
MCF51QU128 Reference Manual

Supports the MCF51QU32, MCF51QU64, and MCF51QU128

Document Number: MCF51QU128RM
Rev. 3, 08/2012

Contents

Section number	Title	Page
Chapter 1		
About This Document		
1.1	Overview.....	55
1.1.1	Purpose.....	55
1.1.2	Audience.....	55
1.2	Conventions.....	55
1.2.1	Numbering systems.....	55
1.2.2	Typographic notation.....	56
1.2.3	Special terms.....	56
1.2.4	Register reset.....	57
Chapter 2		
Introduction		
2.1	ColdFire+ Portfolio Introduction.....	59
2.2	MCF51QU128 Block Diagram.....	60
2.3	MCF51QU Feature Summary.....	61
2.4	MCF51QU Features by Package.....	65
Chapter 3		
Chip Configuration		
3.1	Introduction.....	67
3.2	Module to Module Interaction Summary.....	67
3.3	Core modules.....	69
3.3.1	Version 1 (V1) ColdFire Core Configuration.....	69
3.3.2	Debug Configuration.....	69
3.3.2.1	VREG in BDM.....	70
3.4	System modules.....	70
3.4.1	Crossbar Switch Configuration.....	70
3.4.1.1	Crossbar Switch Master Assignments.....	71
3.4.1.2	Crossbar Switch Slave Assignments.....	72

Section number	Title	Page
3.4.2	Peripheral Bridge Configuration.....	72
3.4.2.1	Peripheral bridge interfaces.....	72
3.4.2.2	Memory map and module register access.....	73
3.4.3	DMA Controller Configuration.....	73
3.4.3.1	DMA Request Sources.....	73
3.4.4	Interrupt Controller (INTC) Configuration.....	74
3.4.4.1	Interrupt priority levels.....	75
3.4.4.2	Interrupt channel assignments.....	75
3.4.5	Low-Leakage Wakeup Unit (LLWU) Configuration.....	77
3.4.5.1	LLWU wakeup sources.....	78
3.4.5.2	Reset due to LLWU wakeup event.....	79
3.4.5.3	LLWU register reset.....	79
3.4.6	Computer Operating Properly (COP) Watchdog Configuration.....	80
3.4.6.1	COP clocks.....	80
3.4.6.2	COP watchdog operation.....	80
3.4.7	System Mode Controller (SMC) Configuration.....	82
3.4.7.1	SMC register reset.....	82
3.4.8	Power Management Controller (PMC) Configuration.....	83
3.4.8.1	PMC register reset.....	83
3.4.9	Reset Control Module (RCM) Configuration.....	83
3.4.9.1	RCM register reset.....	84
3.4.10	Voltage Regulator (VREG) Configuration.....	84
3.4.10.1	VREG operation controls.....	85
3.4.10.2	VREG in BDM.....	85
3.4.11	System Integration Module (SIM) Configuration.....	85
3.4.11.1	SIM register reset.....	86
3.5	Clock Modules.....	86
3.5.1	Multipurpose Clock Generator (MCG) Configuration.....	86
3.5.1.1	MCG oscillator-frequency trim settings: factory and custom.....	87

Section number	Title	Page
3.5.2	Oscillator (OSC) Configuration.....	88
3.6	Memories and Memory Interfaces.....	89
3.6.1	RAM Configuration.....	89
3.6.1.1	RAM overview.....	89
3.6.1.2	RAM sizes.....	89
3.6.1.3	RAM retention in low power modes.....	90
3.6.1.4	RAM accesses.....	90
3.6.2	Flash Memory Controller (FMC) Configuration.....	90
3.6.3	Flash Memory Module (FTFL) Configuration.....	91
3.6.3.1	Flash Memory Types.....	92
3.6.3.2	Flash Memory Sizes.....	92
3.6.3.3	Flash Memory Map.....	93
3.6.3.4	Flash Security.....	94
3.6.3.5	Flash Modes.....	94
3.6.3.6	Erase All Flash Contents.....	94
3.6.3.7	FTFL_FOPT Register.....	94
3.6.4	System Register File Configuration.....	94
3.6.4.1	Register file details.....	95
3.6.5	EzPort Configuration.....	95
3.6.5.1	EzPort and BDM.....	96
3.6.5.2	Flash Option Register (FOPT).....	96
3.6.5.3	EzPort Clocking.....	96
3.6.6	Mini-FlexBus Configuration.....	97
3.6.6.1	Mini-FlexBus instantiation information.....	97
3.6.6.2	Mini-FlexBus CSCR0 reset value.....	98
3.6.6.3	Mini-FlexBus security.....	98
3.7	Security.....	98
3.7.1	Cyclic Redundancy Check (CRC) Configuration.....	98
3.7.1.1	Module register width and serialization of accesses.....	99

Section number	Title	Page
3.8	Analog.....	99
3.8.1	12-bit Analog-to-Digital Converter (ADC) Configuration.....	99
3.8.1.1	Module register width and serialization of accesses.....	100
3.8.1.2	ADC instantiation information.....	100
3.8.1.3	DMA support on ADC.....	100
3.8.1.4	ADC0 Channel Assignments.....	101
3.8.1.5	ADC Reference, Triggers, and Alternate Clock.....	102
3.8.1.6	Clock Gating.....	102
3.8.2	Comparator (CMP) Configuration.....	103
3.8.2.1	CMP instantiation information.....	103
3.8.2.2	External window/sample input.....	104
3.8.3	12-bit Digital-to-Analog Converter (DAC) Configuration.....	105
3.8.3.1	12-bit DAC Overview.....	105
3.8.3.2	12-bit DAC Instantiation.....	105
3.8.3.3	12-bit DAC Reference.....	105
3.8.3.4	DAC DMA request	106
3.8.4	Voltage Reference (VREF) Configuration.....	106
3.8.4.1	VREF Overview.....	106
3.9	Timers.....	107
3.9.1	Programmable Delay Block (PDB) Configuration.....	107
3.9.1.1	Module register width and serialization of accesses.....	107
3.9.1.2	PDB Overview.....	108
3.9.1.3	PDB instantiation.....	108
3.9.1.4	PDB Module Interconnections.....	108
3.9.1.5	PDB acknowledgement connections.....	109
3.9.1.6	PDB Interval Trigger Connection to DAC.....	109
3.9.1.7	DAC External Trigger Input Connection.....	109
3.9.1.8	Pulse-Out Connection.....	109
3.9.1.9	Pulse-Out Enable Register Implementation.....	109

Section number	Title	Page
3.9.2	FlexTimer (FTM) Configuration.....	110
3.9.2.1	FTM overview.....	110
3.9.2.2	FTM instantiation information.....	110
3.9.2.3	FTM external clock options.....	112
3.9.3	Modulo Timer (MTIM) Configuration.....	112
3.9.3.1	MTIM overview.....	112
3.9.4	Low Power Timer (LPTMR) Configuration.....	113
3.9.4.1	LPTMR overview.....	113
3.9.4.2	LPTMR pin connections.....	114
3.9.4.3	LPTMR clock options.....	114
3.9.4.4	LPTMR register reset.....	114
3.9.5	Carrier Modulator Transmitter (CMT) Configuration.....	115
3.9.5.1	CMT instantiation information.....	115
3.9.5.2	CMT IRO drive strength.....	115
3.10	Communication interfaces.....	116
3.10.1	Serial Peripheral Interface (SPI) Configuration.....	116
3.10.1.1	Number and instantiation of SPI modules.....	116
3.10.1.2	SPI baud rate.....	116
3.10.2	Inter-Integrated Circuit (I2C) Configuration.....	117
3.10.2.1	Number of I2C modules.....	117
3.10.3	Universal Asynchronous Receiver/Transmitter (UART) Configuration.....	118
3.10.3.1	UART instances.....	118
3.10.3.2	UART wakeup.....	118
3.10.3.3	UART support for opto-isolated interface.....	118
3.11	Human-machine interfaces (HMI).....	119
3.11.1	Rapid GPIO (RGPIO) Configuration.....	119
3.11.1.1	Number of available RGPIO pins.....	119
3.11.1.2	RGPIO clock gating.....	120

Section number	Title	Page
3.11.2	Enhanced GPIO (EGPIO) Configuration.....	120
3.11.2.1	Instantiation Information.....	120
3.11.2.2	EGPIO registers.....	121
3.11.3	Touch Sense Input (TSI) Configuration.....	121
3.11.3.1	Module register width and serialization of accesses.....	122
3.11.3.2	Number and instantiation of inputs.....	122
3.11.3.3	TSI clock names.....	122
3.11.3.4	TSI module functionality in MCU operation modes.....	122
3.11.3.5	TSI Interrupts.....	123
3.11.4	External Interrupt (IRQ) Module Configuration.....	123

Chapter 4 Memory Map

4.1	System Memory Map.....	125
4.2	Read-after-write sequence and required serialization of memory operations.....	130

Chapter 5 Clock Distribution

5.1	Introduction.....	131
5.2	Clock distribution.....	131
5.2.1	High-Level device clocking diagram.....	131
5.2.2	Device Clock Summary.....	132
5.2.3	Architecture.....	134
5.2.4	Clock divider requirements.....	134
5.2.5	Clock gating.....	135
5.2.6	Module clocks.....	135
5.2.6.1	VLPR Mode Clocking.....	136
5.2.6.2	UART Clocking.....	136
5.2.6.3	PMC's LPO clock.....	136

Section number	Title	Page
Chapter 6		
Reset and Boot		
6.1	Reset.....	139
6.1.1	MCU reset sources.....	139
6.1.1.1	Power-on reset (POR).....	140
6.1.1.2	External RESET pin (PIN).....	140
6.1.1.3	COP watchdog (WDOG) timer.....	141
6.1.1.4	Illegal opcode detect (ILOP).....	141
6.1.1.5	Illegal address detect (ILAD).....	141
6.1.1.6	Multipurpose Clock Generator loss of clock (LOC).....	142
6.1.1.7	Low voltage detect (LVD).....	142
6.1.1.8	Low leakage wakeup (WAKEUP).....	142
6.1.1.9	Stop mode acknowledge error (SACKERR)	143
6.1.1.10	Background debug forced reset (BDFR).....	143
6.1.2	Reset Pin	143
6.1.3	MCU Resets.....	144
6.1.3.1	POR Only	144
6.1.3.2	Chip POR not VLLS	144
6.1.3.3	Chip POR	144
6.1.3.4	Chip Reset not VLLS	144
6.1.3.5	Early Chip Reset	144
6.1.3.6	Chip Reset	145
6.2	Boot.....	145
6.2.1	Boot sources.....	145
6.2.2	Boot options.....	145
6.2.3	FOPT boot options.....	146
6.2.4	Boot sequence.....	147

Section number	Title	Page
Chapter 7		
Power Management		
7.1	Introduction.....	149
7.2	Power modes.....	149
7.3	Module Operation in Low Power Modes.....	150
Chapter 8		
Security		
8.1	Introduction.....	155
8.2	Flash Security.....	155
8.3	Flash Security Options.....	156
8.3.1	Backdoor Key Access.....	156
8.3.2	Freescale Factory Access.....	156
8.4	Enabling Flash Security.....	157
8.5	Unsecuring the MCU using Backdoor Key Access.....	157
8.6	Unsecuring the MCU using the Erase All Blocks command.....	158
8.7	Security Interactions with other Modules.....	159
8.7.1	Security interactions with Mini-FlexBus.....	159
8.7.2	Security interactions with EzPort.....	159
8.7.3	Security interactions with Debug.....	159
Chapter 9		
Signal Multiplexing and Signal Descriptions		
9.1	Introduction.....	161
9.2	Signal Multiplexing Integration.....	161
9.3	Port Mux Control Features.....	162
9.4	Signal Multiplexing and Pin Assignments.....	163
9.5	Pinout diagrams.....	166
9.6	Module-by-module signals.....	169
9.7	Module Signal Description Tables.....	178
9.7.1	Core Modules.....	178
9.7.2	System Modules.....	178

Section number	Title	Page
9.7.3	Clock Modules.....	179
9.7.4	Memories and Memory Interfaces.....	179
9.7.5	Analog.....	181
9.7.6	Timer Modules.....	181
9.7.7	Communication Interfaces.....	183
9.7.8	Human-Machine Interfaces (HMI).....	184

Chapter 10 Port Mux Control

10.1	Port Mux Control.....	187
10.2	Memory Map and Registers.....	187
10.2.1	Port A Pin Function 1 Register (MXC_PTAPF1).....	188
10.2.2	Port A Pin Function 2 Register (MXC_PTAPF2).....	189
10.2.3	Port A Pin Function 3 Register (MXC_PTAPF3).....	190
10.2.4	Port A Pin Function 4 Register (MXC_PTAPF4).....	190
10.2.5	Port B Pin Function 1 Register (MXC_PTBPF1).....	191
10.2.6	Port B Pin Function 2 Register (MXC_PTBPF2).....	192
10.2.7	Port B Pin Function 3 Register (MXC_PTBPF3).....	193
10.2.8	Port B Pin Function 4 Register (MXC_PTBPF4).....	193
10.2.9	Port C Pin Function 1 Register (MXC_PTCPF1).....	194
10.2.10	Port C Pin Function 2 Register (MXC_PTCPF2).....	195
10.2.11	Port C Pin Function 3 Register (MXC_PTCPF3).....	196
10.2.12	Port C Pin Function 4 Register (MXC_PTCPF4).....	196
10.2.13	Port D Pin Function 1 Register (MXC_PTDPF1).....	197
10.2.14	Port D Pin Function 2 Register (MXC_PTDPF2).....	198
10.2.15	Port D Pin Function 3 Register (MXC_PTDPF3).....	199
10.2.16	Port D Pin Function 4 Register (MXC_PTDPF4).....	199
10.2.17	Port E Pin Function 1 Register (MXC_PTEPF1).....	200
10.2.18	Port E Pin Function 2 Register (MXC_PTEPF2).....	201
10.2.19	Port E Pin Function 3 Register (MXC_PTEPF3).....	202

Section number	Title	Page
10.2.20	Port E Pin Function 4 Register (MXC_PTEPF4).....	202
10.2.21	Port F Pin Function 1 Register (MXC_PTFPF1).....	203
10.2.22	Port F Pin Function 2 Register (MXC_PTFPF2).....	204
10.2.23	Port F Pin Function 3 Register (MXC_PTFPF3).....	205
10.2.24	Port F Pin Function 4 Register (MXC_PTFPF4).....	205

Chapter 11 Core

11.1	Introduction.....	207
11.1.1	Overview.....	207
11.2	Memory Map/Register Description.....	209
11.2.1	Data registers (D0–D7).....	211
11.2.2	Address registers (A0–A6).....	212
11.2.3	Supervisor/user stack pointers (A7 and OTHER_A7).....	212
11.2.4	Condition code register (CCR).....	214
11.2.5	Program counter (PC).....	215
11.2.6	Vector base register (VBR).....	215
11.2.7	CPU configuration register (CPUCR).....	216
11.2.8	Status register (SR).....	219
11.3	Functional Description.....	220
11.3.1	Instruction Set Architecture.....	220
11.3.2	Exception Processing Overview.....	221
11.3.2.1	Exception Stack Frame Definition.....	224
11.3.2.2	S08 and ColdFire Exception Processing Comparison.....	225
11.3.3	Processor Exceptions.....	226
11.3.3.1	Access Error Exception.....	226
11.3.3.2	Address Error Exception.....	227
11.3.3.3	Illegal Instruction Exception.....	228
11.3.3.4	Divide-By-Zero.....	229
11.3.3.5	Privilege Violation.....	229

Section number	Title	Page
11.3.3.6	Trace Exception.....	230
11.3.3.7	Unimplemented Line-A Opcode.....	230
11.3.3.8	Unimplemented Line-F Opcode.....	231
11.3.3.9	Debug Interrupt	231
11.3.3.10	RTE and Format Error Exception	231
11.3.3.11	TRAP Instruction Exception.....	232
11.3.3.12	Unsupported Instruction Exception.....	232
11.3.3.13	Interrupt Exception.....	232
11.3.3.14	Fault-on-Fault Halt.....	232
11.3.3.15	Reset Exception.....	233
11.3.4	Instruction Execution Timing.....	236
11.3.4.1	Timing Assumptions.....	236
11.3.4.2	MOVE Instruction Execution Times.....	237
11.3.4.3	Standard One Operand Instruction Execution Times.....	238
11.3.4.4	Standard Two Operand Instruction Execution Times.....	239
11.3.4.5	Miscellaneous Instruction Execution Times.....	240
11.3.4.6	EMAC Instruction Execution Times.....	241
11.3.4.7	Branch Instruction Execution Times.....	243

Chapter 12 Enhanced Multiply-Accumulate Unit (EMAC)

12.1	Introduction.....	245
12.1.1	Overview.....	245
12.1.1.1	Introduction to the MAC.....	246
12.2	Memory Map/Register Definition.....	247
12.2.1	MAC Status Register (MACSR).....	248
12.2.2	Mask Register (MASK).....	250
12.2.3	Accumulator Registers (ACC0-3).....	252
12.2.4	Accumulator Extension Registers (ACCext01, ACCext23).....	253

Section number	Title	Page
12.3	Functional Description.....	254
12.3.1	Fractional Operation Mode.....	256
12.3.1.1	Rounding.....	257
12.3.1.2	Saving and Restoring the EMAC Programming Model.....	258
12.3.1.3	MULS/MULU.....	259
12.3.1.4	Scale Factor in MAC or MSAC Instructions.....	259
12.3.2	EMAC Instruction Set Summary.....	259
12.3.3	EMAC Instruction Execution Times.....	260
12.3.4	Data Representation.....	261
12.3.5	MAC Opcodes.....	261

Chapter 13 System Integration Module (SIM)

13.1	Introduction.....	267
13.2	Memory Map and Registers.....	267
13.2.1	System Options Register 1 (SIM_SOPT1).....	269
13.2.2	System Options Register 2 (SIM_SOPT2).....	270
13.2.3	System Options Register 3 (SIM_SOPT3).....	271
13.2.4	System Options Register 4 (SIM_SOPT4).....	272
13.2.5	System Options Register 5 (SIM_SOPT5).....	273
13.2.6	System Options Register 6 (SIM_SOPT6).....	273
13.2.7	System Options Register 7 (SIM_SOPT7).....	274
13.2.8	COP Control Register (SIM_COPC).....	275
13.2.9	Service COP Register (SIM_SRV COP).....	276
13.2.10	Oscillator 1 Control Register (SIM_OSC1).....	277
13.2.11	Device Identification High Register (SIM_SDIDH).....	278
13.2.12	Device Identification Low Register (SIM_SDIDL).....	278
13.2.13	Clock Gate Control Register 1 (SIM_SCGC1).....	279
13.2.14	Clock Gate Control Register 2 (SIM_SCGC2).....	280
13.2.15	Clock Gate Control Register 3 (SIM_SCGC3).....	281

Section number	Title	Page
13.2.16	Clock Gate Control Register 4 (SIM_SCGC4).....	282
13.2.17	Clock Gate Control Register 5 (SIM_SCGC5).....	283
13.2.18	Clock Gate Control Register 6 (SIM_SCGC6).....	284
13.2.19	Clockout Register (SIM_CLKOUT).....	285
13.2.20	Clock Divider 0 Register (SIM_CLKDIV0).....	286
13.2.21	Flash Configuration Register (SIM_SPCR).....	287
13.2.22	Unique Identification Register (SIM_UIDH3).....	288
13.2.23	Unique Identification Register (SIM_UIDH2).....	289
13.2.24	Unique Identification Register (SIM_UIDH1).....	290
13.2.25	Unique Identification Register (SIM_UIDH0).....	290
13.2.26	Unique Identification Register (SIM_UIDMH3).....	291
13.2.27	Unique Identification Register (SIM_UIDMH2).....	292
13.2.28	Unique Identification Register (SIM_UIDMH1).....	292
13.2.29	Unique Identification Register (SIM_UIDMH0).....	293
13.2.30	Unique Identification Register (SIM_UIDML3).....	294
13.2.31	Unique Identification Register (SIM_UIDML2).....	294
13.2.32	Unique Identification Register (SIM_UIDML1).....	295
13.2.33	Unique Identification Register (SIM_UIDML0).....	296
13.2.34	Unique Identification Register (SIM_UIDL3).....	296
13.2.35	Unique Identification Register (SIM_UIDL2).....	297
13.2.36	Unique Identification Register (SIM_UIDL1).....	298
13.2.37	Unique Identification Register (SIM_UIDL0).....	298

Chapter 14 Crossbar Switch

14.1	Introduction.....	301
14.1.1	Features.....	301
14.2	Memory Map / Register Definition.....	302
14.3	Functional Description.....	302
14.3.1	General operation.....	302

Section number	Title	Page
14.3.2	Arbitration.....	303
14.3.2.1	Arbitration During Undefined Length Bursts.....	303
14.3.2.2	Fixed-priority operation.....	303
14.3.2.3	Round-robin priority operation.....	304
14.3.2.4	Priority Elevation.....	304
14.4	Initialization/application information.....	305

Chapter 15 Interrupt Controller (INTC)

15.1	Introduction.....	307
15.1.1	Overview.....	308
15.1.2	Features.....	311
15.1.3	Modes of Operation.....	312
15.2	External Signal Description.....	312
15.3	Interrupt Request Level and Priority Assignments.....	312
15.4	Memory Map and Registers.....	313
15.4.1	Interrupt Mask Register High (INTC_IMRH).....	314
15.4.2	Interrupt Mask Register Low (INTC_IMRL).....	316
15.4.3	Force Interrupt Register (INTC_FRC).....	320
15.4.4	INTC Programmable Level 6 Priority Registers (INTC_PL6Pn).....	321
15.4.5	INTC Wakeup Control Register (INTC_WCR).....	322
15.4.6	Set Interrupt Mask Register (INTC_SIMR).....	323
15.4.7	Clear Interrupt Mask Register (INTC_CIMR).....	324
15.4.8	INTC Set Interrupt Force Register (INTC_SFRC).....	325
15.4.9	INTC Clear Interrupt Force Register (INTC_CFRC).....	326
15.4.10	INTC Software IACK Register (INTC_SWIACK).....	327
15.4.11	INTC Level- <i>n</i> IACK Registers (INTC_LVL <i>n</i> IACK).....	327
15.5	Functional Description.....	328
15.5.1	Handling of Non-Maskable Level 7 Interrupt Requests.....	328
15.6	Initialization Information.....	329

Section number	Title	Page
15.7	Application Information.....	329
15.7.1	Emulation of the HCS08's 1-Level IRQ Handling.....	329
15.7.2	Using INTC_PL6P{7,6} Registers.....	330
15.7.3	More on Software IACKs.....	331

Chapter 16 Low Leakage Wakeup Unit (LLWU)

16.1	Introduction.....	335
16.1.1	Features.....	335
16.1.2	Modes of operation.....	336
16.1.2.1	LLS mode.....	336
16.1.2.2	VLLS modes.....	336
16.1.2.3	Non-low leakage modes.....	336
16.1.2.4	Debug mode.....	337
16.1.3	Block diagram.....	337
16.2	LLWU signal descriptions.....	338
16.3	Memory map/register definition.....	339
16.3.1	LLWU Pin Enable 1 register (LLWU_PE1).....	340
16.3.2	LLWU Pin Enable 2 register (LLWU_PE2).....	341
16.3.3	LLWU Pin Enable 3 register (LLWU_PE3).....	342
16.3.4	LLWU Pin Enable 4 register (LLWU_PE4).....	343
16.3.5	LLWU Module Enable register (LLWU_ME).....	344
16.3.6	LLWU Flag 1 register (LLWU_F1).....	346
16.3.7	LLWU Flag 2 register (LLWU_F2).....	347
16.3.8	LLWU Flag 3 register (LLWU_F3).....	349
16.3.9	LLWU Pin Filter 1 register (LLWU_FILT1).....	351
16.3.10	LLWU Pin Filter 2 register (LLWU_FILT2).....	352
16.3.11	LLWU Reset Enable register (LLWU_RST).....	353
16.4	Functional description.....	354
16.4.1	LLS mode.....	354

Section number	Title	Page
16.4.2	VLLS modes.....	354
16.4.3	Initialization.....	355

Chapter 17 Reset Control Module (RCM)

17.1	Introduction.....	357
17.2	Reset memory map and register descriptions.....	357
17.2.1	System Reset Status Register 0 (RCM_SRS0).....	357
17.2.2	System Reset Status Register 1 (RCM_SRS1).....	359
17.2.3	Reset Pin Filter Control register (RCM_RPFC).....	360
17.2.4	Reset Pin Filter Width register (RCM_RPFW).....	361
17.2.5	Mode Register (RCM_MR).....	363

Chapter 18 System Mode Controller (SMC)

18.1	Introduction.....	365
18.2	Modes of operation.....	365
18.3	Memory map and register descriptions.....	367
18.3.1	Power Mode Protection register (SMC_PMPROT).....	367
18.3.2	Power Mode Control register (SMC_PMCTRL).....	368
18.3.3	VLLS Control register (SMC_VLLSCTRL).....	370
18.3.4	Power Mode Status register (SMC_PMSTAT).....	371
18.4	Functional description.....	372
18.4.1	Power mode transitions.....	372
18.4.2	Power mode entry/exit sequencing.....	375
18.4.2.1	Stop mode entry sequence.....	376
18.4.2.2	Stop mode exit sequence.....	377
18.4.2.3	Aborted stop mode entry.....	377
18.4.2.4	Transition to wait modes.....	377
18.4.2.5	Transition from stop modes to Debug mode.....	377

Section number	Title	Page
18.4.3	Run modes.....	377
18.4.3.1	RUN mode.....	378
18.4.3.2	Very-Low Power Run (VLPR) mode.....	378
18.4.3.3	BDM in Run and VLPR Mode.....	379
18.4.4	Wait modes.....	379
18.4.4.1	WAIT mode.....	379
18.4.4.2	Very-Low-Power Wait (VLPW) mode.....	380
18.4.4.3	BDM in Wait and VLPW Mode.....	380
18.4.5	Stop modes.....	381
18.4.5.1	STOP mode.....	381
18.4.5.2	Very-Low-Power Stop (VLPS) mode.....	382
18.4.5.3	BDM in Stop and VLPS Modes.....	382
18.4.5.4	Low-Leakage Stop (LLS) mode.....	383
18.4.5.5	Very-Low-Leakage Stop (VLLSx) modes.....	383
18.4.5.6	BDM in LLS and VLLSx Modes.....	384

Chapter 19 Power Management Controller (PMC)

19.1	Introduction.....	385
19.2	Features.....	385
19.3	Low-voltage detect (LVD) system.....	385
19.3.1	LVD reset operation.....	386
19.3.2	LVD interrupt operation.....	386
19.3.3	Low-voltage warning (LVW) interrupt operation.....	386
19.4	I/O retention.....	387
19.5	Memory map and register descriptions.....	387
19.5.1	Low Voltage Detect Status And Control 1 register (PMC_LVDSC1).....	387
19.5.2	Low Voltage Detect Status And Control 2 register (PMC_LVDSC2).....	389
19.5.3	Regulator Status And Control register (PMC_REGSC).....	390

Section number	Title	Page
Chapter 20		
Voltage Regulator (VREG)		
20.1	Introduction.....	393
20.1.1	Overview.....	393
20.1.2	Features.....	394
20.1.3	Modes of Operation.....	395
20.2	Voltage Regulator Module Signal Descriptions.....	395
Chapter 21		
DMA Controller		
21.1	Introduction.....	397
21.1.1	Overview.....	397
21.1.2	Features.....	398
21.2	DMA Transfer Overview.....	399
21.3	Memory Map and Registers.....	400
21.3.1	DMA Request Control Register (DMA_REQC).....	401
21.3.2	Source Address Register (DMA_SAR n).....	405
21.3.3	Destination Address Register (DMA_DAR n).....	406
21.3.4	DMA Status Register / Byte Count Register (DMA_DSR_BCR n).....	406
21.3.5	DMA Control Register (DMA_DCR n).....	409
21.4	Functional Description.....	412
21.4.1	Transfer Requests (Cycle-Steal and Continuous Modes).....	413
21.4.2	Channel Initialization and Startup.....	413
21.4.2.1	Channel Prioritization.....	413
21.4.2.2	Programming the DMA Controller Module.....	414
21.4.3	Dual-Address Data Transfer Mode.....	415
21.4.4	Advanced Data Transfer Controls: Auto-Alignment.....	416
21.4.5	Termination.....	417

Section number	Title	Page
Chapter 22		
Multipurpose Clock Generator (MCG)		
22.1	Introduction.....	419
22.1.1	Features.....	419
22.1.2	Modes of Operation.....	423
22.2	External Signal Description.....	423
22.3	Memory Map/Register Definition.....	423
22.3.1	MCG Control 1 Register (MCG_C1).....	423
22.3.2	MCG Control 2 Register (MCG_C2).....	425
22.3.3	MCG Control 3 Register (MCG_C3).....	426
22.3.4	MCG Control 4 Register (MCG_C4).....	426
22.3.5	MCG Control 5 Register (MCG_C5).....	428
22.3.6	MCG Control 6 Register (MCG_C6).....	429
22.3.7	MCG Status Register (MCG_S).....	430
22.3.8	MCG Auto Trim Control Register (MCG_ATC).....	432
22.3.9	MCG Auto Trim Compare Value High Register (MCG_ATCVH).....	432
22.3.10	MCG Auto Trim Compare Value Low Register (MCG_ATCVL).....	433
22.4	Functional Description.....	433
22.4.1	MCG mode state diagram.....	433
22.4.1.1	MCG modes of operation.....	434
22.4.1.2	MCG mode switching.....	437
22.4.2	Low Power Bit Usage.....	438
22.4.3	MCG Internal Reference Clocks.....	438
22.4.3.1	MCG Internal Reference Clock.....	438
22.4.4	External Reference Clock.....	439
22.4.5	MCG Fixed frequency clock	439
22.4.6	MCG Background Debug Controller Clock.....	439
22.4.7	MCG PLL clock	440
22.4.8	MCG Auto TRIM (ATM).....	440

Section number	Title	Page
22.5	Initialization / Application information.....	441
22.5.1	MCG module initialization sequence.....	441
22.5.1.1	Initializing the MCG.....	441
22.5.2	Using a 32.768 kHz reference.....	443
22.5.3	MCG mode switching.....	444
22.5.3.1	Example 1: Moving from FEI to PEE mode: External Crystal = 4 MHz, MCGOUTCLK frequency = 48 MHz.....	445
22.5.3.2	Example 2: Moving from PEE to BLPI mode: MCGOUTCLK frequency =32 kHz.....	449
22.5.3.3	Example 3: Moving from BLPI to FEE mode.....	451

Chapter 23 Oscillator (OSC)

23.1	Introduction.....	455
23.2	Features and Modes.....	455
23.3	Block Diagram.....	456
23.4	OSC Signal Descriptions.....	456
23.5	External Crystal / Resonator Connections.....	457
23.6	External Clock Connections.....	459
23.7	Memory Map/Register Definitions.....	459
23.7.1	OSC Memory Map/Register Definition.....	460
23.7.1.1	OSC Control Register (OSC _x _CR).....	460
23.7.1.2	OSC Test Control Register (OSC _x _TSTCTR).....	461
23.8	Functional Description.....	462
23.8.1	OSC Module States.....	462
23.8.1.1	Off.....	463
23.8.1.2	Oscillator Start-Up.....	463
23.8.1.3	Oscillator Stable.....	464
23.8.1.4	External Clock Mode.....	464
23.8.2	OSC Module Modes.....	464
23.8.2.1	Low-Frequency, High-Gain Mode.....	465

Section number	Title	Page
23.8.2.2	Low-Frequency, Low-Power Mode.....	465
23.8.2.3	High-Frequency, High-Gain Mode.....	465
23.8.2.4	High-Frequency, Low-Power Mode.....	466
23.8.3	Counter.....	466
23.8.4	Reference Clock Pin Requirements.....	466
23.9	Reset.....	466
23.10	Low Power Modes Operation.....	467
23.11	Interrupts.....	467

Chapter 24 Flash Memory Controller (FMC)

24.1	Introduction.....	469
24.1.1	Overview.....	469
24.1.2	Features.....	469
24.2	Modes of operation.....	470
24.3	External signal description.....	470
24.4	Memory map and register descriptions.....	470
24.5	Functional description.....	471

Chapter 25 Flash Memory Module (FTFL)

25.1	Introduction.....	473
25.1.1	Features.....	474
25.1.1.1	Program Flash Memory Features.....	474
25.1.1.2	FlexNVM Memory Features.....	474
25.1.1.3	FlexRAM Features.....	474
25.1.1.4	Other Flash Memory Module Features.....	475
25.1.2	Block Diagram.....	475
25.1.3	Glossary.....	476
25.2	External Signal Description.....	478

Section number	Title	Page
25.3	Memory Map and Registers.....	478
25.3.1	Flash Configuration Field Description.....	479
25.3.2	Program Flash IFR Map.....	479
25.3.2.1	Program Once Field.....	479
25.3.3	Data Flash IFR Map.....	480
25.3.3.1	EEPROM Data Set Size.....	480
25.3.3.2	FlexNVM Partition Code.....	481
25.3.4	Register Descriptions.....	482
25.3.4.1	Flash Option Register (FTFL_FOPT).....	483
25.3.4.2	Flash Security Register (FTFL_FSEC).....	484
25.3.4.3	Flash Configuration Register (FTFL_FCENFG).....	485
25.3.4.4	Flash Status Register (FTFL_FSTAT).....	487
25.3.4.5	Flash Common Command Object Registers (FTFL_FCCOB n).....	489
25.3.4.6	Program Flash Protection Registers (FTFL_FPROT n).....	490
25.3.4.7	Data Flash Protection Register (FTFL_FDPROT).....	491
25.3.4.8	EEPROM Protection Register (FTFL_FEPROT).....	492
25.4	Functional Description.....	493
25.4.1	Flash Protection.....	493
25.4.2	FlexNVM Description.....	495
25.4.2.1	FlexNVM Block Partitioning for FlexRAM.....	495
25.4.2.2	EEPROM User Perspective.....	496
25.4.2.3	EEPROM Implementation Overview.....	497
25.4.2.4	Write endurance to FlexRAM for EEPROM.....	498
25.4.3	Interrupts.....	499
25.4.4	Flash Operation in Low-Power Modes.....	500
25.4.4.1	Wait Mode.....	500
25.4.4.2	Stop Mode.....	500
25.4.5	Functional Modes of Operation.....	500
25.4.6	Flash Reads and Ignored Writes.....	500

Section number	Title	Page
25.4.7	Read While Write (RWW).....	501
25.4.8	Flash Program and Erase.....	501
25.4.9	Flash Command Operations.....	501
25.4.9.1	Command Write Sequence.....	502
25.4.9.2	Flash Commands.....	504
25.4.9.3	Flash Commands by Mode.....	507
25.4.9.4	Allowed Simultaneous Flash Operations.....	507
25.4.10	Margin Read Commands.....	508
25.4.11	Flash Command Description.....	509
25.4.11.1	Read 1s Block Command.....	510
25.4.11.2	Read 1s Section Command.....	511
25.4.11.3	Program Check Command.....	512
25.4.11.4	Read Resource Command.....	513
25.4.11.5	Program Longword Command.....	514
25.4.11.6	Erase Flash Block Command.....	515
25.4.11.7	Erase Flash Sector Command.....	516
25.4.11.8	Program Section Command.....	519
25.4.11.9	Read 1s All Blocks Command.....	521
25.4.11.10	Read Once Command.....	523
25.4.11.11	Program Once Command.....	523
25.4.11.12	Erase All Blocks Command.....	524
25.4.11.13	Verify Backdoor Access Key Command.....	525
25.4.11.14	Program Partition Command.....	527
25.4.11.15	Set FlexRAM Function Command.....	529
25.4.12	Security.....	530
25.4.12.1	Flash Memory Access by Mode and Security.....	531
25.4.12.2	Changing the Security State.....	531
25.4.13	Reset Sequence.....	532

Section number	Title	Page
Chapter 26		
External Bus Interface (Mini-FlexBus)		
26.1	Introduction.....	535
26.1.1	Definition.....	535
26.1.2	Features.....	536
26.2	Signal descriptions.....	536
26.3	Memory Map/Register Definition.....	537
26.3.1	Chip Select Address Register (FB_CSAR n).....	538
26.3.2	Chip Select Mask Register (FB_CSMR n).....	539
26.3.3	Chip Select Control Register (FB_CSCR n).....	540
26.4	Functional description.....	542
26.4.1	Modes of operation.....	542
26.4.2	Address comparison.....	542
26.4.3	Address driven on address bus.....	543
26.4.4	Connecting address/data lines.....	543
26.4.5	Bit ordering.....	543
26.4.6	Data transfer signals.....	543
26.4.7	Signal transitions.....	543
26.4.8	Data-byte alignment and physical connections.....	544
26.4.9	Address/data bus multiplexing.....	545
26.4.9.1	Mini-FlexBus multiplexed operating modes.....	545
26.4.10	Data transfer states.....	546
26.4.11	Mini-FlexBus Timing Examples.....	546
26.4.11.1	Basic Read Bus Cycle.....	547
26.4.11.2	Basic Write Bus Cycle.....	548
26.4.11.3	Bus Cycle Sizing.....	549
26.4.11.4	Timing Variations.....	553
26.4.12	Bus errors.....	562

Section number	Title	Page
26.5	Initialization/Application Information.....	562
26.5.1	Initializing a chip-select.....	563
26.5.2	Reconfiguring a chip-select.....	563

Chapter 27 EzPort

27.1	Overview.....	565
27.1.1	Introduction.....	565
27.1.2	Features.....	566
27.1.3	Modes of operation.....	566
27.2	External signal description.....	567
27.2.1	EzPort Clock (EZP_CK).....	567
27.2.2	EzPort Chip Select (EZP_CS).....	567
27.2.3	EzPort Serial Data In (EZP_D).....	568
27.2.4	EzPort Serial Data Out (EZP_Q).....	568
27.3	Command definition.....	568
27.3.1	Command descriptions.....	569
27.3.1.1	Write Enable.....	569
27.3.1.2	Write Disable.....	569
27.3.1.3	Read Status Register.....	569
27.3.1.4	Read Data.....	571
27.3.1.5	Read Data at High Speed.....	571
27.3.1.6	Section Program.....	572
27.3.1.7	Sector Erase.....	572
27.3.1.8	Bulk Erase.....	572
27.3.1.9	EzPort Reset Chip.....	573
27.3.1.10	Write FCCOB Registers.....	573
27.3.1.11	Read FCCOB Registers at High Speed.....	573
27.3.1.12	Write FlexRAM.....	574
27.3.1.13	Read FlexRAM.....	574

Section number	Title	Page
27.3.1.14	Read FlexRAM at High Speed.....	575
27.4	Flash memory map for EzPort access.....	575

Chapter 28 Cyclic Redundancy Check (CRC)

28.1	Introduction.....	577
28.1.1	Features.....	577
28.1.2	Block diagram.....	577
28.1.3	Modes of operation.....	578
28.1.3.1	Run mode.....	578
28.1.3.2	Low-power modes (Wait or Stop).....	578
28.2	Memory map and register descriptions.....	578
28.2.1	CRC Data Register (CRC_CRC).....	579
28.2.2	CRC Polynomial Register (CRC_GPOLY).....	580
28.2.3	CRC Control Register (CRC_CTRL).....	580
28.3	Functional description.....	581
28.3.1	CRC initialization/reinitialization.....	581
28.3.2	CRC calculations.....	582
28.3.2.1	16-bit CRC.....	582
28.3.2.2	32-bit CRC.....	582
28.3.3	Transpose feature.....	583
28.3.3.1	Types of transpose.....	583
28.3.4	CRC result complement.....	585

Chapter 29 Analog-to-Digital Converter (ADC)

29.1	Introduction.....	587
29.1.1	Features.....	587
29.1.2	Block diagram.....	588
29.2	ADC Signal Descriptions.....	589
29.2.1	Analog Power (VDDA).....	590

Section number	Title	Page
29.2.2	Analog Ground (VSSA).....	590
29.2.3	Voltage Reference Select.....	590
29.2.4	Analog Channel Inputs (ADx).....	591
29.3	Register definition.....	591
29.3.1	ADC Status and Control Registers 1 (ADCx_SC1n).....	592
29.3.2	ADC Configuration Register 1 (ADCx_CFG1).....	595
29.3.3	ADC Configuration Register 2 (ADCx_CFG2).....	597
29.3.4	ADC Data Result Register (ADCx_Rn).....	598
29.3.5	Compare Value Registers (ADCx_CVn).....	599
29.3.6	Status and Control Register 2 (ADCx_SC2).....	600
29.3.7	Status and Control Register 3 (ADCx_SC3).....	602
29.3.8	ADC Offset Correction Register (ADCx_OFS).....	603
29.3.9	ADC Plus-Side Gain Register (ADCx_PG).....	604
29.3.10	ADC Plus-Side General Calibration Value Register (ADCx_CLPD).....	604
29.3.11	ADC Plus-Side General Calibration Value Register (ADCx_CLPS).....	605
29.3.12	ADC Plus-Side General Calibration Value Register (ADCx_CLP4).....	605
29.3.13	ADC Plus-Side General Calibration Value Register (ADCx_CLP3).....	606
29.3.14	ADC Plus-Side General Calibration Value Register (ADCx_CLP2).....	606
29.3.15	ADC Plus-Side General Calibration Value Register (ADCx_CLP1).....	607
29.3.16	ADC Plus-Side General Calibration Value Register (ADCx_CLP0).....	607
29.4	Functional description.....	608
29.4.1	Clock select and divide control.....	608
29.4.2	Voltage reference selection.....	609
29.4.3	Hardware trigger and channel selects.....	609
29.4.4	Conversion control.....	610
29.4.4.1	Initiating conversions.....	611
29.4.4.2	Completing conversions.....	612
29.4.4.3	Aborting conversions.....	612
29.4.4.4	Power control.....	612

Section number	Title	Page
29.4.4.5	Sample time and total conversion time.....	613
29.4.4.6	Conversion time examples.....	615
29.4.4.7	Hardware average function.....	617
29.4.5	Automatic compare function.....	617
29.4.6	Calibration function.....	619
29.4.7	User-defined offset function.....	620
29.4.8	Temperature sensor.....	621
29.4.9	MCU wait mode operation.....	622
29.4.10	MCU Normal Stop mode operation.....	622
29.4.10.1	Normal Stop mode with ADACK disabled.....	622
29.4.10.2	Normal Stop mode with ADACK enabled.....	623
29.4.11	MCU Low-Power Stop mode operation.....	623
29.5	Initialization information.....	624
29.5.1	ADC module initialization example.....	624
29.5.1.1	Initialization sequence.....	624
29.5.1.2	Pseudo-code example.....	624
29.6	Application information.....	626
29.6.1	External pins and routing.....	626
29.6.1.1	Analog supply pins.....	626
29.6.1.2	Analog voltage reference pins.....	627
29.6.1.3	Analog input pins.....	628
29.6.2	Sources of error.....	628
29.6.2.1	Sampling error.....	628
29.6.2.2	Pin leakage error.....	629
29.6.2.3	Noise-induced errors.....	629
29.6.2.4	Code width and quantization error.....	630
29.6.2.5	Linearity errors.....	630
29.6.2.6	Code jitter, non-monotonicity, and missing codes.....	631

