be calculated as:

 $I_{\text{PEAK(MAX)}} = \frac{0.85V}{R_S}$

Fig. 16

A 230nS leading-edge blanking (LEB) time is included in the input of CS pin to prevent false-trigger from the current spike. In those low power applications, if the total pulse width of the turn-on spikes is less than 230nS and the negative spike on the CS pin below -0.3V, then, the R-C filter is free to eliminate. (As shown in Fig.17).

However, the total pulse width of the turn-on spike is determined according to output power, circuit design and PCB layout. It is strongly recommended to adopt a smaller R-C filter (as shown in Fig. 18) for larger power application to avoid the CS pin being damaged by the negative turn-on spike.

Output Stage and Maximum Duty-Cycle

An output stage of a CMOS buffer of 300mA driving capability typically is incorporated to drive a power MOSFET directly. And the maximum duty-cycle of LD7536S is limited to 75% to avoid the transformer saturation.

LD7536S

Voltage Feedback Loop

The voltage feedback signal is provided from TL431 at the secondary side through the photo-coupler to the COMP pin of the LD7536S. Similar to UC3842, the LD7536S would carry a diode voltage offset at the stage to feed the voltage divider at the ratio of RA and RB, that is

$$V_{-(PWM_{COMPARATOR})} = \frac{RB}{RA + RB} \times (V_{COMP} - V_{F})$$

A pull-high resistor is embedded internally and can be eliminated externally.

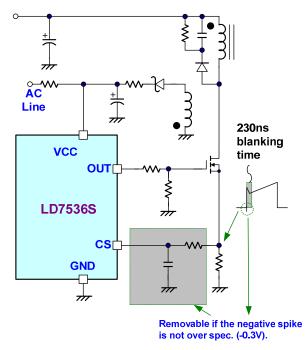

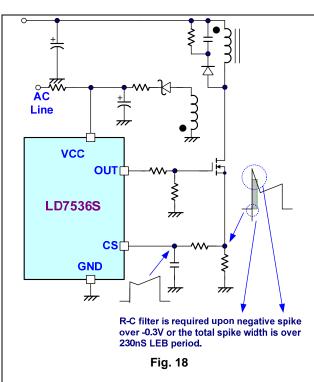

Fig. 17

Internal Slope Compensation

In the conventional applications, the problem of the stability is a critical issue for current mode controlling, when it operates over 50% duty-cycle. As UC384X, It takes slope compensation with injecting the ramp signal of the RT/CT pin through a coupling capacitor. It therefore requires no extra design for the LD7536S since it has integrated it already.

Oscillator and Switching Frequency

The LD7536S is implemented with Frequency Swapping function which helps the power supply designers to both optimize EMI performance and lower system cost. The switching frequency substantially centers at 65KHz, and swap between a range of \pm 4KHz.

Green-Mode Operation

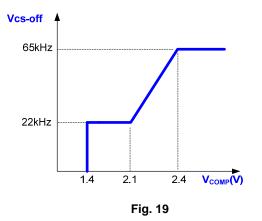

By using the green-mode control, the switching frequency can be reduced under the light load condition. It helps to improve the efficiency in light load conditions. The green-mode control is Leadtrend Technology's own

LD7536S

property. Fig. 19 shows the characteristics of the switching frequency vs. the comp pin voltage (V_{COMP})

On/Off Control

The LD7536S can be turned off by pulling COMP below 1.4V. The gate output pin of the LD7536S will be disabled immediately under such condition. The off-mode can be released when the pull-low signal is removed.

Over Load Protection (OLP) - Auto

Recovery

12

To protect the circuit from damage due to over-load condition and short or open-loop condition, the LD7536S is implemented with smart OLP function. It also features auto recovery. See Fig. 20 for the waveform. In case of fault condition, the feedback system will force the voltage loop toward the saturation and then pull the voltage high on COMP pin (VCOMP). When the V_{COMP} ramps up to the OLP threshold of 4.5V and continues over OLP delay time, the protection will be activated and then turn off the gate output to stop the switching of power circuit.

With the protection mechanism, the average input power will be minimized to remain the component temperature and stress within the safe operating area.

