

# 1.2A, 1.5MHz Step-Down Switching Regulator with Output Current Limit

## FEATURES

- **Wide Input Range:**  
Operation from 7.5V to 36V  
Overvoltage Lockout Protects Circuit through 60V Transients
- **Programmable Output Current Limit (0.4A to 1.2A)**
- **Integrated Boost Diode**
- 1.5MHz Fixed Frequency, Peak Current Mode Control
- Low Switch  $V_{CESAT}$ : 275mV at 1A
- Internally Compensated
- Thermal Protection
- Thermally Enhanced 2mm × 3mm DFN Package

## APPLICATIONS

- Distributed Supply Regulation
- Automotive Battery Regulation
- Industrial Supplies
- Wall Transformer Regulation

## DESCRIPTION

The LT<sup>®</sup>3663 is a 1.5MHz current mode step-down switching regulator with programmable output current limit. The current limit accurately controls the system power dissipation and reduces the size of the power path components.

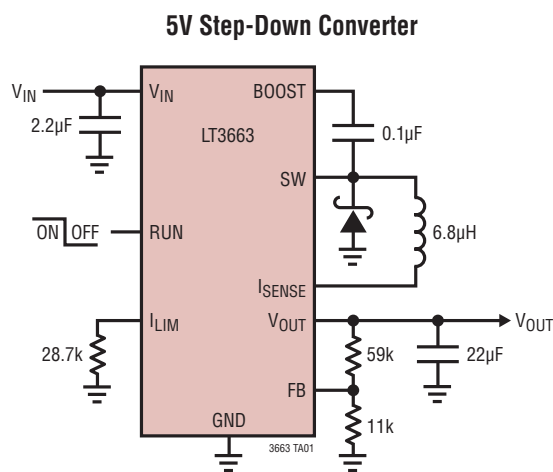

The wide operating input voltage range of 7.5V to 36V (60V transient) suits the LT3663 to a variety of input sources, including unregulated 12V wall adapters, 24V industrial supplies, and automotive power.

The LT3663 includes a low current shutdown mode, input overvoltage and undervoltage lockout, and thermal shutdown. Internal compensation and boost diode minimize the number of external components.

The LT3663 is available in an 8-lead (2mm × 3mm) package with an exposed pad for low thermal resistance.

LT, LT, LTC, LTM, Linear Technology and the Linear logo are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

## TYPICAL APPLICATION

## ABSOLUTE MAXIMUM RATINGS

(Note 1)

Input Voltage ( $V_{IN}$ ) (Note 2)	60V
BOOST Pin Voltage	50V
BOOST Pin Above SW Pin	25V
$V_{OUT}$ , $I_{SENSE}$ , FB Pins	6V
RUN Pin (Note 2)	60V
Operating Junction Temperature Range (Note 3)	
LT3663E	-40°C to 125°C
LT3663I	-40°C to 125°C
Storage Temperature	-65°C to 150°C

## ELECTRICAL CHARACTERISTICS

The ● denotes the specifications which apply over the full operating temperature range, otherwise specifications are at  $T_A = 25^\circ\text{C}$ .  $V_{\text{IN}} = 12\text{V}$ ,  $V_{\text{BOOST}} = 17\text{V}$ ,  $V_{\text{SW}} = 0\text{V}$ ,  $R_{\text{ILIM}} = 36.5\text{k}$  unless otherwise noted.

PARAMETER	CONDITIONS		MIN	TYP	MAX	UNITS
Feedback Voltage		●	784	800	816	mV
FB Bias Current	$V_{\text{FB}} = 0.8\text{V}$			50	150	nA
Switch Peak Current Limit	(Note 5)	●	1.6	2	2.5	A
Switch $V_{\text{CESAT}}$	$I_{\text{SW}} = 1\text{A}$			275		mV
Minimum BOOST Voltage	$I_{\text{SW}} = 1\text{A}$ (Note 6)			1.85	2.2	V
Boost Diode Drop	$I_{\text{DIODE}} = 60\text{mA}$			0.9	1.2	V
Boost Pin Current	$I_{\text{SW}} = 1\text{A}$			28		mA

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** Absolute Maximum Voltage at  $V_{\text{IN}}$  and RUN pins is 60V for nonrepetitive 1 second transients.

