DATA SHEET

An ON Semiconductor Company

Bi-CMOS IC Low power consumption and high efficiency **Step-down Switching Regulator**

Overview

LV5980MX is 1ch DC-DC converter with built-in power Pch MOSFET. The recommended operating range is 4.5V to 23V. The maximum current is 3A. The operating current is about 60µA, and low power consumption is achieved.

Features and Functions

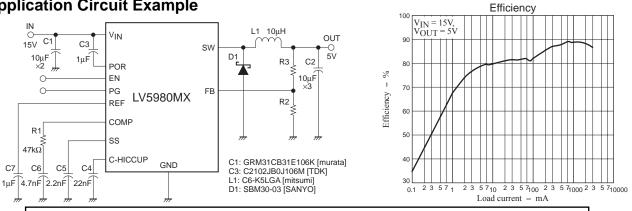

- 1ch SBD rectification DC-DC converter IC with built-in power Pch MOSFET
- Typical value of light load mode current is 60µA
- $100m\Omega$ High-side switch
- The oscillatory frequency is 370kHz
- When P-by-P is generated continuously, it shifts to the HICCUP operation
- If connect C-HICCUP to GND pin, then latch-off when over current
- Under voltage lock-out, thermal shutdown and power good indication

Applications

- DVD/Blu-ray™ drivers and HDD
- Point of load DC/DC converters

Application Circuit Example

- 4.5V to 23V Operating input voltage range
- Output voltage adjustable to 1.235V
- built-in OCP circuit with P-by-P method
- External capacitor Soft-start
- LCD monitors and TVs
- Office supplies

- Any and all SANYO Semiconductor Co.,Ltd. products described or contained herein are, with regard to "standard application", intended for the use as general electronics equipment. The products mentioned herein shall not be intended for use for any "special application" (medical equipment whose purpose is to sustain life, aerospace instrument, nuclear control device, burning appliances, transportation machine, traffic signal system, safety equipment etc.) that shall require extremely high level of reliability and can directly threaten human lives in case of failure or malfunction of the product or may cause harm to human bodies, nor shall they grant any guarantee thereof. If you should intend to use our products for new introduction or other application different from current conditions on the usage of automotive device, communication device, office equipment, industrial equipment etc., please consult with us about usage condition (temperature, operation time etc.) prior to the intended use. If there is no consultation or inquiry before the intended use, our customer shall be solely responsible for the use.
- Specifications of any and all SANYO Semiconductor Co., Ltd. products described or contained herein stipulate the performance, characteristics, and functions of the described products in the independent state, and are not guarantees of the performance, characteristics, and functions of the described products as mounted in the customer's products or equipment. To verify symptoms and states that cannot be evaluated in an independent device, the customer should always evaluate and test devices mounted in the customer's products or equipment.

10	PG	Power good pin. Connect to open drain of MOS-FET in ICs inside. Setting output voltage to "L", when FB voltage is 1.02V or less.	PG
11	EN	ON/OFF Pin.	V _{IN} 4.8MΩ EN 4.8MΩ GND
12	VIN	Supply voltage pin. It is observed by the UVLO function. When its voltage becomes 3.7V or more, ICs startup in soft start.	VIN GND

Detailed Description

Power-save Feature

The LV5980MX has Power-saving feature to enhance efficiency when the load is light. By shutting down unnecessary circuits, operating current of the IC is minimized and high efficiency is realized.

Output Voltage Setting

Output voltage (V_{OUT}) is configurable by the resistance R3 between V_{OUT} and FB and the R2 between FB and GND. V_{OUT} is given by the following equation (1).

$$V_{OUT} = (1 + \frac{R3}{R2}) \times V_{REF} = (1 + \frac{R3}{R2}) \times 1.235$$
[V] (1)

Soft Start

Soft start time (T_{SS}) is configurable by the capacitor (C5) between SS and GND. The setting value of T_{SS} is given by the equation (2).

$$T_{SS} = C5 \times \frac{V_{REF}}{I_{SS}} = C5 \times \frac{1.235}{1.8 \times 10^{-6}} \quad [ms]$$
(2)