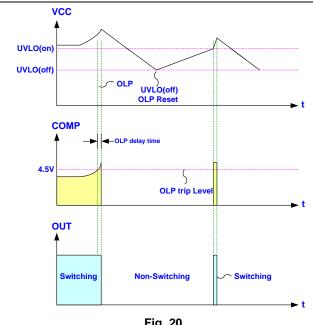

Fig. 20

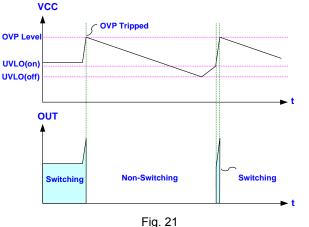

OVP (Over Voltage Protection) on Vcc -**Auto Recovery**

The maximum VGS ratings of the power MOSFETs are mostly for 30V. To prevent the VGS enter fault condition, LD7536S series are implemented with OVP function on Vcc. Whenever the Vcc voltage is higher than the OVP threshold, the output gate drive circuit will be shutdown simultaneously and the switching of the power MOSFET is disabled until the next UVLO(on).

The Vcc OVP functions of LD7536S are auto-recoverable. If the OVP condition, usually caused by open-loop of feedback, is not released, the Vcc will tripped the OVP level again and re-shutdown the output. The Vcc works in hiccup mode. Figure 21 shows its operation.

Otherwise, when the OVP condition is removed, the Vcc level will be resumed and the output will automatically return to the normal operation.

OTP Pin --- Latched Mode Protection

To protect the power circuit from damage due to system failure, over temperature protection (OTP) is required. The OTP circuit is implemented to sense a hot-spot of power circuit like power MOSFET or output rectifier. It can be easily achieved by connecting a NTC with OTP pin of LD7536S. As the device temperature or ambient temperature rises, the resistance of NTC decreases. So, the voltage on the OTP pin could be written as below.

$$V_{OTP} = 100 \mu A \cdot R_{NTC}$$

When the V_{OTP} is below the defined voltage threshold (typ. 0.95V), LD7536S will shutdown the gate output and latch off the power supply. There are 2 conditions required to restart it successfully. First, cool down the circuit so that NTC resistance will increase and raise VOTP up above 1.05V. Then, remove the AC power cord and restart AC power-on recycling.

Fault Protection

There are several critical protections integrated in the LD7536S to prevent from damage to the power supply. Those damages usually come from open or short conditions on the pins of LD7536S.

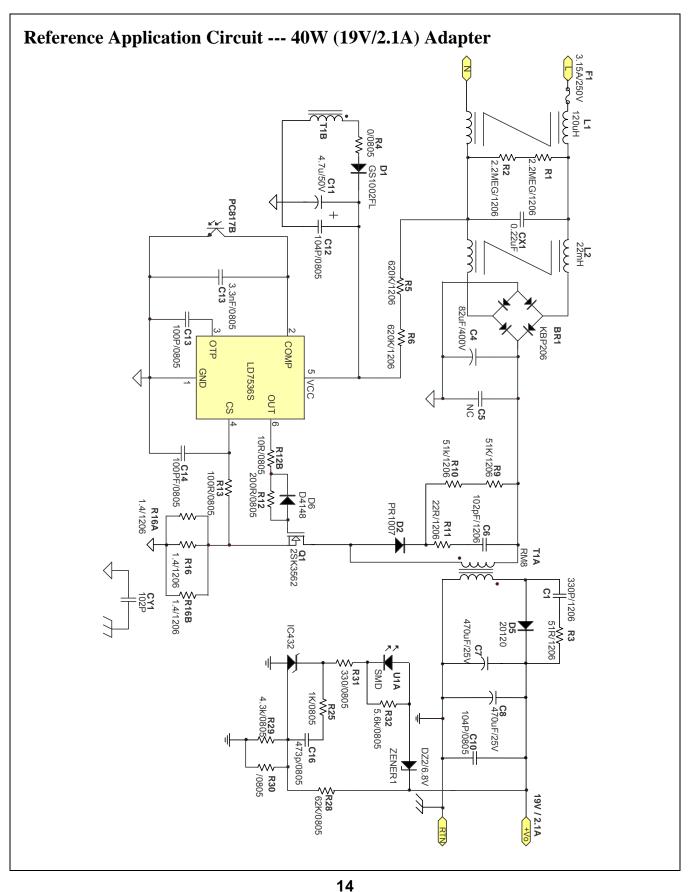

In case under such conditions listed below, the gate output will turn off immediately to protect the power circuit.