**Note 3:** The LT3663E is guaranteed to meet performance specifications from  $0^\circ\text{C}$  to  $125^\circ\text{C}$ . Specifications over the  $-40^\circ\text{C}$  to  $125^\circ\text{C}$  operating temperature range are assured by design, characterization, and correlation

with statistical process controls. The LT3663I specifications are guaranteed over the full  $-40^\circ\text{C}$  to  $125^\circ\text{C}$  temperature range. High junction temperatures degrade operating lifetimes. Operating lifetime is derated at junction temperatures greater than  $125^\circ\text{C}$ .

**Note 4:** Current flows into pin.

**Note 5:** Switch Peak Current Limit guaranteed by design and/or correlation to static test.

**Note 6:** This is the minimum voltage across the boost capacitor needed to guarantee full saturation of the switch.

## TYPICAL PERFORMANCE CHARACTERISTICS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

# TYPICAL PERFORMANCE CHARACTERISTICS $T_A = 25^\circ\text{C}$ , unless otherwise noted.

## PIN FUNCTIONS

**V<sub>IN</sub> (Pin 1):** The V<sub>IN</sub> pin supplies current to the LT3663's internal regulator and internal power switch. Capacitively bypass the pin to ground.

**RUN (Pin 2):** The Run pin is used to put the LT3663 into shutdown mode. Tie to ground to shut down the LT3663. Tie to 2.5V or more for normal operation. If the shutdown feature is not used, connect this pin to V<sub>IN</sub>.

**FB (Pin 3):** The LT3663 regulates the FB pin to 0.8V. Connect the feedback resistor divider tap to this pin.

**I<sub>LIM</sub> (Pin 4):** Output Current Limit Program Pin. Connect a resistor to ground to program the regulator output current limit.

**V<sub>OUT</sub> (Pin 5):** The V<sub>OUT</sub> pin is connected to the negative terminal of the internal output current limit sense resistor.