Section number	Title	Page
Chapter 30		
Comparator (CMP)		
30.1	Introduction.....	633
30.2	CMP features.....	633
30.3	6-bit DAC key features.....	634
30.4	ANMUX key features.....	635
30.5	CMP, DAC and ANMUX diagram.....	635
30.6	CMP block diagram.....	636
30.7	Memory map/register definitions.....	638
30.7.1	CMP Control Register 0 (CMP _x _CR0).....	638
30.7.2	CMP Control Register 1 (CMP _x _CR1).....	639
30.7.3	CMP Filter Period Register (CMP _x _FPR).....	641
30.7.4	CMP Status and Control Register (CMP _x _SCR).....	641
30.7.5	DAC Control Register (CMP _x _DACCR).....	643
30.7.6	MUX Control Register (CMP _x _MUXCR).....	643
30.8	Functional description.....	644
30.8.1	CMP functional modes.....	645
30.8.1.1	Disabled mode (# 1).....	646
30.8.1.2	Continuous mode (#s 2A & 2B).....	646
30.8.1.3	Sampled, Non-Filtered mode (#s 3A & 3B).....	647
30.8.1.4	Sampled, Filtered mode (#s 4A & 4B).....	649
30.8.1.5	Windowed mode (#s 5A & 5B).....	651
30.8.1.6	Windowed/Resampled mode (# 6).....	653
30.8.1.7	Windowed/Filtered mode (#7).....	654
30.8.2	Power modes.....	654
30.8.2.1	Wait mode operation.....	654
30.8.2.2	Stop mode operation.....	655
30.8.2.3	Low-Leakage mode operation.....	655
30.8.2.4	Background Debug Mode Operation.....	655

Section number	Title	Page
30.8.3	Startup and operation.....	655
30.8.4	Low-pass filter.....	656
30.8.4.1	Enabling filter modes.....	656
30.8.4.2	Latency issues.....	657
30.9	CMP interrupts.....	658
30.10	DMA support.....	658
30.11	Digital-to-analog converter.....	659
30.12	DAC functional description.....	660
30.12.1	Voltage reference source select.....	660
30.13	DAC resets.....	660
30.14	DAC clocks.....	660
30.15	DAC interrupts.....	660

Chapter 31 12-bit Digital-to-Analog Converter (DAC)

31.1	Introduction.....	661
31.2	Features.....	661
31.3	Block diagram.....	661
31.4	Memory map/register definition.....	663
31.4.1	DAC Data High Register (DACx_DATnH).....	664
31.4.2	DAC Data Low Register (DACx_DATnL).....	664
31.4.3	DAC Status Register (DACx_SR).....	665
31.4.4	DAC Control Register (DACx_C0).....	665
31.4.5	DAC Control Register 1 (DACx_C1).....	667
31.4.6	DAC Control Register 2 (DACx_C2).....	667
31.5	Functional description.....	668
31.5.1	DAC data buffer operation.....	668
31.5.1.1	DAC data buffer interrupts.....	668
31.5.1.2	Modes of DAC data buffer operation.....	669
31.5.2	DMA operation.....	669

Section number	Title	Page
31.5.3	Resets.....	669
31.5.4	Low-Power mode operation.....	669
31.5.5	Background Mode Operation.....	670

Chapter 32 Voltage Reference (VREF)

32.1	Introduction.....	671
32.1.1	Overview.....	672
32.1.2	Features.....	672
32.1.3	Modes of Operation.....	673
32.1.4	VREF Signal Descriptions.....	673
32.2	Memory Map and Register Definition.....	674
32.2.1	VREF Trim Register (VREF_TRM).....	674
32.2.2	VREF Status and Control Register (VREF_SC).....	675
32.3	Functional Description.....	676
32.3.1	Voltage Reference Disabled, SC[VREFEN] = 0.....	676
32.3.2	Voltage Reference Enabled, SC[VREFEN] = 1.....	677
32.3.2.1	SC[MODE_LV]=00.....	677
32.3.2.2	SC[MODE_LV] = 01.....	677
32.3.2.3	SC[MODE_LV] = 10.....	677
32.3.2.4	SC[MODE_LV] = 11.....	677
32.4	Initialization/Application Information.....	678

Chapter 33 Programmable Delay Block (PDB)

33.1	Introduction.....	679
33.1.1	Features.....	679
33.1.2	Implementation.....	680
33.1.3	Back-to-back acknowledgment connections.....	681
33.1.4	DAC External Trigger Input Connections.....	681
33.1.5	Block diagram.....	681

Section number	Title	Page
33.1.6	Modes of operation.....	683
33.2	PDB signal descriptions.....	683
33.3	Memory map and register definition.....	683
33.3.1	Status and Control Register (PDBx_SC).....	684
33.3.2	Modulus Register (PDBx_MOD).....	687
33.3.3	Counter Register (PDBx_CNT).....	687
33.3.4	Interrupt Delay Register (PDBx_IDLY).....	688
33.3.5	Channel n Control Register 1 (PDBx_CHnC1).....	688
33.3.6	Channel n Status Register (PDBx_CHnS).....	689
33.3.7	Channel n Delay 0 Register (PDBx_CHnDLY0).....	690
33.3.8	Channel n Delay 1 Register (PDBx_CHnDLY1).....	690
33.3.9	DAC Interval Trigger n Control Register (PDBx_DACINTCn).....	691
33.3.10	DAC Interval n Register (PDBx_DACINTn).....	692
33.3.11	Pulse-Out n Enable Register (PDBx_POnEN).....	692
33.3.12	Pulse-Out n Delay Register (PDBx_POnDLY).....	693
33.4	Functional description.....	693
33.4.1	PDB pre-trigger and trigger outputs.....	693
33.4.2	PDB trigger input source selection.....	695
33.4.3	DAC interval trigger outputs.....	695
33.4.4	Pulse-Out's.....	696
33.4.5	Updating the delay registers.....	696
33.4.6	Interrupts.....	698
33.4.7	DMA.....	698
33.5	Application information.....	698
33.5.1	Impact of using the prescaler and multiplication factor on timing resolution.....	698

Chapter 34 Modulo Timer (MTIM)

34.1	Introduction.....	701
------	-------------------	-----

Section number	Title	Page
34.2	Features	701
34.2.1	Block Diagram	702
34.2.2	Modes of Operation	702
34.2.2.1	MTIM16 in Wait Mode	702
34.2.2.2	MTIM16 in Stop Modes.....	702
34.2.2.3	MTIM16 in Active Background Mode	703
34.3	External Signal Description	703
34.3.1	TCLK — External Clock Source Input into MTIM16	703
34.4	Memory Map and Register Descriptions.....	704
34.4.1	MTIM16 status and control register (MTIMx_SC).....	704
34.4.2	MTIM16 clock configuration register (MTIMx_CLK).....	705
34.4.3	MTIM16 counter register high (MTIMx_CNTH).....	706
34.4.4	MTIM16 counter register low (MTIMx_CNTL).....	707
34.4.5	MTIM16 modulo register high (MTIMx_MODH).....	708
34.4.6	MTIM16 modulo register low (MTIMx_MODL).....	709
34.5	Functional Description	709
34.5.1	MTIM16 Operation Example	711

Chapter 35 Low Power Timer (LPTMR)

35.1	Introduction.....	713
35.1.1	Features.....	713
35.1.2	Modes of operation.....	713
35.2	LPTMR signal descriptions.....	714
35.2.1	Detailed signal descriptions.....	714
35.3	Memory map and register definition.....	715
35.3.1	Low Power Timer Control Status Register (LPTMRx_CSR).....	715
35.3.2	Low Power Timer Prescale Register (LPTMRx_PSR).....	717
35.3.3	Low Power Timer Compare Register (LPTMRx_CMR).....	718
35.3.4	Low Power Timer Counter Register (LPTMRx_CNR).....	719

Section number	Title	Page
35.4	Functional description.....	719
35.4.1	LPTMR power and reset.....	719
35.4.2	LPTMR clocking.....	719
35.4.3	LPTMR prescaler/glitch filter.....	720
35.4.3.1	Prescaler enabled.....	720
35.4.3.2	Prescaler bypassed.....	720
35.4.3.3	Glitch filter.....	720
35.4.3.4	Glitch filter bypassed.....	721
35.4.4	LPTMR compare.....	721
35.4.5	LPTMR counter.....	721
35.4.6	LPTMR hardware trigger.....	722
35.4.7	LPTMR interrupt.....	722

Chapter 36 Carrier Modulator Transmitter (CMT)

36.1	Introduction.....	725
36.2	Features.....	725
36.3	Block diagram.....	726
36.4	Modes of operation.....	727
36.4.1	Wait mode operation.....	728
36.4.2	Stop mode operation.....	729
36.4.2.1	Normal Stop mode operation.....	729
36.4.2.2	Low-Power Stop mode operation.....	729
36.4.3	Background Debug Mode Operation.....	729
36.5	CMT external signal descriptions.....	729
36.5.1	CMT_IRO — Infrared Output.....	730
36.6	Memory map/register definition.....	730
36.6.1	CMT Carrier Generator High Data Register 1 (CMT_CGH1).....	731
36.6.2	CMT Carrier Generator Low Data Register 1 (CMT_CGL1).....	732
36.6.3	CMT Carrier Generator High Data Register 2 (CMT_CGH2).....	732

Section number	Title	Page
36.6.4	CMT Carrier Generator Low Data Register 2 (CMT_CGL2).....	733
36.6.5	CMT Output Control Register (CMT_OC).....	733
36.6.6	CMT Modulator Status and Control Register (CMT_MSC).....	734
36.6.7	CMT Modulator Data Register Mark High (CMT_CMD1).....	736
36.6.8	CMT Modulator Data Register Mark Low (CMT_CMD2).....	737
36.6.9	CMT Modulator Data Register Space High (CMT_CMD3).....	737
36.6.10	CMT Modulator Data Register Space Low (CMT_CMD4).....	738
36.6.11	CMT Primary Prescaler Register (CMT_PPS).....	738
36.6.12	CMT Direct Memory Access Register (CMT_DMA).....	739
36.7	Functional description.....	740
36.7.1	Clock divider.....	740
36.7.2	Carrier generator.....	740
36.7.3	Modulator.....	743
36.7.3.1	Time mode.....	744
36.7.3.2	Baseband mode.....	745
36.7.3.3	FSK mode.....	746
36.7.4	Extended space operation.....	747
36.7.4.1	EXSPC operation in Time mode.....	747
36.7.4.2	EXSPC operation in FSK mode.....	748
36.8	CMT interrupts and DMA.....	749

Chapter 37 FlexTimer (FTM)

37.1	Introduction.....	751
37.1.1	FlexTimer philosophy.....	751
37.1.2	Features.....	752
37.1.3	Modes of operation.....	753
37.1.4	Block diagram.....	754
37.2	Signal description.....	756
37.2.1	EXTCLK — FTM external clock.....	756

Section number	Title	Page
37.2.2	CH _n — FTM channel (n) I/O pin.....	756
37.2.3	FAULT _j — FTM fault input.....	756
37.2.4	PHA — FTM Quadrature Decoder Phase A Input.....	757
37.2.5	PHB — FTM Quadrature Decoder Phase B Input.....	757
37.3	Memory map and register definition.....	757
37.3.1	Module memory map.....	757
37.3.2	Register descriptions.....	758
37.3.3	Status and Control (FTM _x _SC).....	761
37.3.4	Counter High (FTM _x _CNTH).....	762
37.3.5	Counter Low (FTM _x _CNTL).....	763
37.3.6	Modulo High (FTM _x _MODH).....	764
37.3.7	Modulo Low (FTM _x _MODL).....	764
37.3.8	Channel Status and Control (FTM _x _CnSC).....	765
37.3.9	Channel Value High (FTM _x _CnVH).....	768
37.3.10	Channel Value Low (FTM _x _CnVL).....	769
37.3.11	Counter Initial Value High (FTM _x _CNTINH).....	769
37.3.12	Counter Initial Value Low (FTM _x _CNTINL).....	770
37.3.13	Capture and Compare Status (FTM _x _STATUS).....	771
37.3.14	Features Mode Selection (FTM _x _MODE).....	772
37.3.15	Synchronization (FTM _x _SYNC).....	774
37.3.16	Initial State for Channel Output (FTM _x _OUTINIT).....	776
37.3.17	Output Mask (FTM _x _OUTMASK).....	777
37.3.18	Function for Linked Channels (FTM _x _COMBINE _n).....	779
37.3.19	Deadtime Insertion Control (FTM _x _DEADTIME).....	780
37.3.20	External Trigger (FTM _x _EXTTRIG).....	781
37.3.21	Channels Polarity (FTM _x _POL).....	782
37.3.22	Fault Mode Status (FTM _x _FMS).....	784
37.3.23	Input Capture Filter Control (FTM _x _FILTER _n).....	786
37.3.24	Fault Input Filter Control (FTM _x _FLTFILTER).....	787

Section number	Title	Page
37.3.25	Fault Input Control (FTM _x _FLTCTRL).....	787
37.3.26	Quadrature Decoder Control and Status (FTM _x _QDCTRL).....	789
37.4	Functional Description.....	790
37.4.1	Clock Source.....	791
37.4.1.1	Counter Clock Source.....	791
37.4.2	Prescaler.....	792
37.4.3	Counter.....	792
37.4.3.1	Up counting.....	792
37.4.3.2	Up-down counting.....	795
37.4.3.3	Free running counter.....	796
37.4.3.4	Counter reset.....	797
37.4.4	Input capture mode.....	797
37.4.4.1	Filter for input capture mode.....	798
37.4.5	Output compare mode.....	799
37.4.6	Edge-aligned PWM (EPWM) mode.....	801
37.4.7	Center-aligned PWM (CPWM) mode.....	803
37.4.8	Combine mode.....	805
37.4.8.1	Asymmetrical PWM.....	812
37.4.9	Complementary mode.....	812
37.4.10	Update of the registers with write buffers.....	813
37.4.10.1	CNTINH:L registers.....	813
37.4.10.2	MODH:L registers.....	813
37.4.10.3	CnVH:L registers.....	814
37.4.11	PWM synchronization.....	815
37.4.11.1	Hardware trigger.....	815
37.4.11.2	Software trigger.....	816
37.4.11.3	Boundary cycle.....	817
37.4.11.4	MODH:L registers synchronization.....	818
37.4.11.5	CnVH:L registers synchronization.....	820

Section number	Title	Page
37.4.11.6	OUTMASK register synchronization.....	820
37.4.11.7	FTM counter synchronization.....	822
37.4.11.8	Summary of PWM synchronization.....	824
37.4.12	Deadtime insertion.....	826
37.4.12.1	Deadtime insertion corner cases.....	827
37.4.13	Output mask.....	829
37.4.14	Fault control.....	830
37.4.14.1	Automatic fault clearing.....	832
37.4.14.2	Manual fault clearing.....	833
37.4.15	Polarity control.....	833
37.4.16	Initialization.....	834
37.4.17	Features priority.....	834
37.4.18	Channel trigger output.....	834
37.4.19	Initialization trigger.....	835
37.4.20	Capture test mode.....	837
37.4.21	DMA.....	838
37.4.22	Dual edge capture mode.....	839
37.4.22.1	One-shot capture mode.....	840
37.4.22.2	Continuous capture mode.....	841
37.4.22.3	Pulse width measurement.....	841
37.4.22.4	Period measurement.....	843
37.4.22.5	Read coherency mechanism.....	845
37.4.23	Quadrature Decoder Mode.....	847
37.4.23.1	Quadrature Decoder Boundary Conditions.....	850
37.4.24	TPM emulation.....	851
37.4.24.1	MODH:L and CnVH:L synchronization.....	851
37.4.24.2	Free running counter.....	851
37.4.24.3	Write to SC.....	852
37.4.24.4	Write to CnSC.....	852

Section number	Title	Page
37.4.25	BDM mode.....	852
37.5	Reset overview.....	853
37.6	FTM Interrupts.....	855
37.6.1	Timer overflow interrupt.....	855
37.6.2	Channel (n) interrupt.....	855
37.6.3	Fault interrupt.....	855

Chapter 38 Serial Peripheral Interface (SPI)

38.1	Introduction.....	857
38.1.1	Features.....	857
38.1.2	Modes of Operation.....	858
38.1.3	Block Diagrams.....	859
38.1.3.1	SPI System Block Diagram.....	859
38.1.3.2	SPI Module Block Diagram.....	860
38.2	External Signal Description.....	862
38.2.1	SPSCK — SPI Serial Clock.....	863
38.2.2	MOSI — Master Data Out, Slave Data In.....	863
38.2.3	MISO — Master Data In, Slave Data Out.....	863
38.2.4	SS — Slave Select.....	863
38.3	Memory Map and Register Descriptions.....	864
38.3.1	SPI control register 1 (SPIx_C1).....	865
38.3.2	SPI control register 2 (SPIx_C2).....	866
38.3.3	SPI baud rate register (SPIx_BR).....	868
38.3.4	SPI status register (SPIx_S).....	869
38.3.5	SPI data register high (SPIx_DH).....	872
38.3.6	SPI data register low (SPIx_DL).....	873
38.3.7	SPI match register high (SPIx_MH).....	874
38.3.8	SPI match register low (SPIx_ML).....	874
38.3.9	SPI control register 3 (SPIx_C3).....	875

Section number	Title	Page
38.3.10	SPI clear interrupt register (SPIx_CI).....	876
38.4	Functional Description.....	878
38.4.1	General.....	878
38.4.2	Master Mode.....	878
38.4.3	Slave Mode.....	880
38.4.4	SPI FIFO Mode.....	881
38.4.5	SPI Transmission by DMA.....	882
38.4.5.1	Transmit by DMA.....	882
38.4.5.2	Receive by DMA.....	884
38.4.6	Data Transmission Length.....	885
38.4.7	SPI Clock Formats.....	885
38.4.8	SPI Baud Rate Generation.....	889
38.4.9	Special Features.....	889
38.4.9.1	SS Output.....	889
38.4.9.2	Bidirectional Mode (MOMI or SISO).....	890
38.4.10	Error Conditions.....	891
38.4.10.1	Mode Fault Error.....	891
38.4.11	Low Power Mode Options.....	892
38.4.11.1	SPI in Run Mode.....	892
38.4.11.2	SPI in Wait Mode.....	892
38.4.11.3	SPI in Stop Mode.....	893
38.4.12	Reset.....	893
38.4.13	Interrupts.....	894
38.4.13.1	MODF.....	894
38.4.13.2	SPRF.....	894
38.4.13.3	SPTEF.....	895
38.4.13.4	SPMF.....	895
38.4.13.5	TNEAREF	895
38.4.13.6	RNFULLF	895

Section number	Title	Page
38.5	Initialization/Application Information.....	896
38.5.1	Initialization Sequence.....	896
38.5.2	Pseudo-Code Example.....	896

Chapter 39 Inter-Integrated Circuit (I2C)

39.1	Introduction.....	901
39.1.1	Features.....	901
39.1.2	Modes of operation.....	902
39.1.3	Block diagram.....	902
39.2	I2C signal descriptions.....	903
39.3	Memory map and register descriptions.....	903
39.3.1	I2C Address Register 1 (I2Cx_A1).....	905
39.3.2	I2C Frequency Divider register (I2Cx_F).....	906
39.3.3	I2C Control Register 1 (I2Cx_C1).....	907
39.3.4	I2C Status register (I2Cx_S).....	908
39.3.5	I2C Data I/O register (I2Cx_D).....	910
39.3.6	I2C Control Register 2 (I2Cx_C2).....	911
39.3.7	I2C Programmable Input Glitch Filter register (I2Cx_FLT).....	912
39.3.8	I2C Range Address register (I2Cx_RA).....	912
39.3.9	I2C SMBus Control and Status register (I2Cx_SMB).....	913
39.3.10	I2C Address Register 2 (I2Cx_A2).....	914
39.3.11	I2C SCL Low Timeout Register High (I2Cx_SLTH).....	915
39.3.12	I2C SCL Low Timeout Register Low (I2Cx_SLTL).....	915
39.4	Functional description.....	915
39.4.1	I2C protocol.....	915
39.4.1.1	START signal.....	916
39.4.1.2	Slave address transmission.....	917
39.4.1.3	Data transfers.....	917
39.4.1.4	STOP signal.....	918

Section number	Title	Page
39.4.1.5	Repeated START signal.....	918
39.4.1.6	Arbitration procedure.....	918
39.4.1.7	Clock synchronization.....	918
39.4.1.8	Handshaking.....	919
39.4.1.9	Clock stretching.....	919
39.4.1.10	I2C divider and hold values.....	920
39.4.2	10-bit address.....	921
39.4.2.1	Master-transmitter addresses a slave-receiver.....	921
39.4.2.2	Master-receiver addresses a slave-transmitter.....	922
39.4.3	Address matching.....	922
39.4.4	System management bus specification.....	923
39.4.4.1	Timeouts.....	923
39.4.4.2	FAST ACK and NACK.....	925
39.4.5	Resets.....	926
39.4.6	Interrupts.....	926
39.4.6.1	Byte transfer interrupt.....	926
39.4.6.2	Address detect interrupt.....	927
39.4.6.3	Exit from low-power/stop modes.....	927
39.4.6.4	Arbitration lost interrupt.....	927
39.4.6.5	Timeout interrupt in SMBus.....	928
39.4.7	Programmable input glitch filter.....	928
39.4.8	Address matching wakeup.....	928
39.4.9	DMA support.....	929
39.5	Initialization/application information.....	929

Chapter 40 Universal Asynchronous Receiver/Transmitter (UART)

40.1	Introduction.....	933
40.1.1	Features.....	933

Section number	Title	Page
40.1.2	Modes of operation.....	935
40.1.2.1	Run mode.....	935

44.6.1	General Control and Status Register (TSLx_GENCS).....	1056
44.6.2	SCAN control register (TSLx_SCANC).....	1059
44.6.3	Pin enable register (TSLx_PEN).....	1062
44.6.4	Status Register (TSLx_STATUS).....	1065
44.6.5	Counter Register (TSLx_CNTR n).....	1068
44.6.6	Channel n threshold register (TSLx_THRESHL Dn).....	1068
44.7	Functional descriptions.....	1069
44.7.1	Capacitance measurement.....	1069
44.7.1.1	TSI electrode oscillator.....	1069
44.7.1.2	Electrode oscillator and counter control.....	1070
44.7.1.3	TSI reference oscillator.....	1071
44.7.2	TSI measurement result.....	1072
44.7.3	Electrode scan unit.....	1072
44.7.3.1	Active electrodes.....	1073
44.7.3.2	Scan trigger.....	1073
44.7.3.3	Software trigger mode.....	1074
44.7.3.4	Periodic scan control.....	1074
44.7.4	Touch detection unit.....	1076
44.7.4.1	Capacitance change threshold.....	1076
44.7.4.2	Error interrupt.....	1077
44.8	Application information.....	1077
44.8.1	TSI module sensitivity.....	1077

Chapter 45

External Interrupt (IRQ)

45.1	Introduction.....	1079
45.1.1	Features.....	1079
45.1.2	Modes of Operation.....	1079
45.1.3	Block Diagram.....	1080

Section number	Title	Page
45.2	Signal Description.....	1080
45.2.1	Detailed Signal Descriptions.....	1080
45.3	Memory Map and Register Description.....	1081
45.3.1	Interrupt status and control register (IRQ_SC).....	1081
45.4	Functional Description.....	1082
45.4.1	External Interrupt Pin.....	1082
45.4.2	IRQ Edge Select.....	1082
45.4.3	IRQ Sensitivity.....	1083
45.4.4	IRQ Interrupts.....	1083
45.4.5	Clearing an IRQ Interrupt Request.....	1083
45.4.6	Exit from Low-Power Modes.....	1084
45.4.6.1	Wait.....	1084
45.4.6.2	Stop modes.....	1084
45.5	Resets.....	1084
45.6	Interrupts.....	1084

Chapter 46 Debug

46.1	Introduction.....	1087
46.1.1	Overview.....	1088
46.1.2	Features.....	1089
46.1.3	Modes of Operation.....	1090
46.2	External Signal Descriptions.....	1092
46.3	Memory Map and Register Descriptions.....	1093
46.3.1	Configuration/Status Register (CSR).....	1095
46.3.2	Extended Configuration/Status Register (XCSR).....	1098
46.3.3	Configuration/Status Register 2 (CSR2).....	1101
46.3.4	Configuration/Status Register 3 (CSR3).....	1105
46.3.5	Debug Control Register (DBGCR) and Debug Status Register (DBGSR).....	1106
46.3.6	BDM Address Attribute Register (BAAR).....	1108

Section number	Title	Page
46.3.7	Address Attribute Trigger Register (AATR).....	1109
46.3.8	Trigger Definition Register (TDR).....	1111
46.3.9	Program Counter Breakpoint/Mask Registers (PBR0–3, PBMR).....	1115
46.3.10	Address Breakpoint Registers (ABLR, ABHR).....	1117
46.3.11	Data Breakpoint and Mask Registers (DBR, DBMR).....	1118
46.3.12	Resulting Set of Possible Trigger Combinations.....	1120
46.3.13	PST Buffer (PSTB).....	1120
46.4	Functional Description.....	1122
46.4.1	Background Debug Mode (BDM).....	1122
46.4.1.1	CPU Halt.....	1123
46.4.1.2	Background Debug Serial Interface Controller (BDC).....	1125
46.4.1.3	BDM Communication Details.....	1126
46.4.1.4	BDM Command Set Descriptions.....	1129
46.4.1.5	BDM Command Set Summary.....	1131
46.4.1.6	Serial Interface Hardware Handshake Protocol.....	1148
46.4.1.7	Hardware Handshake Abort Procedure.....	1151
46.4.2	Real-Time Debug Support.....	1154
46.4.3	Trace Support	1154
46.4.3.1	Begin Execution of Taken Branch (PST = 0x05).....	1157
46.4.3.2	PST Trace Buffer (PSTB) Entry Format.....	1158
46.4.3.3	PST/DDATA Example.....	1159
46.4.3.4	Processor Status, Debug Data Definition.....	1160
46.4.4	Freescale-Recommended BDM Pinout.....	1166

Chapter 1

About This Document

1.1 Overview

1.1.1 Purpose

This document describes the features, architecture, and programming model of Freescale's MCF51QU32, MCF51QU64, and MCF51QU128 microcontrollers.

1.1.2 Audience

This document is primarily for system architects and software application developers who are using or considering using these microcontrollers in a system.

1.2 Conventions

1.2.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix <i>0b</i> .
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix <i>0x</i> .

1.2.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
<i>placeholder, x</i>	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
code	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: <ul style="list-style-type: none"> • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.2.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: <ul style="list-style-type: none"> • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: <ul style="list-style-type: none"> • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). <p>In some cases, deasserted signals are described as <i>negated</i>.</p>
reserved	Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

1.2.4 Register reset

Information provided about every register includes each bit's value upon a reset event. The documented devices support multiple types of reset. The specific reset type that effects particular reset values can vary by module, by register within a module's programming model, and even by bit within a register.

For details about the reset type(s) affecting a module's registers, refer to the module's [Chip Configuration](#) information and register descriptions. When a register's details specify a reset type, in some cases other reset types do not affect the register.

For information about the various reset types, refer to the [Reset](#) details.

When a register's description does not specify a reset type, the reset type is Chip Reset (including Early Chip Reset).

Chapter 2

Introduction

2.1 ColdFire+ Portfolio Introduction

Freescale's ColdFire+ 32-bit microcontrollers are built on the Version 1 (V1) ColdFire® core and enabled by innovative 90 nm thin film storage (TFS) flash process technology with FlexMemory. The ColdFire+ portfolio consists of six families featuring ultra-low power capabilities in small footprint solutions with embedded flash memory that scales from 32 KB to 128 KB. The families offer a rich combination of additive peripherals including USB, high performance mixed signal capabilities, hardware encryption, an innovative touch sensing interface (TSI), and more. These key features make ColdFire+ microcontrollers ideal for portable handheld devices, wireless nodes, peripherals that require device authentication, building control security pads, and advanced remote control devices.

The feature superset of all six pin- and software-compatible families includes:

- Innovative FlexMemory enabling up to 2 KB of enhanced EEPROM or additional 32 KB of flash
- 10 flexible low power modes, ideal for extending battery life
- 16-bit or 12-bit ADC and 12-bit DAC to provide flexible and powerful mixed signal capabilities
- Cryptographic Acceleration Unit (CAU) and Random Number Generator (RNG) for secure communications
- Integrated capacitive touch sensing support: low power touch sensing interface (TSI)
- Integrated USB 2.0 Full-Speed Device/Host/OTG Controller supporting connection via USB and battery charging
- Synchronous audio interface (SAI) providing a direct interface to codecs and to Inter-IC Sound (I2S) audio devices
- Wide operating voltage range from 1.71 V to 3.6 V with flash programmability and full analog functionality over entire range
- Various timers that support general purpose, PWM, and motor control functions
- GPIO with pin interrupt functionality

MCF51QU128 Block Diagram

- Small footprint packages designed for space-constrained applications
- Rich suite of complimentary runtime software including Freescale's MQX RTOS, a full set of USB class drivers, a cryptographic library, a motor control library, and much more

The ColdFire+ device families are the MCF51QU, MCF51QM, MCF51JU, and MCF51JF.

V1 ColdFire+ MCU Families

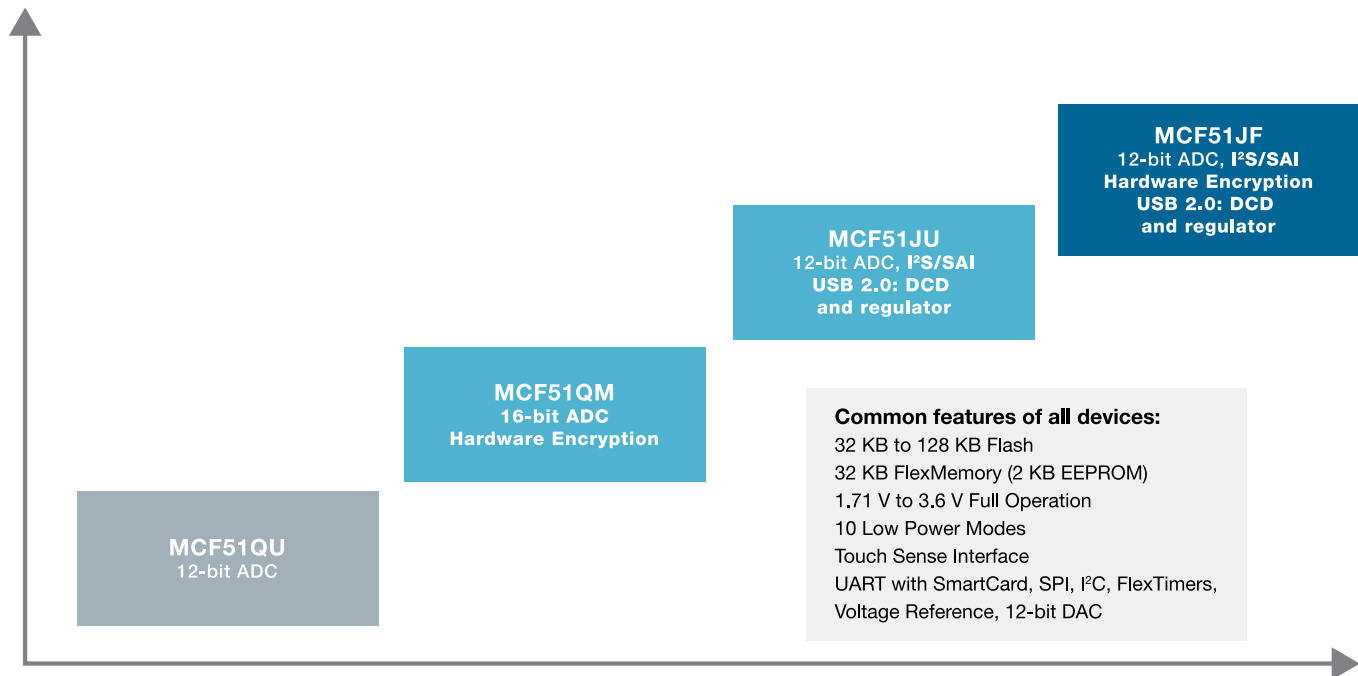

Figure 2-1. ColdFire+ Portfolio

2.2 MCF51QU128 Block Diagram

The block diagram shows the feature categories of all ColdFire+ device families. Within each category, the diagram shows the superset of modules and number of module instances on the 64-pin members of the MCF51QU family.

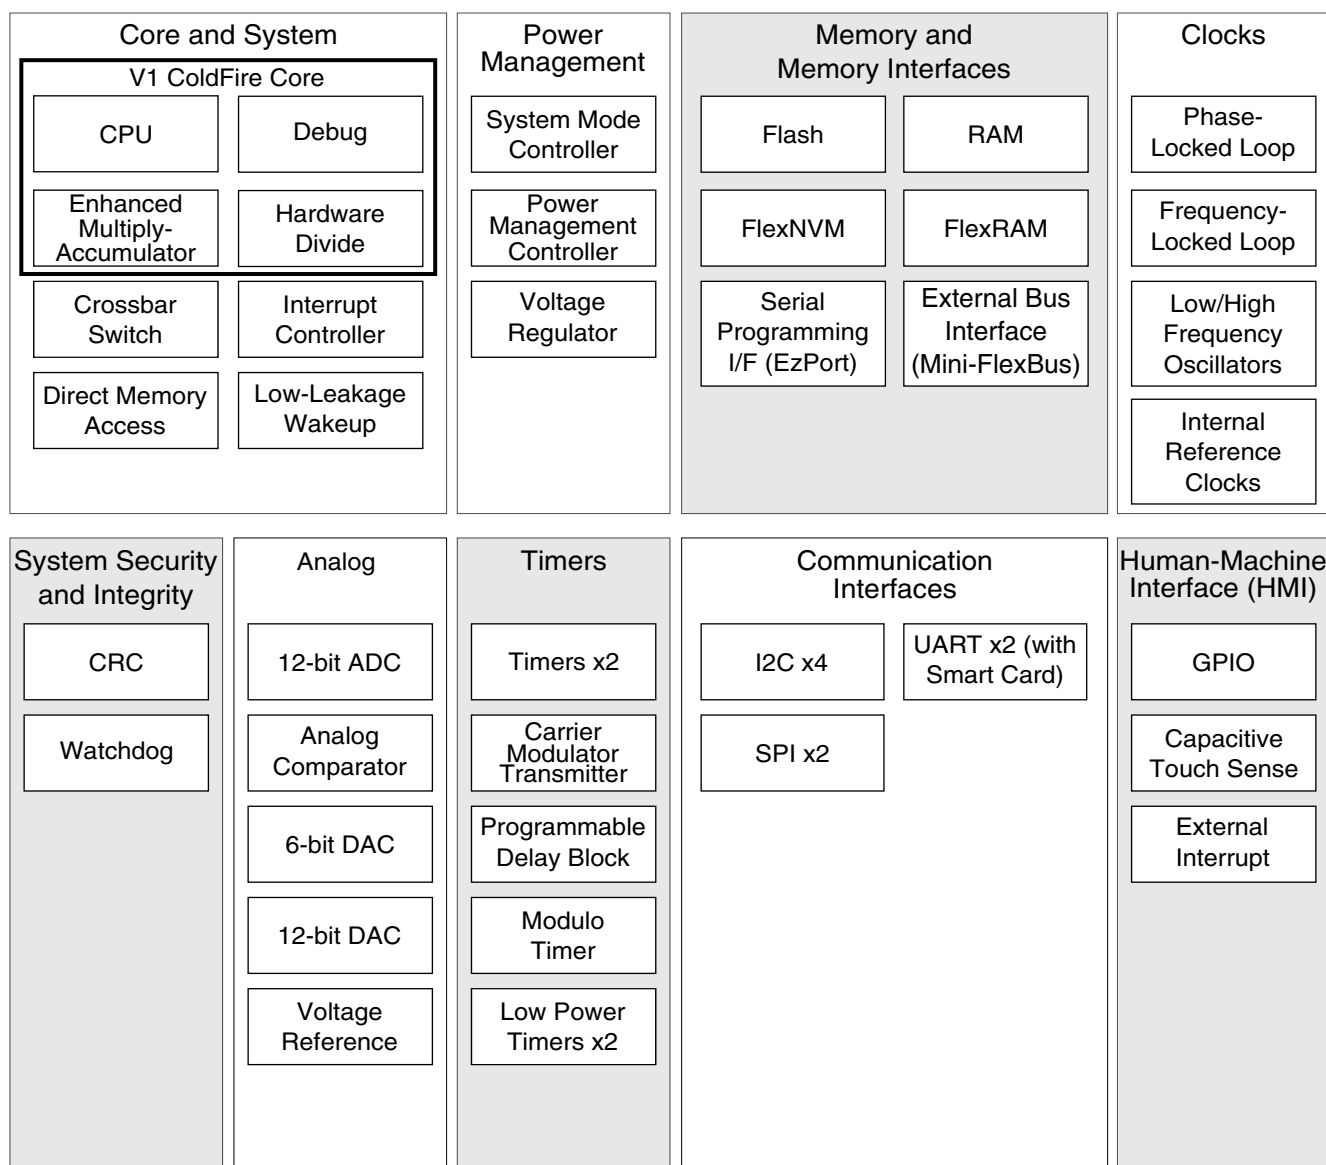

Figure 2-2. MCF51QU128 (64-pin) Block Diagram

2.3 MCF51QU Feature Summary

The following table summarizes the features integrated on all MCF51QU devices. For MCF51QU device features that vary by package, refer to [MCF51QU Features by Package](#).

Table 2-1. Feature Summary

Feature	Details
Hardware Characteristics	
Voltage range	1.71 V to 3.6 V

Table continues on the next page...

Table 2-1. Feature Summary (continued)

Feature	Details
Flash write voltage	Down to 1.71 V
Packages	32-pin QFN (5 x 5 mm ²) 44-pin Laminate QFN (5 x 5 mm ²) 48-pin LQFP (7 x 7 mm ²) 64-pin LQFP (10 x 10 mm ²)
Temperature range, ambient (T _A)	-40°C to 105°C (V temperature)
Temperature range, junction (T _J)	-40°C to 115°C
Core and System	
Central processing unit (CPU)	High-performance Version 1 (V1) ColdFire core with EMAC and DIV hardware acceleration Implements instruction set revision C (ISA_C)
Maximum CPU frequency	50 MHz
Dhrystone 2.1 performance	1.10 DMIPS per MHz performance when executing from internal RAM 0.99 DMIPS per MHz when executing from flash
Interrupt controller (INTC)	Supports 7 priority levels and software interrupt acknowledges
Direct memory access (DMA) controller	Four independently programmable channels provide the means to transfer data directly between system memory and I/O peripherals
Low-leakage wakeup unit (LLWU)	16 external wakeup pins with digital glitch filter 4 internal wakeup sources RESET pin can be treated as reset wakeup in low leakage (LLS and VLLS) modes
Debug	Integrated ColdFire DEBUG_Rev_B+ interface with single wire BDM Real-time debug support, with six hardware breakpoints that can be configured to halt the processor or generate debug interrupt Capture of compressed processor status and debug data into trace buffer On-chip trace buffer that provides programmable start/stop recording conditions
Power Management	
Power management controller (PMC)	Various stop, wait, and run modes to enable low power applications: <ul style="list-style-type: none"> • Run and stop regulation modes to enable low power MCU operation • Several low power and low leakage stop modes Peripheral clock enable register can disable clocks to unused modules, further reducing current consumption Low voltage warning and detect with selectable trip points
3.3 V voltage regulator (VREG)	5 V input, 3.3 V output, up to 120 mA
Memory and Memory Interfaces	
Total flash memory	Up to 160 KB (128 KB + 32 KB)
Program flash	Up to 128 KB
FlexNVM	Up to 32 KB
FlexRAM	Up to 2 KB
RAM	Up to 32 KB

Table continues on the next page...

Table 2-1. Feature Summary (continued)

Feature	Details
Total random access memory (RAM)	Up to 34 KB (32 KB + 2 KB)
FlexMemory (FlexNVM plus FlexRAM) configuration examples ¹	Example 1: 32 KB additional program flash, no data flash or EEPROM, 2 KB additional RAM Example 2: 32 KB data flash memory, 2 KB additional RAM Example 3: Up to 2 KB high-endurance, nonvolatile, enhanced EEPROM Example 4: Partial data flash and EEPROM
Low-leakage standby memory	Full RAM in LLS and VLLS3 power modes, 1 KB RAM or 8KB RAM in VLLS2 mode 32-byte register file in all power modes, including VLLS1 mode
External bus interface (Mini-FlexBus)	Supports glueless connections to external memories and peripherals Up to 20 address and 8 data lines (non-muxed mode) Up to 20 address lines and 16 data lines (muxed mode) 2 chip selects
Serial programming interface (EzPort)	Supports flash in-system programming
Clocks	
External crystal oscillator or resonator	Low range, low power, or full-swing: 32 kHz to 40 kHz Medium range, low power, or full-swing: 1 MHz to 8 MHz High range, low power, or full-swing: 8 MHz to 32 MHz
External clock	DC to 50 MHz
Internal clock references	Two internal trimmable reference clocks <ul style="list-style-type: none"> • 32 kHz • 2 MHz Internal 1 kHz low power oscillator
Phase-locked loop (PLL)	Up to 100 MHz VCO
Frequency-locked loop (FLL)	1
System Security and Integrity	
Cyclic redundancy check (CRC) module	User configurable 16/32-bit hardware CRC generator circuit with programmable generator polynomial Supports checksumming of any memory image
COP watchdog module	1
Memory	Flash security features and block protection
Unique chip identification (ID) number	128 bits wide
Analog	
Analog-to-digital converter (ADC): 12-bit	1 successive approximation (SAR) ADC Up to 19 single-ended channels
12-bit digital-to-analog converter (DAC)	1
High-speed comparator (CMP)	1 with 6-bit DAC
Programmable voltage reference (VREF)	1
Timers	
Programmable delay block (PDB)	1 ADC channel (with 2 triggers), 1 DAC channel, and 1 pulse-out to CMP

Table continues on the next page...

Table 2-1. Feature Summary (continued)

Feature	Details
16-bit flexible timer (FTM0)	Up to 2 channels, with quadrature decoder
16-bit flexible timer (FTM1)	6 channels
16-bit modulo timer (MTIM)	1
Carrier modulator transmitter (CMT)	1
Low-power timers (LPTMR0 and LPTMR1)	Support Time of Day function with an external 32.768 kHz low power crystal oscillator 1-channel, 16-bit pulse counter or periodic interrupt
Communication Interfaces	
16-bit serial peripheral interface (SPI0)	1 with independent 8-byte transmit and receive FIFOs
16-bit serial peripheral interface (SPI1)	1 (without FIFO)
Inter-Integrated Circuit (I ² C)	Up to 4
Universal asynchronous receivers/transmitters (UART0 and UART1)	Serial communications interface (SCI) Support for ISO 7816 protocol for interfacing with smart cards Hardware flow control Higher baud rates (CPU clock) Independent data FIFO for transmit and receive
Human-Machine Interface (HMI)	
Rapid general-purpose input/output (RGPIO) ²	Up to 16 bits of high-speed GPIO functionality connected to the processor's local 32-bit bus with faster set, clear, and toggle functionality
Enhanced general-purpose input/output (EGPIO)	Up to 48 Pin interrupt / DMA request capability Up to 16 EGPIOs (PORTB and PORTC) with digital glitch filter Hysteresis and configurable pullup/pulldown device on all input pins Configurable slew rate and drive strength on all output pins
Touch sensing inputs (TSI)	Up to 16
Interrupt Request Pin (IRQ)	Rising or falling edge selection Level sensitivity option Configurable internal pullup/pulldown Defined as a nonmaskable interrupt request

1. FlexNVM can be used as program flash, as data flash, or, in conjunction with FlexRAM, as high-endurance EEPROM or a combination of data flash and EEPROM.
2. Shared with EGPIO pins

2.4 MCF51QU Features by Package

The following summary identifies aspects of MCF51QU features that vary by package.