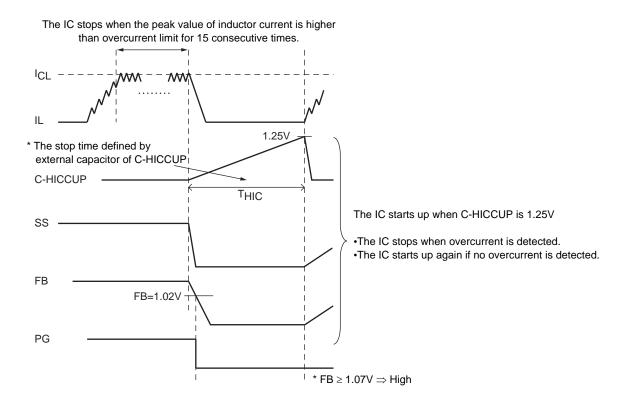

Power Good

FB constantly monitors V_{OUT}. When FB voltage is lower than 1.02V, PG is pulled down to Low. PG comparator has hysteresis of 50mV. Because PG is open-drain output, you can connect other ICs with PG to realize wired-or with other ICs.

Hiccup Over Current Protection

Over current limit (I_{CL}) is set to 4.7A in the IC. When the peak value of inductor current is higher than 4.7A for 15 consecutive times, the protection deems it as over current and stops the IC. Stop period (T_{HIC}) is defined by the external capacitor of the C-HICCUP. When C-HICCUP is about 1.25V, the IC starts up. Regardless of a status; whether it starts up or SS charge, once over current is detected, the IC stops again and when the protection does not detect over current status, the IC starts up again. The setting value of T_{HIC} is given by the equation (3).

$$T_{\rm HIC} = \frac{C4 \times V_{\rm tHIC}}{I_{\rm HIC}} = \frac{C4 \times 1.25}{1.8 \times 10^{-6}} \quad [s]$$
(3)

Design Procedure

Inductor Selection

When conditions for input voltage, output voltage and ripple current are defined, the following equations (4) give inductance value.

$$\begin{pmatrix}
L = \frac{V_{IN} - V_{OUT}}{\Delta I_R} \times T_{ON} \\
T_{ON} = \frac{1}{\{((V_{IN} - V_{OUT}) \div (V_{OUT} + VF)) + 1\} \times F_{OSC} \\
F_{OSC} : Oscillatory Frequency \\
VF : Forward voltage of Schottky Barrier diode \\
V_{IN} : Input voltage \\
V_{OUT} : Output voltage
\end{cases}$$
(4)

• Inductor current: Peak value (IRP)

Current peak value (IRP) of the inductor is given by the equation (5).

$$I_{RP} = I_{OUT} + \frac{V_{IN} - V_{OUT}}{2L} \times T_{ON}$$
(5)

Make sure that rating current value of the inductor is higher than a peak value of ripple current.

- Inductor current: ripple current (ΔI_R)
- Ripple current (ΔI_R) is given by the equation (6).

$$\Delta I_{R} = \frac{V_{IN} - V_{OUT}}{L} \times T_{ON}$$
(6)

When load current (IOUT) is less than 1/2 of the ripple current, inductor current flows discontinuously.

Output Capacitor Selection

Make sure to use a capacitor with low impedance for switching power supply because of large ripple current flows through output capacitor.

This IC is a switching regulator which adopts current mode control method. Therefore, you can use capacitor such as ceramic capacitor and OS capacitor in which equivalent series resistance (ESR) is exceedingly small.

Effective value is given by the equation (7) because the ripple current (AC) that flows through output capacitor is saw tooth wave.

$$I_{C_{OUT}} = \frac{1}{2\sqrt{3}} \times \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{L \times F_{OSC} \times V_{IN}} \quad [Arms]$$
(7)

Input Capacitor Selection

Ripple current flows through input capacitor which is higher than that of the output capacitors.

Therefore, caution is also required for allowable ripple current value.

The effective value of the ripple current flows through input capacitor is given by the equation (8).

$$I_{C_{IN}} = \sqrt{D(1 - D)} \times I_{OUT} \quad [Arms]$$
(8)

$$D = \frac{T_{ON}}{T} = \frac{V_{OUT}}{V_{IN}}$$

In (8), D signifies the ratio between ON/OFF period. When the value is 0.5, the ripple current is at a maximum. Make sure that the input capacitor does not exceed the allowable ripple current value given by (8). With (8), if $V_{IN}=15V$, $V_{OUT}=5V$, $I_{OUT}=1.0A$ and $F_{OSC}=370$ kHz, then I_{C} IN value is about 0.471 Arms.