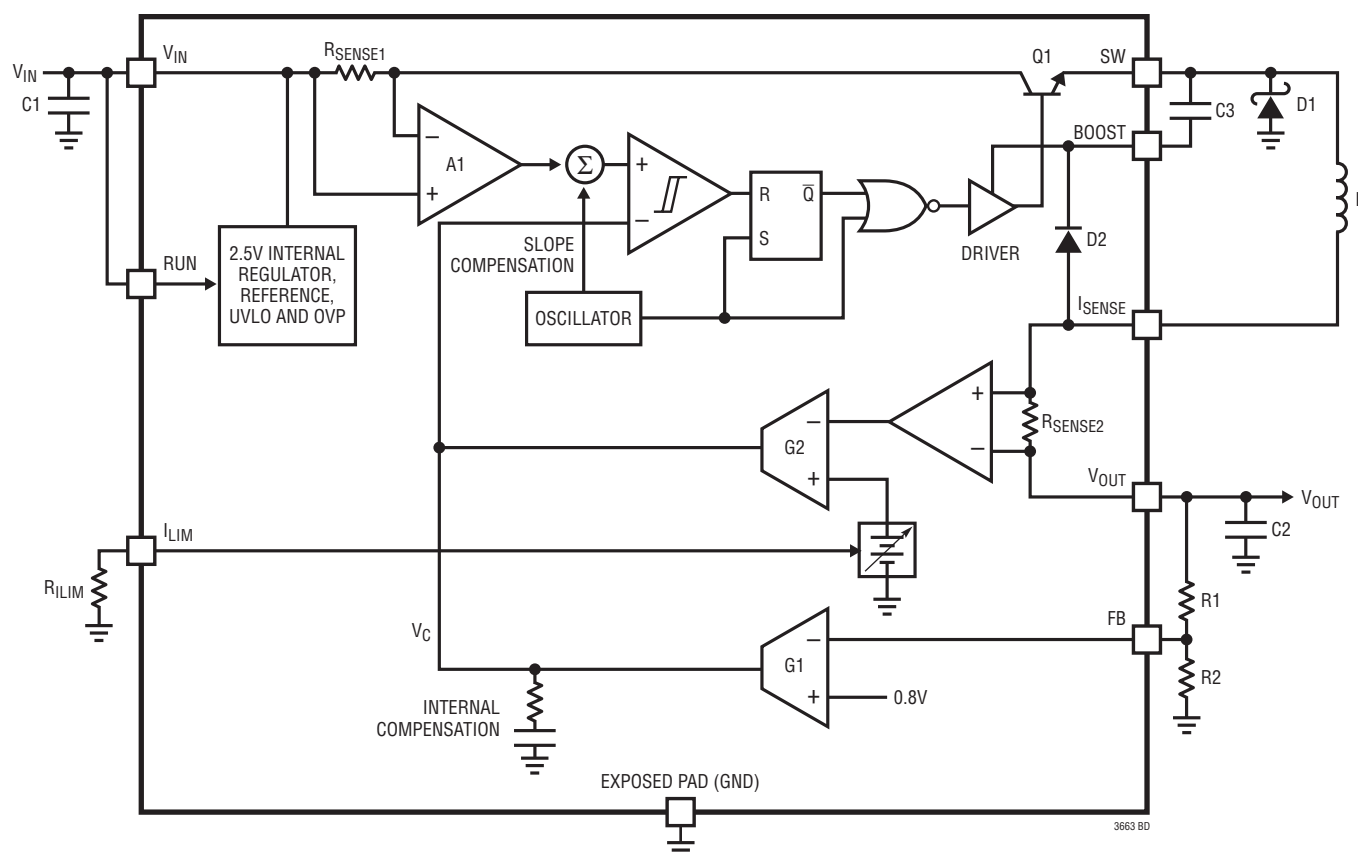

**I<sub>SENSE</sub> (Pin 6):** The I<sub>SENSE</sub> pin is the positive input to the internal output current limit sense resistor. The I<sub>SENSE</sub> pin is also the anode to the internal BOOST diode.

**BOOST (Pin 7):** The BOOST pin is used to provide a drive voltage, higher than the input voltage, to the internal power switch. The BOOST pin is also internally connected to the cathode of the BOOST diode.

**SW (Pin 8):** The SW pin is the output of the internal power switch. Connect this pin to the inductor, catch diode and boost capacitor.

**Exposed Pad (Pin 9):** Ground. The Exposed Pad must be soldered to the PCB and electrically connected to ground. Use a large ground plane and thermal vias to optimize thermal performance.

## FUNCTIONAL BLOCK DIAGRAM

## OPERATION (Refer to Block Diagram)

The LT3663 is a constant frequency, current mode step down regulator. A switch cycle is initiated when the oscillator enables the RS flip flop, turning on the internal power switch, Q1. The sense amplifier (A1) monitors the switch current via the voltage dropped across the current sense resistor  $R_{SENSE1}$ . The comparator compares the amplified current signal with the output ( $V_C$ ) of the error amplifier (G1). The switch is turned off when this current exceeds a value determined by the  $V_C$  voltage. The error amplifier monitors the  $V_{OUT}$  voltage through an internal resistor divider and, when not driven externally, servos the  $V_C$  voltage to regulate  $V_{OUT}$ . If the  $V_{OUT}$  voltage drops, the  $V_C$  voltage will be driven higher increasing the output current and  $V_{OUT}$  voltage. An active clamp (not shown) on the  $V_C$  node provides current limit. The LT3663 is internally compensated with a pole-zero combination on the  $V_C$  node.

An external capacitor and internal diode, D2, generate a voltage at the BOOST pin that is higher than the input supply.

This allows the driver to fully saturate the internal bipolar NPN power switch for efficient operation. The switch driver operates from either  $V_{IN}$  or BOOST to ensure startup.

An internal regulator provides power to the control circuitry. This regulator includes input undervoltage and overvoltage protection which disables switching action when  $V_{IN}$  is out of range. When switching is disabled, the LT3663 safely sustains input voltages up to 60V. Note that while switching is disabled the output will discharge.

Output current limiting is provided via the servo action of amplifier G2. The voltage across sense resistor,  $R_{SENSE2}$ , is compared to a voltage programmed by external resistor  $R_{LIM}$  on the  $I_{LIM}$  pin. A capacitor averages the inductor ripple current. If the average inductor current exceeds the programmed value then the  $V_C$  voltage is pulled low, reducing the current in the regulator. The output current limit circuit allows for a lower current rated inductor and diode and provides better control of system power dissipation.

