

## Low Voltage 1:15 Differential $\div 1/\div 2$ ECL/PECL Clock Driver

The MC100LVE222 is a low voltage, low skew 1:15 differential  $\div 1/\div 2$  ECL fanout buffer designed with clock distribution in mind. The device features fully differential clock paths to minimize both device and system skew. The LVE222 can be used as a simple fanout buffer or outputs can be configured to provide half frequency outputs. The combination of 1x and 1/2x frequencies is flexible providing for a myriad of combinations. All timing differences between the 1x and 1/2x signals are compensated for internal to the chip so that the output-to-output skew is identical regardless of what output frequencies are selected.

- Fifteen Differential Outputs
- 200ps Part-to-Part Skew
- 50ps Output-to-Output Skew
- Selectable 1x or 1/2x Frequency Outputs
- Extended Power Supply Range of -3.0V to -5.25V (+3.0V to +5.25V)
- 52-Lead TQFP Packaging
- ESD > 2000V

The fsel and CLK\_Sel input pins are asynchronous control signals. As a result, changing these inputs could cause indeterminate excursions on the outputs immediately following the changes on the inputs.

For applications which require a single-ended input, the  $V_{BB}$  reference voltage is supplied. For single-ended input applications the  $V_{BB}$  reference should be connected to the CLK input and bypassed to ground via a 0.01 $\mu$ f capacitor. The input signal is then driven into the CLK input.

To ensure that the tight skew specification is met it is necessary that both sides of the differential output are terminated into 50 $\Omega$ , even if only one side is being used. In most applications all fifteen differential pairs will be used and therefore terminated. In the case where fewer than fifteen pairs are used it is necessary to terminate at least the output pairs adjacent to the output pair being used in order to maintain minimum skew. Failure to follow this guideline will result in small degradations of propagation delay (on the order of 10–20ps) of the outputs being used, while not catastrophic to most designs this will result in an increase in skew. Note that the package corners isolate outputs from one another such that the guideline expressed above holds only for outputs on the same side of the package.

The MC100LVE222, as with most ECL devices, can be operated from a positive  $V_{CC}$  supply in PECL mode. This allows the LVE222 to be used for high performance clock distribution in +3.3V systems. Designers can take advantage of the LVE222's performance to distribute low skew clocks across the backplane or the board. In a PECL environment series or Thevenin line, terminations are typically used as they require no additional power supplies, if parallel termination is desired a terminating voltage of  $V_{CC}-2.0V$  will need to be provided. For more information on using PECL, designers should refer to Motorola Application Note AN1406/D.

The MC100LVE222 is packaged in the 52-lead TQFP package. For a 3.3V supply this package provides the optimum performance and minimizes board space requirements. The LVE222 will operate from a standard 100E -4.5V supply or a 5.0V PECL supply. The 52-lead TQFP utilizes a 10x10mm body with a lead pitch of 0.65mm.

1. The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals. See *Definitions and Testing of ECLinPS AC Parameters* in Chapter 1 (page 1–12) of the Motorola High Performance ECL Data Book (DL140/D).
2. The single-ended propagation delay is defined as the delay from the 50% point of the input signal to the 50% point of the output signal. See *Definitions and Testing of ECLinPS AC Parameters* in Chapter 1 (page 1–12) of the Motorola High Performance ECL Data Book (DL140/D).
3. The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
4.  $V_{PP}(\text{min})$  is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The  $V_{PP}(\text{min})$  is AC limited for the LVE222. A differential input as low as 50 mV will still produce full ECL levels at the output.
5.  $V_{CMR}$  is defined as the range within which the  $V_{IH}$  level may vary, with the device still meeting the propagation delay specification. The  $V_{IL}$  level must be such that the peak to peak voltage is less than 1.0 V and greater than or equal to  $V_{PP}(\text{min})$ .