In the board wiring from input capacitor, \overline{V}_{IN} to GND, make sure that wiring is wide enough to keep impedance low because of the current fluctuation. Make sure to connect input capacitor near output capacitor to lower voltage bound due to regeneration current. When change of load current is excessive (I_{OUT}: high \Rightarrow low), the power of output electric capacitor is regenerated to input capacitor. If input capacitor is small, input voltage increases. Therefore, you need to implement a large input capacitor. Regeneration power changes according to the change of output voltage, inductance of a coil and load current.

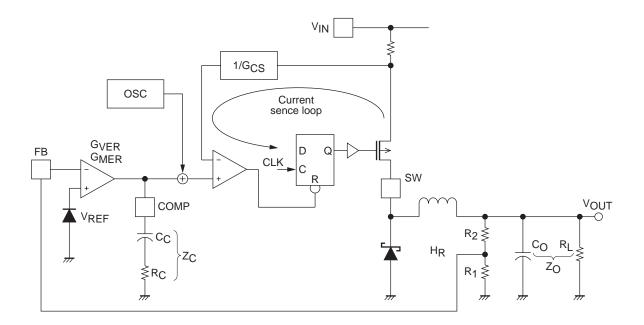

Selection of external phase compensation component

This IC adopts current mode control which allows use of ceramic capacitor with low ESR and solid polymer capacitor such as OS capacitor for output capacitor with simple phase compensation. Therefore, you can design long-life and high quality step-down power supply circuit easily.

Frequency Characteristics

The frequency characteristic of this IC is constituted with the following transfer functions.

• •	-
(1) Output resistance breeder	: <i>H</i> _R
(2) Voltage gain of error amplifier	: GVEA
Current gain	: <i>GMEA</i>
(3) Impedance of phase compensation external element	: ZC
(4) Current sense loop gain	: G _{CS}
(5) Output smoothing impedance	: Z0

Closed loop gain is obtained with the following formula (9).

$$G = H_{R} \cdot G_{MER} \cdot Z_{C} \cdot G_{CS} \cdot Z_{O}$$
$$= \frac{V_{REF}}{V_{OUT}} \cdot G_{MER} \cdot \left(R_{C} + \frac{1}{SC_{C}}\right) \cdot G_{CS} \cdot \frac{R_{L}}{1 + SC_{O} \cdot R_{L}}$$
(9)

Frequency characteristics of the closed loop gain is given by pole fp1 consists of output capacitor C_O and output load resistance R_L , zero point fz consists of external capacitor C_C of the phase compensation and resistance R_C , and pole fp2 consists of output impedance Z_{ER} of error amplifier and external capacitor of phase compensation C_C as shown in formula (9). fp1, fz, fp2 are obtained with the following equations (10) to (12).

$$fp1 = \frac{1}{2\pi \cdot C_{\rm O} \cdot R_{\rm L}} \tag{10}$$

$$fz = \frac{1}{2\pi \cdot C_C \cdot R_C}$$
(11)

$$fp2 = \frac{1}{2\pi \cdot Z_{ER} \cdot C_C}$$
(12)

LV5980MX

Calculation of external phase compensation constant

Generally, to stabilize switching regulator, the frequency where closed loop gain is 1 (zero-cross frequency f_{ZC}) should be 1/10 of the switching frequency (or 1/5). Since the switching frequency of this IC is 370kHz, the zero-cross frequency should be 37kHz. Based on the above condition, we obtain the following formula (13).

$$\frac{V_{REF}}{V_{OUT}} \bullet G_{MER} \bullet \left(R_{C} + \frac{1}{SC_{C}} \right) \bullet G_{CS} \bullet \frac{R_{L}}{1 + SC_{O} \bullet R_{L}} = 1$$
(13)

As for zero-cross frequency, since the impedance element of phase compensation is $RC >> 1/SC_C$, the following equation (14) is obtained.

$$\frac{V_{REF}}{V_{OUT}} \cdot G_{MER} \cdot R_{C} \cdot G_{CS} \cdot \frac{R_{L}}{1 + 2\pi \cdot f_{ZC} \cdot C_{O} \cdot R_{L}} = 1$$
(14)