## APPLICATIONS INFORMATION

### FB Resistor Network

The output voltage is programmed with a resistor divider. Choose the 1% resistors according to:

$$R1 = R2 (V_{OUT}/0.8 - 1)$$

Reference designators refer to the Block Diagram.

### Minimum Duty Cycle

As the input voltage increases the duty cycle decreases. At some point, the minimum duty cycle of the IC is reached and pulse skipping begins. The output voltage continues to regulate but the output voltage ripple increases. The input voltage at which this occurs is calculated as follows:

$$V_{IN} = \frac{(V_{OUT} + V_F)}{DC_{MIN}} - V_F + V_{SW}$$

Where  $V_F$  is the forward voltage drop of the catch diode, D1, and  $V_{SW}$  is the voltage drop on the internal switch, Q1.  $DC_{MIN}$  is typically 0.12.

For  $V_F = 0.4V$ ,  $V_{SW} = 0.3V$ , and  $V_{OUT} = 3.3V$  pulse skipping occurs at about 24.5V.

Figure 1 illustrates switching waveforms in normal mode for a 3.3V output application with  $V_{IN} = 20V$ .

Figure 2. illustrates switching waveforms in pulse skip mode a 3.3V output application with  $V_{IN} = 30V$ .

Figure 1. Normal Operation

## APPLICATIONS INFORMATION

Figure 2. Pulse-Skip Mode

### Inductor Selection

A good first choice for the inductor value is:

$$L = V_{OUT} + V_D (\mu\text{H})$$

where  $V_D$  is the voltage drop of the catch diode ( $\sim 0.4\text{V}$ ) and  $L$  is in  $\mu\text{H}$ . With this value there is no sub-harmonic oscillation for applications with 50% or greater duty cycle. The inductor's RMS current rating must be greater than the maximum load current. Size the inductor so the saturation current rating is about 30% higher than the maximum load current. The output current limit circuit tightly controls the maximum average inductor current, therefore the inductor RMS current rating does not have to be overrated to handle short circuit or overload conditions. For high efficiency, keep the series resistance (DCR) less than  $0.1\Omega$ . A higher value inductor is larger in size and slows transient response but reduces output voltage ripple. A lower value inductor has higher ripple currents but is physically smaller or, for the same size, it has lower DCR typically resulting in higher efficiency.

### Catch Diode

The catch diode conducts current only during switch-off time. Average forward current in normal operation is calculated from:

$$I_{D(AVG)} = I_{OUT} \frac{V_{IN} - V_{OUT}}{V_{IN}}$$

where  $I_{OUT}$  is the maximum output load current programmed by the  $I_{LIM}$  resistor. Peak reverse voltage is equal

to the regulator input voltage. Use a Schottky diode with a reverse voltage rating greater than the input voltage. The overvoltage protection feature in the LT3663 keeps the switch off when  $V_{IN} > 39\text{V}$  (typical) allowing the use of a 45V rated Schottky even when  $V_{IN}$  ranges up to 60V.

### Input Capacitor

Bypass the input of the LT3663 circuit with a  $1\mu\text{F}$  or higher value ceramic capacitor of X7R or X5R type. Y5V types have poor performance over temperature and applied voltage and are not recommended. If the input power source has high impedance, or there is significant inductance due to long wires or cables, additional bulk capacitance may be necessary. This can be provided with a low performance electrolytic capacitor. Step-down regulators draw current from the input supply in pulses with very fast rise and fall times. The input capacitor is required to reduce the resulting voltage ripple at the LT3663 and to force this very high frequency switching current into a tight local loop, minimizing EMI. Place the capacitor in close proximity to the LT3663 and the catch diode; (see the PCB Layout section).

### Output Capacitor

A  $10\mu\text{F}$  or greater ceramic capacitor is recommended to provide low output ripple and good transient response. Ceramic capacitors have very low equivalent series resistance (ESR) and provide the best ripple performance. Use X5R or X7R types and keep in mind that a ceramic capacitor biased with  $V_{OUT}$  has less than its specified nominal capacitance.

High performance electrolytic capacitors can be used for the output capacitor. Low ESR is important, so choose one that is intended for use in switching regulators. Keep the ESR less than  $0.1\Omega$ .