Table 2-2. Feature Summary by Package

Part number	MCF51QU32VFM	MCF51QU32VHS	MCF51QU64VLF	MCF51QU64VHS	MCF51QU128VHS	MCF51QU128VLH
Package type and number of pins	32-pin QFN	44-pin QFN ¹	48-pin LQFP	44-pin QFN ¹		64-pin LQFP
Package dimensions (mm x mm)	5x5	5x5	7x7	5x5		10x10
Core Processor						
V1 ColdFire core with EMAC and DIV	Yes					
Maximum CPU frequency (MHz)	50					
Memory and Memory Interfaces						
Total flash memory (KB)	Up to 48		Up to 96		Up to 160	
Flash (KB)	32		64		128	
FlexNVM (KB)	16		32			
FlexRAM (KB)	Up to 1		Up to 2			
RAM (KB)	8		16		32	
External bus interface (Mini-FlexBus)	None	8 data / 2 CS				20 address / 8 data / 2 CS
Serial programming interface (EzPort)	Yes					
Clocks						
Multipurpose clock generator (MCG)	FLL + PLL + internal oscillator (32 kHz or 2 MHz)					
System Security and Integrity						
Cyclic redundancy check (CRC)	1					
COP watchdog module	1					
Analog						
12-bit ADC single ended	8 ch	11 ch	13 ch	11 ch		19 ch
12-bit DAC	1					
CMP (with 6-bit DAC) external inputs	1	2				4
VREF	No	Yes				
Timers						
FlexTimer (FTM0 with quad decoder) channel pins ²	None	1 ch				2 ch
FlexTimer (FTM1) channel pins	6 ch

Pin interrupts	22	31	35	31		48
RGPIO	5	8	10	8		16

1. Laminate QFN

2. When an FTM channel pin is not present in a package, the channel's internal functionality remains available. In packages where FTM0 channel 0 is not available, the comparator can be used to connect an external input to FTM channel 0.

3. GPIO numbers include RGPIO

Chapter 3

Chip Configuration

3.1 Introduction

This chip configuration information consists of details about the individual modules that are specific to the chip. The information includes:

- module block diagrams showing immediate connections within the device,
- specific module-to-module interactions not necessarily discussed in the individual module chapters, and
- links for more information.

NOTE

For clock gating information that applies to modules generally, refer to [Clock gating](#). Any additional clock gating info that is specific to a module appears in the module's dedicated chip configuration details.

3.2 Module to Module Interaction Summary

This device contains internal connections between peripherals to support a number of different target applications. The following table summarizes these connections.

Table 3-1. Module to Module Interactions Summary

Use Case	Function	Peripherals	Description	Control
Motor control	Speed detection / tachometer pulse counting	CMP, FTM0, LPTMR1, LPTMR0	FTM input capture or an LPTMR input is connected to CMP_OUT.	The ACFTM bit in the SIM's SOPT7 register enables CMP_OUT to the FTM0 channel 0 input. The LPTMR's CSR[TPS] bits can be set to 00 to select the CMP_OUT.
	FTM synchronization	CMP, FTM0, FTM1, FTMxSYNC bits	The CMP_OUT signal can be used to synchronize the count of FTM0 and FTM1.	Make the selection with the CHxTRIG bits in the FTMs' EXTTRIG register.
	Programmable fault detection	CMP, FTM0, FTM1	The CMP_OUT signal is connected to the FTM0 and FTM1 fault inputs.	Make the selection with the FAULTxEN bits in the FTMs' FLTCTRL register.
Analog / signal analysis	Low power adjustable pulse counting	CMP, LPTMR1, FTM0	CMP_OUT is connected to the LPTMR1 input for pulse counting or to FTM0 channel 0 for pulse width measurement.	The ACFTM bit in the SIM's SOPT7 register enables CMP_OUT to the FTM0 channel 0 input. The LPTMR's CSR[TPS] bits can be set to 00 to select the CMP_OUT.
	Low power ADC conversion	LPTMR0, ADC	An LPTMR overflow generates an ADC conversion trigger.	The ADTRGS bit in the SIM's SOPT7 register selects ADC trigger source. Then the LPTMR should generate a trigger for the ADC's SC1A register only.
	PDB triggering of DAC	DAC, PDB	A PDB interval trigger is used to generate DAC triggers.	Set up using the PDB.
	PDB triggering of ADC conversion triggering	PDB with LPTMR0, LPTMR1, CMP, PDB EXTRG, FTM0, FTM1, MTIM	Using the PDB, various modules can be used to initiate an ADC conversion.	Combine PDB configuration and initialization of the desired peripheral.
	Internal voltage reference signals	DAC, VREF, ADC, CMP	DAC and VREF outputs are available as ADC channels and CMP inputs.	DAC and VREF outputs must be enabled: use the ADC's SC1n register to select the DAC or VREF. The CMP can also be used to select the DAC or VREF.
	Accurate reference for analog peripherals	VREF, ADC, DAC	The VREF output is connected to the ADC reference or DAC reference.	The VREF is enabled by VREF control registers. The ADC or DAC chooses VREF as the reference (REFSEL bits in the ADC's SC2 register).
Communications	UART optical isolation	UART1, FTMx, MTIM, CMP	The UART1_Rx input can be connected to CMP_OUT, and the TX output can be modulated with the output of one of the timers (FTM0, FTM1, MTIM) before being transmitted off chip.	Configure the CMP so its external input pin is used as the source of the RX signal with the SIM's SOPT6[RX1IN] bit. The FTMx or MTIM modulation is selected by the MTBASE[0:1] bits. The MODTX1 bit enables the UART modulation.
	I ² C dual role functionality (separate slave and master control and interrupts)	(I ² C0 and I ² C1) and (I ² C2 and I ² C3)	I ² C0 and I ² C1 or I ² C2 and I ² C3 are connected to allow separate status/control and interrupts for I ² C.	Use the I2CDR0 or I2CDR2 bit in the SIM's SOPT7 register to connect I ² C0 and I ² C1 or I ² C2 and I ² C3, respectively.

3.3 Core modules

3.3.1 Version 1 (V1) ColdFire Core Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

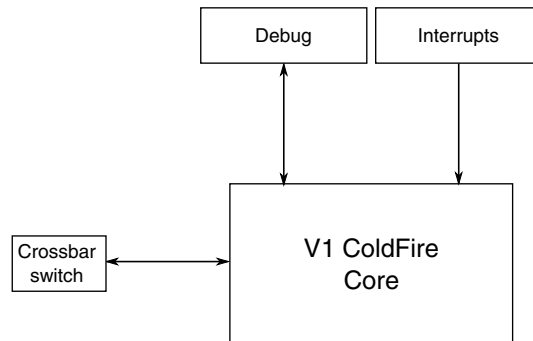

Figure 3-1. Core configuration

Table continues on the next page...

Table 3-10. Exception vector assignments (continued)

Address offset	Vector number	Level (Priority) ¹	Assignment
0x1CC-0x3FC	115-255	-	RESERVED - Unused for ColdFire core devices

1. In the format x(y): x is the interrupt level and y is the priority within the level.
2. Upon exiting LLS mode, core instruction execution goes directly to the low leakage wakeup interrupt. For wakeup from VLLSx modes:
 - One or two pending interrupts are serviced. One is serviced if the wakeup is from the LLWU wakeup pins, or two are serviced if the wakeup is from a TSI, CMP, or LPTMR module.
 - Then instruction execution resumes via the reset vectors.
3. All of the UART0 interrupt sources are joined in this single vector.
4. All of the UART1 interrupt sources are joined in this single vector.

Table 3-11. ColdFire Level, Priority within Level Matrix Interrupt Assignments

Priority	Level	Priority within Level ¹								
		7	6	5	4	Midpoint	3	2	1	0
Highest	7					IRQ	LVD	Low Leakage Wakeup	MCG Loss of Clock	Level 7 SWI
	6	INTC_PL 6P7	INTC_PL 6P6	Flash	DMA Channel 0	x	DMA Channel 1	DMA Channel 2	DMA Channel 3	Level 6 SWI
	5	Reserved	Reserved	FTM1 Fault + Overflow	FTM1 Channel 0	x	FTM1 Channel 1	FTM1 Channel 2	FTM1 Channel 3	Level 5 SWI
	4	FTM1 Channel 4	FTM1 Channel 5	CMP	FTM0 Fault + Overflow	x	FTM0 Channel 0	FTM0 Channel 1	SPI0	Level 4 SWI
	3	UART0	Reserved	Reserved	I ² C0	x	I ² C2	SPI1	UART1	Level 3 SWI
	2	I ² C1	I ² C3	ADC	TSI	x	DAC	CMT	PDB	Level 2 SWI
Lowest	1	LPTMR0	LPTMR1	MTIM	Reserved	x	PORT A PORT B	PORT D PORT C	PORT F PORT E	Level 1 SWI

1. Within a level, priorities are evaluated numerically: that is, the higher the number, the higher the priority.

3.4.5 Low-Leakage Wakeup Unit (LLWU) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

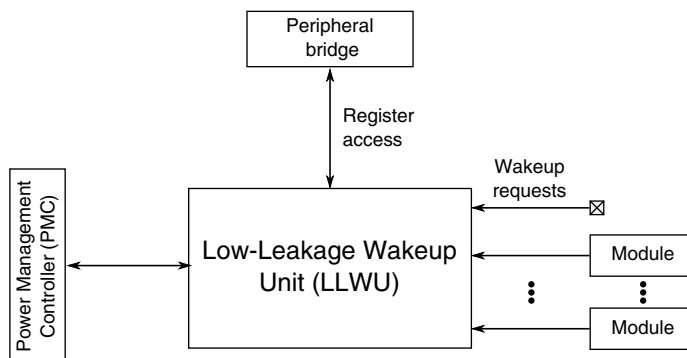

Figure 3-7. Low-Leakage Wakeup Unit configuration

Power management		Power management
	Power Management Controller (PMC)	PMC configuration
Wakeup requests		LLWU wakeup sources

3.4.5.1 LLWU wakeup sources

The LLWU module has the following internal and external inputs. WUP0-WUP15 are external pin inputs, and module interrupt flags (M0IF-M3IF) are internal peripheral connections.

NOTE

The $\overline{\text{RESET}}$ pin is also a wakeup source when the LLWU's RST[LLRSTE] bit is 1 and the pin is enabled as $\overline{\text{RESET}}$ or GPIO via port mux control.

NOTE

The signal selected as a wakeup source pin must be a digital pin, as selected in the Port Mux Control registers.

Table 3-13. LLWU Inputs

Wakeup Pin	Source	Wakeup Pin	Source
LLWU_P0	PTC7/UART0_RX/I2C0_SDA/RGPIO7/ SPI1_MISO/FBa_AD12	LLWU_P10	PTF2/SPI0_MISO/FBa_AD7
LLWU_P1	PTD1/UART0_RTS/I2C1_SCL/RGPIO9/ SPI1_SS/FBa_AD14	LLWU_P11	PTF3/SPI0_MOSI/RGPIO1/FBa_AD8
LLWU_P2	PTA5/UART1_RTS/I2C2_SDA/ FTM1_CH5/SPI1_MOSI/CLKOUT	LLWU_P12	PTC2/UART1_RTS/SPI1_SS/RGPIO2/ FBa_AD18
LLWU_P3	PTA7/UART0_TX/FTM0_QD_PHA/ FBa_D5	LLWU_P13	PTF5/UART1_RX/SPI1_MISO/FBa_D2/ FBa_RW
LLWU_P4	PTD7/UART0_CTS/I2C3_SCL/RGPIO15/ FBa_D3	LLWU_P14	PTC3/UART0_CTS/RGPIO3/SPI0_SCLK/ CLKOUT
LLWU_P5	PTB0/I2C0_SCL/IRQ	LLWU_P15	PTC4/UART0_RX/RGPIO4/SPI0_MISO/ PDB0_EXTRG
LLWU_P6	PTB1/SPI0_SCLK/I2C0_SDA/FTM_FLT2/ LPTMR_ALT2/FTM0_QD_PHB/ FB_CLKOUT	LLWU_M0IF	LPTMR0 ¹
LLWU_P7	PTB2/SPI0_MISO/FBa_CS0	LLWU_M1IF	LPTMR1 ¹
LLWU_P8	PTE7/UART0_TX/PDB0_EXTRG/ SPI1_MOSI/FBa_RW/FBa_AD4	LLWU_M2IF	CMP0 ¹
LLWU_P9	PTB4/BKGD/MS	LLWU_M3IF	TSI ¹

1. Requires the peripheral and the peripheral interrupt to be enabled. The internal module's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.

3.4.5.2 Reset due to LLWU wakeup event

During a reset sequence initiated via the LLWU, if neither BDM nor EzPort mode is latched, the CPU immediately fetches the LLWU interrupt service routine (ISR). Upon completion of the ISR, the CPU resumes the reset sequence.

3.4.5.3 LLWU register reset

All LLWU registers are reset by Chip Reset not VLLS and by other reset types that trigger Chip Reset not VLLS. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS. For more information about the types of reset available on this chip, refer to the [Reset](#) details.

3.4.6 Computer Operating Properly (COP) Watchdog Configuration

This section summarizes how the module has been configured in the chip.

Table 3-14. Reference links to related information

Topic	Related module	Reference
Clocking		Clock distribution
Power management		Power management
Programming model	System Integration Module (SIM)	SIM

3.4.6.1 COP clocks

The two clock inputs for the COP are the 1 kHz clock and the bus clock.

3.4.6.2 COP watchdog operation

The COP watchdog is intended to force a system reset when the application software fails to execute as expected. To prevent a system reset from the COP timer (when it is enabled), application software must reset the COP counter periodically. If the application program gets lost and fails to reset the COP counter before it times out, a system reset is generated to force the system back to a known starting point.

After any reset, the COP watchdog is enabled. If the COP watchdog is not used in an application, it can be disabled by clearing COPC[COPT] in the SIM.

The COP counter is reset by writing 0x55 and 0xAA (in that order) to the address of the SIM's Service COP (SRVCOP) register during the selected timeout period. Writes do not affect the data in the SRVCOP register. As soon as the write sequence is complete, the COP timeout period is restarted. If the program fails to perform this restart during the timeout period, the microcontroller resets. Also, if any value other than 0x55 or 0xAA is written to the SRVCOP register, the microcontroller immediately resets.

The SIM's COPC[COPCLKS] field selects the clock source used for the COP timer. The clock source options are either the bus clock or an internal 1 kHz clock source. With each clock source, there are three associated timeouts controlled by COPC[COPT]. The

following table summarizes the control functions of the COPCLKS and COPT bits. The COP watchdog defaults to operation from the 1 kHz clock source and the longest timeout for that clock source (2^{10} cycles).

Control Bits		Clock Source	COP Window Opens (COPC[COPW] = 1)	COP Overflow Count
COPC[COPCLKS]	COPC[COPT]			
N/A	00	N/A	N/A	COP is disabled
0	01	1 kHz	N/A	2^5 cycles (32 ms)
0	10	1 kHz	N/A	2^8 cycles (256 ms)
0	11	1 kHz	N/A	2^{10} cycles (1,024 ms)
1	01	Bus	6,144 cycles	2^{13} cycles
1	10	Bus	49,152 cycles	2^{16} cycles
1	11	Bus	196,608 cycles	2^{18} cycles

After the bus clock source is selected, windowed COP operation is available by setting COPC[COPW] in the SIM. In this mode, writes to the SRVCOP register to clear the COP timer must occur in the last 25% of the selected timeout period. A premature write immediately resets the chip. When the 1 kHz clock source is selected, windowed COP operation is not available.

The COP counter is initialized by the first writes to the SIM's COPC register and after any system reset. Subsequent writes to the SIM's COPC register have no effect on COP operation. Even if an application uses the reset default settings of the COPT, COPCLKS, and COPW bits, the user should write to the write-once COPC register during reset initialization to lock in the settings. This approach prevents accidental changes if the application program becomes lost.

The write to the SRVCOP register that services (clears) the COP counter should not be placed in an interrupt service routine (ISR) because the ISR could continue to be executed periodically even if the main application program fails.

If the bus clock source is selected, the COP counter does not increment while the microcontroller is in background debug mode or while the system is in stop (including VLPS or LLS) mode. The COP counter resumes when the microcontroller exits background debug mode or stop mode.

If the 1 kHz clock source is selected, the COP counter is re-initialized to zero upon entry to either background debug mode or stop (including VLPS or LLS) mode. The counter begins from zero upon exit from background debug mode or stop mode.

Regardless of the bus selected, the COP is disabled when the chip enters a VLLSx mode. Upon a reset that wakes the chip from the VLLSx mode, the COP is re-initialized and enabled as for any reset.

3.4.7 System Mode Controller (SMC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

3.5 Clock Modules

3.5.1 Multipurpose Clock Generator (MCG) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

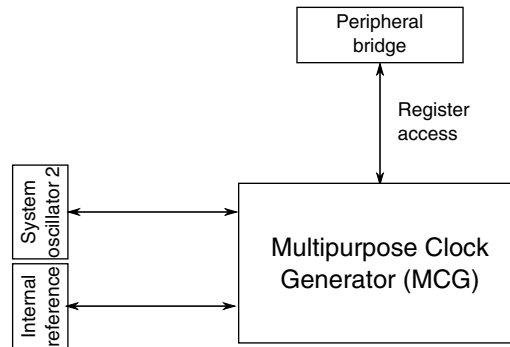

Figure 3-13. MCG configuration

Table 3-21. Reference links to related information

Topic	Related module	Reference
Full description	MCG	MCG
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management

3.5.1.1 MCG oscillator-frequency trim settings: factory and custom

Factory-programmed values for trimming oscillator frequency are stored in the nonvolatile information register (IFR) and are automatically loaded into the MCG's C3 and C4 registers after any reset.

A portion of the chip's program flash memory can be used to store other, custom settings for frequency trimming. These locations appear as FTRIM and TRIM in the following table.

Table 3-22. Flash memory addresses for custom oscillator-frequency trim settings

Address	Register	7	6	5	4	3	2	1	0
0x(00)00_03FD	Storage of other custom settings	—	—	—	—	—	—	—	—
0x(00)00_03FE	Storage of FTRIM	0	0	0	0	0	0	0	FTRIM
0x(00)00_03FF	Storage of TRIM	TRIM							

To override the factory-programmed settings with custom settings:

- Using Freescale's BDM tools, users and third parties can reprogram the TRIM and FTRIM values stored in the reserved flash memory addresses.
- User code must copy the value of FTRIM to the MCG's C4[SCFTRIM] bit and the value of TRIM to the MCG's C3[SCTTRIM] field.

3.5.2 Oscillator (OSC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

3.6 Memories and Memory Interfaces

3.6.1 RAM Configuration

This section summarizes how the module has been configured in the chip.

Figure 3-16. RAM configuration

Table 3-24. Reference links to related information

Topic	Related module	Reference
Description	RAM	RAM overview
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management

3.6.1.1 RAM overview

The microcontroller includes up to 32 KB of static RAM. RAM is most efficiently accessed using the A5-relative addressing mode (address register indirect with displacement mode). Any single bit in this area can be accessed with the bit manipulation instructions (BCLR, BSET, and so on).

At power-on, the contents of RAM are uninitialized. RAM data is unaffected by any reset provided that the supply voltage does not drop below the minimum value for RAM retention (V_{RAM}).

3.6.1.2 RAM sizes

The embedded RAM is tightly coupled with the V1 ColdFire core. The following table describes the amount of RAM (not counting FlexRAM) for the chips covered by this document.

Chip	RAM (KB)
MCF51QU32	8
MCF51QU64	16
MCF51QU128	32

For all chips, the RAM has partitions that operate as a single unit:

- RAM1: 1 KB partition
- RAM2: 7 KB partition
- RAM3: 0 KB, 8 KB, or 24 KB partition (according to the total sizes in the preceding table)

For example, for the MCF51QU128, RAM3 is a 24 KB partition.

3.6.1.3 RAM retention in low power modes

The RAM1, RAM2, and RAM3 partitions are retained in low power modes down to VLLS3 mode.

In VLLS2 mode: The RAM1 partition is powered, the RAM2 partition is optionally powered using the RAM2PO bit, and the RAM3 partition is not powered.

In VLLS1 mode: The RAM1, RAM2, and RAM3 partitions are not powered. However, the [32-byte register file](#) remains available in VLLS1 mode.

3.6.1.4 RAM accesses

The RAM's interface with the crossbar switch is 32 bits wide.

3.6.2 Flash Memory Controller (FMC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

3.6.3.1 Flash Memory Types

This device contains multiple types of flash memory as defined below:

- Program flash: nonvolatile flash memory that can execute program code
- FlexMemory: memory block that can be configured as additional program flash, data flash, and/or EEPROM. It allows user configuration of the EEPROM and data flash sizes, as well as EEPROM endurance, to fulfill application requirements.
 - FlexNVM: nonvolatile flash memory that can execute program code, store data, or back up EEPROM data
 - FlexRAM: RAM memory that can be used as traditional RAM or as high-endurance EEPROM storage

3.6.3.2 Flash Memory Sizes

The devices covered in this document contain:

- 1 block of program flash
- 1 block of FlexNVM
- 1 block of FlexRAM

The flash memory sector size is 1 KB.

The following table describes the amounts of memory for the devices covered in this document.

Device	Program flash (KB)	FlexNVM (KB)	FlexRAM (KB)
MCF51QU32	32	16	1
MCF51QU64	64	32	2
MCF51QU128	128	32	2

3.6.3.3 Flash Memory Map

The various flash memories and the flash registers are located at different base addresses as shown in the following figure. The base address for each is specified in [System Memory Map](#).

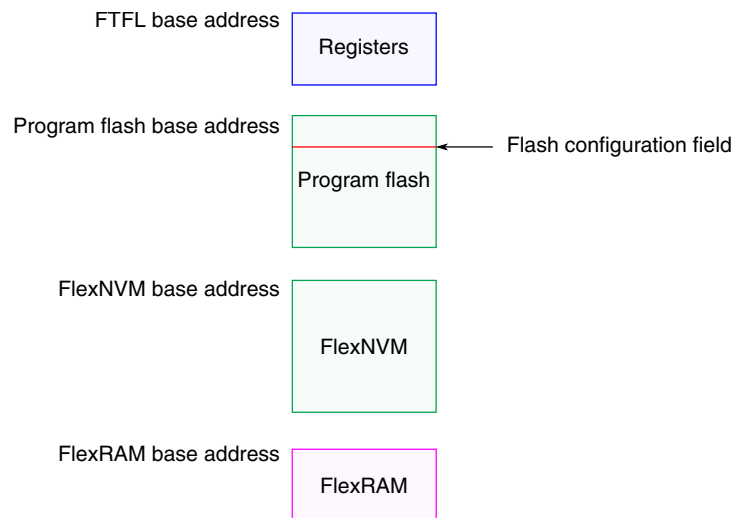

Figure 3-19. Flash memory map

The following table identifies subdivisions within the chip's program flash memory space. It also indicates where to find additional information about each area.

Table 3-27. High Level Program Flash Memory Map

Address range	Purpose	Reference
0x(00)00_0000 to 0x(00)00_03FC	Standard program flash memory, interrupt vector table	Interrupt channel assignments
0x(00)00_03FD to 0x(00)00_03FF	Standard program flash memory, space for custom oscillator-frequency trim settings	MCG oscillator-frequency trim settings: factory and custom
0x(00)00_0400 to 0x(00)00_040F	Flash Configuration Field	Flash Configuration Field Description
0x(00)00_0410 to upper limit	Standard program flash memory	

3.6.3.4 Flash Security

How flash security is implemented on the device is described in [Chip Security](#).

3.6.3.5 Flash Modes

The flash memory operates in NVM normal and NVM special modes. The flash memory enters NVM special mode when the EzPort is enabled ($\overline{\text{EZP_CS}}$ is asserted during reset) and in background debug mode (BDM). Otherwise, flash memory operates in NVM normal mode.

3.6.3.6 Erase All Flash Contents

In addition to software, the entire flash memory may be erased external to the flash memory in two ways:

1. Via the EzPort by issuing a [bulk erase \(BE\) command](#).
2. Via background debug by using DBGCR[0] and DBGSR[0]. Refer to [Debug Control Register \(DBGCR\)](#) and [Debug Status Register \(DBGSR\)](#) for details.

3.6.3.7 FTFL_FOPT Register

The flash memory's FTFL_FOPT register allows the user to customize the operation of the MCU at boot time. See [FOPT boot options](#) for details of its definition.

3.6.4 System Register File Configuration

This section summarizes how the module has been configured in the chip.

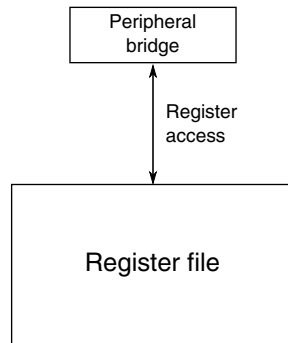

Figure 3-20. System Register file configuration

Table 3-28. Reference links to related information

Topic	Related module	Reference
Full description	Register file	Register file
System memory map		System memory map
Clocking		Clock Distribution
Power management		Power management

3.6.4.1 Register file details

The chip includes a 32-byte register file, consisting of eight 32-bit registers, that is accessible in all power modes and retains contents during low-voltage detect (LVD) events.

The register file can be accessed via 8-bit, 16-bit, and 32-bit accesses. The 16-bit and 32-bit accesses are serialized on the 8-bit peripheral bus.

The register file is reset exclusively by the POR Only reset type. It is unaffected by other reset types. For information about the various reset types on this chip, refer to the [Reset](#) details.

3.6.5 EzPort Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-21. EzPort configuration

Table 3-29. Reference links to related information

Topic	Related module	Reference
Full description	EzPort	EzPort
System memory map		System memory map
Clocking		Clock distribution
Transfers	Crossbar switch	Crossbar switch
Signal multiplexing	Port mux control	Signal multiplexing

3.6.5.1 EzPort and BDM

EzPort mode and active background debug mode (BDM) cannot be used at the same time. Attempts to use both simultaneously can lead to unexpected behavior.

BDM has priority over EzPort mode. For more information, refer to the [detailed Boot description](#).

3.6.5.2 Flash Option Register (FOPT)

The FOPT[EZPORT_DIS] bit can be used to prevent entry into EzPort mode during reset. If the FOPT[EZPORT_DIS] bit is cleared, then the state of the chip select signal ($\overline{\text{EZP_CS}}$) is ignored and the MCU always boots in normal mode.

This option is useful for systems that use the $\overline{\text{EZP_CS}}/\text{IRQ}$ signal configured for its IRQ function. Disabling EzPort mode prevents possible unwanted entry into EzPort mode if the external circuit that drives the NMI signal asserts it during reset.

The FOPT register is loaded from the flash option byte. If the flash option byte is modified, the new value takes effect for any subsequent resets, until the value is changed again. For more information about the FOPT register, refer to [FOPT boot options](#).

3.6.5.3 EzPort Clocking

The EzPort module is enabled only when the device is operating in EzPort mode. The module clocks are active only in this mode. When the device is operating in normal mode, the EzPort clock is disabled.

No register bits control the ezPort module clock because the clocking is determined by operating mode.

3.6.6 Mini-FlexBus Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

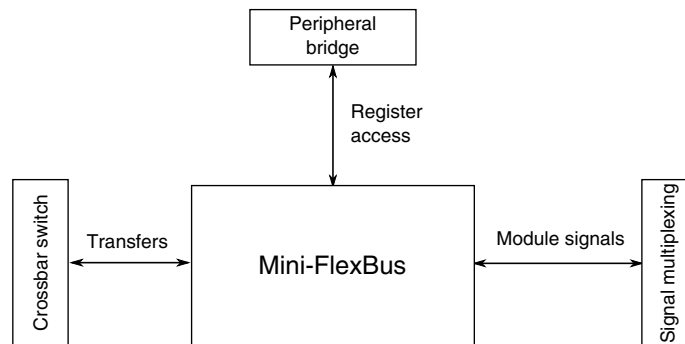

Figure 3-22. Mini-FlexBus configuration

Table 3-30. Reference links to related information

Topic	Related module	Reference
Full description	Mini-FlexBus	Mini-FlexBus
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.6.6.1 Mini-FlexBus instantiation information

The chip instantiates the Mini-FlexBus module with 20 address lines, 2 control signals, 8 data lines and 2 chip selects. The full functionality of the Mini-FlexBus is available only on the 64-pin versions of the chip. The 44-pin and 48-pin versions offer the limited functionality of the DATA bus for interfacing with peripherals such as graphical displays. The 32-pin version does not support Mini-FlexBus functionality.

To use DATA bus functionality, set the pin muxing controls to make available the necessary functions. The DATA bus portion of [Module-by-module signals](#) identifies the pins needed to support an 8-bit data bus.

The Mini-FlexBus modes of operation for 64-pin devices are:

- Up to a 20-bit address (non-multiplexed) with 8-bit data
- Up to a 20-bit address (multiplexed) with 16-bit data (write masking of upper/lower bytes not supported)
- Up to a 20-bit address (multiplexed) with 8-bit data

3.6.6.2 Mini-FlexBus CSCR0 reset value

On this device, the CSCR0 resets to 0x003F_FC00. Configure this register as needed before performing any Mini-FlexBus access.

3.6.6.3 Mini-FlexBus security

When security is enabled on the device, Mini-FlexBus accesses may be restricted by configuring the MBSL field in the SIM's SOPT6 register. See [System Integration Module \(SIM\)](#) for details.

3.7 Security

3.7.1 Cyclic Redundancy Check (CRC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-23. CRC configuration

Table 3-31. Reference links to related information

Topic	Related module	Reference
Full description	CRC	CRC
System memory map		System memory map
Power management		Power management

3.7.1.1 Module register width and serialization of accesses

This module's registers are 32 bits wide. Accesses via the 8-bit peripheral bus are serialized: 32-bit accesses are serialized into four 8-bit accesses.

3.8 Analog

3.8.1 12-bit Analog-to-Digital Converter (ADC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

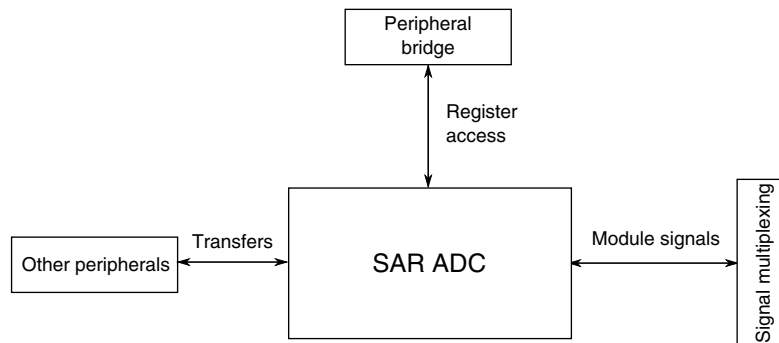

Figure 3-24. 12-bit SAR ADC configuration

Signal multiplexing	Port mux control	Signal multiplexing

3.8.1.1 Module register width and serialization of accesses

This module's registers are 32 bits wide. Accesses via the 8-bit peripheral bus are serialized: 32-bit accesses are serialized into four 8-bit accesses.

3.8.1.2 ADC instantiation information

This device contains one ADC. The ADC has an option for the ADC clock altclk. For this chip, altclk is connected to OSC2ERCLK.

The number of ADC channels present on the device is determined by the pinout of the specific device package. For details, refer to [Signal Multiplexing](#).

The 32-pin version of the chip does not bond out VREFL and VREFH to package pins. For this reason, this package cannot achieve the same level of ADC performance as the packages with larger numbers of pins.

3.8.1.3 DMA support on ADC

Applications may require continuous sampling of the ADC (4K samples/second) that may impose considerable load on the CPU. Though using PDB to trigger ADC may reduce some CPU load, the ADC supports DMA request functionality for higher performance when the ADC is sampled at a very high rate or for cases where the PDB is bypassed. The ADC can trigger the DMA (via DMA req) on conversion completion.

3.8.1.4 ADC0 Channel Assignments

ADC Channel (ADCH)	Channel	Input
00000	AD0	ADC0_SE0
00001	AD1	ADC0_SE1

Table continues on the next page...

ADC Channel (ADCH)	Channel	Input
11110	AD30	VREFL
11111	AD31	Module disabled

3.8.1.5 ADC Reference, Triggers, and Alternate Clock

ADC Reference

Select the reference on the ADC using the ADC's SC2[REFSEL] field. The available options are:

- VREFH/VREFL - connected as the primary reference option
- 1.2 V VREF_OUT - connected as the V_{ALT} reference option

ADC Triggers

In addition to the PDB, the LPTMR0 module is connected to the ADC as a trigger source. LPTMR0 can trigger the ADC in low power modes where the PDB does not work. Triggering by the LPTMR0 module allows the ADC to perform conversion in a low power mode and store the output in the result register. When the data is ready in the result register, the ADC generates an interrupt that will wake the system from low power mode.

Select the trigger source for the ADC using the SIM's SOPT7[ADTRGS] bit.

- PDB trigger (run mode)
- LPTMR0 overflow (can work in stop mode)

Alternate Clock

The ADC's alternate clock is connected to OSC2ERCLK.

3.8.1.6 Clock Gating

The clock to the ADC module can be gated on and off using the SIM's SCGCx[ADC] bit. This bit is cleared after any reset, which disables the clock to the module to conserve power. Before initializing the ADC, set the SCGCx[ADC] bit to enable the clock.

NOTE

The clock to the ADC cannot be gated during an active conversion.

During a low power mode of operation, where the external clock to the ADC is gated, the ADC can also operate on an internally generated clock. In this case, after the conversion is complete, an asynchronous interrupt can wake the system, enabling the clocks (including the clock to the ADC) so the conversion results can be read.

3.8.2 Comparator (CMP) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

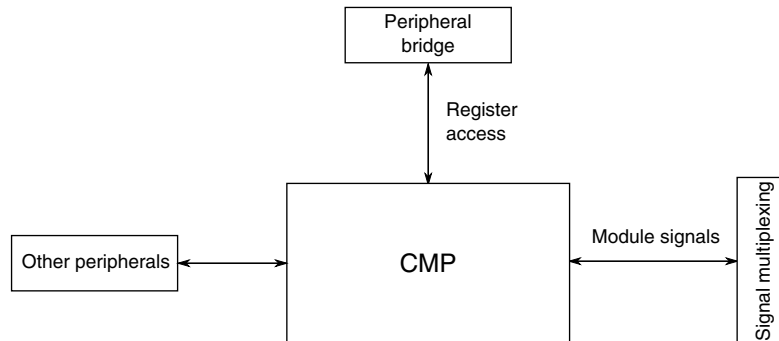

Figure 3-25. CMP configuration

Table 3-33. Reference links to related information

Topic	Related module	Reference
Full description	Comparator (CMP)	Comparator
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.8.2.1 CMP instantiation information

This chip has one high speed comparator module with an integrated 6-bit DAC and analog mux. The CMP's 6-bit DAC sub-block supports selection of two voltage references. For this chip, the references implemented are:

Analog

- CMP V_{in1} is connected to VREF_OUT.
- CMP V_{in2} is connected to V_{DD} .

Table 3-34. CMP instantiation

CMP0 feature	Details
Number of 6-bit DACs	1
Analog mux size	8 input
Number of CMP OUT pins	1
External inputs on CMP0	4

The following table and list show the fixed internal connections to and output connections of the CMP, respectively. For information about the specific pins to which the input and output signals are assigned on a particular package, refer to the CMP portion of the [Module-by-module signals](#).

Table 3-35. CMP Input connections

CMP inputs	CMP	Pin name
CMP Input1	External input	CMP0_IN0
CMP Input2	External input	CMP0_IN1
CMP Input3	External input	CMP0_IN2
CMP Input4	External input	CMP0_IN3
CMP Input5	12-bit DAC reference	
CMP Input6	VREF output	
CMP Input7	Reserved	
CMP Input8	6-bit DAC reference	

CMP output (CMPO) connections are:

- CMP output (CMP0_OUT) pin
- FTM0 channel 0 (set this connection using the SIM's SOPT7[ACFTM] bit)
- LPTMR0 clock input and LPTMR1 clock input (pulse count)
- FTM0 fault input
- FTM1 fault input
- FTM0 trigger
- FTM 1 trigger
- UART1 Rx input

3.8.2.2 External window/sample input

The analog comparator's external window/sample input is connected to the PDB channel 2's pulse-out.

3.8.3 12-bit Digital-to-Analog Converter (DAC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-26. 12-bit DAC configuration

Table 3-36. Reference links to related information

Topic	Related module	Reference

System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.8.3.1 12-bit DAC Overview

The chip includes one 12-bit DAC with a 16 x 12 FIFO for DMA support.

3.8.3.2 12-bit DAC Instantiation

The output of this DAC can be placed on an external pin or set as one of the inputs to the CMP or ADC.

3.8.3.3 12-bit DAC Reference

For this chip, VREF_OUT and VDDA are available as the DAC reference. VREF_OUT is connected to the DACREF_1 input and VDDA is connected to the DACREF_2 input. Use the DACx_C0[DACRFS] control bit to select between these two options. Be aware that if the DAC and ADC use the VREF_OUT reference simultaneously, some degradation of ADC accuracy is to be expected due to DAC switching.

3.8.3.4 DAC DMA request

The DAC can generate a DMA request. The DAC generates requests in order to be updated at the maximum speed. As soon as the DAC is ready to receive new data, it generates a DMA request, triggering the next DAC data update.

3.8.4 Voltage Reference (VREF) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

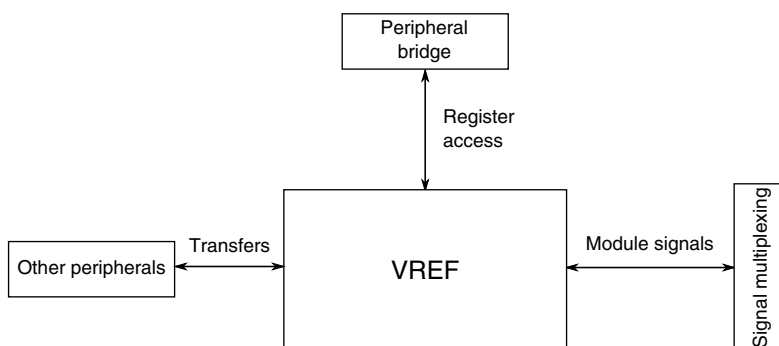

Figure 3-27. VREF configuration

Table 3-37. Reference links to related information

Topic	Related module	Reference
Full description	VREF	VREF
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.8.4.1 VREF Overview

The chip includes a voltage reference (VREF) intended to supply an accurate voltage output that can be trimmed using the module's TRM[TRIM] field.

The VREF can provide a reference voltage to external peripherals or a reference to analog peripherals, such as the ADC or CMP.

The VREF is not available on the 32-pin package.

3.9 Timers

3.9.1 Programmable Delay Block (PDB) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

3.9.1.1 Module register width and serialization of accesses

This module's registers are 32 bits wide. Accesses via the 8-bit peripheral bus are serialized: 32-bit accesses are serialized into four 8-bit accesses.

3.9.1.2 PDB Overview

Many applications need to synchronize the time that multiple ADC samples are taken with respect to an external trigger or event. The programmable delay block provides controllable delays from an external trigger or a programmable interval tick to the sample trigger input of the ADCs and DACs.

3.9.1.3 PDB instantiation

Table 3-39. PDB output channels

PDB feature	Details
Number of channels for ADC	1
Number of triggers per ADC channel	2
Number of channels for DAC	1
Number of DAC triggers	1
Additional channel for PulseOut	1

The following table identifies PDB input trigger options.

PDB trigger	Trigger configuration	PDB input
Trigger 0	0b0000	PDB_EXTRG
Trigger 1	0b0001	CMP Output
Trigger 2	0b0010	reserved
Trigger 3	0b0011	reserved
Trigger 4	0b0100	reserved
Trigger 5	0b0101	reserved
Trigger 6	0b0110	reserved
Trigger 7	0b0111	reserved
Trigger 8	0b1000	FTM0 Init and Ext Trigger Outputs
Trigger 9	0b1001	FTM1 Init and Ext Trigger Outputs
Trigger 10	0b1010	reserved
Trigger 11	0b1011	MTIM output
Trigger 12	0b1100	LPTMR0
Trigger 13	0b1101	reserved
Trigger 14	0b1110	LPTMR1
Trigger 15	0b1111	Software trigger

3.9.1.4 PDB Module Interconnections

- PDB channel 0 is dedicated to the ADC.
- PDB channel 1 is dedicated to the DAC.
- PDB channel 2 is dedicated to the CMP.

3.9.1.5 PDB acknowledgement connections

- PDB channel 0 pre-trigger 0 acknowledgement input: ADC0SC1B_COCO
- PDB channel 0 pre-trigger 1 acknowledgement input: ADC0SC1A_COCO

3.9.1.6 PDB Interval Trigger Connection to DAC

In this chip, one PDB interval trigger connection to the DAC is implemented: PDB interval trigger 0 connects to the DAC0 hardware trigger input.

3.9.1.7 DAC External Trigger Input Connection

In this chip, one DAC external trigger input is implemented:

- DAC external trigger input 0: ADC0SC1A_COCO

3.9.1.8 Pulse-Out Connection

The Pulse-Out of the PDB is connected to all the CMP blocks and used as the sample window.

3.9.1.9 Pulse-Out Enable Register Implementation

The following table shows the comparison of the pulse-out enable register at the module and chip level.

Table 3-40. PDB pulse-out enable register

Register	Module implementation	Chip implementation
POnEN	7:0 - POEN 31:8 - Reserved	0 - POEN 31:1 - Reserved

3.9.2 FlexTimer (FTM) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

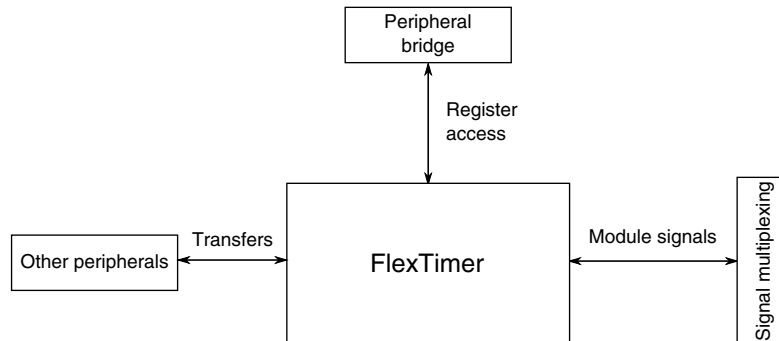

Figure 3-29. FlexTimer configuration

Table 3-41. Reference links to related information

Topic	Related module	Reference
Full description	FlexTimer	FlexTimer
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.9.2.1 FTM overview

The FlexTimer (FTM) module supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM's time reference is a 16-bit counter that can be used as an unsigned or signed counter.

3.9.2.2 FTM instantiation information

The chip contains two FlexTimer modules. The following table shows how these modules are configured.

Table 3-42. FTM Instantiations

FTM instance	Number of channels	Target application	Additional features supported
FTM0	2 (channels 0-1)	General purpose	Quadrature decoder
FTM1	6 (channels 0-5)	3-phase motor and general purpose	

FTM0 and FTM1 have four fault inputs. The output of the CMP is connected to the fault input 3 of both FTM0 and FTM1.

Table 3-43. FTM fault input sources

FTMx fault input	FTM0 fault source	FTM1 fault source
Fault 0	FTM_FLT0	FTM_FLT0
Fault 1	FTM_FLT1	FTM_FLT1
Fault 2	FTM_FLT2	FTM_FLT2
Fault 3	CMP_OUT	CMP_OUT

Table 3-44. FTM trigger sources

Trigger source	FTMx synchronization
FTMxSYNC bits (in SIM)	FTM0 and FTM1 Trigger0
CMP COUT	FTM0 and FTM1 Trigger1
FTM0_CH0	FTM1 Trigger 2
FTM1_CH0	FTM0 Trigger 2

The 2-channel FTM0 pins are available only on the 64-pin packages of the chip. Although 1 channel is available on 44-pin and 48-pin packages and neither of the FTM0 pins is available on 32-pin packages, they remain available for software timer functions and internal connections from the CMP OUT.