Phase compensation external resistance can be obtained with the following formula (15), the variation of the formula (14). Since $2\pi \cdot f_{ZC} \cdot C_O \cdot R_L >> 1$ in the equation (15), we know that the external resistance is independent of load resistance.

$$R_{C} = \frac{V_{OUT}}{V_{REF}} \cdot \frac{1}{G_{MER}} \cdot \frac{1}{G_{CS}} \cdot \frac{1 + 2\pi \cdot f_{ZC} \cdot C_{O} \cdot R_{L}}{R_{L}}$$
(15)

When output is 5V and load resistance is 5 Ω (1A load), the resistances of phase compensation are as follows. G_{CS} = 2.7A/V, G_{MER} = 220 μ A/V, f_{ZC} = 37kHz

$$R_{C} = \frac{5}{1.235} \times \frac{1}{220 \times 10^{-6}} \times \frac{1}{2.7} \times \frac{1 + 2 \times 3.14 \times (37 \times 10^{3}) \times (30 \times 10^{-6}) \times 5}{5} = 48.898 \dots \times 10^{3}$$

 $= 48.90 [k\Omega]$

If frequency of zero point fz and pole fp1 are in the same position, they cancel out each other. Therefore, only the pole frequency remains for frequency characteristics of the closed loop gain.

In other words, gain decreases at -20dB/dec and phase only rotates by 90° and this allows characteristics where oscillation never occurs.

$$fp1 = fz$$

$$\frac{1}{2\pi \cdot C_{O} \cdot R_{L}} \cdot \frac{1}{2\pi \cdot C_{O} \cdot R_{C}}$$

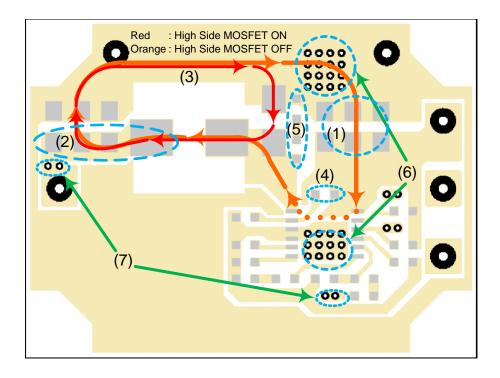

$$C_{C} = \frac{R_{L} \cdot C_{O}}{R_{C}} \cdot \frac{5 \times (30 \times 10^{-6})}{48.9 \times 10^{3}} = 3.067... \times 10^{-9}$$

$$= 3.07 [nF]$$

The above shows external compensation constant obtained through ideal equations. In reality, we need to define phase constant through testing to verify constant IC operation at all temperature range, load range and input voltage range. In the evaluation board for delivery, phase compensation constants are defined based on the above constants. The zero-cross frequency required in the actual system board, in other word, transient response is adjusted by external compensation resistance. Also, if the influence of noise is significant, use of external phase compensation capacitor with higher value is recommended.

Caution in pattern design

Pattern design of the board affects the characteristics of DC-DC converter. This IC switches high current at a high speed. Therefore, if inductance element in a pattern wiring is high, it could be the cause of noise. Make sure that the pattern of the main circuit is wide and short.

(1) Pattern design of the input capacitor

Connect a capacitor near the IC for noise reduction between V_{IN} and the GND. The change of current is at the largest in the pattern between an input capacitor and V_{IN} as well as between GND and an input capacitor among all the main circuits. Hence make sure that the pattern is as fat and short as possible.

(2) Pattern design of an inductor and the output capacitor

High electric current flows into the choke coil and the output capacitor. Therefore this pattern should also be as fat and short as possible.

(3) Pattern design with current channel into consideration

Make sure that when High side MOSFET is ON (red arrow) and OFF (orange arrow), the two current channels runs through the same channel and an area is minimized.

(4) Pattern design of the capacitor between VIN-PDR

Make sure that the pattern of the capacitor between V_{IN} and PDR is as short as possible.

(5) Pattern design of the snubber circuit

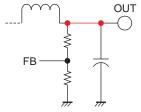

Locate a snubber circuit in parallel with the Schottky barrier diode.