### $I_{LIM}$ Resistor

The LT3663 output current limit controls the maximum current delivered from the LT3663 regulator. This allows tighter control of the system power dissipation and also protects the inductor and diode from overheating during an overload or short circuit condition. A resistor con-

## APPLICATIONS INFORMATION

ected from  $I_{LIM}$  pin to GND programs the output current. Table 1 details the  $I_{LIM}$  resistor values for specific output current limits.

**Table 1. Output Current Limit vs  $R_{LIM}$  Value**

OUTPUT CURRENT LIMIT (A)	$R_{LIM}$ VALUE (k $\Omega$ )
0.4	140
0.6	75
0.8	48.7
1.0	36.5
1.2	28.7

There may be a reason in some applications to move the output current limit. The following simple circuit demonstrates how the output current limit can be adjusted:

**Figure 3. Circuit for Multiple Values of Output Current Limit**

### BOOST and BIAS Pin Considerations

Capacitor C3 and the internal boost diode (see the Block Diagram) are used to generate a boost voltage that is higher than the input voltage. In most cases a 0.1 $\mu$ F capacitor works well. Figure 4 shows three ways to arrange the boost circuit. The BOOST pin must be more than 2.3V above the SW pin for best efficiency. For outputs of 3V and above, the standard circuit (Figure 4a) is best. For outputs between 2.8V and 3V, use a 1 $\mu$ F boost capacitor. A 2.5V output presents a special case because it is marginally adequate to support the boosted drive stage while using the internal boost diode. For reliable BOOST pin operation with 2.5V outputs use a good external Schottky diode (such as the ON Semi, MBR0540) and a 1 $\mu$ F boost capacitor (see Figure 4b). For lower output voltages connect an external Schottky

diode to the input (Figure 4c), or to another supply greater than 2.8V. Using  $V_{IN}$  reduces the maximum input voltage to 25V. The circuit in Figure 4a is more efficient because the BOOST pin current comes from a lower voltage source. Take care to ensure that the maximum voltage ratings of the BOOST pin is not exceeded.

**(4a) For  $V_{OUT} > 2.8V$**

**(4b) For  $2.5V < V_{OUT} < 2.8V$**

**(4c) For  $V_{OUT} < 2.5V$ ;  $V_{IN(MAX)} = 25V$**

**Figure 4. Three Circuits to Generate BOOST Pin Voltage**

## APPLICATIONS INFORMATION

### PCB Layout

Proper operation and minimum EMI, requires careful printed circuit board layout. Figure 5 shows the recommended component placement with trace, ground plane and via locations. Note that large, switched currents flow in the LT3663's  $V_{IN}$  and SW pins, the catch diode (D2) and the input capacitor (C1). Keep the loop formed by these components as small as possible and tied to system ground in only one place. Locate these components, along with the inductor and output capacitor, on the same side of the circuit board, and keep their connections on that layer. Place a local, unbroken ground plane below these components, and tie this ground plane to system ground at one location, ideally at the ground terminal of the output capacitor C1. Make the SW and BOOST nodes as small as possible. Include vias near the exposed GND pad of the LT3663 to help remove heat from the LT3663 to the ground plane.

### High Temperature Considerations

The die temperature of the LT3663 must not exceed the maximum rating of 125°C. This is generally not a concern

unless the ambient temperature is above 85°C. For higher temperatures, take care in the layout of the circuit to ensure good heat sinking of the LT3663. De-rate the maximum load current as the ambient temperature approaches 125°C. Calculate the die temperature by multiplying the LT3663 power dissipation by the thermal resistance from junction to ambient. Estimate the power dissipation within the LT3663 by calculating the total power loss from an efficiency measurement and subtracting the catch diode loss. Thermal resistance depends on the layout of the circuit board, but 64°C/W is typical for the (2mm × 3mm) DFN (DCB) package.

### Other Linear Technology Publications

Application Notes 19, 35 and 44 contain more detailed descriptions and design information for Buck regulators and other switching regulators. The LT1376 data sheet has a more extensive discussion of output ripple, loop compensation and stability testing. Design Note 100 shows how to generate a bipolar output supply using a Buck regulator.