The CMP OUT is connected to FTM0 Channel 0 to facilitate motor control applications.

Several FTM signals are and can be routed to multiple pins. For details about these pins and about programming port mux control registers to assign an FTM function to those pins, refer to [signal multiplexing](#).

3.9.2.3 FTM external clock options

By default, each FTM is clocked by the chip's system clock (the FTM itself also refers to it as the system clock). Each module has a register setting that allows the module to be clocked from an external clock instead. There are two external TMR_CLKINx pins that can be selected by either FTM module via the SOPT5 register in the SIM module.

3.9.3 Modulo Timer (MTIM) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

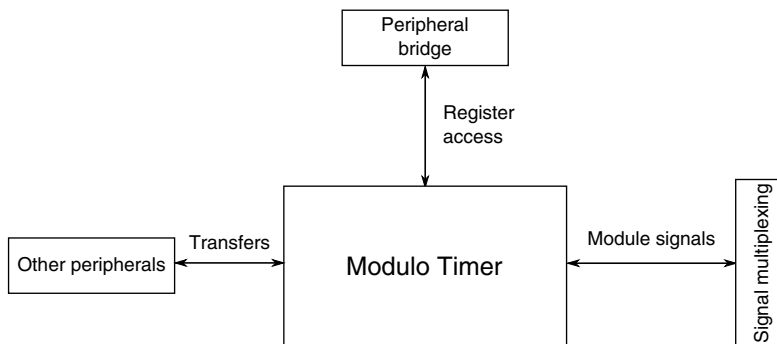

Figure 3-30. MTIM configuration

Table 3-45. Reference links to related information

Topic	Related module	Reference

System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.9.3.1 MTIM overview

The MTIM is a simple 16-bit modulo timer with several software selectable clock sources and a programmable interrupt. The chip has one MTIM module.

The MTIM shares the TMR_CLKINx pins with the FlexTimer modules.

3.9.4 Low Power Timer (LPTMR) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

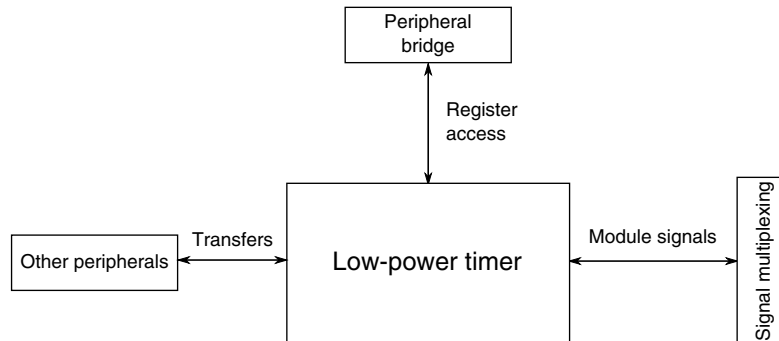

Figure 3-31. LPTMR configuration

Table 3-46. Reference links to related information

Topic	Related module	Reference
Full description	Low power timer	LPTMR
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.9.4.1 LPTMR overview

The chip contains two 16-bit low power timer (LPTMR) modules that operate in all of the chip's power modes (including LLS and VLLSx). The LPTMRs can operate as either a real time interrupt or as a pulse accumulator. They include a 5-bit prescaler (real time interrupt mode) or glitch filter (pulse accumulator mode) and can be clocked from the internal reference clock, external reference clock, or internal 1 kHz LPO. An interrupt is generated (and the counter can reset) when the counter equals the value in the 16-bit compare register.

To use an LPTMR as a wakeup source for the LLWU, refer to [LLWU wakeup sources](#) about the particular LLWU inputs to enable.

NOTE

The internal reference clock (IRC) is generated by the MCG module and can be set to be in the 30 kHz range or to the 2 MHz range.

3.9.4.2 LPTMR pin connections

Each LPTMR module has one 16-bit channel.

There are three LPTMR pins: LPTMR_ALT1, LPTMR_ALT2, and LPTMR_ALT3. Each of these are connected to both LPTMR0 and LPTMR1 and can be selected by each module's CSR[TPS] field with the settings 01, 10, and 11, respectively.

The CMP output pin can also be connected to both LPTMR0 and LPTMR1 by setting each module's CSR[TPS] field to 00. This configuration allows pulse counting of the CMP output.

3.9.4.3 LPTMR clock options

Each module's PSR[PCS] field controls the selection of external clock options. For both LPTMR0 and LPTMR1:

- Setting PSR[PCS] to 00 selects the MCGIRCLK internal reference clock (not available in low leakage power modes).
- Setting PSR[PCS] to 01 selects the internal 1 kHz LPO clock.
- Setting PSR[PCS] to 10 selects OSC1_32KCLK, the 32.768 kHz clock from OSC1. This connection is optimized for minimal power consumption in stop modes.

The effect of setting PSR[PCS] to 11 differs for the two LPTMRs:

- For LPTMR0, this setting selects the bus clock.
- For LPTMR1, this setting selects OSC2ERCLK.

3.9.4.4 LPTMR register reset

All LPTMR registers are reset by Chip POR not VLLS and by POR Only, which triggers Chip POR not VLLS. LPTMR registers are unaffected by other reset types. For information about the various reset types on this chip, refer to the [Reset](#) details.

3.9.5 Carrier Modulator Transmitter (CMT) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

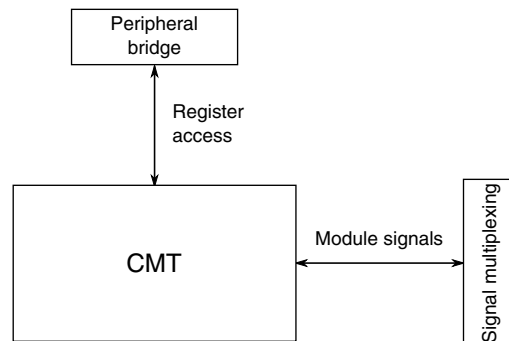

Figure 3-32. CMT configuration

Table 3-47. Reference links to related information

Topic	Related module	Reference
Full description	Carrier modulator transmitter (CMT)	CMT
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.9.5.1 CMT instantiation information

The chip contains one CMT module, which supports DMA.

3.9.5.2 CMT IRO drive strength

The IRO pad requires higher current drive than can be obtained from a single pad. For this chip, the pin associated with the CMT_IRO signal is doubled bonded to two pads.

The SIM's SOPT6[PTC5PAD] bit can be used to configure the pin associated with the CMT_IRO signal as a higher current output port pin.

3.10 Communication interfaces

3.10.1 Serial Peripheral Interface (SPI) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

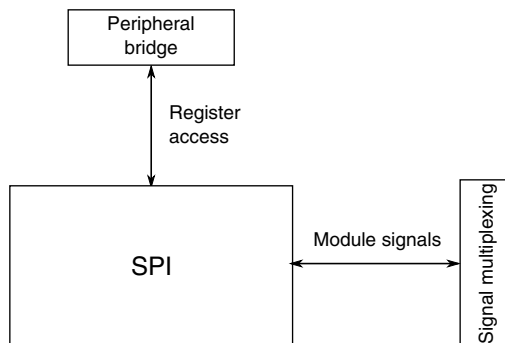

Figure 3-33. SPI configuration

Table 3-48. Reference links to related information

Topic	Related module	Reference
Full description	SPI	SPI
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.10.1.1 Number and instantiation of SPI modules

The device contains two SPI modules. SPI0 has a 64-bit FIFO; SPI1 does not have a FIFO. In other regards, the two modules are identical.

3.10.1.2 SPI baud rate

The SPI is designed to run at a baud rate up to the bus clock divided by two when the module is in master mode and up to the bus clock divided by four when the module is in slave mode.

The device's maximum CPU frequency is 50 MHz with a maximum bus clock of 25 MHz. As a result, the SPI design supports a master baud rate up to 12.5 Mbps and a slave baud rate up to 6.25 Mbps.

NOTE

For the actual maximum SPI baud rate in master and slave modes, refer to the device's Data Sheet.

3.10.2 Inter-Integrated Circuit (I2C) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

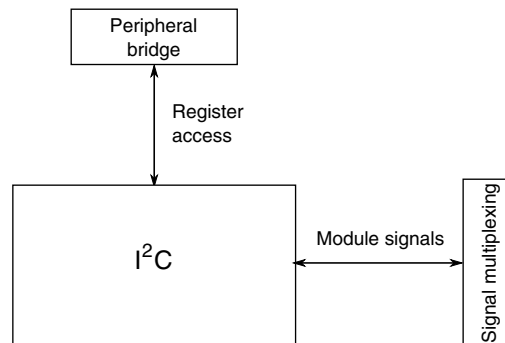

Figure 3-34. I2C configuration

Table 3-49. Reference links to related information

Topic	Related module	Reference
Full description	I ² C	I2C
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.10.2.1 Number of I2C modules

The device's 64-pin packages have four identical I²C modules.

Each of the device's other packages has three identical I²C modules.

3.10.3 Universal Asynchronous Receiver/Transmitter (UART) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

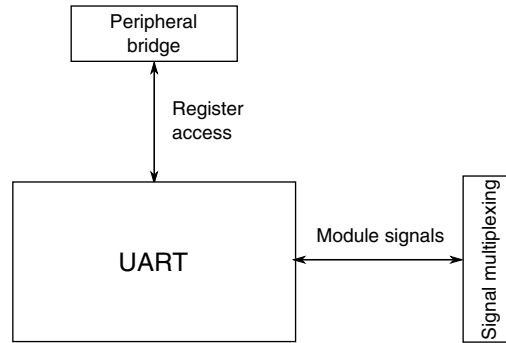

Figure 3-35. UART configuration

Table 3-50. Reference links to related information

Topic	Related module	Reference
Full description	UART	UART
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port mux control	Signal multiplexing

3.10.3.1 UART instances

This device contains two identical UART modules. Each UART:

- is clocked by the system clock (SYSCLK).
- has 8-entry transmit and 8-entry receive (64-bit) FIFOs. In the PFIFO register of each UART, the TXFIFOSIZE and RXFIFOSIZE fields both reset to 010b.

3.10.3.2 UART wakeup

The UART can be configured to generate an interrupt/wakeup on the first active edge that it receives.

3.10.3.3 UART support for opto-isolated interface

The PTC5 pin, to which the UART0_TX signal can be muxed, supports high drive strength to provide an opto-isolated interface. To enable this feature, use the PTC5PAD bit in the SIM.

Similarly: The PTF6 pin, to which the UART1_TX signal can be muxed, supports high drive strength to provide an opto-isolated interface. To enable this feature, use the PTF6PAD bit in the SIM.

3.11 Human-machine interfaces (HMI)

3.11.1 Rapid GPIO (RGPIO) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-36. RGPIO configuration

Table 3-51. Reference links to related information

Topic	Related module	Reference
Full description	RGPIO	RGPIO
System memory map		System memory map
Clocking		Clock distribution
Power management		Power management
Transfers	Crossbar switch	Crossbar switch
Signal multiplexing	Port mux control	Signal multiplexing

3.11.1.1 Number of available RGPIO pins

The maximum number of 16 RGPIO pins is available in the 64-pin packages. Smaller packages have fewer available RGPIO pins. For details, refer to package pinout information in [Signal Multiplexing](#).

3.11.1.2 RGPIO clock gating

Clock gating is not available for RGPIO.

3.11.2 Enhanced GPIO (EGPIO) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-37. EGPIO configuration

Table 3-52. Reference links to related information

Topic	Related module	Reference
Full description	EGPIO	Parallel Input/Output Control
System memory map		System memory map
Clocking		Clock distribution

Signal multiplexing	Port mux control	Signal multiplexing

3.11.2.1 Instantiation Information

The maximum total number of GPIO pins for general purpose is 48 in the 64-pin packages. Smaller packages have fewer available GPIO pins. For details, refer to package pinout information in [Signal Multiplexing](#).

GPIO pins are configured in 8-pin ports. The peripheral bus interface for the EGPIO operates at the bus clock.

Only two EGPIO ports have the digital filter feature: Port B and Port C. The other ports do not have this feature.

3.11.2.2 EGPIO registers

Every EGPIO port has two banks of registers. Each bank has a separate base address shared by all ports' registers in that bank.

1. One bank consists of registers for general port control. For details about these registers, refer to [Port Control](#).
2. The other bank's registers control functions such as configurable slew rate, drive strength, pullups/pulldowns, and passive input filters. For details about these registers, refer to [Parallel Input/Output Control](#).

3.11.3 Touch Sense Input (TSI) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

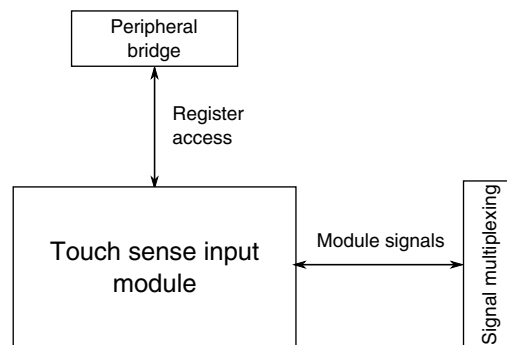

Figure 3-38. TSI configuration

Table 3-53. Reference links to related information

3.11.3.1 Module register width and serialization of accesses

This module's registers are 32 bits wide. Accesses via the 8-bit peripheral bus are serialized: 32-bit accesses are serialized into four 8-bit accesses.

3.11.3.2 Number and instantiation of inputs

This device includes one TSI module containing 16 inputs. The maximum number of 16 inputs is available in the 64-pin packages. Smaller packages have fewer available TSI inputs. For details, refer to package pinout information in [Signal Multiplexing](#).

In low power modes, one selectable pin is active and able to wake the MCU.

3.11.3.3 TSI clock names

This table shows clock names in the TSI module's chapter and the corresponding names of the chip clocks.

Table 3-54. TSI clock connections

Module clock name	Chip clock name
BUSCLK	BUSCLK
MCGIRCLK	MCGIRCLK
OSCERCLK	OSC2ERCLK
LPOCLK	LPO
VLPOSCCLK	OSC1_32KCLK

3.11.3.4 TSI module functionality in MCU operation modes

Table 3-55. TSI module functionality in MCU operation modes

MCU operation mode	TSI clock sources	TSI operation mode when GENCS[TSIEN] is 1	Functional electrode pins	Required GENCS[STPE] state
Run	BUSCLK, MCGIRCLK, OSC2ERCLK	Active mode	All	Don't care
Wait	BUSCLK, MCGIRCLK, OSC2ERCLK	Active mode	All	Don't care
Stop	MCGIRCLK, OSC2ERCLK	Active mode	All	1

Table continues on the next page...

Table 3-55. TSI module functionality in MCU operation modes (continued)

MCU operation mode	TSI clock sources	TSI operation mode when GENCS[TSIEN] is 1	Functional electrode pins	Required GENCS[STPE] state
VLPR	BUSCLK, MCGIRCLK, OSC2ERCLK	Active mode	All	Don't care
VLPW	BUSCLK, MCGIRCLK, OSC2ERCLK	Active mode	All	Don't care
VLPS	OSC2ERCLK	Active mode	All	1
LLS	LPO, OSC1_32KCLK	Low power mode	Determined by PEN[LPSP]	1

VLLS1	LPO, OSC1_32KCLK	Low power mode	Determined by PEN[LPSP]	1

3.11.3.5 TSI Interrupts

The TSI has multiple sources of interrupt requests. However, these sources are ORed together to generate a single interrupt request. When a TSI interrupt occurs, read the TSI status register to determine the exact interrupt source.

3.11.4 External Interrupt (IRQ) Module Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

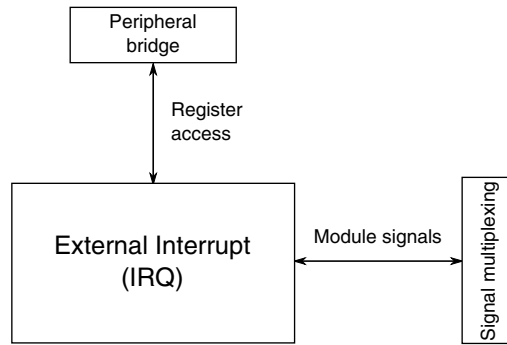

Figure 3-39. IRQ module configuration

Chapter 4

Memory Map

4.1 System Memory Map

Depending on the device variant and package, the chip supports up to 128 KB of program flash and 32 KB of FlexNVM. This configuration provides up to 160 KB of program flash, up to 2 KB of high-endurance EEPROM, or other partitioning options.

64-pin versions of the device allow flash and memory to be supplemented with off-chip storage via the Mini-FlexBus. The off-chip memory storage space is marked as available for off-chip expansion.

Address Range	V1 ColdFire Memory Usage
0x(00)00_0000	Allocated to on-chip flash memory
0x(00)3F_FFFF	
0x(00)40_0000	Available for off-chip expansion
0x(00)7F_FFFF	
0x(00)80_0000	Allocated to on-chip RAM
0x(00)9F_FFFF	
0x(00)A0_0000	Available for off-chip expansion
0x(00)BF_FFFF	
0x(00)C0_0000	ColdFireRapid GPIO
0x(00)C0_000F	
0x(00)C0_0010	Unimplemented
0x(FF)FF_7FFF	
0x(FF)FF_8000	Slave Peripherals
0x(FF)FF_FFFF	

Figure 4-1. Generic V1 ColdFire Memory Map

Regions within the memory map are subject to restrictions with regard to the types of CPU accesses allowed. The following table outlines these restrictions. Unsupported access types terminate the bus cycle with an error. In response to a bus error termination, the chip can be configured to generate a system reset, such as by ensuring the CPUCR[ARD] bit is 0.

Table 4-1. CPU Access Type Allowed by Region

Base Address	Region	Read ¹			Write ¹		
		Byte	Word	Long	Byte	Word	Long
0x(00)00_0000	Program flash ²	x	x	x	—	—	—
0x(00)20_0000	FlexNVM ²	x	x	x	—	—	—
0x(00)28_0000	FlexRAM	x	x	x	x	x	x
0x(00)40_0000	Mini-FlexBus	x	x	x	x	x	x
0x(00)80_0000	RAM	x	x	x	x	x	x

Table continues on the next page...

Table 4-1. CPU Access Type Allowed by Region (continued)

Base Address	Region	Read ¹			Write ¹		
		Byte	Word	Long	Byte	Word	Long
0x(00)A0_0000	Mini-FlexBus	x	x	x	x	x	x
0x(00)C0_0000	Rapid GPIO	x	x	x	x	x	x
0x(FF)FF_8000	Peripherals on 8-bit peripheral bus ³	x	x	x	x	x	x

1. Byte is 8-bit, Word is 16-bit, and Long is 32-bit.
2. Flash writes occur via a programming algorithm described in the flash memory details.
3. Allowed access types are peripheral specific. The peripheral bus bridge serializes 16-bit and 32-bit accesses into multiple 8-bit accesses. When using 8-bit peripherals, ensure that all accesses are properly aligned and only desired 8-bit locations are accessed.

The slave peripherals section of the memory map is further subdivided as the following table shows.

Table 4-2. High Level System Memory Map

Memory	Description	Comment
0x(00)00_0000 - 0x(00)01_FFFF	Program flash space	Smaller areas for 32 KB and 64 KB derivatives
0x(00)02_0000 - 0x(00)1F_FFFF	Unimplemented	Bus error - illegal address
0x(00)20_0000 - 0x(00)20_7FFF	FlexNVM space	Shared memory with EEPROM that can be used as program flash if no data flash or EEPROM is used
0x(00)20_8000 - 0x(00)27_FFFF	Unimplemented	Bus error - illegal address
0x(00)28_0000 - 0x(00)28_07FF	FlexRAM space	Up to 2 KB RAM available ¹ if no EEPROM is used
0x(00)28_8000 - 0x(00)3F_FFFF	Unimplemented	Bus error - illegal address
0x(00)40_0000 - 0x(00)7F_FFFF	Mini-FlexBus	
0x(00)80_0000 - 0x(00)9F_FFFF	RAM mirrored in intervals of the chip's RAM size ²	Mirrored all across this space
0x(00)A0_0000 - 0x(00)BF_FFFF	Mini-FlexBus	Memory expansion
0x(00)C0_0000 - 0x(00)C0_000F	RGPIO	16 RGPIO pins
0x(00)C0_000F - 0x(FF)FF_7FFF	Unimplemented	Bus error - illegal address
0x(FF)FF_8000 - 0x(FF)FF_FFFF	Peripheral Bus	See Table 4-4

1. Refer to [Feature Summary by Package](#) for information about FlexRAM size for your specific chip.
2. RAM size is 8 KB, 16 KB, or 32 KB. See [RAM sizes](#) for your specific chip's RAM size.

Mini-FlexBus	External Memory Interface	MB	0x(FF)FF_E800
INTC	V1 ColdFire Interrupt Controller	INTC	0x(FF)FF_FFC0

All Version 1 ColdFire+ microcontroller devices use an 8-bit peripheral bus. The bus bridge from the ColdFire system bus to the peripheral bus is capable of serializing 16-bit accesses into two 8-bit accesses and 32-bit access into four 8-bit accesses. This approach can speed access to properly aligned peripheral registers. However, not all peripheral registers are aligned to take advantage of this feature.

CPU accesses to the parts of the memory map that are marked as unimplemented result in an illegal address reset if CPUCR[ARD] is 0 or result in an address error exception if CPUCR[ARD] is 1. Similarly, in the memory maps for the DMA controller and Mini-FlexBus modules, CPU accesses to unimplemented spaces result in an illegal address reset if CPUCR[ARD] is 0 or result in an address error exception if CPUCR[ARD] is 1. For other slave peripherals with addresses from 0x(FF)FF_8000 to 0x(FF)FF_FFFF, CPU accesses do not generate an illegal address reset or exception regardless of the CPUCR[ARD] bit's state.

The lower 32 KB of flash memory and the slave peripherals section of the memory map are most efficiently accessed using the ColdFire absolute short addressing mode. RAM is most efficiently accessed using the A5-relative addressing mode (address register indirect with displacement mode).

4.2 Read-after-write sequence and required serialization of memory operations

In some situations, a write to a peripheral must be completed fully before a subsequent action can occur. Examples of such situations include:

- Exiting an interrupt service routine (ISR)
- Changing a mode
- Configuring a function

In these situations, application software must perform a read-after-write sequence to guarantee the required serialization of the memory operations:

1. Write the peripheral register.
2. Read the written peripheral register to verify the write.
3. Continue with subsequent operations.

NOTE

One factor contributing to these situations is processor write buffering. The processor architecture has a programmable configuration bit to disable write buffering: CPUCCR[BWD]. However, disabling buffered writes is likely to degrade system performance much more than simply performing the required memory serialization for the situations that truly require it.

Chapter 5

Clock Distribution

5.1 Introduction

The multipurpose clock generator (MCG) module controls which clock source is used to derive the system clocks. The clock generation logic divides the selected clock source into a variety of clock domains, including the clocks for the system bus masters, system bus slaves, and flash memory. The clock generation logic also implements module-specific clock gating to allow granular shutoff of modules.

5.2 Clock distribution

The primary clocks for the system are generated from the MCGOUTCLK clock. The clock generation circuitry provides several clock dividers that allow different portions of the device to be clocked at different frequencies. This allows for tradeoffs between performance and power dissipation.

Various modules have module-specific clocks that can be generated from the MCGPLLCLK clock. In addition, there are various other module-specific clocks that have other alternate sources. Clock selection for most modules is controlled by the SOPT registers in the SIM module.

5.2.1 High-Level device clocking diagram

The high-level clock diagram is shown below.

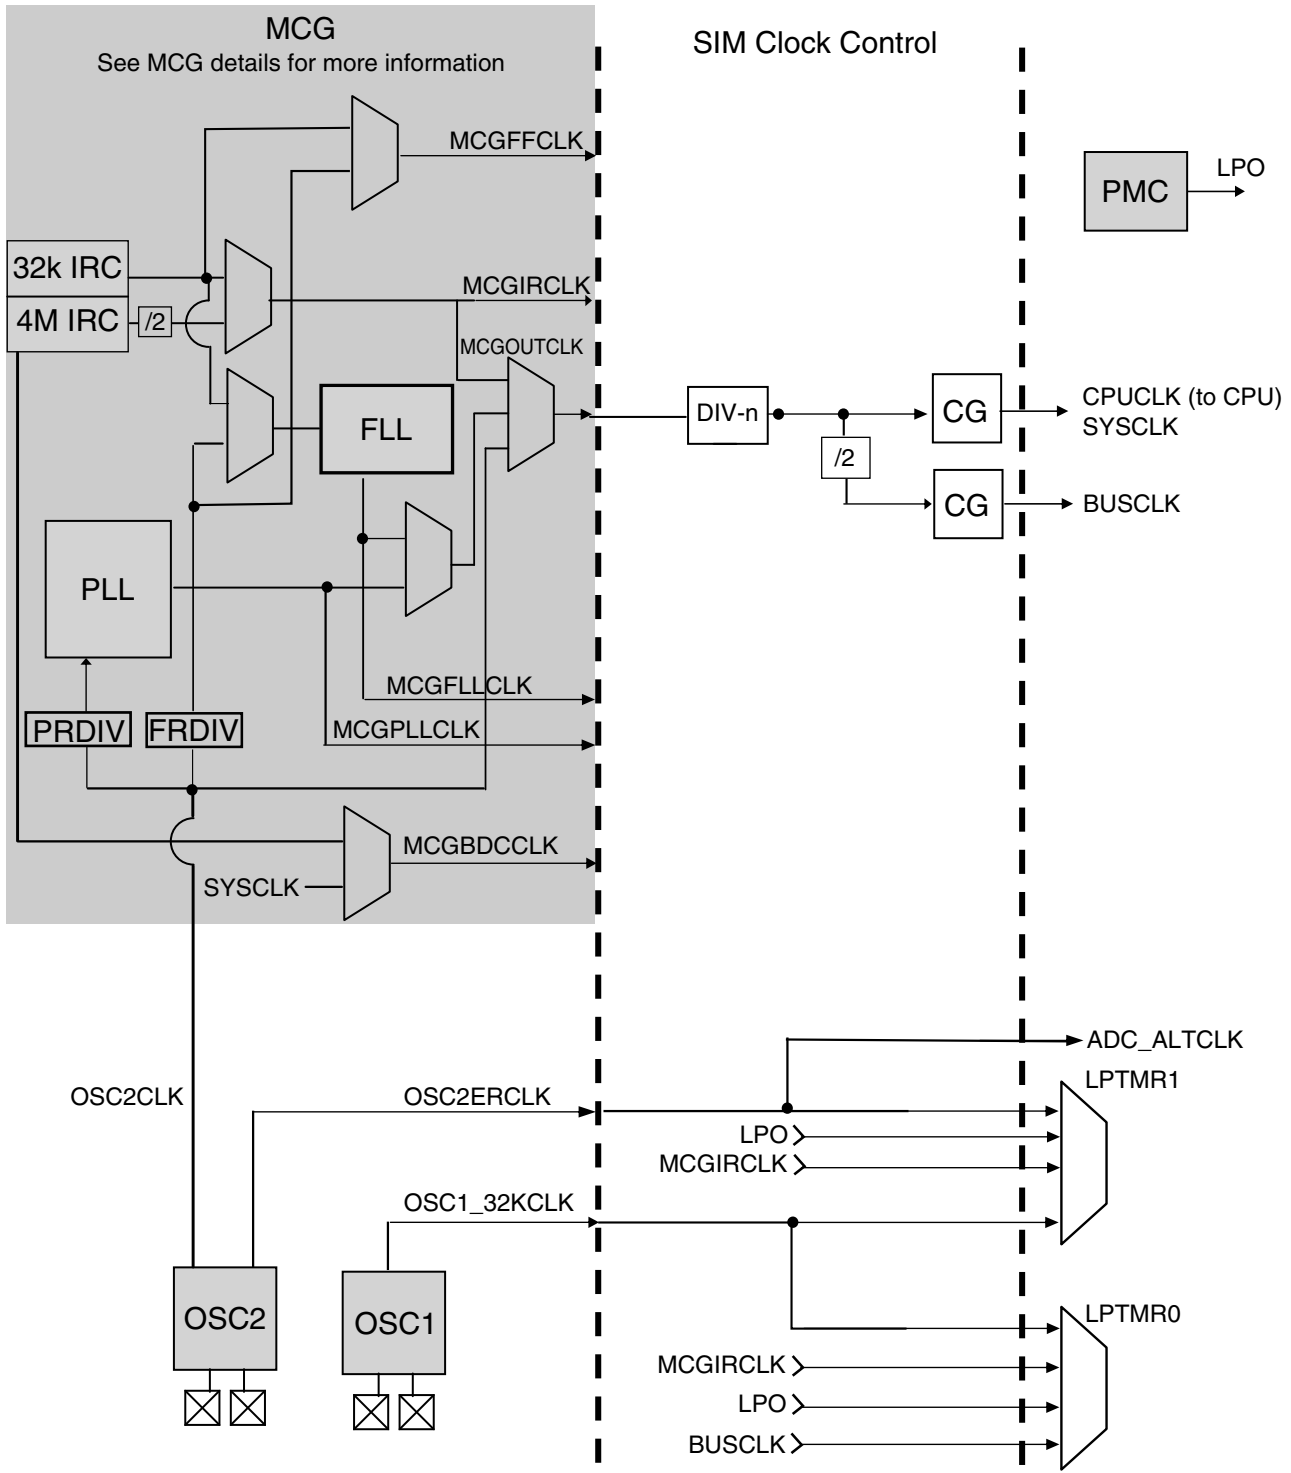

Figure 5-1. Clocking diagram

5.2.2 Device Clock Summary

The following table summarizes the on-chip clocks.

Table 5-1. MCG clock references

MCG reference clock name	Description
OSC2CLK	OSC2 output, crystal or external clock
IRC (fast and slow)	Internal reference of the MCG

Table 5-2. Device clock summary

Clock name	Run mode clock frequency	VLPR mode clock frequency	Clock source	Clock is disabled...
MCGOUTCLK	Up to 100 MHz ¹	Up to 2 MHz	MCG	In all stop modes
Core clock (CPUCLK)	Up to 50 MHz	Up to 2 MHz	System clock	In wait and all stop modes
System clock (SYSCLK)	Up to 50 MHz	Up to 2 MHz	MCGOUTCLK clock divider	In all stop modes
Bus clock (BUSCLK)	Up to 25 MHz	Up to 1 MHz	MCGOUTCLK clock divider	In all stop modes
Fixed frequency clock (MCGFFCLK)	Up to 39.0625 kHz	N/A	Slow IRC or OSC2CLK	In all stop modes
FLL output clock (MCGFLLCLK)	Up to 100 MHz ¹	N/A	MCG	In all stop modes
PLL output clock (MCGPLLCLK)	Up to 100 MHz ¹	N/A	MCG	In stop mode when the MCG's C5[PLLSTEN] bit is cleared, or In VLPS, LLS, or a VLLSx mode
Background Debug Controller (BDC) clock (MCGBDCCLK)	Up to 50 MHz	Up to 4 MHz	MCG: SYSCLK (50 MHz) or fast IRC (4 MHz)	In all stop modes
Internal reference (MCGIRCLK)	30-40 kHz or 2 MHz	2 MHz only	Internal source	When MCG's C1[IRCLKEN] bit is cleared, In stop mode when the MCG's C1[IREFSTEN] bit is cleared, or In VLPS, LLS, or a VLLSx mode
External reference (OSC1ERCLK)	Up to 50 MHz (bypass), 30-40 kHz (low-range crystal), or 1-32 MHz (high-range crystal)	Up to 4 MHz (bypass), 30-40 kHz (low-range crystal), or Up to 4 MHz (high-range crystal)	OSC1	When OSC1_CR[ERCLKEN] is cleared, or In all stop modes when both OSC1_CR[EREFSTEN] and SIM_OSC1[OSC1EN] are cleared
External reference (OSC1_32KCLK)	30-40 kHz (low-range crystal)	30-40 kHz (low-range crystal)	OSC1	When OSC1_CR[ERCLKEN] is cleared and SIM_OSC1[OSC1EN] is cleared, or In all stop modes when both OSC1_CR[EREFSTEN] and SIM_OSC1[OSC1EN] are cleared

Table continues on the next page...

Table 5-2. Device clock summary (continued)

Clock name	Run mode clock frequency	VLPR mode clock frequency	Clock source	Clock is disabled...
External reference (OSC2ERCLK)	Up to 50 MHz (bypass), 30-40 kHz (low-range crystal), or 1-32 MHz (high-range crystal)	Up to 4 MHz (bypass), 30-40 kHz (low-range crystal), or Up to 4 MHz (high-range crystal)	OSC2	When OSC2_CR[ERCLKEN] is cleared, or In all stop modes when OSC2_CR[EREFSTEN] is cleared
External reference (OSC2CLK)	Up to 50 MHz (bypass), 30-40 kHz (low-range crystal), or 1-32 MHz (high-range crystal)	Up to 4 MHz (bypass), 30-40 kHz (low-range crystal), or Up to 4 MHz (high-range crystal)	OSC2	In all stop modes where OSC2ERCLK is disabled
Low power oscillator clock (LPO)	1 kHz	1 kHz	PMC	Never

- When MCGOUTCLK, MCGFLLCLK, or MCGPLLCLK is used as the source of CPUCLK/SYSCLK and BUSCLK, it must be divided down to ensure CPUCLK/SYSCLK and BUSCLK remain within their specified ranges.

5.2.3 Architecture

Various clocks are generated by dividing the MCGOUTCLK clock:

- Core (CPU) clock (CPUCLK): Clocks the ColdFire V1 core
- System clock (SYSCLK): Clocks the crossbar switch and bus masters directly connected to the crossbar. In addition, this clock is used for UART0 and UART1.
- Bus clock (BUSCLK): Clocks the bus slaves and peripherals (excluding memories)

5.2.4 Clock divider requirements

The flash memory's LPBOOT bit of the option byte loaded to the FTFLL_FOPT register controls the reset value of the core clock, system clock, and bus clock dividers. For a definition of LPBOOT and other bits of the option byte, refer to [FOPT boot options](#).

Table 5-3. LPBOOT's effect on clock dividers

LPBOOT	SIM_CLKDIV0[OUTDIV]	Core/system clock	Bus clock	Description
0	0xF	Divide by 16	Divide by 32	Low power boot
1	0x0	Divide by 1	Divide by 2	Fast clock boot

The LPBOOT bit provides the flexibility to select a lower frequency, low power boot option. The flash erased state defaults to fast clocking mode, because where the low power boot (LPBOOT) bit resides in flash is logic 1 in the flash erased state.

To enable the low power boot option, program LPBOOT (in the option byte of the FTFM module's flash configuration field) to 0. During the reset sequence, if LPBOOT is 0, the system is in a slow clock configuration. Upon any system reset, the clock dividers return to this configurable reset state.

5.2.5 Clock gating

The clock to each module can be individually gated on and off using the SIM's SCGCx registers. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing a module, set the corresponding bit in SCGCx register to enable the clock. Before turning off the clock, disable the module or place the module in its default configuration.

Turning off the clock for an enabled, working module can produce unexpected behavior.

5.2.6 Module clocks

The following table summarizes the clocks associated with each module.

Table 5-4. Module clock options

Module	Bus interface clock	Internal clocks	I/O interface clocks
Core and system peripherals			
CPU	CPUCLK	CPUCLK	
DBG	SYSCLK		
BDC	SYSCLK	MCGBDCCLK	
EzPort	SYSCLK		EZP_CLK
DMA	SYSCLK		
RAM	SYSCLK		
Flash (and FlexMemory)			
BUSCLK			
External memory interface			
Mini-FlexBus	SYSCLK		FB_CLKOUT ¹
CRC	BUSCLK		
Timers			
MTIM	BUSCLK	MCGFFCLK, FTM0_CH1, FTM1_CH1	TMR_CLKIN0 pin, TMR_CLKIN1 pin
LPTMR1	BUSCLK	LPO, OSC2ERCLK, OSC1_32KCLK, MCGIRCLK	
LPTMR0	BUSCLK	MCGIRCLK, OSC1_32KCLK, LPO	
COP	BUSCLK	LPO	

Table continues on the next page...

Table 5-4. Module clock options (continued)

Module	Bus interface clock	Internal clocks	I/O interface clocks
FTM0, FTM1	SYSCLK	MCGFFCLK	TMR_CLKIN0 pin, TMR_CLKIN1 pin
PDB	BUSCLK		
CMT	BUSCLK		
Analog			
ADC	BUSCLK	OSC2ERCLK, ADC asynchronous clock	
VREF	BUSCLK		
CMP	BUSCLK		
DAC	BUSCLK		
Communications			
SPI0, SPI1	BUSCLK		SPIx_SCLK
UART0, UART1	SYSCLK		
I ² C0, I ² C1, I ² C2, I ² C3	BUSCLK		
Human-machine interface			
TSI	BUSCLK	LPO, OSC1_32KCLK, OSC2ERCLK, MCGIRCLK	
EGPIO	BUSCLK		
RGPIO	SYSCLK		
IRQ	BUSCLK		

1. The frequency of FB_CLKOUT is 25 MHz.

Internally generated module clocks include:

- ADC asynchronous clock: Internally generated ADC conversion clock

5.2.6.1 VLPR Mode Clocking

The clock dividers cannot be changed while in VLPR mode. They must be programmed prior to entering VLPR mode to guarantee the core/system clocks are less than or equal to 2 MHz.

5.2.6.2 UART Clocking

The UART0 and UART1 modules operate from SYSCLK, which provides a higher performance level for these modules. The maximum baud rate is (UART Clock)/16 or 3.125 MHz.

5.2.6.3 PMC's LPO clock

The PMC generates a 1 kHz low power oscillator clock (LPO) that operates in all modes of operation, including all low power modes (whenever the PMC is powered).

This clock is a source for the following destinations:

- LPTMR0/LPTMR1
- EGPIO filter
- Touch sensing interface (TSI)
- COP watchdog

Chapter 6

Reset and Boot

6.1 Reset

This section discusses the Reset Control Module (RCM), basic reset mechanisms, and the various sources of reset on the chip. See the [Reset Control Module](#) for RCM register details.

Some modules that cause resets can be configured to cause interrupts instead. Consult the individual peripherals' chapters for more information.

6.1.1 MCU reset sources

Resetting the MCU provides a way to start processing from a known set of initial conditions.

When the ColdFire processor exits reset, it fetches initial 32-bit values for the supervisor stack pointer and program counter from locations 0x(00)00_0000 and 0x(00)00_0004, respectively.

The on-chip peripheral modules are disabled and the non-analog I/O pins are initially configured as disabled. The pins with analog functions assigned to them default to their analog function after reset.

During and following a reset, the input pin associated with the BKGD pin is configured with pullup enabled.

This series of devices has the following sources for reset:

- Power-on reset (POR)
- External $\overline{\text{RESET}}$ pin (PIN)
- COP watchdog (WDOG) timer
- Illegal opcode detect (ILOP)
- Illegal address detect (ILAD)
- Multipurpose Clock Generator loss of clock (LOC)

- Low-voltage detect (LVD)
- Low leakage wakeup (WAKEUP)
- Stop mode acknowledge error (SACKERR)
- EzPort RESET command (EZPT)
- Background debug forced reset (BDFR)

Each of these sources has an associated bit in the system reset status (SRS) registers.

6.1.1.1 Power-on reset (POR)

When power is initially applied to the MCU, or when the supply voltage drops below the power-on reset re-arm voltage level (VPOR), the POR circuit causes a POR reset condition.

As the supply voltage rises, the LVD circuit holds the MCU in reset until the supply rises above the LVD low threshold (VLVDL). The RCM's SRS0[POR] and SRS0[LVD] bits are both set following a POR.

6.1.1.2 External $\overline{\text{RESET}}$ pin (PIN)

On this series of devices, the $\overline{\text{RESET}}$ pin is multiplexed with GPIO. By default, the $\overline{\text{RESET}}$ function on this pin is enabled. This pin is open drain and has an internal pullup device and an optional digital filter. Asserting $\overline{\text{RESET}}$ low can wake the device from any mode.

6.1.1.2.1 Reset Pin Filter

The $\overline{\text{RESET}}$ pin filter supports filtering from both the 1 kHz LPO clock and the bus clock. A separate filter is implemented for each clock source. In stop and VLPS mode operation, this logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected.

The RPF0[RSTFLTSS], RPF0[RSTFLTSRW], and RPF0[RSTFLTSEL] fields in the reset control (RCM) register set control this functionality. The filters are asynchronously reset by Chip POR. The reset value for each filter assumes the $\overline{\text{RESET}}$ pin is negated.

The two clock options for the $\overline{\text{RESET}}$ pin filter when the chip is not in low leakage modes are the LPO (1 kHz) and bus clock. For low leakage modes, the LLWU provides control of an optional fixed digital filter running the LPO.

The 1 kHz filter has a fixed filter value of 3. Due to a synchronizer on the input data, there is also some associated latency (2 cycles). As a result, 5 cycles are required to complete a transition from low to high or high to low.

The bus filter should synchronously prime to off (logic 1) when the bus filter is not enabled. The bus clock is used when the filter selects bus clock, and the number of counts is controlled by the RPFW[RSTFLTSEL] field.

6.1.1.3 COP watchdog (WDOG) timer

The computer operating properly (COP) watchdog timer monitors the operation of the system by expecting periodic communication from the software. This communication is generally known as servicing (or refreshing) the COP watchdog. If this periodic refreshing does not occur, the watchdog issues a system reset. The COP reset causes the RCM's SRS0[WDOG] bit to set.

6.1.1.4 Illegal opcode detect (ILOP)

By default, the V1 ColdFire core generates a MCU reset when attempting to execute an illegal instruction (except for the ILLEGAL opcode), illegal line-A instruction, illegal line-F instruction, or a supervisor instruction while in user mode (privilege violation). You may set the core's CPUCR[IRD] bit to generate the appropriate exception instead of forcing a reset.

NOTE

The attempted execution of the STOP instruction is treated as an illegal instruction if entry to stop or wait mode is disabled because the STOPE or WAITE bit is cleared in the SIM's SOPT4 register.

NOTE

The attempted execution of the HALT instruction is treated as an illegal instruction if the core's XCSR[ENBDM] bit is cleared.

6.1.1.5 Illegal address detect (ILAD)

By default, the V1 ColdFire core generates an MCU reset when detecting an address error, bus error termination, RTE format error, or fault-on-fault condition. If the core's CPUCR[ARD] bit is set, the processor generates the appropriate exception instead of forcing a reset, or simply halts the processor in response to the fault-on-fault condition.

6.1.1.6 Multipurpose Clock Generator loss of clock (LOC)

The MCG module supports an external reference clock.

If the C6[CME] bit in the MCG module is set, the clock monitor is enabled. If the external reference falls below f_{loc_low} or f_{loc_high} , as controlled by the C2[RANGE] field in the MCG module, the MCU resets. The RCM's SRS0[LOC] bit is set to indicate this reset source.

NOTE

This reset source does not cause a reset if the chip is in any stop mode.

6.1.1.7 Low voltage detect (LVD)

The chip includes a system for managing low voltage conditions to protect memory contents and control MCU system states during supply voltage variations. The system consists of a power-on reset (POR) circuit and an LVD circuit with a user-selectable trip voltage. The LVD system is always enabled in normal run, wait, or stop mode. The LVD system is disabled when entering VLPx, LLS, or VLLSx modes.