(6) Pattern design of the small signal GND

The GND of the small signal should be separated from the power GND.

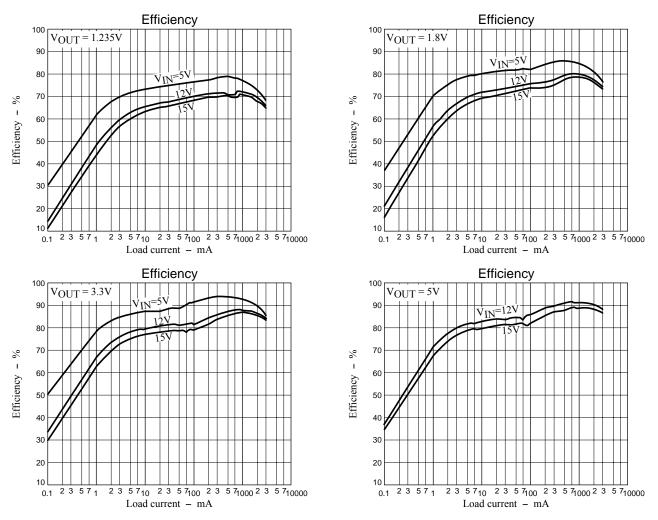

(7) Pattern design of the FB-OUT line

Wire the line shown in red between FB and OUT to the output capacitor as near as possible.

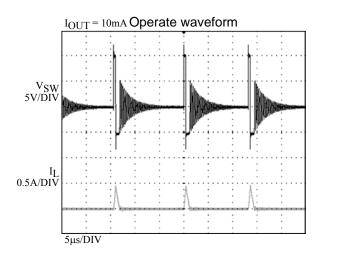

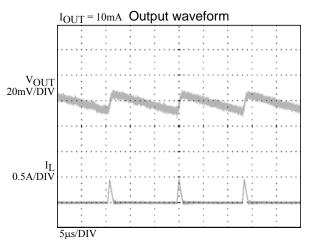

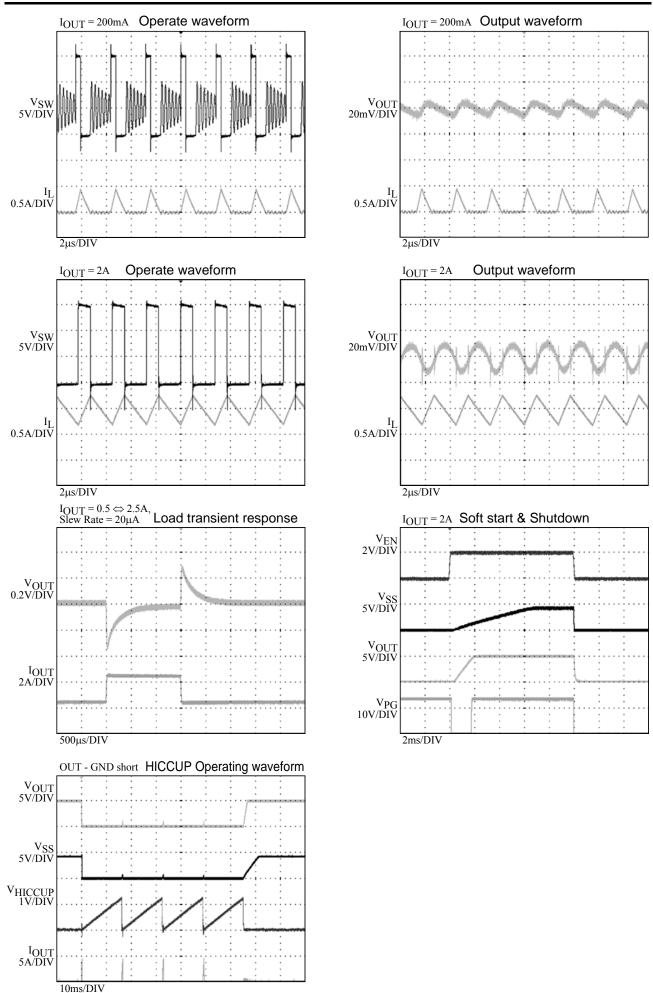

Typical Performance Characteristics Application Curves at $Ta = 25^{\circ}C$