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting the PMC's LVDSC1[LVDRE] bit to 1. The low voltage detection threshold is determined by the PMC's LVDSC1[LVDV] field. After an LVD reset has occurred, the LVD system holds the MCU in reset until the supply voltage has risen above the low voltage detection threshold. The RCM's SRS0[LVD] bit is set following either an LVD reset or POR.

6.1.1.8 Low leakage wakeup (WAKEUP)

The LLWU module provides the means for a number of external pins, the $\overline{\text{RESET}}$ pin, and a number of internal peripherals to wake the MCU from low leakage power modes. The LLWU module is functional only in low leakage power modes.

- In LLS mode, only the $\overline{\text{RESET}}$ pin via the LLWU can generate a system reset.
- In VLLSx modes, all enabled inputs to the LLWU can generate a system reset.

After a system reset, the LLWU retains the flags indicating the input source of the last wakeup until the user clears them.

NOTE

During a reset sequence initiated via the LLWU, if neither BDM nor EzPort mode is latched, the CPU immediately fetches the LLWU interrupt service routine (ISR). Upon completion of the ISR, the CPU resumes the reset sequence.

NOTE

Some flags are cleared in the LLWU and some flags are required to be cleared in the peripheral module. Refer to the individual peripheral specifications for more information.

6.1.1.9 Stop mode acknowledge error (SACKERR)

This reset is generated if the core attempts to enter stop mode, but not all modules acknowledge stop mode within 1025 cycles of the 1 kHz LPO clock.

A module might not acknowledge the entry to stop mode if an error condition occurs. The error can be caused by a failure of an external clock input to a module.

6.1.1.10 Background debug forced reset (BDFR)

A host debug system, when connected to the MCU via the BKGD pin, can force a background debug reset by setting the CSR2[BDFR] bit in the ColdFire debug register set. To show that this event was the source of a reset, the RCM's SRS1[BDFR] bit is 1 after the reset.

6.1.2 Reset Pin

For all reset sources except a VLLS Wakeup that does not occur via the $\overline{\text{RESET}}$ pin, the $\overline{\text{RESET}}$ pin is driven low by the MCU for at least 128 bus clock cycles and until flash initialization has completed.

After flash initialization has completed, the $\overline{\text{RESET}}$ pin is released, and the internal Chip Reset negates after the $\overline{\text{RESET}}$ pin is pulled high. Keeping the $\overline{\text{RESET}}$ pin asserted externally delays the negation of the internal Chip Reset.

6.1.3 MCU Resets

A variety of resets are generated by the MCU to reset different modules.

6.1.3.1 POR Only

The POR Only reset asserts on the POR reset source only. It resets the PMC and Register File.

The POR Only reset also causes all other reset types to occur.

6.1.3.2 Chip POR not VLLS

The Chip POR not VLLS reset asserts on POR and LVD reset sources. It resets parts of the SMC and SIM. It also resets the LPTMR.

The Chip POR not VLLS reset also causes these resets to occur: Chip POR, Chip Reset not VLLS, and Chip Reset (including Early Chip Reset).

6.1.3.3 Chip POR

The Chip POR asserts on POR, LVD, and VLLS Wakeup reset sources. It resets the Reset Pin Filter registers and parts of the SIM and MCG.

The Chip POR also causes the Chip Reset (including Early Chip Reset) to occur.

6.1.3.4 Chip Reset not VLLS

The Chip Reset not VLLS reset asserts on all reset sources except a VLLS Wakeup that does not occur via the $\overline{\text{RESET}}$ pin. It resets parts of the SMC, LLWU, and other modules that remain powered during VLLS mode.

The Chip Reset not VLLS reset also causes the Chip Reset (including Early Chip Reset) to occur.

6.1.3.5 Early Chip Reset

The Early Chip Reset asserts on all reset sources. It resets only the flash memory module. It negates before flash memory initialization begins ("earlier" than when the Chip Reset negates).

6.1.3.6 Chip Reset

Chip Reset asserts on all reset sources and only negates after flash initialization has completed and the $\overline{\text{RESET}}$ pin has also negated. It resets the remaining modules (the modules not reset by other reset types).

6.2 Boot

The boot description includes information about boot sources and boot options available in the MCU.

6.2.1 Boot sources

The chip only supports booting from internal flash. Any secondary boot must go through an initialization sequence in flash.

6.2.2 Boot options

The device's functional mode is controlled by the two mode select (MS) pins, which have the following relative priority:

1. The BKGD/MS pin is used to select between active background debug mode (BDM) and single chip modes.
2. The $\overline{\text{EZP_MS}}$ pin selects between EzPort serial flash programming mode and single chip mode.

The mode select functionality on these pins does not depend on the pin muxing setting of the pins. Upon power on reset, these pins are analyzed and the different modes are entered depending on the level provided on these pins.

By default, the device comes out of reset in functional mode. In functional mode, the device will be in single chip (default) mode. While in single chip mode only, the device can be in run mode or various low power modes described in [Modes of operation](#).

Table 6-1. BKGD/MS mode select decoding

Mode select (BKGD/MS)	Description
0	Active background debug mode (BDM)
1	Single chip (default)

Table 6-2. EZP_MS mode select decoding

Mode select (EZP_MS)	Description
0	Serial flash programming mode (EzPort)
1	Single chip (default)

6.2.3 FOPT boot options

The flash option (FOPT) register in the flash memory module (FTFL) allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's option byte in the flash configuration field. The user can reprogram the option byte in flash to change the FOPT values that are used for subsequent resets. For more details on programming the option byte (OPT field), refer to the detailed description of the [flash memory module](#).

The MCU uses the FTFL_FOPT register bits to configure the device at reset as shown in the following table.

Table 6-3. Flash Option Register (FTFL_FOPT) Bit Definitions

Bit Num	Field	Value	Definition
7-2	Reserved		Reserved for future expansion.
1	EZPORT_DIS	0	EzPort operation is disabled. If the device boots with the EZP_MS signal low, then the device boots in normal mode. This mode might be desired if the EZP_MS/IRQ pin is used for its IRQ function.
		1	EzPort operation is enabled. The state of the EZP_MS pin during reset determines whether the device enters EzPort mode.

Table continues on the next page...

**Table 6-3. Flash Option Register (FTFL_FOPT) Bit Definitions
(continued)**

Bit Num	Field	Value	Definition
0	LPBOOT	0	Low-power boot: At reset exit, the OUTDIV field's value in the SIM_CLKDIV0 register is auto-configured to 0xF for higher divide values (divide by 16) to produce lower power consumption at reset exit.
		1	Normal boot: At reset exit, the OUTDIV field's value in the SIM_CLKDIV0 register is auto-configured to 0x0 for lower divide values (divide by 1) to produce faster operating frequencies at reset exit.

6.2.4 Boot sequence

At power up, the on-chip regulator holds the system in a POR state until the input supply is above the POR threshold. The system continues to be held in this static state until the internally regulated supplies have reached a safe operating voltage as determined by the LVD. The Mode Controller reset logic then controls a sequence to exit reset.

1. A system reset is held on internal logic, the $\overline{\text{RESET}}$ pin is driven out low, and the MCG is enabled in its default clocking mode.
2. Required clocks are enabled: Core Clock, System Clock, and any Bus Clocks that do not have clock gate control.
3. The system reset on internal logic continues to be held, but the Flash Controller is released from reset and begins initialization operation while the Mode Control logic continues to drive the $\overline{\text{RESET}}$ pin out low for a count of ~128 Bus Clock cycles.
4. The $\overline{\text{RESET}}$ pin and system reset on internal logic continues to be asserted while the Flash Controller continues initialization.
 - a. Active background debug mode (BDM) will be selected instead of normal CPU execution if BKGD/MS is pulled low at the end of the $\overline{\text{RESET}}$ drive out low.
 - b. If BDM is not selected, EzPort mode will be selected instead of normal CPU execution if $\overline{\text{EZP_MS}}$ is pulled low at the end of the $\overline{\text{RESET}}$ drive out low. EzPort mode can be disabled if the EZPORT_DIS bit of the option byte loaded to the FTFL_FOPT register is configured for the disabled setting.
5. During flash initialization, clocking is switched to a slow clock if the LPBOOT bit of the option byte loaded to the FTFL_FOPT register is configured for low power boot.

6. When flash initialization completes, the $\overline{\text{RESET}}$ pin is released. After the $\overline{\text{RESET}}$ pin is released, if $\overline{\text{RESET}}$ continues to be asserted (an indication of a slow rise time on the $\overline{\text{RESET}}$ pin or external drive in low), the system continues to be held in reset. After the $\overline{\text{RESET}}$ pin is detected high, the system is released from reset.
7. When the system exits reset, the processor fetches initial 32-bit values for the supervisor stack pointer and program counter (PC) from the locations 0x(00)00_0000 and 0x(00)00_0004, respectively. The CPU begins execution at the PC location, but at this time:
 - a. If active background debug mode was latched during the sequence, BDM is entered instead of normal CPU execution.
 - b. If BDM was not latched but EzPort mode was latched during the sequence, EzPort mode is entered instead of normal CPU execution.
 - c. If neither BDM nor EzPort mode was latched, and if the reset event was caused by a low leakage wakeup interrupt, the CPU immediately fetches the LLWU interrupt service routine (ISR). Upon completion of the ISR, the CPU resumes execution at the PC location.
8. If FlexNVM is enabled, the Flash Controller continues to restore the FlexNVM data. This data is not available immediately out of reset, and the system should not access this data until the Flash Controller completes this initialization step as indicated by the EEERDY flag.

Subsequent system resets follow this reset flow beginning with the step where system clocks are enabled.

Chapter 7

Power Management

7.1 Introduction

This chapter describes the various MCU power modes and functionality of the individual modules in these modes.

7.2 Power modes

The V1 ColdFire CPU has two primary modes of operation, run and stop. The STOP instruction can invoke both stop and wait modes. The CPU does not differentiate between stop and wait modes. Stop, wait, and run are augmented in a number of ways to provide a lower power MCU based on application needs.

The [System Mode Controller \(SMC\)](#) module in ColdFire+ device families provides multiple power options. The Very Low Power Run (VLPR) operating mode can reduce runtime power when maximum processor frequency is not required. Corresponding wait and stop modes are the Very Low Power Wait (VLPW) and Very Low Power Stop (VLPS) modes.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down, or full power down of certain logic and/or memory. I/O states are held in all modes of operation. The following table compares the various power modes available.

Table 7-1. MCU power modes

Power mode	Description	Normal recovery method
Normal run	Allows maximum performance of MCU.	-
Normal wait	Allows peripherals to function while allowing CPU to sleep, reducing power.	Interrupt
Normal stop	Places MCU in static state. Lowest power mode that retains all registers while maintaining LVD protection.	Interrupt

Table continues on the next page...

Table 7-1. MCU power modes (continued)

Power mode	Description	Normal recovery method
VLPR (Very Low Power Run)	Regulator in low power mode, LVD off. Maximum 2 MHz clock source to core and 1 MHz to peripherals and flash. ¹	Interrupt
VLPW (Very Low Power Wait)	Similar to VLPR, with CPU in sleep to further reduce power.	Interrupt
VLPS (Very Low Power Stop)	Places MCU in static state, with LVD operation off. Lowest power mode with ADC and pin interrupts functional. LPTMRs, TSI, CMP, 12-bit DAC functional.	Interrupt
LLS (Low Leakage Stop)	State retention power mode. LLWU, LPTMRs, TSI, CMP, 12-bit DAC functional. All RAM and 32-byte Register File powered.	LLWU interrupt
VLLS3 (Very Low Leakage Stop3)	LLWU, LPTMRs, TSI, CMP, 12-bit DAC functional. All RAM and 32-byte Register File powered.	Wakeup reset
VLLS2 (Very Low Leakage Stop2)	LLWU, LPTMRs, TSI, CMP, 12-bit DAC functional. Portion of RAM powered off. 32-byte Register File powered.	Wakeup reset
VLLS1 (Very Low Leakage Stop1)	LLWU, LPTMRs, TSI, CMP, 12-bit DAC functional. All RAM powered off. 32-byte Register File powered.	Wakeup reset

1. Some peripherals, such as the UARTs, use the system clock.

For additional information, refer to [Power mode transitions](#).

7.3 Module Operation in Low Power Modes

The following table illustrates the available functionality of each module while the MCU is in each of the low power modes (stop, VLPx, LLS, and VLLSx).

Table 7-2. Module operation in low power modes

Module	STOP	VLPR	VLPW	VLPS	LLS	VLLSx

IRQ	Wakeup	FF	FF	Wakeup	Static, pins latched	OFF, pins latched

- Using the LLWU module, the external pins available for this MCU do not require the associated peripheral function to be enabled. The only requirement is for the function controlling the pin (GPIO or peripheral) to be configured as an input to allow a transition to occur to the LLWU.
- For the RAM3 size on a particular device, refer to [RAM sizes](#) or to the total RAM size provided in [Feature Summary by Package](#).
- In VLPR mode, FlexRAM enabled as EEPROM is not writable (writes are ignored) but can be read. There are no access restrictions in VLPR mode for FlexRAM configured as traditional RAM.
- FlexRAM is always powered off in VLLSx modes.
- Before executing an entry to VLPR mode, the MCG must be in one of two of its operating modes, each with a particular clock source selected:
 - Either the MCG must be in its BLPE operating mode with only the low gain oscillator selected, or
 - The MCG must be in its BLPI operating mode with only the 2 MHz IRC selected.
- The CMP in stop or VLPS mode supports high speed or low speed, external pin-to-pin or external pin-to-DAC compares. Windowed, sampled, and filtered modes of operation are not available in stop, VLPS, LLS, or VLLSx modes.
- The CMP in LLS or VLLSx mode supports only low speed, external pin-to-pin or external pin-to-DAC compares. Windowed, sampled, and filtered modes of operation are not available in stop, VLPS, LLS, or VLLSx modes.
- In VLLSx modes, the CMP0_OUT signal is gated until after MCU recovery.
- The SPISWAI bit must be cleared for master mode operation in wait modes.
- TSI wakeup from LLS and VLLSx modes is limited to a single selectable pin.

NOTE

- ON* means the module is operational by default in the designated power mode.
- FF* means "full functionality." The user has the option to enable the module's operation in the designated power mode. In VLPR and VLPW modes, the system frequency might limit some modules.
- Static* means the digital modules' register states and associated memories are held.
- Powered* means memory is powered to retain contents.

- *Low power* means flash has a low power state that retains configuration registers to support faster wakeup.
- *Wakeup* means the module can serve as a wakeup source for the chip. For more information, refer to the [LLWU module's dedicated chapter](#) and to [its Chip Configuration details](#).
- *OFF* means the module is powered off and is in a reset state upon wakeup.

Chapter 8

Security

8.1 Introduction

The device implements security based on the mode selected from the flash module. The primary function of security is to prevent the contents of the flash memory (main array) from being read or changed by external entities. An external entity is anything other than the normal application code that is stored in the on-chip program flash memory and is executed by the on-chip CPU. An external entity can be connected through the JTAG or EzPort interface. The internal application code can always change the security state, securing an unsecured device or unsecuring a currently secured device.

8.2 Flash Security

The flash module provides security information to the MCU based on the state held by the flash memory (FTFL) module's FSEC[SEC] bits. The MCU, in turn, confirms the security request and limits access to flash resources. During reset, the flash module initializes the FSEC register using data read from the security byte of the flash configuration field. For more information, refer to the [Flash Configuration Field Description](#).

NOTE

The security features apply only to external accesses via debug and EzPort. CPU accesses to the flash are not affected by the status of FSEC.

In the unsecured state, all flash commands are available to the programming interfaces (BDM and EzPort) and so is user code execution of Flash Controller commands. When the flash is secured, programmer interfaces have no access to memory locations and are allowed only to launch mass erase operations.

Further information regarding the flash security options and enabling/disabling flash security is available in the detailed description of the [flash memory module](#). Further information regarding the flash security options and enabling/disabling flash security in BDM is available in the detailed description of [V1 ColdFire debug](#).

8.3 Flash Security Options

In addition to enabling and disabling security, the flash security byte configures various security options.

8.3.1 Backdoor Key Access

The FSEC[KEYEN] field's setting allows flash security to be disabled temporarily by entering an 8-byte key value.

Table 8-1. Flash Key Enable States

KEYEN[1:0]	Status of Backdoor Key Access
00	Disabled
01	Disabled (preferred setting to disable backdoor key access)
10	Enabled
11	Disabled

8.3.2 Freescale Factory Access

The FSEC[FSLACC] field's setting enables or disables access to flash memory contents during returned part failure analysis at Freescale. When SEC is secure and FSLACC is denied, access to the program flash contents is denied and any failure analysis performed by Freescale factory testing must begin with a full erase operation to unsecure the part.

When access is granted (SEC is unsecure, or SEC is secure and FSLACC is granted), Freescale factory testing has visibility of the current flash memory contents. The state of the FSLACC bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the FSLACC setting does not matter.

Table 8-2. Freescale Factory Access States

FSLACC[1:0]	Freescale Factory Access
00	Granted

Table continues on the next page...

**Table 8-2. Freescale Factory Access States
(continued)**

FSLACC[1:0]	Freescale Factory Access
01	Denied
10	Denied
11	Granted

8.4 Enabling Flash Security

Flash security can be enabled by programming the security byte of the flash configuration field. This assumes that flash is currently unsecured and that the region of the P-Flash containing the Flash Configuration Field is unprotected. If the Flash security byte is successfully programmed, its new value will take affect after the next MCU reset.

NOTE

Once enabled, the security options cannot be modified without disabling security first. The backdoor key access enable, 8-byte backdoor key, and Freescale access bits should be programmed to the desired settings before enabling security.

8.5 Unsecuring the MCU using Backdoor Key Access

The MCU may be unsecured by using the backdoor key access feature, which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field. If the KEYEN[1:0] bits are in the enabled state, the Verify Backdoor Access Key command can be run. This command allows the user to present prospective keys for comparison to the stored keys. If the keys match, the SEC bits in the FSEC register change to unsecure the MCU until the next reset.

NOTE

The entire 8-byte key cannot be 0000_0000_0000_0000h or FFFF_FFFF_FFFF_FFFFh. These values are not accepted by the Verify Backdoor Access Key command as valid comparison values.

While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data. The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN[1:0] bits are in the enabled state, the MCU can be unsecured by this backdoor key access sequence:

1. Execute the Verify Backdoor Access Key command with the 8-byte key value loaded into the flash memory module's FCCOB0 to FCCOB7 registers.
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the SEC[1:0] bits in the FSEC register are forced to the unsecure state.
3. If the backdoor keys do not match, security is not released, all future attempts to execute the Verify Backdoor Access Key command are immediately aborted, and the ACCERR bit in the FSTAT register is (again) set to 1 until a power-down (cold) reset occurs.

A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only; it does not alter the security byte or the keys stored in the Flash Configuration Field. After the next reset of the MCU, the security state of the flash memory module reverts to the value of the flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the flash protection (FPROT) registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field, reprogram the flash security byte to the unsecure state, and change the backdoor keys to any desired value.

8.6 Unsecuring the MCU using the Erase All Blocks command

The Erase All Blocks operation erases the entirety of the program flash memory, FlexNVM, and FlexRAM used as EEPROM; verifies the erase; and then releases MCU security.

When the chip is in BDM, the functionality of the Erase All Blocks command is also available in an uncommanded fashion using the DGBCR[0] bit. When invoked, this function erases all program flash memory, FlexNVM, and FlexRAM used as EEPROM regardless of the protection settings. This function, like the normal command activation,

also initializes all locations in the FlexRAM used as EEPROM to the address FFFFh. If the Flash Erase Verify passes, the routine then releases security by setting the FSEC[SEC] field to the unsecure state.

8.7 Security Interactions with other Modules

The flash security settings will be used by the SoC to determine what resources are available. The following sections describe the interactions between modules and the flash security settings or the impact that the flash security has on non-flash modules.

8.7.1 Security interactions with Mini-FlexBus

If flash security is enabled, the SOPT6[MBSL] field in the SIM enables/disables off-chip accesses through the Mini-FlexBus interface. The field controls whether both instruction accesses and data accesses are allowed, whether both instruction accesses and data accesses are disallowed, or whether instruction accesses are disallowed while data accesses are allowed.

8.7.2 Security interactions with EzPort

When flash memory security is active, the MCU can still boot in EzPort mode. The EzPort module can execute an erase all blocks command (mass erase). The mass erase can be used to disable flash memory security, but all of the flash memory's contents are lost in the process.

8.7.3 Security interactions with Debug

When flash memory security is active, the BDM port cannot be used to access the MCU's internal flash memory. Scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read out flash contents.

Although most debug functions are disabled when flash memory security is active, the debug port can be used to execute an erase all blocks command (mass erase).

Chapter 9

Signal Multiplexing and Signal Descriptions

9.1 Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The [Port Mux Control](#) block controls which signal is present on the external pin. Refer to that chapter to find which register controls the operation of a specific pin.

9.2 Signal Multiplexing Integration

This section summarizes how the module is integrated into the device. For a comprehensive description of the module itself, see the module's dedicated chapter.

9.3 Port Mux Control Features

Package pins can be programmed for up to sixteen different functions using the mux control registers. Controls are organized by GPIO port. Each GPIO port has four mux control registers, consisting of 4 bits per package pin. Most mux registers reset to 00h. Alternate values for each function match the column number in which that function occurs in the pin summary table. Generally, default functions are assigned value 00h, ALT1 functions 01h, and so on.

CAUTION

Not all pins described in the port mux are available on every package in the device family. Do not change the port mux control field for pins that do not appear on the device in use. For example, in a 32-pin package, mask the PTCPF1[C6] field when writing to the PTCPF1 register. Changing the port mux control field for such unavailable pins can generate unnecessary current leakage.

Table 9-2. Port mux control registers overview

Address	Peripheral	Register	Bit 7	6	5	4	3	2	1	Bit 0

9.4 Signal Multiplexing and Pin Assignments

The following table shows the signals available on each pin and the locations of these pins on the devices supported by this document. The Port Mux Control module is responsible for selecting which ALT functionality is available on each pin.

NOTE

- On PTB0, EZP_MS_b is active only during reset. Refer to the detailed boot description.
- PTC1 is open drain.

9.5 Pinout diagrams

The following diagrams show pinouts for the 64-pin, 48-pin, 44-pin, and 32-pin packages. These diagrams are representations for ease of reference. See the package drawings for mechanical details.

For each pin, the diagrams show the default function or (when disabled is the default) the ALT1 signal for a GPIO function. However, many signals may be multiplexed onto a single pin.

Figure 9-2. 64-pin LQFP

Figure 9-3. 48-pin LQFP

Figure 9-4. 44-pin Laminated QFN

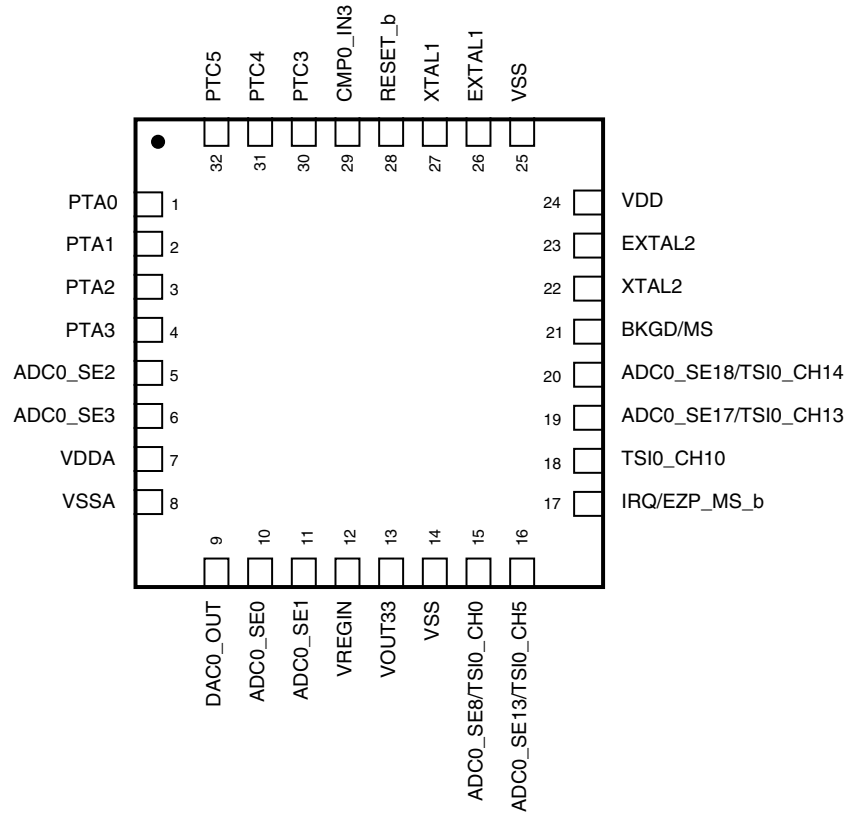

Figure 9-5. 32-pin QFN

9.6 Module-by-module signals

NOTE

- On PTB0, EZP_MS_b is active only during reset. Refer to the detailed boot description.
- PTC1 is open drain.

9.7 Module Signal Description Tables

The following sections correlate the chip-level signal name with the signal name used in the module's chapter. They also briefly describe the signal function and direction.

9.7.1 Core Modules

Table 9-4. Background Debug Signal Descriptions

Chip signal name	Module signal name	Description	I/O
BKGD	BKGD	Single-wire background debug interface pin	I/O

9.7.2 System Modules

Table 9-5. System Signal Descriptions

Chip signal name	Module signal name	Description	I/O
RESET	—	Reset input signal	I
VDD	—	MCU power	I
VSS	—	MCU ground	I

Table continues on the next page...

Table 9-5. System Signal Descriptions (continued)

Chip signal name	Module signal name	Description	I/O
CLKOUT	—	External clock reference	O

Table 9-6. LLWU Signal Descriptions

Chip signal name	Module signal name	Description	I/O
LLWU_Pn	LLWU_Pn	Wakeup inputs (n = 0-15)	I

Table 9-7. VREG Signal Descriptions

Chip signal name	Module signal name	Description	I/O
VOUT33	reg33_out	Regulator output voltage	O
VREGIN	reg33_in	Unregulated power supply	I

9.7.3 Clock Modules

Table 9-8. OSC1 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EXTAL1	EXTAL	External clock/Oscillator input	I
XTAL1	XTAL	Oscillator output	O

Table 9-9. OSC2 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EXTAL2	EXTAL	External clock/Oscillator input	I
XTAL2	XTAL	Oscillator output	O

9.7.4 Memories and Memory Interfaces

Table 9-10. EzPort Signal Descriptions

Chip signal name	Module signal name	Description	I/O
EZP_CLK	EZP_CK	EzPort Clock	Input
$\overline{\text{EZP_CS}}$	$\overline{\text{EZP_CS}}$	EzPort Chip Select	Input
EZP_DI	EZP_D	EzPort Serial Data In	Input
EZP_DO	EZP_Q	EzPort Serial Data Out	Output
$\overline{\text{EZP_MS}}$	—	Selects between EzPort serial flash programming mode and single chip mode	I

Table 9-11. Mini-FlexBus Signal Descriptions

Chip signal name	Module signal name	Description	I/O
FB_CLKOUT	FB_CLK	O	FlexBus Clock Output
FBa_AD[19:0]	FB_A19–FB_A0	Address Bus When FlexBus is used in a nonmultiplexed configuration, this is the address bus, FB_A. When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD. When FlexBus is used in a multiplexed configuration, the full 20-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD19–FB_AD16, and in 8-bit mode, the lower address is driven on FB_AD19–FB_AD8.	I/O
FBa_ALE	$\overline{\text{FB_TS}}$	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. When FlexBus is used in a multiplexed configuration, an inverted $\overline{\text{FB_TS}}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus. FB_TS/FB_ALE is asserted for one bus clock cycle.	O
$\overline{\text{FBa_CS0}}$	FB_CS1–FB_CS0	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].	O
FBa_D[7:0]	FB_D7–FB_D0	Data Bus When FlexBus is used in a nonmultiplexed configuration, this is the data bus. When FlexBus is used in a multiplexed configuration, this bus is not used.	I/O
FBa_OE	FB_OE	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.	O
FBa_RW	FB_R/W	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low).	O

9.7.5 Analog

Table 9-12. ADC0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
ADC0_SE[22:8,3:2]	AD n	Single-Ended Analog Channel Inputs	I
VREFH	V _{REFSH}	Voltage Reference Select High	I
VREFL	V _{REFSL}	Voltage Reference Select Low	I
VDDA	V _{DDA}	Analog Power Supply	I
VSSA	V _{SSA}	Analog Ground	I

Table 9-13. CMP0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
CMP0_IN[3:0]	IN[3:0]	Analog voltage inputs	I
CMP0_OUT	CMPO	CMP output	O

Table 9-14. DAC0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
DAC0_OUT	—	DAC output	O

Chip signal name	Module signal name	Description	I/O
PTE[7:0] ¹	PTE[7:0]	General purpose input/output	I/O
PTF[7:0] ¹	PTF[7:0]	General purpose input/output	I/O

1. The available GPIO pins depend on the specific package. See the [signal multiplexing details](#) for which exact GPIO signals are available.

Table 9-31. RGPIO Signal Descriptions

Chip signal name	Module signal name	Description	I/O
RGPIO[15:0]	RGPIO[15:0]	Data Input/Output. When configured as an input, the state of this signal is reflected in the read data register. When configured as an output, this signal is the output of the write data register.	I/O

Table 9-32. TSI0 Signal Descriptions

Chip signal name	Module signal name	Description	I/O
TSI0_CH[15:0]	TSI_IN[15:0]	TSI pins. Switchable driver that connects directly to the electrode pins TSI[15:0] can operate as GPIO pins	I/O

Table 9-33. IRQ Signal Descriptions

Chip signal name	Module signal name	Description	I/O
IRQ	IRQ	External interrupt pin	I

Chapter 10

Port Mux Control

10.1 Port Mux Control

Package pins can be programmed for up to sixteen different functions using the mux control registers. Controls are organized by GPIO port. Each GPIO port has four mux control registers, consisting of 4 bits per package pin. Most mux registers reset to 00h. Alternate values for each function match the column number in which that function occurs in the pin summary table. Generally, default functions are assigned value 00h, ALT1 functions 01h, and so on.

CAUTION

Not all pins described in the port mux are available on every package in the device family. Do not change the port mux control field for pins that do not appear on the device in use. For example, in a 32-pin package, mask the PTCPF1[C6] field when writing to the PTCPF1 register. Changing the port mux control field for such unavailable pins can generate unnecessary current leakage.

10.2 Memory Map and Registers

MXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8080	Port A Pin Function 1 Register (MXC_PTAPF1)	8	R/W	00h	10.2.1/188

Chapter 11

Core

11.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This section describes the organization of the Version 1 (V1) ColdFire® processor core and an overview of the program-visible registers. For detailed information on instructions, see the ISA_C definition in the *ColdFire Family Programmer's Reference Manual*.

11.1.1 Overview

As with all ColdFire cores, the V1 ColdFire core consists of two separate pipelines decoupled by an instruction buffer.

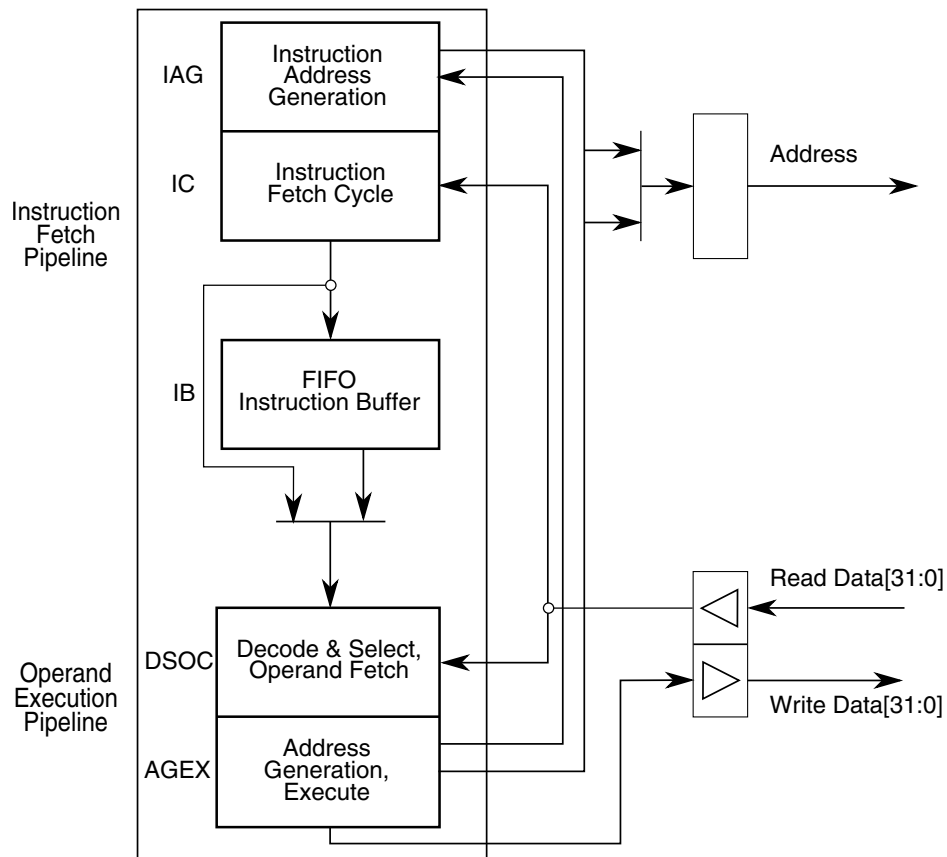

Figure 11-1. V1 ColdFire Core Pipelines

The instruction fetch pipeline (IFP) is a two-stage pipeline for prefetching instructions. The prefetched instruction stream is then gated into the two-stage operand execution pipeline (OEP), that decodes the instruction, fetches the required operands, and then executes the required function. Because the IFP and OEP pipelines are decoupled by an instruction buffer serving as a FIFO queue, the IFP is able to prefetch instructions in advance of their actual use by the OEP thereby minimizing time stalled waiting for instructions.

The V1 ColdFire core pipeline stages include the following:

- Two-stage instruction fetch pipeline (IFP) (plus optional instruction buffer stage)
 - Instruction address generation (IAG) — Calculates the next prefetch address
 - Instruction fetch cycle (IC) — Initiates prefetch on the processor's local bus
 - Instruction buffer (IB) — Optional buffer stage minimizes fetch latency effects using FIFO queue
- Two-stage operand execution pipeline (OEP)

- Decode and select/operand fetch cycle (DSOC) — Decodes instructions and fetches the required components for effective address calculation, or the operand fetch cycle
- Address generation/execute cycle (AGEX) — Calculates operand address or executes the instruction

When the instruction buffer is empty, opcodes are loaded directly from the IC cycle into the operand execution pipeline. If the buffer is not empty, the IFP stores the contents of the fetched instruction in the IB until it is required by the OEP. The instruction buffer on the V1 core contains three longwords of storage.

For register-to-register and register-to-memory store operations, the instruction passes through both OEP stages once. For memory-to-register and read-modify-write memory operations, an instruction is effectively staged through the OEP twice; the first time to calculate the effective address and initiate the operand fetch on the processor's local bus, and the second time to complete the operand reference and perform the required function defined by the instruction.

The resulting pipeline and local bus structure allow the V1 ColdFire core to deliver sustained high performance across a variety of demanding embedded applications.

11.2 Memory Map/Register Description

The following sections describe the processor registers in the user and supervisor programming models. The programming model is selected based on the processor privilege level (user mode or supervisor mode) as defined by the S bit of the status register (SR).

The user-programming model consists of the following registers:

- 16 general-purpose 32-bit registers (D0–D7, A0–A7)
- 32-bit program counter (PC)
- 8-bit condition code register (CCR)
- EMAC registers (refer to EMAC description)
 - Four 48-bit accumulator registers partitioned as follows:

- Four 32-bit accumulators (ACC0–ACC3)
- Eight 8-bit accumulator extension bytes (two per accumulator). These are grouped into two 32-bit values for load and store operations (ACCEXT01 and ACCEXT23).

Accumulators and extension bytes can be loaded, copied, and stored, and results from EMAC arithmetic operations generally affect the entire 48-bit destination.

- One 16-bit mask register (MASK)
- One 32-bit status register (MACSR) including four indicator bits signaling product or accumulation overflow (one for each accumulator: PAV0–PAV3)

The supervisor programming model is to be used only by system control software to implement restricted operating system functions, I/O control, and memory management. All accesses that affect the control features of ColdFire processors are in the supervisor programming model, that consists of registers available in user mode as well as the following control registers:

- 16-bit status register (SR)
- 32-bit supervisor stack pointer (SSP)
- 32-bit vector base register (VBR)
- 32-bit CPU configuration register (CPUCR)

Table 11-1. ColdFire core programming model

Load: 0xEE Store: 0xCE	Status register (SR)	16	R/W	0x27--	No

1. The values listed in this column represent the 8-bit BDM command code used when accessing the core registers via the 1-pin BDM port. For details, see information about ColdFire debug operation. (These BDM commands are not similar to those of non-V1 ColdFire processors.)
2. The EMAC registers are available only if the EMAC module is present on the device.
3. If the given register is written using the MOVEC instruction, the 12-bit control register address (Rc) is also specified.

11.2.1 Data registers (D0–D7)

These registers are for bit (1-bit), byte (8-bit), word (16-bit) and longword (32-bit) operations; they can also be used as index registers.

NOTE

The D0 and D1 registers contain hardware configuration details after reset. See [Reset Exception](#) for more details.

Table 11-2. Data registers (D0–D7)

BDM:	Load: 0x60 + n; n = 0–7 (Dn)												Access: User read/write

Reset	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

11.2.3 Supervisor/user stack pointers (A7 and OTHER_A7)

This ColdFire architecture supports two independent stack pointer (A7) registers: the supervisor stack pointer (SSP) and the user stack pointer (USP). The hardware implementation of these two program-visible 32-bit registers does not identify one as the SSP and the other as the USP. Instead, the hardware uses one 32-bit register as the active A7 and the other as OTHER_A7. Thus, the register contents are a function of the processor operation mode, as shown in the following:

```
if SR[S] = 1
    then      A7 = Supervisor Stack Pointer
             OTHER_A7 = User Stack Pointer
    else      A7 = User Stack Pointer
             OTHER_A7 = Supervisor Stack Pointer
```

The BDM programming model supports direct reads and writes to A7 and OTHER_A7. It is the responsibility of the external development system to determine, based on the setting of SR[S], the mapping of A7 and OTHER_A7 to the two program-visible definitions (SSP and USP).

To support dual stack pointers, the following two supervisor instructions are included in the ColdFire instruction set architecture to load/store the USP:

```
move.l Ay,USP;move to USP
move.l USP,Ax;move from USP
```

The *ColdFire Family Programmer's Reference Manual* describes these instructions. All other instruction references to the stack pointer, explicit or implicit, access the active A7 register.

NOTE

The USP must be initialized using the

```
move.l Ay,USP
```

instruction before any entry into user mode.

The SSP is loaded during reset exception processing with the contents of location 0x(00)00_0000.

Table 11-4. Stack pointer registers (A7 and OTHER_A7)

BDM:	Load: 0x6F (A7) Store: 0x4F (A7) Load: 0xE0 (OTHER_A7) Store: 0xC0 (OTHER_A7)	Access: A7: User or BDM read/ write OTHER_A7: Supervisor or BDM read/write

R	Address															
W	Address															
Reset	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

11.2.4 Condition code register (CCR)

The CCR is the LSB of the processor status register (SR). Bits 4–0 act as indicator flags for results generated by processor operations. The extend bit (X) is also an input operand during multiprecision arithmetic computations. The CCR register must be explicitly loaded after reset and before any CMP, Bcc, or Scc instructions are executed.

Table 11-5. Condition code register (CCR)

BDM:	LSB of status register (SR)								Access: User read/write			
	Load: 0xEE (SR)								BDM read/write			
	Store: 0xCE (SR)

Field	Description
7–5	Reserved; must be cleared.
4	Extend condition code
X	This bit is set to the C bit's value for arithmetic operations; otherwise not affected or set to a specified result.
3	Negative condition code
N	This bit is set if the most significant bit of the result is set; otherwise cleared.
2	Zero condition code
Z	This bit is set if result equals zero; otherwise cleared.

Table continues on the next page...

Table 11-6. CCR field descriptions (continued)

Field	Description
1 V	Overflow condition code This bit is set if an arithmetic overflow occurs implying the result cannot be represented in operand size; otherwise cleared.
0 C	Carry condition code This bit is set if a carry out of the operand msb occurs for an addition or if a borrow occurs in a subtraction; otherwise cleared.

11.2.5 Program counter (PC)

The PC contains the currently executing instruction address. During instruction execution and exception processing, the processor automatically increments PC contents or places a new value in the PC. The PC is a base address for PC-relative operand addressing.

The PC is initially loaded during reset exception processing with the contents at location 0x(00)00_0004.

Table 11-7. Program counter (PC) register

BDM:	Load: 0xEF (PC)								Access: User read/write							
	Store: 0xCF (PC)								BDM read/write

R	Address															
W																
Reset	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

11.2.6 Vector base register (VBR)

The VBR contains the base address of the exception vector table in the memory. To access the vector table, the displacement of an exception vector is added to the value in VBR. The lower 20 bits of the VBR are not implemented by ColdFire processors. They are assumed to be zero, forcing the table to be aligned on a 1 MB boundary.

In addition, because the V1 ColdFire core supports a 16 MB address space, the upper byte of the VBR is also forced to zero. The VBR can be used to relocate the exception vector table from its default position in the flash memory (address 0x(00)00_0000) to the base of the RAM (address 0x(00)80_0000) if needed.

Table 11-8. Vector base register (VBR)

W																
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

11.2.7 CPU configuration register (CPUCR)

This register provides supervisor mode configurability of specific core functionality. Particular hardware features can be enabled/disabled individually based on the state of the CPUCR.

NOTE

Program the Flash Memory Controller's configuration and control settings only while the Flash Memory Controller is idle. Changing settings while a flash access is in progress can lead to non-deterministic behavior.

NOTE

System software is required to maintain memory coherence when any segment of the program flash memory cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

Table 11-9. CPU configuration register (CPUCR)

Field	Description				
31 ARD	<p>Address-related reset disable</p> <p>Used to disable the generation of a reset event in response to a processor exception caused by an address error, a bus error, an RTE format error, or a fault-on-fault halt condition.</p> <table border="1"> <tr> <td>0</td> <td>The detection of these types of exception conditions or the fault-on-fault halt condition generate a reset event.</td> </tr> <tr> <td>1</td> <td>No reset is generated in response to these exception conditions.</td> </tr> </table>	0	The detection of these types of exception conditions or the fault-on-fault halt condition generate a reset event.	1	No reset is generated in response to these exception conditions.
0	The detection of these types of exception conditions or the fault-on-fault halt condition generate a reset event.				
1	No reset is generated in response to these exception conditions.				
30 IRD	<p>Instruction-related reset disable</p> <p>Used to disable the generation of a reset event in response to a processor exception caused by the attempted execution of an illegal instruction (except for the ILLEGAL opcode), illegal line A, illegal line F instructions, or a privilege violation.</p> <table border="1"> <tr> <td>0</td> <td>The detection of these types of exception conditions generate a reset event.</td> </tr> <tr> <td>1</td> <td>No reset is generated in response to these exception conditions.</td> </tr> </table>	0	The detection of these types of exception conditions generate a reset event.	1	No reset is generated in response to these exception conditions.
0	The detection of these types of exception conditions generate a reset event.				
1	No reset is generated in response to these exception conditions.				
29 IAE	<p>Interrupt acknowledge (IACK) enable</p> <p>Forces the processor to generate an IACK read cycle from the interrupt controller during exception processing to retrieve the vector number of the interrupt request being acknowledged. The processor's execution time for an interrupt exception is slightly improved when this bit is cleared.</p> <table border="1"> <tr> <td>0</td> <td>The processor uses the vector number provided by the interrupt controller at the time the request is signaled.</td> </tr> <tr> <td>1</td> <td>IACK read cycle from the interrupt controller is generated.</td> </tr> </table>	0	The processor uses the vector number provided by the interrupt controller at the time the request is signaled.	1	IACK read cycle from the interrupt controller is generated.
0	The processor uses the vector number provided by the interrupt controller at the time the request is signaled.				
1	IACK read cycle from the interrupt controller is generated.				
28 IME	<p>Interrupt mask enable</p> <p>Forces the processor to raise the interrupt level mask (SR[I]) to 7 during every interrupt exception.</p> <table border="1"> <tr> <td>0</td> <td>As part of an interrupt exception, the processor sets SR[I] to the level of the interrupt being serviced.</td> </tr> <tr> <td>1</td> <td>As part of an interrupt exception, the processor sets SR[I] to 7. This disables all level 1-6 interrupt requests but allows recognition of the edge-sensitive level 7 requests.</td> </tr> </table>	0	As part of an interrupt exception, the processor sets SR[I] to the level of the interrupt being serviced.	1	As part of an interrupt exception, the processor sets SR[I] to 7. This disables all level 1-6 interrupt requests but allows recognition of the edge-sensitive level 7 requests.
0	As part of an interrupt exception, the processor sets SR[I] to the level of the interrupt being serviced.				
1	As part of an interrupt exception, the processor sets SR[I] to 7. This disables all level 1-6 interrupt requests but allows recognition of the edge-sensitive level 7 requests.

Table 11-10. CPUCR field descriptions (continued)

Field	Description
20 FICDIS	Flash instruction caching disable Disables the caching of instruction fetches from the flash memory controller.
	0 Instruction fetches via the flash controller cache are enabled.
	1 Instruction fetches via the flash controller cache are disabled.
19 FCCLR	Clear flash controller cache Setting this bit to 1 clears (invalidates) the cache immediately. This bit always reads as 0.
18–0	Reserved; must be cleared.

11.2.8 Status register (SR)

This register stores the processor status and includes the CCR, the interrupt priority mask, and other control bits. In supervisor mode, software can access the entire SR. In user mode, only the lower 8 bits (the CCR) are accessible. The control bits indicate the following states for the processor: trace mode (T bit), supervisor or user mode (S bit), and master or interrupt state (M bit). All defined bits in the SR have read/write access when in supervisor mode. The lower byte of the SR (the CCR) must be loaded explicitly after reset and before any compare (CMP), Bcc, or Scc instructions execute.

Table 11-11. Status register (SR)

BDM:	Load: 0xEE (SR) Store: 0xCE (SR)												Access: Supervisor read/ write BDM read/write			
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	T	0	S	M	0				0	0	0	X	N	Z	V	C
W							I									
Reset	0	0	1	0	0	1	1	1	0	0	0	–	–	–	–	–

Table 11-12. SR field descriptions

Field	Description
15 T	Trace enable When this bit is set, the processor performs a trace exception after every instruction.
14	Reserved; must be cleared.
13 S	Supervisor/user state
	0 User mode
	1 Supervisor mode

Table continues on the next page...

Table 11-12. SR field descriptions (continued)

Field	Description
12 M	Master/interrupt state This bit is cleared by an interrupt exception, and software can set it during execution of the RTE or move to SR instructions.
11	Reserved; must be cleared.
10–8 I	Interrupt level mask Defines current interrupt level. Interrupt requests are inhibited for all priority levels less than or equal to current level, except edge-sensitive level 7 requests, which cannot be masked.
7–0	Refer to Condition code register (CCR)

11.3 Functional Description

11.3.1 Instruction Set Architecture

The original ColdFire instruction set architecture (ISA_A) was derived from the M68000 family opcodes based on extensive analysis of embedded application code. The ISA was optimized for code compiled from high-level languages where the dominant operand size was the 32-bit integer declaration. This approach minimized processor complexity and cost, while providing excellent performance for compiled applications.

After the initial ColdFire compilers were created, developers noted there were certain ISA additions that would enhance code density and overall performance. Additionally, as users implemented ColdFire-based designs into a wide range of embedded systems, they found certain frequently-used instruction sequences that could be improved by the creation of additional instructions.

The original ISA definition minimized support for instructions referencing byte- and word-sized operands. Full support for the move byte and move word instructions was provided, but the only other opcodes supporting these data types are CLR (clear) and TST (test). A set of instruction enhancements has been implemented in subsequent ISA revisions, ISA_B and ISA_C. The new opcodes primarily addressed three areas:

1. Enhanced support for byte and word-sized operands
2. Enhanced support for position-independent code
3. Miscellaneous instruction additions to address new functionality

The following table summarizes the instructions added to revision ISA_A to form revision ISA_C. For more details see the *ColdFire Family Programmer's Reference Manual*.

Table 11-13. Instruction Enhancements over Revision ISA_A

Instruction	Description
BITREV	The contents of the destination data register are bit-reversed; that is, new Dn[31] equals old Dn[0], new Dn[30] equals old Dn[1], ..., new Dn[0] equals old Dn[31].
BYTEREV	The contents of the destination data register are byte-reversed; that is, new Dn[31:24] equals old Dn[7:0], ..., new Dn[7:0] equals old Dn[31:24].
FF1	The data register, Dn, is scanned, beginning from the most-significant bit (Dn[31]) and ending with the least-significant bit (Dn[0]), searching for the first set bit. The data register is then loaded with the offset count from bit 31 where the first set bit appears.
MOV3Q.L	Moves 3-bit immediate data to the destination location.
Move from USP	User Stack Pointer → Destination register
Move to USP	Source register → User Stack Pointer
MVS.{B,W}	Sign-extends source operand and moves it to destination register.
MVZ.{B,W}	Zero-fills source operand and moves it to destination register.
SATS.L	Performs saturation operation for signed arithmetic and updates destination register, depending on CCR[V] and bit 31 of the register.
TAS.B	Performs indivisible read-modify-write cycle to test and set addressed memory byte.
Bcc.L	Branch conditionally, longword
BSR.L	Branch to sub-routine, longword
CMP.{B,W}	Compare, byte and word
CMPA.W	Compare address, word
CMPI.{B,W}	Compare immediate, byte and word
MOVEI	Move immediate, byte and word to memory using Ax with displacement
STLDSR	Pushes the contents of the status register onto the stack and then reloads the status register with the immediate data value.

11.3.2 Exception Processing Overview

Exception processing for ColdFire processors is streamlined for performance. The ColdFire processors differ from the M68000 family because they include:

- A simplified exception vector table
- Reduced relocation capabilities using the vector-base register
- A single exception stack frame format
- Use of separate system stack pointers for user and supervisor modes.

All ColdFire processors use an instruction restart exception model.

Exception processing includes all actions from fault condition detection to the initiation of fetch for first handler instruction. Exception processing is comprised of four major steps:

1. The processor makes an internal copy of the SR and then enters supervisor mode by setting the S bit and disabling trace mode by clearing the T bit. The interrupt exception also forces the M bit to be cleared and the interrupt priority mask to set to current interrupt request level.
2. The processor determines the exception vector number. For all faults except interrupts, the processor performs this calculation based on exception type. For interrupts, the processor performs an interrupt-acknowledge (IACK) bus cycle to obtain the vector number from the interrupt controller if CPUCR[IAE] is set. The IACK cycle is mapped to special locations within the interrupt controller's address space with the interrupt level encoded in the address. If CPUCR[IAE] is cleared, the processor uses the vector number supplied by the interrupt controller at the time the request was signaled for improved performance.
3. The processor saves the current context by creating an exception stack frame on the system stack. The exception stack frame is created at a 0-modulo-4 address on top of the system stack pointed to by the supervisor stack pointer (SSP). As shown in [Figure 11-2](#), the processor uses a simplified fixed-length stack frame for all exceptions. The exception type determines whether the program counter placed in the exception stack frame defines the location of the faulting instruction (fault) or the address of the next instruction to be executed (next).
4. The processor calculates the address of the first instruction of the exception handler. By definition, the exception vector table is aligned on a 1 MB boundary. This instruction address is generated by fetching an exception vector from the table located at the address defined in the vector base register. The index into the exception table is calculated as $(4 \times \text{vector number})$. After the exception vector has been fetched, the vector contents determine the address of the first instruction of the desired handler. After the instruction fetch for the first opcode of the handler has initiated, exception processing terminates and normal instruction processing continues in the handler.

All ColdFire processors support a 1024-byte vector table aligned on any 1 MB address boundary (see [Table 11-14](#)). For the V1 ColdFire core, the only practical locations for the vector table are based at 0x(00)00_0000 in the flash or 0x(00)80_0000 in the internal SRAM.

The table contains 256 exception vectors; the first 64 are defined for the core and the remaining 192 are device-specific peripheral interrupt vectors. See the interrupt chapter for details on the device-specific interrupt sources.

For the V1 ColdFire core, the table is partially populated with the first 64 reserved for internal processor exceptions, while vectors 64-102 are reserved for the peripheral I/O requests and the seven software interrupts. Vectors 103–255 are unused and reserved.

Table 11-14. Exception Vector Assignments

Vector Number(s)	Vector Offset (Hex)	Stacked Program Counter ¹	Assignment
0	0x000	—	Initial supervisor stack pointer
1	0x004	—	Initial program counter
2	0x008	Fault	Access error
3	0x00C	Fault	Address error
4	0x010	Fault	Illegal instruction
5	0x014	Fault	Divide by zero
6–7	0x018–0x01C	—	Reserved
8	0x020	Fault	Privilege violation
9	0x024	Next	Trace
10	0x028	Fault	Unimplemented line-A opcode
11	0x02C	Fault	Unimplemented line-F opcode
12	0x030	Next	Debug interrupt
13	0x034	—	Reserved
14	0x038	Fault	Format error
15–23	0x03C–0x05C	—	Reserved
24	0x060	Next	Spurious interrupt
25–31	0x064–0x07C	—	Reserved
32–47	0x080–0x0BC	Next	Trap # 0-15 instructions
48–60	0x0C0–0x0F0	—	Reserved
61	0x0F4	Fault	Unsupported instruction
62–63	0x0F8–0x0FC	—	Reserved
64–102	0x100–0x198	Next	Device-specific interrupts
103–255	0x19C–0x3FC	—	Reserved

1. Fault refers to the PC of the instruction that caused the exception.

Next refers to the PC of the instruction that follows the instruction that caused the fault.

All ColdFire processors inhibit interrupt sampling during the first instruction of all exception handlers. This allows any handler to disable interrupts effectively, if necessary, by raising the interrupt mask level contained in the status register. In addition, the ISA_C architecture includes an instruction (STLDSR) that stores the current interrupt mask level and loads a value into the SR. This instruction is specifically intended for use as the first instruction of an interrupt service routine that services multiple interrupt requests with different interrupt levels. Finally, the V1 ColdFire core includes the CPUCR[IME] bit

that forces the processor to automatically raise the mask level to 7 during the interrupt exception, removing the need for any explicit instruction in the service routine to perform this function. For more details, see *ColdFire Family Programmer's Reference Manual*.

11.3.2.1 Exception Stack Frame Definition

The following figures shows the exception stack frame. The first longword contains the 16-bit format/vector word (F/V) and the 16-bit status register, and the second longword contains the 32-bit program counter address.

Figure 11-2. Exception Stack Frame Form

The 16-bit format/vector word contains three unique fields:

- A 4-bit format field at the top of the system stack is always written with a value of 4, 5, 6, or 7 by the processor, indicating a two-longword frame format. See [Table 11-15](#).

Table 11-15. Format Field Encodings

Original SSP @ Time of Exception, Bits 1:0	SSP @ 1st Instruction of Handler	Format Field
00	Original SSP - 8	0100
01	Original SSP - 9	0101
10	Original SSP - 10	0110
11	Original SSP - 11	0111

- There is a 4-bit fault status field, FS[3:0], at the top of the system stack. This field is defined for access and address errors only and written as zeros for all other exceptions. See [Table 11-16](#).

Table 11-16. Fault Status Encodings

FS[3:0]	Definition
00xx	Reserved
0100	Error on instruction fetch

Table continues on the next page...

**Table 11-16. Fault Status Encodings
(continued)**

FS[3:0]	Definition
0101	Reserved
011x	Reserved
1000	Error on operand write
1001	Reserved
101x	Reserved
1100	Error on operand read
1101	Reserved
111x	Reserved

- The 8-bit vector number, vector[7:0], defines the exception type and is calculated by the processor for all internal faults and represents the value supplied by the interrupt controller in case of an interrupt . See [Table 11-14](#) .

11.3.2.2 S08 and ColdFire Exception Processing Comparison

This section presents a brief summary comparing the exception processing differences between the S08 and V1 ColdFire processor families.

Table 11-17. Exception Processing Comparison

Attribute	S08	V1 ColdFire
Exception Vector Table	32, 2-byte entries, fixed location at upper end of memory	103, 4-byte entries, located at lower end of memory at reset, relocatable with the VBR
More on Vectors	2 for CPU + 30 for IRQs, reset at upper address	64 for CPU + 39 for IRQs, reset at lowest address
Exception Stack Frame	5-byte frame: CCR, A, X, PC	8-byte frame: F/V, SR, PC; General-purpose registers (An, Dn) must be saved/restored by the ISR
Interrupt Levels	1 = f(CCR[I])	7 = f(SR[I]) with automatic hardware support for nesting
Non-Maskable IRQ Support	No	Yes, with level 7 interrupts
Core-enforced IRQ Sensitivity	No	Level 7 is edge sensitive, else level sensitive
INTC Vectoring	Fixed priorities and vector assignments	Fixed priorities and vector assignments, plus any 2 IRQs can be remapped as the highest priority level 6 requests
Software IACK	No	Yes
Exit Instruction from ISR	RTI	RTE

The notion of a software IACK refers to the ability to query the interrupt controller near the end of an interrupt service routine (after the current interrupt request has been cleared) to determine if there are any pending (but currently masked) interrupt requests. If the response to the software IACK's byte operand read is non-zero, the service routine uses the value as the vector number of the highest pending interrupt request and passes control to the appropriate new handler. This process avoids the overhead of a context restore and RTE instruction execution followed immediately by another interrupt exception and context save. In system environments with high rates of interrupt activity, this mechanism can improve overall performance noticeably.

Emulation of the S08's 1-level IRQ processing can easily be managed by software convention within the ColdFire interrupt service routines. For this type of operation, only two of the seven interrupt levels are used:

- SR[I] equals 0 indicates interrupts are enabled
- SR[I] equals 7 indicates interrupts are disabled

Recall that ColdFire treats true level 7 interrupts as edge-sensitive, non-maskable requests. Typically, only the IRQ input pin and a low-voltage detect are assigned as level 7 requests. All the remaining interrupt requests (levels 1-6) are masked when SR[I] equals 7. In any case, all ColdFire processors guarantee that the first instruction of any exception handler is executed before interrupt sampling resumes. By making the first instruction of the ISR a store/load status register (STLDSR #0x2700) or a move-to-SR (MOVE.W #2700,SR) instruction, interrupts can be safely disabled until the service routine is exited with an RTE instruction that lowers the SR[I] back to level 0. The same functionality can also be provided without an explicit instruction by setting CPUCCR[IME] because this forces the processor to load SR[I] with 7 on each interrupt exception.

11.3.3 Processor Exceptions

11.3.3.1 Access Error Exception

The default operation of the V1 ColdFire processor is the generation of an illegal address reset event if an access error (also known as a bus error) is detected. If CPUCCR[ARD] is set, the reset is disabled and a processor exception is generated as detailed below.

The exact processor response to an access error depends on the memory reference being performed. For an instruction fetch, the processor postpones the error reporting until the faulted reference is needed by an instruction for execution. Therefore, faults during

instruction prefetches followed by a change of instruction flow do not generate an exception. When the processor attempts to execute an instruction with a faulted opword and/or extension words, the access error is signaled and the instruction is aborted. For this type of exception, the programming model has not been altered by the instruction generating the access error.

If the access error occurs on an operand read, the processor immediately aborts the current instruction's execution and initiates exception processing. In this situation, any address register updates attributable to the auto-addressing modes, (for example, (An)+, -(An)), have already been performed, so the programming model contains the updated An value. In addition, if an access error occurs during a MOVEM instruction loading from memory, any registers already updated before the fault occurs contain the operands from memory.

The V1 ColdFire processor uses an imprecise reporting mechanism for access errors on operand writes. Because the actual write cycle may be decoupled from the processor's issuing of the operation, the signaling of an access error appears to be decoupled from the instruction that generated the write. Accordingly, the PC contained in the exception stack frame merely represents the location in the program when the access error was signaled. All programming model updates associated with the write instruction are completed. The NOP instruction can collect access errors for writes. This instruction delays its execution until all previous operations, including all pending write operations, are complete. If any previous write terminates with an access error, it is guaranteed to be reported on the NOP instruction.

11.3.3.2 Address Error Exception

The default operation of the V1 ColdFire processor is the generation of an illegal address reset event if an address error is detected. If CPUCCR[ARD] equals 1, then the reset is disabled and a processor exception is generated as detailed below.

Any attempted execution transferring control to an odd instruction address (if bit 0 of the target address is set) results in an address error exception.

Any attempted use of a word-sized index register (Xn.w) or a scale factor of eight on an indexed effective addressing mode generates an address error, as does an attempted execution of a full-format indexed addressing mode, which is defined by bit 8 of extension word 1 being set.

If an address error occurs on an RTS instruction, the Version 1 ColdFire processor overwrites the faulting return PC with the address error stack frame.

11.3.3.3 Illegal Instruction Exception

The default operation of the V1 ColdFire processor is the generation of an illegal opcode reset event if an illegal instruction is detected. If CPUCCR[IRD] is set, the reset is disabled and a processor exception is generated as detailed below. There is one special case involving the ILLEGAL opcode (0x4AFC); attempted execution of this instruction always generates an illegal instruction exception, regardless of the state of the CPUCCR[IRD] bit.

The ColdFire variable-length instruction set architecture supports three instruction sizes: 16, 32, or 48 bits. The first instruction word is known as the operation word (or opword), while the optional words are known as extension word 1 and extension word 2. The opword is further subdivided into three sections: the upper four bits segment the entire ISA into 16 instruction lines, the next 6 bits define the operation mode (opmode), and the low-order 6 bits define the effective address. The opword line definition is shown below.

Figure 11-3. ColdFire Instruction Operation Word (Opword) Format

Table 11-18. ColdFire Opword Line Definition

Opword[Line]	Instruction Class
0x0	Bit manipulation, Arithmetic and Logical Immediate
0x1	Move Byte
0x2	Move Long
0x3	Move Word
0x4	Miscellaneous
0x5	Add (ADDQ) and Subtract Quick (SUBQ), Set according to Condition Codes (Scc)
0x6	PC-relative change-of-flow instructions Conditional (Bcc) and unconditional (BRA) branches, subroutine calls (BSR)
0x7	Move Quick (MOVEQ), Move with sign extension (MVS) and zero fill (MVZ)
0x8	Logical OR (OR)
0x9	Subtract (SUB), Subtract Extended (SUBX)
0xA	EMAC, Move 3-bit Quick (MOV3Q)
0xB	Compare (CMP), Exclusive-OR (EOR)
0xC	Logical AND (AND), Multiply Word (MUL)
0xD	Add (ADD), Add Extended (ADDX)
0xE	Arithmetic and logical shifts (ASL, ASR, LSL, LSR)
0xF	Write DDATA (WDDATA), Write Debug (WDEBUG)

In the original M68000 ISA definition, lines A and F were effectively reserved for user-defined operations (line A) and co-processor instructions (line F). Accordingly, there are two unique exception vectors associated with illegal opcodes in these two lines.

Any attempted execution of an illegal 16-bit opcode (except for line-A and line-F opcodes) generates an illegal instruction exception (vector 4). Additionally, any attempted execution of any non-MAC line-A and most line-F opcodes generate their unique exception types, vector numbers 10 and 11, respectively. ColdFire cores do not provide illegal instruction detection on the extension words on any instruction, including MOVEC.

The V1 ColdFire processor also detects two special cases involving illegal instruction conditions:

1. If execution of the stop instruction is attempted and neither low-power stop nor wait modes are enabled, the processor signals an illegal instruction.
2. If execution of the halt instruction is attempted and BDM is not enabled (XCSR[ENBDM] equals 0), the processor signals an illegal instruction.

In both cases, the processor response is then dependent on the state of CPUCR[IRD]— a reset event or a processor exception.

11.3.3.4 Divide-By-Zero

Attempting to divide by zero causes an exception (vector 5, offset equal 0x014).

11.3.3.5 Privilege Violation

The default operation of the V1 ColdFire processor is the generation of an illegal opcode reset event if a privilege violation is detected. If CPUCR[IRD] is set, the reset is disabled and a processor exception is generated as detailed below.

The attempted execution of a supervisor mode instruction while in user mode generates a privilege violation exception. See *ColdFire Programmer's Reference Manual* for a list of supervisor-mode instructions.

There is one special case involving the HALT instruction. Normally, this opcode is a supervisor mode instruction, but if the debug module's CSR[UHE] is set, then this instruction can be also be executed in user mode for debugging purposes.

11.3.3.6 Trace Exception

To aid in program development, all ColdFire processors provide an instruction-by-instruction tracing capability. While in trace mode, indicated by setting of the SR[T] bit, the completion of an instruction execution (for all but the stop instruction) signals a trace exception. This functionality allows a debugger to monitor program execution.

The stop instruction has the following effects:

1. The instruction before the stop executes and then generates a trace exception. In the exception stack frame, the PC points to the stop opcode.
2. When the trace handler is exited, the stop instruction executes, loading the SR with the immediate operand from the instruction.
3. The processor then generates a trace exception. The PC in the exception stack frame points to the instruction after the stop, and the SR reflects the value loaded in the previous step.

If the processor is not in trace mode and executes a stop instruction where the immediate operand sets SR[T], hardware loads the SR and generates a trace exception. The PC in the exception stack frame points to the instruction after the stop, and the SR reflects the value loaded in step 2.

Because ColdFire processors do not support any hardware stacking of multiple exceptions, it is the responsibility of the operating system to check for trace mode after processing other exception types. As an example, consider a TRAP instruction execution while in trace mode. The processor initiates the trap exception and then passes control to the corresponding handler. If the system requires that a trace exception be processed, it is the responsibility of the trap exception handler to check for this condition (SR[T] in the exception stack frame set) and pass control to the trace handler before returning from the original exception.

11.3.3.7 Unimplemented Line-A Opcode

The default operation of the V1 ColdFire processor is the generation of an illegal opcode reset event if an unimplemented line-A opcode is detected. If CPUCCR[IRD] is set, the reset is disabled and a processor exception is generated as detailed below.

A line-A opcode is defined when bits 15-12 of the opword are 0b1010. This exception is generated by the attempted execution of an undefined line-A opcode.

11.3.3.8 Unimplemented Line-F Opcode

The default operation of the V1 ColdFire processor is the generation of an illegal opcode reset event if an unimplemented line-F opcode is detected. If CPUCCR[IRD] is set, the reset is disabled and a processor exception is generated as detailed below.

A line-F opcode is defined when bits 15-12 of the opword are 0b1111. This exception is generated when attempting to execute an undefined line-F opcode.

11.3.3.9 Debug Interrupt

See the debug chapter for a detailed explanation of this exception, which is generated in response to a hardware breakpoint register trigger. The processor does not generate an IACK cycle, but rather calculates the vector number internally (vector number 12). Additionally, SR[M,I] are unaffected by the interrupt.

11.3.3.10 RTE and Format Error Exception

The default operation of the V1 ColdFire processor is the generation of an illegal address reset event if an RTE format error is detected. If CPUCCR[ARD] is set, the reset is disabled and a processor exception is generated as detailed below.

When an RTE instruction is executed, the processor first examines the 4-bit format field to validate the frame type. For a ColdFire core, any attempted RTE execution (where the format is not equal to {4,5,6,7}) generates a format error. The exception stack frame for the format error is created without disturbing the original RTE frame and the stacked PC pointing to the RTE instruction.

The selection of the format value provides some limited debug support for porting code from M68000 applications. On M68000 family processors, the SR was located at the top of the stack. On those processors, bit 30 of the longword addressed by the system stack pointer is typically zero. Thus, if an RTE is attempted using this old format, it generates a format error on a ColdFire processor.

If the format field defines a valid type, the processor: (1) reloads the SR operand, (2) fetches the second longword operand, (3) adjusts the stack pointer by adding the format value to the auto-incremented address after the fetch of the first longword, and then (4) transfers control to the instruction address defined by the second longword operand within the stack frame.

11.3.3.11 TRAP Instruction Exception

The TRAP #n instruction always forces an exception as part of its execution and is useful for implementing system calls. The TRAP instruction may be used to change from user to supervisor mode.

This set of 16 instructions provides a similar but expanded functionality compared to the S08's SWI (software interrupt) instruction. Do not confuse these instructions and their functionality with the software-scheduled interrupt requests, which are handled like normal I/O interrupt requests by the interrupt controller. The processing of the software-scheduled IRQs can be masked, based on the interrupt priority level defined by the SR[I] field.

11.3.3.12 Unsupported Instruction Exception

If execution of a valid instruction is attempted but the required hardware is not present in the processor (e.g., if the MAC is not present), an unsupported instruction exception is generated. The instruction functionality can then be emulated in the exception handler, if desired.

All ColdFire cores record the processor hardware configuration in the D0 register immediately after the negation of $\overline{\text{RESET}}$. See [Reset Exception](#)," for details.

11.3.3.13 Interrupt Exception

Interrupt exception processing includes interrupt recognition and the fetch of the appropriate vector from the interrupt controller using an IACK cycle or using the previously-supplied vector number, under control of CPUCCR[IAE]. See the interrupt chapter for details on the interrupt controller.

11.3.3.14 Fault-on-Fault Halt

The default operation of the V1 ColdFire processor is the generation of an illegal address reset event if a fault-on-fault halt condition is detected. If CPUCCR[ARD] is set, the reset is disabled and the processor is halted as detailed below.

If a ColdFire processor encounters any type of fault during the exception processing of another fault, the processor immediately halts execution with the catastrophic fault-on-fault condition. A reset is required to to exit this state.

11.3.3.15 Reset Exception

Resetting the processor causes a reset exception. The reset exception has the highest priority of any exception; it provides for system initialization and recovery from catastrophic failure. Reset also aborts any processing in progress when the reset input is recognized. Processing cannot be recovered.

The reset exception places the processor in the supervisor mode by setting the SR[S] bit and disables tracing by clearing the SR[T] bit. This exception also clears the SR[M] bit and sets the processor's SR[I] field to the highest level (level 7, 0b111). Next, the VBR is initialized to zero (0x0000_0000). The control registers specifying the operation of any memories (such as cache and/or RAM modules) connected directly to the processor are disabled.

Note

Other implementation-specific registers are also affected. Refer to each module in this reference manual for details on these registers.

After the processor is granted the bus, it performs two longword read-bus cycles. The first longword at address 0x(00)00_0000 is loaded into the supervisor stack pointer and the second longword at address 0x(00)00_0004 is loaded into the program counter. After the initial instruction is fetched from memory, program execution begins at the address in the PC. If an access error or address error occurs before the first instruction is executed, the processor enters the fault-on-fault state.

ColdFire processors load hardware configuration information into the D0 and D1 general-purpose registers after system reset. The hardware configuration information is loaded immediately after the reset-in signal is negated. This allows an emulator to read out the contents of these registers via the BDM to determine the hardware configuration.

Information loaded into D0 defines the processor hardware configuration as shown in [Table 11-19](#).

Table 11-19. D0 Hardware Configuration Information

BDM:	Load: 0x60 (D0)												Access: User read-only

Table 11-20. D0 Hardware Configuration Information Field Descriptions

Field	Description
31–24 PF	Processor family. This field is fixed to a hex value of 0xCF indicating a ColdFire core is present.
23–20 VER	ColdFire core version number. Defines the hardware microarchitecture version of ColdFire core. 0001 V1 ColdFire core
19–16 REV	Processor revision number
15	Reserved
14 DIV	Divide present. This bit signals if the hardware divider (DIV) is present in the processor core. 0 Divide execute engine not present in core 1 Divide execute engine is present in core
13 EMAC	EMAC present. This bit signals if the optional enhanced multiply-accumulate (EMAC) execution engine is present in processor core. 0 EMAC execute engine not present in core 1 EMAC execute engine is present in core
12	Reserved
11	Reserved
10 CAU	Cryptographic acceleration unit present. This bit signals if the optional cryptographic acceleration unit (CAU) is present in the processor core. 0 CAU coprocessor engine not present in core 1 CAU coprocessor engine is present in core
9–8	Reserved
7–4 ISA	ISA revision. Defines the instruction-set architecture (ISA) revision level implemented in ColdFire processor core. 0010 ISA_C
3–0 DEBUG	Debug module revision number. Defines revision level of the debug module used in the ColdFire processor core. 1001 DEBUG_B+

Information loaded into D1 defines the local memory hardware configuration as shown in the following tables.

Table 11-21. D1 Hardware Configuration Information

BDM:	Load: 0x61 (D1)												Access: User read-only			
	Store: 0x41 (D1)												BDM read-only

21–20 FLEXNVMH	FlexNVM hole Reserved
19–16 EEESIZE	Total available FlexRAM size as defined by the EEESIZE field of data flash IFR. Refer to the detailed description of the flash memory module.
15–12 DEPART	FlexNVM partitioning between data flash and EEPROM as defined by the DEPART field of data flash IFR. Refer to the detailed description of the flash memory module.
11–6	Reserved
5–2 RAMSZ	RAM size 0101: 8 KB 0110: 16 KB 0111: 32 KB Other: Reserved
1–0 RAMH	RAM hole Reserved

11.3.4 Instruction Execution Timing

This section presents processor instruction execution times in terms of processor-core clock cycles. The number of operand references for each instruction is enclosed in parentheses following the number of processor clock cycles. Each timing entry is presented as C(R/W) where:

- C is the number of processor clock cycles, including all applicable operand fetches and writes, and all internal core cycles required to complete the instruction execution.
- R/W is the number of operand reads (R) and writes (W) required by the instruction. An operation performing a read-modify-write function is denoted as (1/1).

This section includes the assumptions concerning the timing values and the execution time details.

11.3.4.1 Timing Assumptions

For the timing data presented in this section, these assumptions apply:

1. The OEP is loaded with the opword and all required extension words at the beginning of each instruction execution. This implies that the OEP does not wait for the IFP to supply opwords and/or extension words.
2. The OEP does not experience any sequence-related pipeline stalls. The most common example of stall involves consecutive store operations, excluding the MOVEM instruction. For all STORE operations (except MOVEM), certain hardware resources within the processor are marked as busy for two clock cycles after the final decode and select/operand fetch cycle (DSOC) of the store instruction. If a subsequent STORE instruction is encountered within this 2-cycle window, it is stalled until the resource again becomes available. Thus, the maximum pipeline stall involving consecutive STORE operations is two cycles. The MOVEM instruction uses a different set of resources and this stall does not apply.
3. The OEP completes all memory accesses without any stall conditions caused by the memory itself. Thus, the timing details provided in this section assume that an infinite zero-wait state memory is attached to the processor core.
4. All operand data accesses are aligned on the same byte boundary as the operand size; for example, 16-bit operands aligned on 0-modulo-2 addresses, 32-bit operands aligned on 0-modulo-4 addresses.

The processor core decomposes misaligned operand references into a series of aligned accesses as shown in [Table 11-23](#).

Table 11-23. Misaligned Operand References

address[1:0]	Size	Bus Operations	Additional C(R/W)
01 or 11	Word	Byte, Byte	2(1/0) if read 1(0/1) if write
01 or 11	Long	Byte, Word, Byte	3(2/0) if read 2(0/2) if write
10	Long	Word, Word	2(1/0) if read 1(0/1) if write

11.3.4.2 MOVE Instruction Execution Times

[Table 11-25](#) lists execution times for MOVE.{B,W} instructions. [Table 11-26](#) lists execution times for MOVE.L.

For all tables in this section, the execution time of any instruction using the PC-relative effective addressing modes is the same for the comparable An-relative mode. Refer to the following table for elaboration.

Table 11-24. Effective addressing modes with equal execution time

PC-relative effective addressing mode	An-relative effective addressing mode
ET with {<ea> = (d16,PC)}	ET with {<ea> = (d16,An)}
ET with {<ea> = (d8,PC,Xi*SF)}	ET with {<ea> = (d8,An,Xi*SF)}

The nomenclature xxx.wl refers to both forms of absolute addressing, xxx.w and xxx.l.

1. Effective address of (d16,PC) not supported

2. Storing an accumulator requires one additional processor clock cycle when saturation is enabled, or fractional rounding is performed (MACSR[7:4] equals 1---, -11-, --11)

Note

The execution times for moving the contents of the Racc, Raccext[01,23], MACSR, or Rmask into a destination location <ea>x shown in this table represent the best-case scenario when the store instruction is executed and there are no load or M{S}AC instructions in the EMAC execution pipeline. In general, these store operations require only a single cycle for

execution, but if they are preceded immediately by a load, MAC, or MSAC instruction, the depth of the EMAC pipeline is exposed and the execution time is three cycles.

Chapter 12

Enhanced Multiply-Accumulate Unit (EMAC)

12.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter describes the functionality, microarchitecture, and performance of the enhanced multiply-accumulate (EMAC) unit in the ColdFire family of processors.

12.1.1 Overview

The EMAC design provides a set of DSP operations that can improve the performance of embedded code while supporting the integer multiply instructions of the baseline ColdFire architecture.

The EMAC provides functionality in three related areas:

1. Signed and unsigned integer multiplication
2. Multiply-accumulate operations supporting signed and unsigned integer operands as well as signed, fixed-point, and fractional operands
3. Miscellaneous register operations

The ColdFire family supports two MAC implementations with different performance levels and capabilities. The original MAC features a three-stage execution pipeline optimized for 16-bit operands, with a 16×16 multiply array and a single 32-bit accumulator. The EMAC features a three-stage pipeline optimized for 32-bit operands, with a fully pipelined 32×32 multiply array and four 48-bit accumulators.

The first ColdFire MAC supported signed and unsigned integer operands and was optimized for 16x16 operations, such as those found in applications including servo control and image compression. As ColdFire-based systems proliferated, the desire for more precision on input operands increased. The result was an improved ColdFire MAC with user-programmable control to optionally enable use of fractional input operands.

EMAC improvements target three primary areas:

- Improved performance of 32×32 multiply operation.
- Addition of three more accumulators to minimize MAC pipeline stalls caused by exchanges between the accumulator and the pipeline's general-purpose registers
- A 48-bit accumulation data path to allow a 40-bit product, plus 8 extension bits increase the dynamic number range when implementing signal processing algorithms

The three areas of functionality are addressed in detail in following sections. The logic required to support this functionality is contained in a MAC module as shown below.

Figure 12-1. Multiply-Accumulate Functionality Diagram

12.1.1.1 Introduction to the MAC

The MAC is an extension of the basic multiplier in most microprocessors. It is typically implemented in hardware within an architecture and supports rapid execution of signal processing algorithms in fewer cycles than comparable non-MAC architectures. For example, small digital filters can tolerate some variance in an algorithm's execution time, but larger, more complicated algorithms such as orthogonal transforms may have more demanding speed requirements beyond scope of any processor architecture and may require full DSP implementation.

To balance speed, size, and functionality, the ColdFire MAC is optimized for a small set of operations that involve multiplication and cumulative additions. Specifically, the multiplier array is optimized for single-cycle pipelined operations with a possible

accumulation after product generation. This functionality is common in many signal processing applications. The ColdFire core architecture is also modified to allow an operand to be fetched in parallel with a multiply, increasing overall performance for certain DSP operations.

Consider a typical filtering operation where the filter is defined as in the following equation.

$$y(i) = \sum_{k=1}^{N-1} a(k)y(i-k) + \sum_{k=0}^{N-1} b(k)x(i-k)$$

Here, the output $y(i)$ is determined by past output values and past input values. This is the general form of an infinite impulse response (IIR) filter. A finite impulse response (FIR) filter can be obtained by setting coefficients $a(k)$ to zero. In either case, the operations involved in computing such a filter are multiplies and product summing. To show this point, reduce the preceding equation to a simple, four-tap FIR filter, shown in the following equation, in which the accumulated sum is a past data values and coefficients sum.

$$y(i) = \sum_{k=0}^3 b(k)x(i-k) = b(0)x(i) + b(1)x(i-1) + b(2)x(i-2) + b(3)x(i-3)$$

12.2 Memory Map/Register Definition

The following table and sections explain the MAC registers.

Table 12-1. EMAC Memory Map

BDM	Register	Width (bits)	Access	Reset Value
Read: 0xE4 Write: 0xC4	MAC status register (MACSR)	32	R/W	0x0000_0000
Read: 0xE5 Write: 0xC5	MAC address mask register (MASK)	32	R/W	0xFFFF_FFFF
Read: 0xE6 Write: 0xC6	MAC accumulator 0 (ACC0)	32	R/W	Undefined
Read: 0xE7 Write: 0xC7	MAC accumulator 0,1 extension bytes (ACCext01)	32	R/W	Undefined
Read: 0xE8 Write: 0xC8	MAC accumulator 2,3 extension bytes (ACCext23)	32	R/W	Undefined
Read: 0xE9 Write: 0xC9	MAC accumulator 1 (ACC1)	32	R/W	Undefined
Read: 0xEA Write: 0xCA	MAC accumulator 2 (ACC2)	32	R/W	Undefined

Table continues on the next page...

Table 12-1. EMAC Memory Map (continued)

BDM	Register	Width (bits)	Access	Reset Value
Read: 0xEB Write: 0xCB	MAC accumulator 2 (ACC3)	32	R/W	Undefined

12.2.1 MAC Status Register (MACSR)

The MAC status register (MACSR) contains a 4-bit operational mode field and condition flags. Operational mode bits control whether operands are signed or unsigned and whether they are treated as integers or fractions. These bits also control the overflow/saturation mode and the way in which rounding is performed. Negative, zero, and multiple overflow condition flags are also provided.

Table 12-2. MAC Status Register (MACSR)

BDM:	Read: 0xE4 (MACSR) Write: 0xC4												Access: Supervisor read/ write BDM read/write

Table 12-3. MACSR Field Descriptions

Field	Description
31–12	Reserved, must be cleared.
11–8 PAVn	Product/accumulation overflow flags. Contains four flags, one per accumulator, that indicate if past MAC or MSAC instructions generated an overflow during product calculation or the 48-bit accumulation. When a MAC or MSAC instruction is executed, the PAVn flag associated with the destination accumulator forms the general overflow flag, MACSR[V]. Once set, each flag remains set until V is cleared by a move.l, MACSR instruction or the accumulator is loaded directly. Bit 11: Accumulator 3 . . . Bit 8: Accumulator 0

Table continues on the next page...

Table 12-3. MACSR Field Descriptions (continued)

Field	Description
7 OMC	Overflow saturation mode. Enables or disables saturation mode on overflow. If set, the accumulator is set to the appropriate constant (see S/U field description) on any operation that overflows the accumulator. After saturation, the accumulator remains unaffected by any other MAC or MSAC instructions until the overflow bit is cleared or the accumulator is directly loaded.
6 S/U	Signed/unsigned operations. In integer mode: S/U determines whether operations performed are signed or unsigned. It also determines the accumulator value during saturation, if enabled.
0	Signed numbers. On overflow, if OMC is enabled, an accumulator saturates to the most positive (0x7FFF_FFFF) or the most negative (0x8000_0000) number, depending on the instruction and the product value that overflowed.
1	Unsigned numbers. On overflow, if OMC is enabled, an accumulator saturates to the smallest value (0x0000_0000) or the largest value (0xFFFF_FFFF), depending on the instruction.
	In fractional mode: S/U controls rounding while storing an accumulator to a general-purpose register.
0	Move accumulator without rounding to a 16-bit value. Accumulator is moved to a general-purpose register as a 32-bit value.
1	The accumulator is rounded to a 16-bit value using the round-to-nearest (even) method when moved to a general-purpose register. The resulting 16-bit value is stored in the lower word of the destination register. The upper word is zero-filled. This rounding procedure does not affect the accumulator value.
5 F/I	Fractional/integer mode. Determines whether input operands are treated as fractions or integers.
0	Integers can be represented in signed or unsigned notation, depending on the value of S/U.
1	Fractions are represented in signed, fixed-point, two's complement notation. Values range from -1 to $1 - 2^{-15}$ for 16-bit fractions and -1 to $1 - 2^{-31}$ for 32-bit fractions.
4 R/T	Round/truncate mode. Controls rounding procedure for move.l ACCx,Rx, or MSAC.L instructions when in fractional mode.
0	Truncate. The product's lsbs are dropped before it is combined with the accumulator. Additionally, when a store accumulator instruction is executed (move.l ACCx,Rx), the 8 lsbs of the 48-bit accumulator logic are truncated.
1	Round-to-nearest (even). The 64-bit product of two 32-bit, fractional operands is rounded to the nearest 40-bit value. If the low-order 24 bits equal 0x80_0000, the upper 40 bits are rounded to the nearest even (lsb = 0) value. Additionally, when a store accumulator instruction is executed (move.l ACCx,Rx), the lsbs of the 48-bit accumulator logic round the resulting 16- or 32-bit value. If MACSR[S/U] is cleared and MACSR[R/T] is set, the low-order 8 bits are used to round the resulting 32-bit fraction. If MACSR[S/U] is set, the low-order 24 bits are used to round the resulting 16-bit fraction.
3 N	Negative. Set if the msb of the result is set, otherwise cleared. N is affected only by MAC, MSAC, and load operations; it is not affected by MULS and MULU instructions.
2 Z	Zero. Set if the result equals zero, otherwise cleared. This bit is affected only by MAC, MSAC, and load operations; it is not affected by MULS and MULU instructions.
1 V	Overflow. Set if an arithmetic overflow occurs on a MAC or MSAC instruction, indicating that the result cannot be represented in the limited width of the EMAC. V is set only if a product overflow occurs or the accumulation overflows the 48-bit structure. V is evaluated on each MAC or MSAC operation and uses the appropriate PAVn flag in the next-state V evaluation.

Table continues on the next page...

Table 12-3. MACSR Field Descriptions (continued)

Field	Description
0 EV	Extension overflow. Signals that the last MAC or MSAC instruction overflowed the 32 lsbs in integer mode or the 40 lsbs in fractional mode of the destination accumulator. However, the result remains accurately represented in the combined 48-bit accumulator structure. Although an overflow has occurred, the correct result, sign, and magnitude are contained in the 48-bit accumulator. Subsequent MAC or MSAC operations may return the accumulator to a valid 32/40-bit result.

This table summarizes the interaction of the MACSR[S/U,F/I,R/T] control bits.

Table 12-4. Summary of S/U, F/I, and R/T Control Bits

S/U	F/I	R/T	Operational Modes
0	0	x	Signed, integer
0	1	0	Signed, fractional Truncate on MAC.L and MSAC.L No round on accumulator stores
0	1	1	Signed, fractional Round on MAC.L and MSAC.L Round-to-32-bits on accumulator stores
1	0	x	Unsigned, integer
1	1	0	Signed, fractional Truncate on MAC.L and MSAC.L Round-to-16-bits on accumulator stores
1	1	1	Signed, fractional Round on MAC.L and MSAC.L Round-to-16-bits on accumulator stores

12.2.2 Mask Register (MASK)

The 32-bit MASK implements the low-order 16 bits to minimize the alignment complications involved with loading and storing only 16 bits. When the MASK is loaded, the low-order 16 bits of the source operand are actually loaded into the register. When it is stored, the upper 16 bits are all forced to ones. This register performs a simple AND with the operand address for MAC instructions. The processor calculates the normal

operand address and, if enabled, that address is then ANDed with {0xFFFF, MASK[15:0]} to form the final address. Therefore, with certain MASK bits cleared, the operand address can be constrained to a certain memory region. This is used primarily to implement circular queues with the (An)+ addressing mode.

This minimizes the addressing support required for filtering, convolution, or any routine that implements a data array as a circular queue. For MAC + MOVE operations, the MASK contents can optionally be included in all memory effective address calculations. The syntax is as follows:

```
mac.sz Ry,RxSF,<ea>y&,Rw
```

The & operator enables the MASK use and causes bit 5 of the extension word to be set. The exact algorithm for the use of MASK is:

```
if extension word, bit [5] = 1, the MASK bit, then
if <ea> = (An)
oa = An & {0xFFFF, MASK}

if <ea> = (An)+
oa = An
An = (An + 4) & {0xFFFF, MASK}

if <ea> = -(An)
oa = (An - 4) & {0xFFFF, MASK}
An = (An - 4) & {0xFFFF, MASK}

if <ea> = (d16,An)
oa = (An + se_d16) & {0xFFFF0x, MASK}
```

Here, oa is the calculated operand address and se_d16 is a sign-extended 16-bit displacement. For auto-addressing modes of post-increment and pre-decrement, the updated An value calculation is also shown.

Use of the post-increment addressing mode, {(An)+} with the MASK is suggested for circular queue implementations.

Table 12-5. Mask Register (MASK)

BDM:	0x5 (MASK)												Access: User read/write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Table 12-6. MASK Field Descriptions

Field	Description
31–12	Reserved; must be set.
15–0 MASK	Performs a simple AND with the operand address for MAC instructions.

12.2.3 Accumulator Registers (ACC0-3)

Each accumulator register stores 32 bits of the MAC operation result. The entire 48-bit accumulator result consists of the accumulator register concatenated with the corresponding fields of the accumulator extension registers.

Table 12-7. Accumulator Registers (ACC0-3)

12.3 Functional Description

The MAC speeds execution of ColdFire integer-multiply instructions (MULS and MULU) and provides additional functionality for multiply-accumulate operations. By executing MULS and MULU in the MAC, execution times are minimized and deterministic compared to the 2-bit/cycle algorithm with early termination that the OEP normally uses if no MAC hardware is present.

The added MAC instructions to the ColdFire ISA provide for the multiplication of two numbers, followed by the addition or subtraction of the product to or from the value in an accumulator. Optionally, the product may be shifted left or right by 1 bit before addition or subtraction. Hardware support for saturation arithmetic can be enabled to minimize software overhead when dealing with potential overflow conditions. Multiply-accumulate operations support 16- or 32-bit input operands in these formats:

- Signed integers
- Unsigned integers
- Signed, fixed-point, fractional numbers

The EMAC is optimized for single-cycle, pipelined 32×32 multiplications. For word- and longword-sized integer input operands, the low-order 40 bits of the product are formed and used with the destination accumulator. For fractional operands, the entire 64-bit product is calculated and truncated or rounded to the most-significant 40-bit result using the round-to-nearest (even) method before it is combined with the destination accumulator.

For all operations, the resulting 40-bit product is extended to a 48-bit value (using sign-extension for signed integer and fractional operands, zero-fill for unsigned integer operands) before being combined with the 48-bit destination accumulator.

The following two figures show relative alignment of input operands, the full 64-bit product, the resulting 40-bit product used for accumulation, and 48-bit accumulator formats.

Figure 12-2. Fractional Alignment

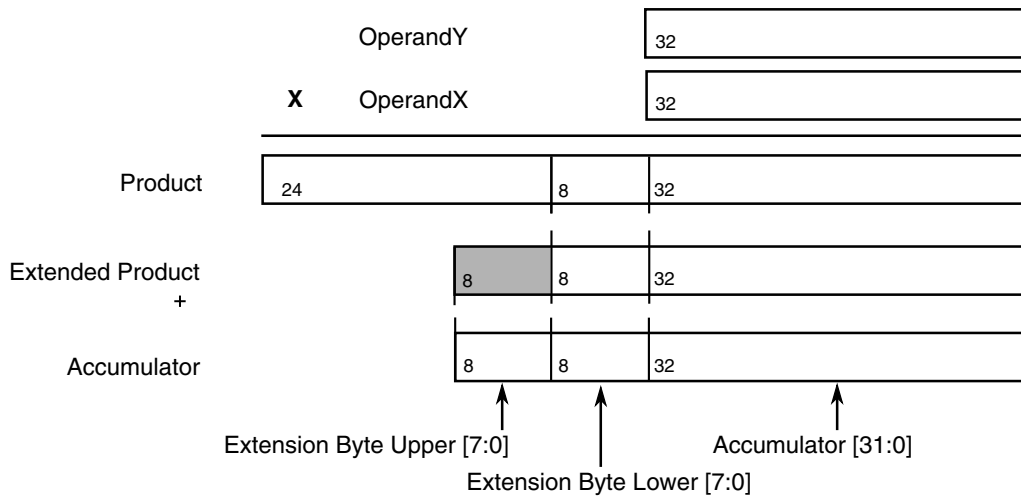

Figure 12-3. Signed and Unsigned Integer Alignment

Functional Description

Therefore, the 48-bit accumulator definition is a function of the EMAC operating mode. Given that each 48-bit accumulator is the concatenation of 16-bit accumulator extension register (*ACCextn*) contents and 32-bit *ACCn* contents, the specific definitions are:

```
if MACSR[6:5] == 00          /* signed integer mode */
    Complete Accumulator[47:0] = {ACCextn[15:0], ACCn[31:0]}
if MACSR[6:5] == 01 or 11    /* signed fractional mode */
    Complete Accumulator [47:0] = {ACCextn[15:8], ACCn[31:0], ACCextn[7:0]}
if MACSR[6:5] == 10          /* unsigned integer mode */
    Complete Accumulator[47:0] = {ACCextn[15:0], ACCn[31:0]}
```

The four accumulators are represented as an array, *ACCn*, where *n* selects the register.

Although the multiplier array is implemented in a three-stage pipeline, all arithmetic MAC instructions have an effective issue rate of 1 cycle, regardless of input operand size or type.

All arithmetic operations use register-based input operands, and summed values are stored in an accumulator. Therefore, an additional MOVE instruction is needed to store data in a general-purpose register. One new feature in EMAC instructions is the ability to choose the upper or lower word of a register as a 16-bit input operand. This is useful in filtering operations if one data register is loaded with the input data and another is loaded with the coefficient. Two 16-bit multiply accumulates can be performed without fetching additional operands between instructions by alternating word choice during calculations.

The EMAC has four accumulator registers versus the MAC's single accumulator. The additional registers improve the performance of some algorithms by minimizing pipeline stalls needed to store an accumulator value back to general-purpose registers. Many algorithms require multiple calculations on a given data set. By applying different accumulators to these calculations, it is often possible to store one accumulator without any stalls while performing operations involving a different destination accumulator.

The need to move large amounts of data presents an obstacle to obtaining high throughput rates in DSP engines. Existing ColdFire instructions can accommodate these requirements. A MOVEM instruction can efficiently move large data blocks. The ability to load an operand simultaneously from memory into a register and execute a MAC instruction makes some DSP operations such as filtering and convolution more manageable.

The programming model includes a mask register (MASK), which can optionally be used to generate an operand address during MAC + MOVE instructions. The register application with auto-increment addressing mode supports efficient implementation of circular data queues for memory operands.

12.3.1 Fractional Operation Mode

This section describes behavior when the fractional mode is used (MACSR[F/I] is set).

12.3.1.1 Rounding

When the processor is in fractional mode, there are two operations during which rounding can occur:

1. Execution of a store accumulator instruction (move.l ACCx,Rx). The lsbs of the 48-bit accumulator logic are used to round the resulting 16- or 32-bit value. If MACSR[S/U] is cleared, the low-order 8 bits round the resulting 32-bit fraction. If MACSR[S/U] is set, the low-order 24 bits are used to round the resulting 16-bit fraction.
2. Execution of a MAC (or MSAC) instruction with 32-bit operands. If MACSR[R/T] is zero, multiplying two 32-bit numbers creates a 64-bit product truncated to the upper 40 bits; otherwise, it is rounded using round-to-nearest (even) method.

To understand the round-to-nearest-even method, consider the following example involving the rounding of a 32-bit number, R0, to a 16-bit number. Using this method, the 32-bit number is rounded to the closest 16-bit number possible. Let the high-order 16 bits of R0 be named R0.U and the low-order 16 bits be R0.L.

- If R0.L is less than 0x8000, the result is truncated to the value of R0.U.
- If R0.L is greater than 0x8000, the upper word is incremented (rounded up).
- If R0.L is 0x8000, R0 is half-way between two 16-bit numbers. In this case, rounding is based on the lsb of R0.U, so the result is always even (lsb = 0).
 - If the lsb of R0.U equals 1 and R0.L equals 0x8000, the number is rounded up.
 - If the lsb of R0.U equals 0 and R0.L equals 0x8000, the number is rounded down.

This method minimizes rounding bias and creates as statistically correct an answer as possible.

The rounding algorithm is summarized in the following pseudocode:

```

if R0.L < 0x8000
    then Result = R0.U
else if R0.L > 0x8000
    then Result = R0.U + 1
else if lsb of R0.U = 0
    /* R0.L = 0x8000 */

```

Functional Description

```
        then Result = R0.U
else Result = R0.U + 1
```

The round-to-nearest-even technique is also known as convergent rounding.

12.3.1.2 Saving and Restoring the EMAC Programming Model

The presence of rounding logic in the EMAC output datapath requires special care during the EMAC's save/restore process. In particular, any result rounding modes must be disabled during the save/restore process so the exact bit-wise contents of the EMAC registers are accessed. Consider the memory structure containing the EMAC programming model:

```
struct  macState {
    int  acc0;
    int  acc1;
    int  acc2;
    int  acc3;
    int  accext01;
    int  accext02;
    int  mask;
    int  macsr;
} macState;
```

The following assembly language routine shows the proper sequence for a correct EMAC state save. This code assumes all Dn and An registers are available for use, and the memory location of the state save is defined by A7.

```
EMAC_state_save:
    move.l  macsr,d7          ; save the macsr
    clr.l   d0                ; zero the register to ...
    move.l  d0,macsr         ; disable rounding in the macsr

    move.l  acc0,d0          ; save the accumulators
    move.l  acc1,d1
    move.l  acc2,d2
    move.l  acc3,d3
    move.l  accext01,d4      ; save the accumulator extensions
    move.l  accext23,d5
    move.l  mask,d6          ; save the address mask

    movem.l #0x00ff,(a7)    ; move the state to memory
```

This code performs the EMAC state restore:

```
EMAC_state_restore:

    movem.l (a7),#0x00ff    ; restore the state from memory

    move.l  d5,acc          ; restore the accumulator
    move.l  d0,acc0         ; restore the accumulators
    move.l  d1,acc1
    move.l  d2,acc2
    move.l  d3,acc3
```

```

move.l d4,accest01      ; restore the accumulator extensions
move.l d5,accest23
move.l d6,mask          ; restore the address mask
move.l d7,macsr         ; restore the macsr

```

Executing this sequence type can correctly save and restore the exact state of the EMAC programming model.

12.3.1.3 MULS/MULU

MULS and MULU are unaffected by fractional-mode operation; operands remain assumed to be integers.

12.3.1.4 Scale Factor in MAC or MSAC Instructions

The scale factor is ignored while the MAC is in fractional mode.

12.3.2 EMAC Instruction Set Summary

The following table summarizes EMAC unit instructions.

Table 12-13. EMAC Instruction Summary

Command	Mnemonic	Description
Multiply Accumulate	mac Ry,RxSF,ACCx msac Ry,RxSF,ACCx	Multiplies two operands and adds/subtracts the product to/from an accumulator
Multiply Accumulate with Load	mac Ry,Rx,<ea>y,Rw,ACCx msac Ry,Rx,<ea>y,Rw,ACCx	Multiplies two operands and combines the product to an accumulator while loading a register with the memory operand
Load Accumulator	move.l {Ry,#imm},ACCx	Loads an accumulator with a 32-bit operand
Store Accumulator	move.l ACCx,Rx	Writes the contents of an accumulator to a CPU register
Copy Accumulator	move.l ACCy,ACCx	Copies a 48-bit accumulator
Load MACSR	move.l {Ry,#imm},MACSR	Writes a value to MACSR
Store MACSR	move.l MACSR,Rx	Write the contents of MACSR to a CPU register
Store MACSR to CCR	move.l MACSR,CCR	Write the contents of MACSR to the CCR
Load MAC Mask Reg	move.l {Ry,#imm},MASK	Writes a value to the MASK register
Store MAC Mask Reg	move.l MASK,Rx	Writes the contents of the MASK to a CPU register
Load Accumulator Extensions 01	move.l {Ry,#imm},ACCext01	Loads the accumulator 0,1 extension bytes with a 32-bit operand
Load Accumulator Extensions 23	move.l {Ry,#imm},ACCext23	Loads the accumulator 2,3 extension bytes with a 32-bit operand

Table continues on the next page...

Table 12-13. EMAC Instruction Summary (continued)

Command	Mnemonic	Description
Store Accumulator Extensions 01	move.l ACCext01,Rx	Writes the contents of accumulator 0,1 extension bytes into a CPU register
Store Accumulator Extensions 23	move.l ACCext23,Rx	Writes the contents of accumulator 2,3 extension bytes into a CPU register
Move and Clear Accumulator	moveclr.l ACCy,Rx	Writes the contents of an accumulator to a destination and then clears the accumulator

12.3.3 EMAC Instruction Execution Times

The instruction execution times for the EMAC can be found in the "EMAC instruction execution times" section of the core chapter.

The EMAC execution pipeline overlaps the AGEX stage of the OEP (the first stage of the EMAC pipeline is the last stage of the basic OEP). EMAC units are designed for sustained, fully-pipelined operation on accumulator load, copy, and multiply-accumulate instructions. However, instructions that store contents of the multiply-accumulate programming model can generate OEP stalls that expose the EMAC execution pipeline depth:

```
mac.w      Ry, Rx, Acc0
move.l     Acc0, Rz
```

The MOVE.L instruction that stores the accumulator to an integer register (Rz) stalls until the program-visible copy of the accumulator is available. The following figure shows EMAC timing.

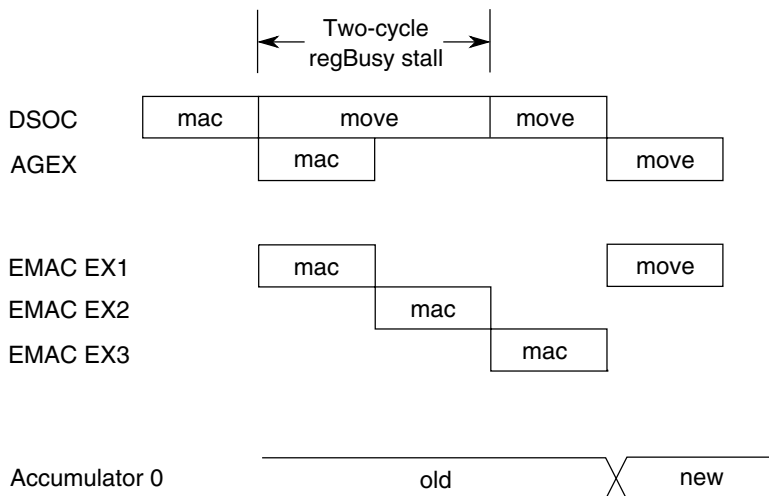

Figure 12-4. EMAC-Specific OEP Sequence Stall

The OEP stalls the store-accumulator instruction for two cycles: the EMAC pipeline depth minus 1. The minus 1 factor is needed because the OEP and EMAC pipelines overlap by a cycle, the AGEX stage. As the store-accumulator instruction reaches the AGEX stage where the operation is performed, the recently updated accumulator 0 value is available.

As with change or use stalls between accumulators and general-purpose registers, introducing intervening instructions that do not reference the busy register can reduce or eliminate sequence-related store-MAC instruction stalls. A major benefit of the EMAC is the addition of three accumulators to minimize stalls caused by exchanges between the accumulator(s) and general-purpose registers.

12.3.4 Data Representation

MACSR[S/U,F/I] selects one of the following three modes, where each mode defines a unique operand type:

1. Two's complement signed integer: In this format, an N-bit operand value lies in the range $-2^{(N-1)} \leq \text{operand} \leq 2^{(N-1)} - 1$. The binary point is right of the lsb.
2. Unsigned integer: In this format, an N-bit operand value lies in the range $0 \leq \text{operand} \leq 2^N - 1$. The binary point is right of the lsb.
3. Two's complement signed fractional: In an N-bit number, the first bit is the sign bit. The remaining bits signify the first N-1 bits after the binary point. Given an N-bit number, $a_{N-1}a_{N-2}a_{N-3}... a_2a_1a_0$, its value is given by the equation in the following equation.

$$\text{value} = -(1a_{N-1}) + \sum_{i=0}^{N-2} 2^{-(i+1-N)} a_i$$

This format can represent numbers in the range $-1 \leq \text{operand} \leq 1 - 2^{-(N-1)}$.

For words and longwords, the largest negative number that can be represented is -1, whose internal representation is 0x8000 and 0x8000_0000, respectively. The largest positive word is 0x7FFF or $(1 - 2^{-15})$; the most positive longword is 0x7FFF_FFFF or $(1 - 2^{-31})$. Thus, the number range for these signed fractional numbers is $[-1.0, ..., 1.0]$.

12.3.5 MAC Opcodes

MAC opcodes are described in the *ColdFire Programmer's Reference Manual*.

Remember the following:

- Unless otherwise noted, the value of MACSR[N,Z] is based on the result of the final operation that involves the product and the accumulator.
- The overflow (V) flag is managed differently. It is set if the complete product cannot be represented as a 40-bit value (this applies to 32 × 32 integer operations only) or if the combination of the product with an accumulator cannot be represented in the given number of bits. The EMAC design includes an additional product/accumulation overflow bit for each accumulator that are treated as sticky indicators and are used to calculate the V bit on each MAC or MSAC instruction. See MAC Status Register (MACSR).
- For the MAC design, the assembler syntax of the MAC (multiply and add to accumulator) and MSAC (multiply and subtract from accumulator) instructions does not include a reference to the single accumulator. For the EMAC, assemblers support this syntax and no explicit reference to an accumulator is interpreted as a reference to ACC0. Assemblers also support syntaxes where the destination accumulator is explicitly defined.
- The optional 1-bit shift of the product is specified using the notation {<< | >>} SF, where <<1 indicates a left shift and >>1 indicates a right shift. The shift is performed before the product is added to or subtracted from the accumulator. Without this operator, the product is not shifted. If the EMAC is in fractional mode (MACSR[F/I] is set), SF is ignored and no shift is performed. Because a product can overflow, the following guidelines are implemented:
 - For unsigned word and longword operations, a zero is shifted into the product on right shifts.
 - For signed, word operations, the sign bit is shifted into the product on right shifts unless the product is zero. For signed, longword operations, the sign bit is shifted into the product unless an overflow occurs or the product is zero, in which case a zero is shifted in.
 - For all left shifts, a zero is inserted into the lsb position.

The following pseudocode explains basic MAC or MSAC instruction functionality. This example is presented as a case statement covering the three basic operating modes with signed integers, unsigned integers, and signed fractionals. Throughout this example, a comma-separated list in curly brackets, { }, indicates a concatenation operation.

```
switch (MACSR[6:5])      /* MACSR[S/U, F/I] */
{
  case 0:                /* signed integers */
    if (MACSR.OMC == 0 || MACSR.PAVn == 0)
      then {
        MACSR.PAVn = 0
```

```

/* select the input operands */
if (sz == word)
  then {if (U/Ly == 1)
        then operandY[31:0] = {sign-extended Ry[31], Ry[31:16]}
        else operandY[31:0] = {sign-extended Ry[15], Ry[15:0]}
        if (U/Lx == 1)
        then operandX[31:0] = {sign-extended Rx[31], Rx[31:16]}
        else operandX[31:0] = {sign-extended Rx[15], Rx[15:0]}
      }
  else {operandY[31:0] = Ry[31:0]
        operandX[31:0] = Rx[31:0]
      }
/* perform the multiply */
product[63:0] = operandY[31:0] * operandX[31:0]
/* check for product overflow */
if ((product[63:39] != 0x0000_00_0) && (product[63:39] != 0xffff_ff_1))
  then { /* product overflow */
        MACSR.PAVn = 1
        MACSR.V = 1
        if (inst == MSAC && MACSR.OMC == 1)
          then if (product[63] == 1)
                 then result[47:0] = 0x0000_7fff_ffff
                 else result[47:0] = 0xffff_8000_0000
          else if (MACSR.OMC == 1)
                 then /* overflowed MAC,
                       saturationMode enabled */
                    if (product[63] == 1)
                      then result[47:0] = 0xffff_8000_0000
                      else result[47:0] = 0x0000_7fff_ffff
                }
        /* sign-extend to 48 bits before performing any scaling */
        product[47:40] = {8{product[39]}} /* sign-extend */
        /* scale product before combining with accumulator */
        switch (SF) /* 2-bit scale factor */
        {
          case 0: /* no scaling specified */
            break;

Chapter 13

System Integration Module (SIM)

13.1 Introduction

The system integration module (SIM) provides system control and chip configuration registers.

13.2 Memory Map and Registers

NOTE

Different SIM registers reset on different MCU reset types. The reset type represented by each register's displayed reset value is as follows:

- For SOPT1-2 registers: Chip POR not VLLS
- For SOPT3-4 registers: Chip Reset not VLLS
- For SOPT5-7, COPC, SRVCOP, OSC1, SCGC1-6, CLKOUT, and CLKDIV1 registers: Chip Reset
- For SDIDH, SDIDL, CLKDIV0, SPCR, and UID* registers: Chip POR

For each list, the registers are reset only by the specified reset type or any reset type that triggers the specified reset type. Other reset types do not affect the registers. For information about the various reset types on this chip, refer to the [Reset](#) details.

SIM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_80C0	System Options Register 1 (SIM_SOPT1)	8	R/W	See section	13.2.1/269
FFFF_80C1	System Options Register 2 (SIM_SOPT2)	8	R/W	Undefined	13.2.2/270
FFFF_80C2	System Options Register 3 (SIM_SOPT3)	8	R/W	00h	13.2.3/271

SIM memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_80F3	Unique Identification Register (SIM_UIDL0)	8	R	Undefined	13.2.37/298

13.2.1 System Options Register 1 (SIM_SOPT1)

NOTE

The following Reset row refers to Chip POR not VLLS. Only that type of reset, or any reset type that triggers Chip POR not VLLS, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 0h offset = FFFF_80C0h

Bit	7	6	5	4	3	2	1	0
Read	REGE	SSTB	VSTB	Reserved			0	
Write								
Reset	1	0	0	*	*	*	0	0

* Notes:

- Reserved field: The value of each bit of this reserved field can be 0 or 1.

SIM_SOPT1 field descriptions

Field	Description
7 REGE	Voltage Regulator enable This bit is writable when the SOPT3[RWE] bit is set. 0 VREG is disabled. 1 VREG is enabled (reset value).
6 SSTB	Voltage Regulator standby in stop modes This bit controls whether the VREG enters standby in stop, VLPS, LLS and VLLS modes. The bit is writable when the SOPT3[SWE] bit is set. 0 VREG does not enter standby in Stop, VLPS, LLS and VLLS modes (reset value) 1 VREG enters standby in Stop, VLPS, LLS and VLLS modes
5 VSTB	Voltage Regulator standby in run/wait modes This bit controls whether the VREG enters standby in VLPW and VLPR modes. The bit is writable when the SOPT3[SWE] bit is set. 0 VREG does not enter standby in VLPW and VLPR modes (reset value) 1 VREG enters standby in VLPW and VLPR modes

Table continues on the next page...

SIM_SOPT1 field descriptions (continued)

Field	Description
4-2 Reserved	This field is reserved. The value of each bit can be 0 or 1.
1-0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

13.2.2 System Options Register 2 (SIM_SOPT2)

NOTE

The following Reset row refers to Chip POR not VLLS. Only that type of reset, or any reset type that triggers Chip POR not VLLS, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 1h offset = FFFF_80C1h

Bit	7	6	5	4	3	2	1	0
Read	RAMSIZE				0	Reserved		
Write						Reserved		
Reset	x*	x*	x*	x*	0	x*	x*	x*

* Notes:

- x = Undefined at reset.

SIM_SOPT2 field descriptions

Field	Description
7-4 RAMSIZE	Size of RAM array Specifies the amount of system RAM available on the device. Its reset value is loaded from IFR bits. 0000 Reserved 0001 8 KB 0010 Reserved 0011 16 KB 0100 Reserved 0101 32 KB Other Reserved
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2-0 Reserved	This field is reserved.

13.2.3 System Options Register 3 (SIM_SOPT3)

NOTE

The following Reset row refers to Chip Reset not VLLS. Only that type of reset, or any reset type that triggers Chip Reset not VLLS, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 2h offset = FFFF_80C2h

Bit	7	6	5	4	3	2	1	0
Read	0						SWE	RWE
Write								
Reset	0	0	0	0	0	0	0	

SIM_SOPT3 field descriptions

Field	Description
7-2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SWE	Standby write enable Writing 1 to this bit allows the SSTB and VSTB bits in the SOPT1 register to be written. This bit clears after a write to SSTB, VSTB, or both (a simultaneous write to SSTB and VSTB is allowed). 0 The SSTB and VSTB bits cannot be written. 1 The SSTB and VSTB bits can be written.
0 RWE	Voltage Regulator write enable Writing 1 to this bit allows the REGE bit in the SOPT1 register to be written. This bit clears after a write to the REGE bit. 0 The REGE bit cannot be written. 1 The REGE bit can be written.

13.2.4 System Options Register 4 (SIM_SOPT4)

NOTE

The following Reset row refers to Chip Reset not VLLS. Only that type of reset, or any reset type that triggers Chip Reset not VLLS, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 3h offset = FFFF_80C3h

Bit	7	6	5	4	3	2	1	0
Read	0		STOPE	WAITE	0			VLLDBGREQ
Write	0		1	0	0			0
Reset	0	0	0	1	0	0	0	0

SIM_SOPT4 field descriptions

Field	Description
7-6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 STOPE	Stop mode enable This bit can be written only once after each reset. NOTE: If the STOPE and WAITE bits are both set to 1, the WAITE bit takes priority. 0 Disable entry to stop mode. 1 Enable entry to stop mode. When the WAITE bit is 0, the SMC's PMCTRL[STOPM] field controls which type of stop mode the chip enters.
4 WAITE	Wait mode enable 0 Disable entry to wait mode 1 Enable entry to wait mode
3-1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 VLLDBGREQ	Very Low Leakage Debug Request upon Wakeup This bit can be written through the BDM interface. 0 Wakeup from a VLLSx mode (except via the $\overline{\text{RESET}}$ pin) is via Chip POR into single chip mode (reset value) 1 Wakeup from a VLLSx mode (except via the $\overline{\text{RESET}}$ pin) is via Chip POR into active background debug mode

13.2.5 System Options Register 5 (SIM_SOPT5)

Address: FFFF_80C0h base + 4h offset = FFFF_80C4h

Bit	7	6	5	4	3	2	1	0
Read	0				MECS		F1ECS	F0ECS
Write								
Reset	0	0	0	0	0	0	1	0

SIM_SOPT5 field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 MECS	MTIM16 external clock source select 00 TMR_CLKIN0 (reset value) 01 TMR_CLKIN1 10 FTM0 Ch1 Out 11 FTM1Ch1 Out
1 F1ECS	FTM1 external clock select 0 TMR_CLKIN0 1 TMR_CLKIN1 (reset value)
0 F0ECS	FTM0 external clock select 0 TMR_CLKIN0 (reset value) 1 TMR_CLKIN1

13.2.6 System Options Register 6 (SIM_SOPT6)

Address: FFFF_80C0h base + 5h offset = FFFF_80C5h

Bit	7	6	5	4	3	2	1	0
Read	MBSL		MTBASE1		RX1IN	MODTX1	PTF6PAD	PTC5PAD
Write								
Reset	0	0	0	0	0	0	0	0

SIM_SOPT6 field descriptions

Field	Description
7–6 MBSL	Mini-FlexBus security level If flash security is enabled, this field affects what CPU operations can access off-chip via the Mini-FlexBus interface. This field has no effect if security is not enabled. 0x All off-chip accesses (opcode and data) by the Mini-FlexBus are disallowed (reset value: 00) 10 Off-chip opcode accesses are disallowed. Data accesses are allowed. 11 Off-chip op code accesses and data accesses are allowed.

Table continues on the next page...

SIM_SOPT6 field descriptions (continued)

Field	Description
5-4 MTBASE1	UART1 TX modulation time base select 00 FTM0 Ch0 (reset value) 01 FTM0 Ch1 10 FTM1 Ch0 11 MTIM
3 RX1IN	UART1 RX input pin selection 0 RX1 is fed from the digital input pin (assuming the RX1 is enabled on that pin via the mux pin registers) (reset value) 1 RX1 is fed from the CMP output
2 MODTX1	Modulate T 0 Do not modulate the output of UART1 (reset value) 1 Modulate the output of UART1 with the timebase selected via the MTBASE1 field
1 PTF6PAD	PTF6 double pad strength 0 Standard drive strength (reset value) 1 High drive strength
0 PTC5PAD	PTC5 pad double pad strength Controls the output drive strength of PTC5 by selecting either one or two pads to drive it. 0 Single-pad drive strength (reset value) 1 Dual-pad drive strength

13.2.7 System Options Register 7 (SIM_SOPT7)

Address: FFFF_80C0h base + 6h offset = FFFF_80C6h

Bit	7	6	5	4	3	2	1	0
Read	0	ADTRGS	ACFTM	I2CDR2	I2CDR0	0	FTM1SYNC	FTM0SYNC
Write								
Reset	0	0	0	0	0	0	0	0

SIM_SOPT7 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ADTRGS	ADC hardware trigger source 0 PDB (reset value) 1 LPTMR0 (trigger ADCSC1A only)
5 ACFTM	CMP output connection to FTM0 Ch0

Table continues on the next page...

SIM_SOPT7 field descriptions (continued)

Field	Description
	0 CMP Output disconnected to FTM0 Ch0 (reset value) 1 CMP Output connected to FTM0 Ch0
4 I2CDR2	I2C Link for I2C2 and I2C3 0 I2C2 and I2C3 operate in their respective pins (reset value) 1 I2C2 and I2C3 have their pins are connected internally
3 I2CDR0	I2C Link for I2C0 and I2C1 0 I2C0 and I2C1 operate in their respective pins (reset value) 1 I2C0 and I2C1 have their pins are connected internally
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FTM1SYNC	FTM1 synchronization trigger 0 No trigger generated. (reset value) 1 Generate a PWM synchronization trigger to the FTM1 modules.
0 FTM0SYNC	FTM0 synchronization trigger 0 No trigger generated. (reset value). 1 Generate a PWM synchronization trigger to the FTM0 module.

13.2.8 COP Control Register (SIM_COPC)

All of the bits in this register can be written only once after a reset.

The following table summarizes the control functions of this register's bitfields for COP clock selection, windowed mode, and timeout count.

Control Bits		Clock Source	COP Window Opens (COPC[COPW] = 1)	COP Overflow Count
COPC[COPCLKS]	COPC[COPT]			
N/A	00	N/A	N/A	COP is disabled
0	01	1 kHz	N/A	2 ⁵ cycles (32 ms)
0	10	1 kHz	N/A	2 ⁸ cycles (256 ms)
0	11	1 kHz	N/A	2 ¹⁰ cycles (1,024 ms)
1	01	Bus	6,144 cycles	2 ¹³ cycles
1	10	Bus	49,152 cycles	2 ¹⁶ cycles
1	11	Bus	196,608 cycles	2 ¹⁸ cycles

Memory Map and Registers

Address: FFFF_80C0h base + Ah offset = FFFF_80CAh

Bit	7	6	5	4	3	2	1	0
Read	0				COPT		COPCLKS	COPW
Write	0				1		1	0
Reset	0	0	0	0	1	1	0	0

SIM_COPC field descriptions

Field	Description
7-4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3-2 COPT	COP watchdog timeout These write-once bits select the timeout period of the COP. The COPT field along with the COPCLKS bit define the COP timeout period.
1 COPCLKS	COP watchdog clock select This write-once bit selects the clock source of the COP watchdog. 0 Internal 1 kHz clock is source to COP (reset value). 1 Bus clock is source to COP.
0 COPW	COP windowed mode 0 Normal mode (reset value). 1 Windowed mode.

13.2.9 Service COP Register (SIM_SRVCOP)

Address: FFFF_80C0h base + Bh offset = FFFF_80CBh

Bit	7	6	5	4	3	2	1	0
Read	0							
Write	SRVCOP							
Reset	0	0	0	0	0	0	0	0

SIM_SRVCOP field descriptions

Field	Description
7-0 SRVCOP	Refer to COP watchdog operation .

13.2.10 Oscillator 1 Control Register (SIM_OSC1)

Controls the OSC1 crystal oscillator.

Address: FFFF_80C0h base + Dh offset = FFFF_80CDh

Bit	7	6	5	4	3	2	1	0
Read	OSC1EN	0	0	OSC1RANGE		OSC1HGO	OSC1EREF S	0
Write								
Reset	0	0	0	0	0	0	0	0

SIM_OSC1 field descriptions

Field	Description
7 OSC1EN	Oscillator 1 enable Enables oscillator 1. 0 Oscillator 1 inactive. 1 Oscillator 1 active.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 OSC1RANGE	Frequency range select Selects the frequency range for the crystal oscillator or external clock source. For details, refer to the OSC chapter. 00 Encoding 0: Low frequency range for the crystal oscillator of 32 kHz to 40 kHz (reset default). 01 Encoding 1: High frequency range selected for the crystal oscillator of 1 MHz to 8 MHz. 1x Encoding 2: Very high frequency range selected for the crystal oscillator of 8 MHz to 32 MHz.
2 OSC1HGO	High gain oscillator select Controls the crystal oscillator mode of operation. For details, refer to the OSC chapter. 0 Configure crystal oscillator for low-power operation. 1 Configure crystal oscillator for high-gain operation.
1 OSC1EREF S	External reference select Selects the source for the external reference clock. Refer to the OSC chapter for details. 0 External reference clock requested. 1 Oscillator requested.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

13.2.11 Device Identification High Register (SIM_SDIDH)

Together, the SDIDH and SDIDL registers contain the 12 ID bits that specify the device identification number set by the IFR bits.

For a definition of the bit encodings for the ID bits in these registers, see the bit encodings for the SDIDL register.

NOTE

The following Reset row refers to Chip POR. Only that type of reset, or any reset type that triggers Chip POR, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 10h offset = FFFF_80D0h

Bit	7	6	5	4	3	2	1	0
Read	REV				ID[11:8]			
Write								
Reset	0	0	0	0	1	1	0	1

SIM_SDIDH field descriptions

Field	Description
7-4 REV	Device Revision Number Specifies the silicon implementation number for the device. This value comes from plugs, not IFR bits.
3-0 ID[11:8]	Device identification number Specifies the device identification number as set by the IFR bits. For information about the bit encodings for this field, see the description of the SDIDL register.

13.2.12 Device Identification Low Register (SIM_SDIDL)

Together, the SDIDH and SDIDL registers contain the 12 ID bits that specify the device identification number set by the IFR bits, whose values replace the default reset values. The bit encodings for all 12 ID bits correspond to the three LSBs in the IFR, which is a range from D01h to D07h (110100000001b to 110100000111b).

NOTE

The following Reset row refers to Chip POR. Only that type of reset, or any reset type that triggers Chip POR, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 11h offset = FFFF_80D1h

Bit	7	6	5	4	3	2	1	0
Read	ID[7:0]							
Write								
Reset	*	*	*	*	*	*	*	*

* Notes:

- ID[7:0] field: Refer to this bitfield's description for its value, which is set by IFR bits.

SIM_SDIDL field descriptions

Field	Description														
7-0 ID[7:0]	<p>Device identification number</p> <p>Specifies the device identification number as set by the IFR bits, whose values replace the default reset values. The bit encodings for bits 2-0 specify the ColdFire+ family of which the chip is a member.</p> <table> <tr><td>00000001</td><td>MCF51JF</td></tr> <tr><td>00000010</td><td>MCF51JU</td></tr> <tr><td>00000011</td><td>MCF51QM</td></tr> <tr><td>00000100</td><td>MCF51QH</td></tr> <tr><td>00000101</td><td>MCF51QF</td></tr> <tr><td>00000110</td><td>MCF51QU</td></tr> <tr><td>00000111</td><td>Reserved</td></tr> </table>	00000001	MCF51JF	00000010	MCF51JU	00000011	MCF51QM	00000100	MCF51QH	00000101	MCF51QF	00000110	MCF51QU	00000111	Reserved

13.2.13 Clock Gate Control Register 1 (SIM_SCGC1)

Each bit in SCGC1 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 12h offset = FFFF_80D2h

Bit	7	6	5	4	3	2	1	0
Read	I2C3	I2C2	I2C1	I2C0	SPI1	SPI0	UART1	UART0
Write								
Reset	0	0	0	0	0	0	0	0

SIM_SCGC1 field descriptions

Field	Description
7 I2C3	<p>I2C3 clock gate control</p> <p>Controls the clock gate to the I2C3 module.</p> <p>0 The clock to the module is disabled. 1 The clock to the module is enabled.</p>
6 I2C2	<p>I2C2 clock gate control</p> <p>Controls the clock gate to the I2C2 module.</p>

Table continues on the next page...

SIM_SCGC1 field descriptions (continued)

Field	Description
	0 The clock to the module is disabled. 1 The clock to the module is enabled.
5 I2C1	I2C1 clock gate control Controls the clock gate to the I2C1 module. 0 The clock to the module is disabled 1 The clock to the module is enabled.
4 I2C0	I2C0 clock gate control Controls the clock gate to the I2C0 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
3 SPI1	SPI1 clock gate control Controls the clock gate to the SPI1 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
2 SPI0	SPI0 clock gate control Controls the clock gate to the SPI0 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
1 UART1	UART1 clock gate control Controls the clock gate to the UART1 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
0 UART0	UART0 clock gate control Controls the clock gate to the UART0 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.

13.2.14 Clock Gate Control Register 2 (SIM_SCGC2)

Each bit in SCGC2 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 13h offset = FFFF_80D3h

Bit	7	6	5	4	3	2	1	0
Read	0	CMP	TSI	VREF	0		ADC	DAC12B
Write	[Shaded]				[Shaded]			
Reset	0	0	0	1	0	0	0	0

SIM_SCGC2 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CMP	CMP clock gate control Controls the clock gate to the CMP module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
5 TSI	TSI clock gate control Controls the clock gate to the TSI module. 0 The clock to the module is disabled 1 The clock to the module is enabled.
4 VREF	VREF clock gate control Controls the clock gate to the VREF module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 ADC	ADC clock gate control Controls the clock gate to the ADC module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
0 DAC12B	12-bit DAC clock gate control Controls the clock gate to the 12-bit DAC module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.

13.2.15 Clock Gate Control Register 3 (SIM_SCGC3)

Each bit in SCGC3 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 14h offset = FFFF_80D4h

Bit	7	6	5	4	3	2	1	0
Read	CRC	PDB	CMT	MTIM	FTM1	FTM0	Reserved	
Write								
Reset	0	0	0	0	0	0	0	0

SIM_SCGC3 field descriptions

Field	Description
7 CRC	CRC clock gate control Controls the clock gate to the CRC module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
6 PDB	PDB clock gate control Controls the clock gate to the PDB module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
5 CMT	CMT clock gate control Controls the clock gate to the CMT module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
4 MTIM	MTIM clock gate control Controls the clock gate to the MTIM module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
3 FTM1	FTM1 clock gate control Controls the clock gate to the FTM1 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
2 FTM0	FTM0 clock gate control Controls the clock gate to the FTM0 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
1-0 Reserved	This field is reserved.

13.2.16 Clock Gate Control Register 4 (SIM_SCGC4)

Each bit in SCGC4 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 15h offset = FFFF_80D5h

Bit	7	6	5	4	3	2	1	0
Read	FTFL	Reserved			DMA	Reserved	IRQ	WDOG
Write								
Reset	1	0	0	0	0	0	0	1

SIM_SCGC4 field descriptions

Field	Description
7 FTFL	FTFL clock gate control Controls the clock gate to the FTFL module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
6–4 Reserved	This field is reserved.
3 DMA	DMA clock gate control Controls the clock gate to the DMA module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
2 Reserved	This field is reserved.
1 IRQ	IRQ clock gate control Controls the clock gate to the IRQ module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
0 WDOG	COP clock gate control Controls the bus clock gate to the COP module. CAUTION: If the COP is using the bus clock and is enabled and counting, and then the bus clock to the COP is disabled: <ul style="list-style-type: none"> • The COP cannot be serviced. • The COP will still time out and cause a reset. 0 The clock to the module is disabled. 1 The clock to the module is enabled.

13.2.17 Clock Gate Control Register 5 (SIM_SCGC5)

Each bit in SCGC5 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 16h offset = FFFF_80D6h

Bit	7	6	5	4	3	2	1	0
Read	0	MFBUS	Reserved			OSC2	OSC1	MCG
Write								
Reset	0	0	0	0	0	0	0	1

SIM_SCGC5 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 MFBUS	MFBUS clock gate control Controls the clock gate to the MFBUS module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
5-3 Reserved	This field is reserved.
2 OSC2	OSC2 clock gate control Controls the clock gate to the OSC2 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
1 OSC1	OSC1 clock gate control Controls the clock gate to the OSC1 module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
0 MCG	MCG clock gate control Controls the clock gate to the MCG module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.

13.2.18 Clock Gate Control Register 6 (SIM_SCGC6)

Each bit in SCGC6 controls the clock gate to its respective module.

Address: FFFF_80C0h base + 17h offset = FFFF_80D7h

Bit	7	6	5	4	3	2	1	0
Read	0		PORTF	PORTE	PORTD	PORTC	PORTB	PORTA
Write	0		0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0

SIM_SCGC6 field descriptions

Field	Description
7-6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 PORTF	Port F clock gate control Controls the clock gate to the Port F module.

Table continues on the next page...

SIM_SCGC6 field descriptions (continued)

Field	Description
	0 The clock to the module is disabled. 1 The clock to the module is enabled.
4 PORTE	Port E clock gate control Controls the clock gate to the Port E module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
3 PORTD	Port D clock gate control Controls the clock gate to the Port D module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
2 PORTC	Port C clock gate control Controls the clock gate to the Port C module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
1 PORTB	Port B clock gate control Controls the clock gate to the Port B module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.
0 PORTA	Port A clock gate control Controls the clock gate to the Port A module. 0 The clock to the module is disabled. 1 The clock to the module is enabled.

13.2.19 Clockout Register (SIM_CLKOUT)

Address: FFFF_80C0h base + 1Ah offset = FFFF_80DAh

Bit	7	6	5	4	3	2	1	0
Read	0	CS			0	CLKOUTDIV		
Write								
Reset	0	0	0	0	0	1	1	1

SIM_CLKOUT field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIM_CLKOUT field descriptions (continued)

Field	Description
6-4 CS	CLKOUT pin clock select 000 Disabled (reset value) 001 OSC1ERCLK (from OSC1) 010 OSC2ERCLK (from OSC2) 011 MCGOUTCLK 100 CPUCLK/SYSCLK (Note: In wait mode, CPUCLK is disabled, but SYSCLK is still available.) 101 BUSCLK (Note: For PTB1, BUSCLK can be used as FB_CLKOUT.) 110 LPO 111 LPTMR0 prescaler clock output
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2-0 CLKOUTDIV	Division of the CLKOUT pin 000 Division by 1 001 Division by 2 010 Division by 4 011 Division by 8 100 Division by 16 101 Division by 32 110 Division by 64 111 Division by 128 (reset value)

13.2.20 Clock Divider 0 Register (SIM_CLKDIV0)

NOTE

The following Reset row refers to Chip POR. Only that type of reset, or any reset type that triggers Chip POR, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 1Bh offset = FFFF_80DBh

Bit	7	6	5	4	3	2	1	0
Read	0				OUTDIV			
Write								
Reset	0	0	0	0	*	*	*	*

* Notes:

- OUTDIV field: At end of reset, loaded with either 0000 or 1111 depending on flash option register bit 0 (FOPT[0])

SIM_CLKDIV0 field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 OUTDIV	<p>Clock output divider value to generate CPU clock</p> <p>Sets the divide value for the core/system clock.</p> <p>NOTE: At the end of reset, this field is loaded with either 0000 or 1111 depending on flash option register bit 0 (FOPT[0]).</p> <p>Restriction: This bitfield cannot be changed when the MCU is in a VLPx mode.</p> <p>Restriction: The CPU clock should never exceed 50 MHz.</p> <p>0000 Divide-by-1 0001 Divide-by-2 0010 Divide-by-3 0011 Divide-by-4 0100 Divide-by-5 0101 Divide-by-6 0110 Divide-by-7 0111 Divide-by-8 1000 Divide-by-9 1001 Divide-by-10 1010 Divide-by-11 1011 Divide-by-12 1100 Divide-by-13 1101 Divide-by-14 1110 Divide-by-15 1111 Divide-by-16</p>

13.2.21 Flash Configuration Register (SIM_SPCR)

NOTE

The following Reset row refers to Chip POR. Only that type of reset, or any reset type that triggers Chip POR, affects this register. Other reset types do not affect this register.

Address: FFFF_80C0h base + 20h offset = FFFF_80E0h

Bit	7	6	5	4	3	2	1	0
Read	NVMSIZE				PFSIZE			
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

SIM_SPCR field descriptions

SIM_UIDL0 field descriptions

Field	Description
7-0 UID[7:0]	Unique identification Provides unique identification for the device. These bits are set by the IFR bits.

Chapter 14

Crossbar Switch

14.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows up to four bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave.

14.1.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
 - Allows concurrent accesses from different masters to different slaves
- 32-bit data bus
- Operation at a 1-to-1 clock frequency with the bus masters
- Dynamic master priority elevation
- Programmable configuration for fixed-priority or round-robin slave port arbitration

14.2 Memory Map / Register Definition

This crossbar switch is designed for minimal gate count. It, therefore, has no memory-mapped configuration registers.

14.3 Functional Description

14.3.1 General operation

When a master accesses the crossbar switch the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
 - An outstanding request to one slave port that has a long response time and
 - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it remains parked with the last master to use the slave port. This is done to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port.

14.3.2 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round robin

The selection of the global slave port arbitration is controlled by MCM_PLACR[ARB]. For fixed priority, set ARB to 0. For round robin, set ARB to 1. This arbitration setting applies to all slave ports.

The crossbar arbitration scheme is controlled by CPUCCR[CBRR] bit in the processor's CPU Configuration Register (CPUCCR). See [CPU Configuration Register \(CPUCCR\)](#) for details. At reset, fixed-priority arbitration is enabled.

14.3.2.1 Arbitration During Undefined Length Bursts

All lengths of burst accesses lock out arbitration until the last beat of the burst.

14.3.2.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level with the highest numbered master having the highest priority (master 1 has lower priority than master 3). If two masters request access to the same slave port, the master with the highest priority gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

Functional Description

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 14-1. How AXBS grants control of a slave port to a master

When	Then AXBS grants control to the requesting master
Both of the following are true: <ul style="list-style-type: none">• The current master is not running a transfer.• The new requesting master's priority level is higher than that of the current master.	At the next clock edge
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: <ul style="list-style-type: none">• An IDLE cycle• A non-IDLE cycle to a location other than the current slave port

14.3.2.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4 and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

The round-robin arbitration mode generally provides a more fair allocation of the available slave-port bandwidth (compared to fixed priority) as the fixed master priority does not affect the master selection.

14.3.2.4 Priority Elevation

The processor master port may elevate its priority level to the slave ports. This is controlled by CPUOCR[HAE] and CPUOCR[FHP] bits. See [CPU Configuration Register \(CPUOCR\)](#) for details. The CPUOCR[FHP] bit always elevates the processor's priority while the CPUOCR[HAE] bit elevates the processor's priority while it is processing any interrupt service routine.

When priority elevation is enabled for the processor's master port, that master port has a higher priority than the other master ports that do not, regardless of the fixed priority level or round robin conditions.

This functionality allows the user to automatically elevate a master port's priority level throughout the crossbar to quickly perform temporary tasks such as servicing interrupts. However, when using this functionality take care to not to occupy 100% of a slave's bandwidth with one master, and essentially locking out the rest of the masters. This should only be used for important temporary tasks, such as interrupt handling.

14.3.2.4.1 Priority Elevation in Round-Robin Mode

If a slave port is programmed for round-robin mode and a master is configured for priority elevation, that master can force the slave port into fixed priority mode. The slave port remains in fixed priority mode while that master's (or any other master's) configured for priority elevation and it attempts access to that particular slave port.

After the masters are no longer configured for priority elevation, or the masters no longer attempt accesses to that particular slave port, the slave port reverts to round-robin priority mode. Then, the pointer is set on the last master to access the slave port.

14.4 Initialization/application information

No initialization is required for the crossbar switch. See the AXBS section of the configuration chapter for the reset state of the arbitration scheme.

Chapter 15

Interrupt Controller (INTC)

15.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The CF1_INTC interrupt controller (CF1_INTC) is intended for use in low-cost microcontroller designs using the Version 1 (V1) ColdFire processor core. In keeping with the general philosophy for devices based on this low-end 32-bit processor, the interrupt controller generally supports less programmability compared to similar modules in other ColdFire microcontrollers and embedded microprocessors. However, CF1_INTC provides the required functionality with a minimal silicon cost.

These requirements guide the CF1_INTC module definition to support Freescale's Controller Continuum:

- The priorities of the interrupt requests between comparable HCS08 and V1 ColdFire devices are identical.
- Supports a mode of operation (through software convention with hardware assists) equivalent to the S08's interrupt processing with only one level of nesting.
- Leverages the current ColdFire interrupt controller programming model and functionality, but with a minimal hardware implementation and cost.

The following table provides a high-level architectural comparison between HCS08 and ColdFire exception processing as these differences are important in the definition of the CF1_INTC module. Throughout this document, the term IRQ refers to an interrupt request and ISR refers to an interrupt service routine to process an interrupt exception.

Table 15-1. Exception Processing Comparison

Attribute	HCS08	V1 ColdFire
Exception Vector Table	32 two-byte entries, fixed location at upper end of memory	115 four-byte entries, located at lower end of memory at reset, relocatable with the VBR
More on Vectors	2 for CPU + 30 for IRQs, reset at upper address	64 for CPU + 39 for IRQs, reset at lowest address
Exception Stack Frame	5-byte frame: CCR, A, X, PC	8-byte frame: F/V, SR, PC; General-purpose registers (An, Dn) must be saved/restored by the ISR
Interrupt Levels	1 = $f(\text{CCR}[\text{I}])$	7 = $f(\text{SR}[\text{I}])$ with automatic hardware support for nesting
Non-Maskable IRQ Support	No	Yes, with level 7 interrupts
Core-enforced IRQ Sensitivity	No	Level 7 is edge sensitive, else level sensitive
INTC Vectoring	Fixed priorities and vector assignments	Fixed priorities and vector assignments, plus any 2 IRQs can be remapped as the highest priority level 6 requests
Software IACK	No	Yes
Exit Instruction from ISR	RTI	RTE

15.1.1 Overview

Interrupt exception processing includes interrupt recognition, aborting the current instruction execution stream, storing an 8-byte exception stack frame in the memory, calculation of the appropriate vector, and passing control to the specified interrupt service routine.

Unless specifically noted otherwise, all ColdFire processors sample for interrupts once during each instruction's execution during the first cycle of execution in the OEP. Additionally, all ColdFire processors use an instruction restart exception model.

The ColdFire processor architecture defines a 3-bit interrupt priority mask field in the processor's status register (SR[I]). This field, and the associated hardware, support seven levels of interrupt requests with the processor providing automatic nesting capabilities. The levels are defined in descending numeric order with $7 > 6 \dots > 1$. Level 7 interrupts are treated as non-maskable, edge-sensitive requests while levels 6–1 are maskable, level-sensitive requests. The SR[I] field defines the processor's current interrupt level. The processor continuously compares the encoded IRQ level from CF1_INTC against SR[I]. Recall that interrupt requests are inhibited for all levels less than or equal to the current level, except the edge-sensitive level 7 request that cannot be masked.

Exception processing for ColdFire processors is streamlined for performance and includes all actions from detecting the fault condition to the initiation of fetch for the first handler instruction. Exception processing is comprised of four major steps.

1. The processor makes an internal copy of the status register (SR) and enters supervisor mode by setting SR[S] and disabling trace mode by clearing SR[T]. The occurrence of an interrupt exception also forces the master mode (M) bit to clear and the interrupt priority mask (I) to set to the level of the current interrupt request.
2. The processor determines the exception vector number. For all faults except interrupts, the processor performs this calculation based on the exception type. For interrupts, the processor performs an IACK bus cycle to obtain the vector number from the interrupt controller if CPUCCR[IAE] equals 1. The IACK cycle is mapped to special locations within the interrupt controller's IPS address space with the interrupt level encoded in the address. If CPUCCR[IAE] equals 0, the processor uses the vector number supplied by the interrupt controller at the time the request was signaled (for improved performance).
3. The processor saves the current context by creating an exception stack frame on the system stack. As a result, exception stack frame is created at a 0-modulo-4 address on top of the system stack defined by the supervisor stack pointer (SSP). The processor uses an 8-byte stack frame for all exceptions. It contains the vector number of the exception, the contents of the status register at the time of the exception, and the program counter (PC) at the time of the exception. The exception type determines whether the program counter placed in the exception stack frame defines the location of the faulting instruction (fault) or the address of the next instruction to be executed (next). For interrupts, the stacked PC is always the address of the next instruction to be executed.
4. The processor calculates the address of the first instruction of the exception handler. By definition, the exception vector table is aligned on a 1MB boundary. This instruction address is generated by fetching a 32-bit exception vector from the table located at the address defined in the vector base register (VBR). The index into the exception table is calculated as $(4 \times \text{vector number})$. After the exception vector has been fetched, the contents of the vector serves as a 32-bit pointer to the address of the first instruction of the desired handler. After the instruction fetch for the first opcode of the handler has been initiated, exception processing terminates and normal instruction processing continues in the handler.

All ColdFire processors support a 1024-byte vector table aligned on any 1 MB address boundary. For the V1 ColdFire core, the only practical locations for the vector table are based at 0x(00)00_0000 in the flash or 0x(00)80_0000 in the RAM. The table contains

256 exception vectors; the first 64 are reserved for internal processor exceptions, and the remaining 192 are device-specific interrupt vectors. The IRQ assignment table is partially populated depending on the exact set of peripherals for the given device.

The basic ColdFire interrupt controller supports up to 63 request sources mapped as nine priorities for each of the seven supported levels (7 levels × 9 priorities per level). Within the nine priorities within a level, the mid-point is typically reserved for package-level IRQ inputs. The levels and priorities within the level follow a descending order: 7 > 6 > ... > 1 > 0.

The HCS08 architecture supports a 32-entry exception vector table: the first two vectors are reserved for internal CPU/system exceptions and the remaining are available for I/O interrupt requests. The requirement for an exact match between the interrupt requests and priorities across two architectures means the sources are mapped to a sparsely-populated two-dimensional ColdFire array of seven interrupt levels and nine priorities within the level. The following association between the HCS08 and ColdFire vector numbers applies:

$$\text{ColdFire Vector Number} = 62 + \text{HCS08 Vector Number}$$

The CF1_INTC performs a cycle-by-cycle evaluation of the active requests and signals the highest-level, highest-priority request to the V1 ColdFire core in the form of an encoded interrupt level and the exception vector associated with the request. The module also includes a byte-wide interface to access its programming model. These interfaces are shown in the following simplified block diagram.

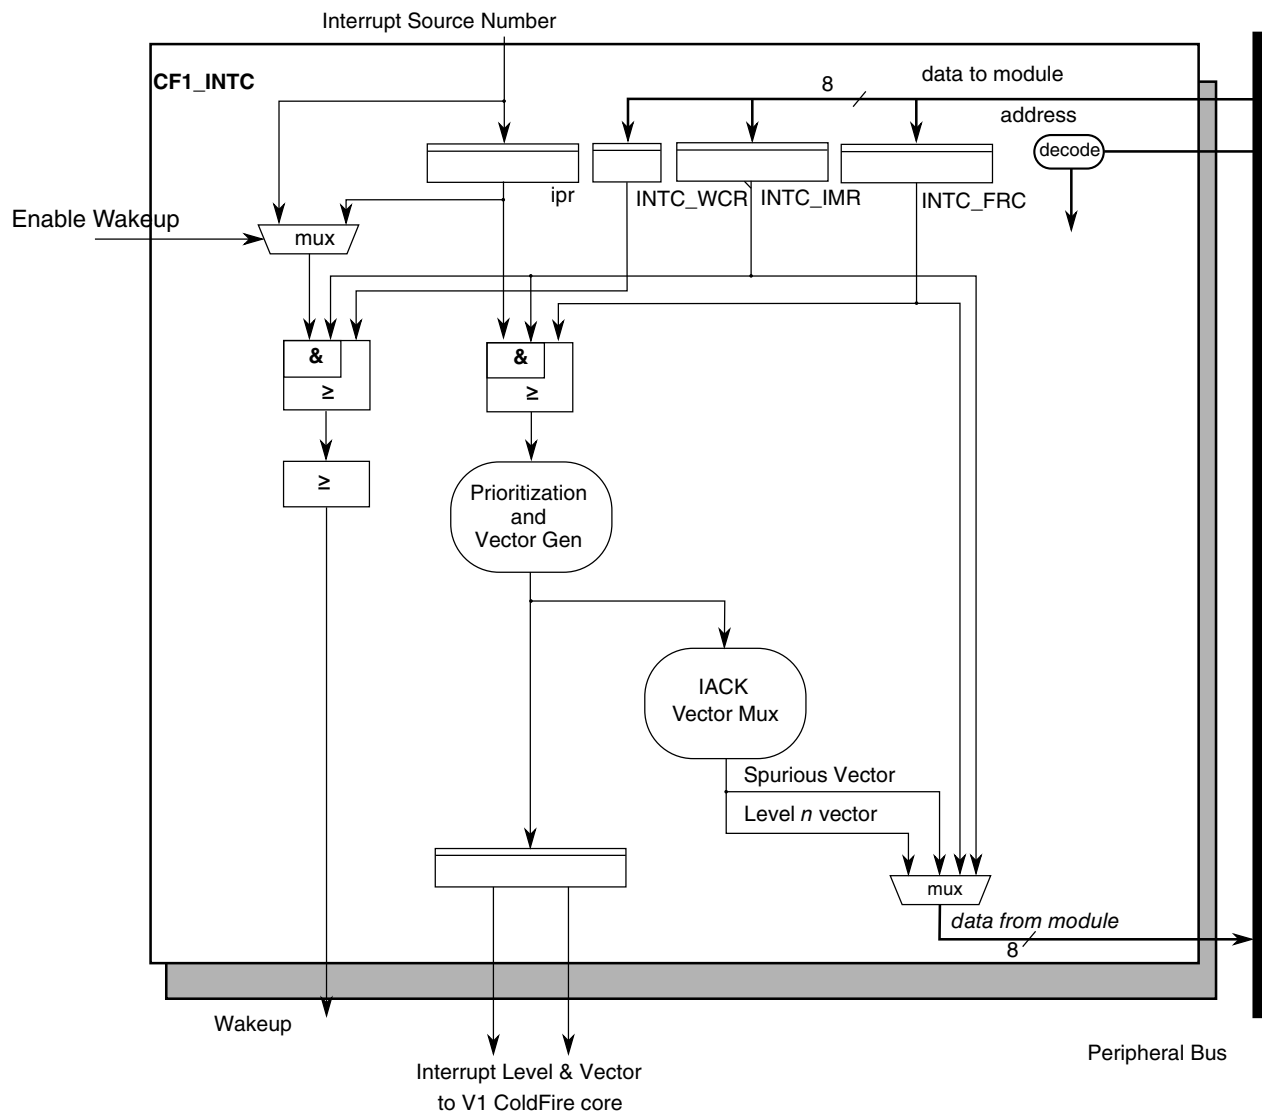

Figure 15-1. CF1_INTC Block Diagram

15.1.2 Features

The Version 1 ColdFire interrupt controller includes:

- Memory-mapped off-platform slave module
 - 64-byte space located at top end of memory: 0x(FF)FF_FFC0–0x(FF)FF_FFFF
 - Programming model accessed via the peripheral bus
 - Encoded interrupt level and vector sent directly to processor core
- Support of 30 peripheral I/O interrupt requests plus seven software (one per level) interrupt requests

- Fixed association between interrupt request source and level plus priority
 - 30 I/O requests assigned across seven available levels and nine priorities per level
 - Exactly matches HCS08 interrupt request priorities
 - Up to two requests can be remapped to the highest maskable level + priority
- Unique vector number for each interrupt source
 - ColdFire vector number = 62 + HCS08 vector number
 - Details on IRQ and vector assignments are device-specific
- Support for service routine interrupt acknowledge (software IACK) read cycles for improved system performance
- Combinatorial path provides wakeup signal from wait and stop modes
- Ability to mask any individual interrupt source, plus global mask-all capability

15.1.3 Modes of Operation

The CF1_INTC module does not support any special modes of operation. As a memory-mapped slave peripheral located on the platform's slave bus, it responds based strictly on the memory addresses of the connected bus.

One special behavior of the CF1_INTC deserves mention. When the device enters a wait or stop mode and certain clocks are disabled, there is an input signal that can be asserted to enable a purely-combinational logic path for monitoring the assertion of an interrupt request. After a request of unmasked level is asserted, this combinational logic path asserts an output signal that is sent to the clock generation logic to re-enable the internal device clocks to exit the low-power mode.

15.2 External Signal Description

The CF1_INTC module does not include any external interfaces.

15.3 Interrupt Request Level and Priority Assignments

The CF1_INTC module implements a sparsely populated 7×9 matrix of levels (7) and priorities within each level (9).

For details, see the chip-specific information about interrupt vector assignments.

Note

For remapped and forced interrupts, the interrupt source number entry indicates the register or register field that enables the corresponding interrupt.

15.4 Memory Map and Registers

The CF1_INTC module provides a 64-byte programming model mapped to the upper region of the 16 MB address space. All the register names are prefixed with INTC_ as an abbreviation for the full module name.

In the programming model, attempted references to undefined (reserved) addresses or with a non-supported access type (for example, a write to a read-only register) generate a bus error termination.

The programming model follows the definition from previous ColdFire interrupt controllers. This compatibility accounts for the various memory holes in this module memory map.

INTC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

15.4.1 Interrupt Mask Register High (INTC_IMRH)

INTC_IMRH, along with INTC_IMRL, provides a bit map for each interrupt to allow the request to be disabled (masked) (1 = disable the request, 0 = enable the request). The IMR is cleared by reset, enabling all interrupt requests to preserve compatibility with earlier V1 ColdFire devices. The IMR can be read and written directly, or individual mask flags can be set or cleared by accessing set/clear interrupt mask registers (INTC_SIMR, INTC_CIMR).

Each bit of the IMR[n] is associated with a corresponding bit of the interrupt request input vector. The equations defining this association are:

For Vectors 64-102, $n = \text{Vector_Number} - 64$, else for Vectors 110-114, $n = \text{Vector_Number} - 71$

Therefore, vector 64 corresponds to $n = 0$, vector 65 to $n = 1$, etc., vector 113 to $n = 42$, and vector 114 to $n = 43$.

Each peripheral request input is first qualified by the contents of the IMR registers before it is used elsewhere in the interrupt controller, that is:

$$\text{qualified_interrupt_request}[n] = \text{interrupt_request_input}[n] + \sim\text{INTC_IMR}[n]$$

Since this interrupt controller supports 44 request inputs, the upper 20 bits of the INTC_IMRH are reserved for future use. Writes to these bits are ignored and reads return zeroes.

The contents of the IMR do not affect the operation of the software settable force interrupt registers.

NOTE

Because this register and the corresponding low register together represent 64 bits, this register's bits are actually numbered 63-32 (not 31-0).

Address: FFFF_FFC0h base + 8h offset = FFFF_FFC8h

15.4.2 Interrupt Mask Register Low (INTC_IMRL)

INTC_IMRL, along with INTC_IMRH, provides a bit map for each interrupt to allow the request to be disabled (masked) (1 = disable the request, 0 = enable the request). The IMR is cleared by reset, enabling all interrupt requests to preserve compatibility with earlier V1 ColdFire devices. The IMR can be read and written directly, or individual mask flags can be set or cleared by accessing set/clear interrupt mask registers (INTC_SIMR, INTC_CIMR).

Each bit of the IMR[n] is associated with a corresponding bit of the interrupt request input vector. The equations defining this association are:

For Vectors 64-102, $n = \text{Vector_Number} - 64$, else for Vectors 110-114, $n = \text{Vector_Number} - 71$

Therefore, vector 64 corresponds to $n = 0$, vector 65 to $n = 1$, etc., vector 113 to $n = 42$, and vector 114 to $n = 43$.

Each peripheral request input is first qualified by the contents of the IMR registers before it is used elsewhere in the interrupt controller, that is:

$$\text{qualified_interrupt_request}[n] = \text{interrupt_request_input}[n] + \sim\text{INTC_IMR}[n]$$

Since this interrupt controller supports 44 request inputs, the upper 20 bits of the INTC_IMRH are reserved for future use. Writes to these bits are ignored and reads return zeroes.

The contents of the IMR do not affect the operation of the software settable force interrupt registers.

15.4.3 Force Interrupt Register (INTC_FRC)

The INTC_FRC register allows software to generate a unique interrupt for each possible level at the lowest priority within the level for functional or debug purposes. These interrupts may be self-scheduled by setting one or more of the bits in the INTC_FRC register. In some cases, the handling of a normal interrupt request may cause critical processing by the service routine along with the scheduling (using the INTC_FRC register) of a lower priority level interrupt request to be processed at a later time for less-critical task handling.

The INTC_FRC register may be modified directly using a read-modify-write sequence or through a simple write operation using the set/clear force interrupt registers (INTC_SFRC, INTC_CFRC).

NOTE

For compatibility with other ColdFire interrupt controllers, this register's bit numbers are actually 63-56 (not 7-0 as shown in the register diagram).

Address: FFFF_FFC0h base + 10h offset = FFFF_FFD0h

Bit	7	6	5	4	3	2	1	0

Field	Description
4 LVL3	Force level 3 interrupt 0 Negates the forced level 3 interrupt request. 1 Forces a level 3 interrupt request.
3 LVL4	Force level 4 interrupt 0 Negates the forced level 4 interrupt request. 1 Forces a level 4 interrupt request.
2 LVL5	Force level 5 interrupt 0 Negates the forced level 5 interrupt request. 1 Forces a level 5 interrupt request.
1 LVL6	Force level 6 interrupt 0 Negates the forced level 6 interrupt request. 1 Forces a level 6 interrupt request.
0 LVL7	Force level 7 interrupt 0 Negates the forced level 7 interrupt request. 1 Forces a level 7 interrupt request.

15.4.4 INTC Programmable Level 6 Priority Registers (INTC_PL6Pn)

The level seven interrupt requests cannot have their levels reassigned. However, any of the remaining peripheral interrupt requests can be reassigned as the highest priority maskable requests using these two registers (INTC_PL6P7 and INTC_PL6P6). The vector number associated with the interrupt requests does not change. Rather, only the interrupt request's level and priority are altered, based on the contents of the INTC_PL6P{7,6} registers.

NOTE

The requests associated with the INTC_FRC register have a fixed level and priority that cannot be altered.

The INTC_PL6P7 register specifies the highest-priority, maskable interrupt request that is defined as the level six, priority seven request. The INTC_PL6P6 register specifies the second-highest-priority, maskable interrupt request defined as the level six, priority six request. Reset clears both registers, disabling any request re-mapping.

For an example of the use of these registers, see [Using INTC_PL6P{7,6} Registers](#).

Memory Map and Registers

Address: FFFF_FFC0h base + 18h offset + (1d × i), where i=0d to 1d

Bit	7	6	5	4	3	2	1	0
Read	0		REQN					
Write	0		0					
Reset	0	0	0	0	0	0	0	0

INTC_PL6Pn field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 REQN	Request number Defines the peripheral IRQ number to be remapped as the level 6, priority 7 (for INTC_PL6P7) request and level 6, priority 6 (for INTC_PL6P6) request. NOTE: The value must be a valid interrupt number. Unused or reserved interrupt numbers are ignored. The selected vector number is derived from the decimal value of the REQN field, which is <i>n</i> in the following mapping formula: for vectors 64-102, $n = \text{Vector_Number} - 64$, while for vectors 110-114, $n = \text{Vector_Number} - 71$. In other words, the REQN field's minimum value is 4d (selecting vector 68) and maximum value is 43d (selecting vector 114).

15.4.5 INTC Wakeup Control Register (INTC_WCR)

The interrupt controller provides a combinatorial logic path to generate a special wakeup signal to exit from the wait or stop modes. The INTC_WCR register defines wakeup condition for interrupt recognition during wait and stop modes. This mode of operation works as follows:

1. Write to the INTC_WCR to enable this operation (set INTC_WCR[ENB]) and define the interrupt mask level needed to force the core to exit wait or stop mode (INTC_WCR[MASK]). The maximum value of INTC_WCR[MASK] is 0x6 (0b110). The INTC_WCR is enabled with a mask level of 0 as the default after reset.
2. Execute a stop instruction to place the processor into wait or stop mode.
3. After the processor is stopped, the interrupt controller enables special logic that evaluates the incoming interrupt sources in a purely combinatorial path; no clocked storage elements are involved.
4. If an active interrupt request is asserted and the resulting interrupt level is greater than the mask value contained in INTC_WCR[MASK], the interrupt controller asserts the wakeup output signal. This signal is routed to the clock generation logic to exit the low-power mode and resume processing.

Typically, the interrupt mask level loaded into the processor's status register field (SR[I]) during the execution of the stop instruction matches the INTC_WCR[MASK] value.

The interrupt controller wakeup signal is defined as:

$$\text{wakeup} = \text{INTC_WCR}[\text{ENB}] + (\text{level of any asserted_int_request} > \text{INTC_WCR}[\text{MASK}])$$

Address: FFFF_FFC0h base + 1Bh offset = FFFF_FFDBh

Bit	7	6	5	4	3	2	1	0
Read	ENB	0			MASK			
Write								
Reset	1	0	0	0	0	0	0	0

INTC_WCR field descriptions

Field	Description
7 ENB	Enable wakeup signal 0 Wakeup signal disabled. 1 Enables the assertion of the combinational wakeup signal to the clock generation logic.
6–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 MASK	Interrupt mask level

15.4.6 Set Interrupt Mask Register (INTC_SIMR)

The INTC_SIMR register provides a simple memory-mapped mechanism to set a given bit in the INTC_IMR{H,L} registers to disable (mask) a given interrupt request. The data value on a register write causes the corresponding bit in the INTC_IMR{H,L} registers to be set. Setting INTC_SIMR[SALL] forces the entire contents of INTC_IMR{H,L} registers to set, masking all interrupts. Attempting to read this register generates an error termination.

IMR[63:44] are reserved for future use, so writes using these data values are ignored.

This register is provided so interrupt service routines can easily mask the given interrupt request without the need to perform a read-modify-write sequence on the INTC_IMR{H,L} registers.

Address: FFFF_FFC0h base + 1Ch offset = FFFF_FFDC h

Bit	7	6	5	4	3	2	1	0
Read	Reserved							
Write	Reserved		SALL	SIMR				
Reset	0	0	0	0	0	0	0	0

Field	Description
7 Reserved	This field is reserved.
6 SALL	Set all Set all bits in the INTC_IMR{H,L} register, masking all interrupt requests. 0 Set only those bits specified in the SIMR field. 1 Set all bits in INTC_IMR{H,L} register. The SIMR field is ignored.
5-0 SIMR	Set IMR Set the corresponding bit in the INTC_IMR{H,L} register, masking the interrupt request.

15.4.7 Clear Interrupt Mask Register (INTC_CIMR)

The INTC_SIMR register provides a simple memory-mapped mechanism to set a given bit in the INTC_IMR{H,L} registers to disable (mask) a given interrupt request. The data value on a register write causes the corresponding bit in the INTC_IMR{H,L} registers to be set. Setting INTC_SIMR[SALL] forces the entire contents of INTC_IMR{H,L} registers to set, masking all interrupts. Attempting to read this register generates an error termination.

IMR[63:44] are reserved for future use, so writes using these data values are ignored.

This register is provided so interrupt service routines can easily mask the given interrupt request without the need to perform a read-modify-write sequence on the INTC_IMR{H,L} registers.

Address: FFFF_FFC0h base + 1Dh offset = FFFF_FFDDh

6 CALL	Clear all Clear all bits in the INTC_IMR{H,L} register, enabling all interrupt requests. 0 Set only those bits specified in the CIMR field. 1 Clear all bits in INTC_IMR{H,L} register. The CIMR field is ignored.

Table continues on the next page...

INTC_CIMR field descriptions (continued)

Field	Description
5–0 CIMR	Clear the corresponding bit in the INTC_IMR{H,L} registers, enabling the interrupt request.

15.4.8 INTC Set Interrupt Force Register (INTC_SFRC)

The INTC_SFRC register provides a simple memory-mapped mechanism to set a given bit in the INTC_FRC register to assert a specific level interrupt request. The data value written causes the appropriate bit in the INTC_FRC register to be set. Attempted reads of this register generate an error termination.

This register is provided so interrupt service routines can generate a forced interrupt request without the need to perform a read-modify-write sequence on the INTC_FRC register.

Address: FFFF_FFC0h base + 1Eh offset = FFFF_FFDEh

15.4.9 INTC Clear Interrupt Force Register (INTC_CFRC)

The INTC_CFRC register provides a simple memory-mapped mechanism to clear a given bit in the INTC_FRC register to negate a specific level interrupt request. The data value on the register write causes the appropriate bit in the INTC_FRC register to be cleared. Attempted reads of this register generate an error termination.

This register is provided so interrupt service routines can negate a forced interrupt request without the need to perform a read-modify-write sequence on the INTC_FRC register.

Address: FFFF_FFC0h base + 1Fh offset = FFFF_FFDFh

15.4.10 INTC Software IACK Register (INTC_SWIACK)

Refer to the description of the Level-*n* IACK registers.

Address: FFFF_FFC0h base + 20h offset = FFFF_FFE0h

Bit	7	6	5	4	3	2	1	0
Read	0	VECN						
Write								
Reset	0	0	0	0	0	0	0	0

INTC_SWIACK field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 VECN	Vector number Indicates the appropriate vector number. It is the highest-level, highest-priority request currently being asserted in the CF1_INTC module. If there are no pending requests, VECN is zero.

15.4.11 INTC Level-*n* IACK Registers (INTC_LVL*n*IACK)

The eight read-only interrupt acknowledge (IACK) registers can be explicitly addressed by the memory-mapped accesses or implicitly addressed by a processor-generated interrupt acknowledge cycle during exception processing when CPUCCR[IAE] is set. In either case, the interrupt controller's actions are similar.

First, consider an IACK cycle to a specific level, a level-*n* IACK. When this type of IACK arrives in the interrupt controller, the controller examines all currently-active level-*n* interrupt requests, determines the highest priority within the level, and then responds with the unique vector number corresponding to that specific interrupt source. The vector number is supplied as the data for the byte-sized IACK read cycle.

If there is no active interrupt source at the time of the level-*n* IACK, a special spurious interrupt vector (vector number 24 [0x18]) is returned. It is the responsibility of the service routine to manage this error situation.

Functional Description

This protocol implies the interrupting peripheral is not accessed during the acknowledge cycle because the interrupt controller completely services the acknowledge. This means the interrupt source must be explicitly disabled in the peripheral device by the interrupt service routine. This approach provides unique vector capability for all interrupt requests, regardless of the complexity of the peripheral device.

Second, the interrupt controller also supports the concept of a software IACK. This is the ability to query the interrupt controller near the end of an interrupt service routine (after the current interrupt request has been negated) to determine if there are any pending (but currently masked) interrupt requests. If the response to the software IACK's byte operand read is non-zero, the service routine uses the returned value as the vector number of the highest pending interrupt request and passes control to the appropriate new handler. If the returned value is zero, there is no pending interrupt request.

This process avoids the overhead of a context restore and RTE instruction execution, followed immediately by another interrupt exception and context save. In system environments with high rates of interrupt activity, this mechanism can noticeably improve overall performance.

Address: $FFFF_FFC0h \text{ base} + 24h \text{ offset} + (4d \times i)$, where $i=0d$ to $6d$

Bit	7	6	5	4	3	2	1	0
Read	0	VECN						
Write								
Reset	0	0	0	1	1	0	0	0

INTC_LVLnIACK field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 VECN	Vector number Indicates the appropriate vector number. It is the highest priority request within the specified level-n. If there are no pending requests within the level, VECN is 0x18 (24) to signal a spurious interrupt.

15.5 Functional Description

The basic operation of the CF1_INTC is detailed in the preceding sections. This section describes special rules applicable to non-maskable level 7 interrupt requests and the module's interfaces.

15.5.1 Handling of Non-Maskable Level 7 Interrupt Requests

In this context of this discussion, the non-maskable level 7 interrupt requests refer only to the masking capability provided by the processor's SR[I] field. The ability to mask individual interrupt requests using the interrupt controller's IMR is always available, regardless of the level of a particular interrupt request.

The CPU treats level 7 interrupts as non-maskable, edge-sensitive requests, while levels 1 through 6 are maskable, level-sensitive requests. As a result of this definition, level 7 interrupt requests are a special case. The edge-sensitive nature of these requests means the encoded 3-bit level input from the CF1_INTC to the V1 ColdFire core must change state before the CPU detects an interrupt. A non-maskable interrupt (NMI) is generated each time the encoded interrupt level changes to level 7 (regardless of the SR[I] field) and each time the SR[I] mask changes from 7 to a lower value while the encoded request level remains at 7.

15.6 Initialization Information

The reset state of the CF1_INTC module enables the default IRQ mappings and clears any software-forced interrupt requests (INTC_FRC is cleared). Immediately after reset, the CF1_INTC begins its cycle-by-cycle evaluation of any asserted interrupt requests and forms the appropriate encoded interrupt level and vector information for the V1 ColdFire processor core. The ability to mask individual interrupt requests using the interrupt controller's IMR is always available, regardless of the level of a particular interrupt request.

15.7 Application Information

This section discusses three application topics: emulation of the HCS08's one level interrupt nesting structure, elevating the priority of two IRQs, and more details on the operation of the software interrupt acknowledge (SWIACK) mechanism.

15.7.1 Emulation of the HCS08's 1-Level IRQ Handling

As noted in Table 10-7, the HCS08 architecture specifies a 1-level IRQ nesting capability. Interrupt masking is controlled by CCR[I], the interrupt mask flag: clearing CCR[I] enables interrupts, while setting CCR[I] disables interrupts. The ColdFire

architecture defines seven interrupt levels, controlled by the 3-bit interrupt priority mask field in the status register, SR[I], and the hardware automatically supports nesting of interrupts.

To emulate the HCS08's 1-level IRQ capabilities on V1 ColdFire, only two SR[I] settings are used:

- Writing 0 to SR[I] enables interrupts.
- Writing 7 to SR[I] disables interrupts.

The ColdFire core treats the level seven requests as non-maskable, edge-sensitive interrupts.

ColdFire processors inhibit interrupt sampling during the first instruction of all exception handlers. This allows any handler to effectively disable interrupts, if necessary, by raising the interrupt mask level contained in the status register as the first instruction in the ISR. In addition, the V1 instruction set architecture (ISA_C) includes an instruction (STLDSR) that stores the current interrupt mask level and loads a value into the SR. This instruction is specifically intended for use as the first instruction of an interrupt service routine that services multiple interrupt requests with different interrupt levels. For more details see the *ColdFire Family Programmer's Reference Manual*. A MOVE-to-SR instruction also performs a similar function.

To emulate the HCS08's 1-level IRQ nesting mechanisms, the ColdFire implementation enables interrupts by clearing SR[I] (typically when using RTE to return to a process) and disables interrupts upon entering every interrupt service routine by one of three methods:

1. Execution of STLDSR #0x2700 as the first instruction of an ISR.
2. Execution of MOVE.w #0x2700,SR as the first instruction of an ISR.
3. Static assertion of CPUCR[IME] that forces the processor to load SR[I] with seven automatically upon the occurrence of an interrupt exception. Because this method removes the need to execute multi-cycle instructions of #1 or #2, this approach improves system performance.

15.7.2 Using INTC_PL6P{7,6} Registers

The INTC Programmable Level 6, Priority {7,6} registers (INTC_PL6P{7,6}) provide the ability to dynamically alter the request level and priority of two IRQs. Specifically, these registers provide the ability to reassign two IRQs to be the highest level 6 (maskable) requests. Consider the following example.

Suppose the system operation desires to remap the receive and transmit interrupt requests of a serial communication device (SCI1) as the highest two maskable interrupts. The default assignments for the SCI1 transmit and receive interrupts are:

- sci1_rx = interrupt source 13 (0Dh) = vector 77 = level 24, priority 6
- sci1_tx = interrupt source 14 (0Eh) = vector 78 = level 24, priority 5

To remap these two requests, the INTC_PL6P{7,6} registers are programmed with the desired interrupt source number:

- Setting INTC_PL6P7 to 13 (0Dh), remaps sci1_rx as level 6, priority 7.
- Setting INTC_PL6P6 to 14 (0Eh), remaps sci1_tx as level 6, priority 6.

The reset state of the INTC_PL6P{7,6} registers disables any request remapping.

15.7.3 More on Software IACKs

As previously mentioned, the notion of a software IACK refers to the ability to query the interrupt controller near the end of an interrupt service routine (after the current interrupt request has been cleared) to determine if there are any pending (but currently masked) interrupt requests. If the response to the software IACK's byte operand read is non-zero, the service routine uses the value as the vector number of the highest pending interrupt request and passes control to the appropriate new handler. This process avoids the overhead of a context restore and RTE instruction execution, followed immediately by another interrupt exception and context save. In system environments with high rates of interrupt activity, this mechanism can improve overall system performance noticeably.

To illustrate this concept, consider the following ISR code snippet shown in [Figure 15-22](#).

```

        align    4
        irqxx_entry:
00588: 4fef fff0 lea    -16(sp),sp      # allocate stack space
0058c: 48d7 0303 movem.l #0x0303,(sp)  # save d0/d1/a0/a1 on stack

        irqxx_alternate_entry:
00590:
        ....

        irqxx_swiack:
005c0: 71b8 ffe0 mvz.b  INTC_SWIACK.w,d0 # perform software IACK
005c4: 0c00 0041 cmpi.b #0x41,d0        # pending IRQ or level 7?
005c8: 6f0a     ble.b  irqxx_exit      # no pending IRQ, then exit
005ca: 91c8     sub.l  a0,a0          # clear a0
005cc: 2270 0c00 move.l 0(a0,d0.l*4),a1 # fetch pointer from xcpt table
005d0: 4ee9 0008 jmp    8(a1)         # goto alternate isr entry point

        align    4
        irqxx_exit:
005d4: 4cd7 0303 movem.l (sp),#0x0303  # restore d0/d1/a0/a1
005d8: 4fef 0010 lea    16(sp),sp      # deallocate stack space
005dc: 4e73     rte                    # return from handler

```

Figure 15-22. ISR Code Snippet with SWIACK

This snippet includes the prologue and epilogue for an interrupt service routine as well as code needed to perform software IACK.

At the entry point (`irqxx_entry`), there is a two-instruction prologue to allocate space on the supervisor stack to save the four volatile registers (`d0`, `d1`, `a0`, `a1`) defined in the ColdFire application binary interface. After saving these registers, the ISR continues at the alternate entry point.

The software IACK is performed near the end of the ISR, after the source of the current interrupt request is negated. First, the appropriate memory-mapped byte location in the interrupt controller is read (`PC = 0x5C0`). The `CF1_INTC` module returns the vector number of the highest priority pending request. If no request is pending, zero is returned. The compare instruction is needed to manage a special case involving pending level seven requests. Because the level seven requests are non-maskable, the ISR is interrupted to service one of these requests. To avoid any race conditions, this check ignores the level seven vector numbers. The result is the conditional branch (`PC = 0x5C8`) is taken if there are no pending requests or if the pending request is a level seven.

If there is a pending non-level seven request, execution continues with a three instruction sequence to calculate and then branch to the appropriate alternate ISR entry point. This sequence assumes the exception vector table is based at address `0x(00)00_0000` and that each ISR uses the same two-instruction prologue shown here. The resulting alternate entry point is a fixed offset (8 bytes) from the normal entry point defined in the exception vector table.

The ISR epilogue includes a three instruction sequence to restore the volatile registers from the stack and return from the interrupt exception.

This example is intentionally simple, but does show how performing the software IACK and passing control to an alternate entry point when there is a pending but masked interrupt request can avoid the execution of the ISR epilogue, another interrupt exception, and the ISR prologue.

Chapter 16

Low Leakage Wakeup Unit (LLWU)

16.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The LLWU module allows the user to select up to 16 external pin sources and up to 8 internal modules as a wakeup source from low-leakage power modes. The input sources are described in the device's chip configuration details. Each of the available wakeup sources can be individually enabled.

The $\overline{\text{RESET}}$ pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit both LLS and VLLS through a reset flow. The LLWU_RST[LLRSTE] bit must be set to allow an exit from low-leakage modes via the $\overline{\text{RESET}}$ pin. On a device where the $\overline{\text{RESET}}$ pin is shared with other functions, the explicit port mux control register must be set for the $\overline{\text{RESET}}$ pin before the $\overline{\text{RESET}}$ pin can be used as a low-leakage reset source.

The LLWU module also includes three optional digital pin filters: two for the external wakeup pins and one for the $\overline{\text{RESET}}$ pin.

16.1.1 Features

The LLWU module features include:

- Support for up to 16 external input pins and up to 8 internal modules with individual enable bits
- Input sources may be external pins or from internal peripherals capable of running in LLS or VLLS. See the chip configuration information for wakeup input sources for this device.

- External pin wakeup inputs, each of which is programmable as falling-edge, rising-edge, or any change
- Wakeup inputs that are activated if enabled after MCU enters a low-leakage power mode
- Optional digital filters provided to qualify an external pin detect and $\overline{\text{RESET}}$ pin detect.

16.1.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from LLS, the LLWU is immediately disabled. After recovery from VLLS, the LLWU continues to detect wakeup events until the user has acknowledged the wakeup via a write to the PMC_REGSC[ACKISO] bit.

16.1.2.1 LLS mode

The LLWU module provides up to 16 external wakeup inputs and up to 8 internal module wakeup inputs. An LLS reset event can be initiated via assertion of the $\overline{\text{RESET}}$ pin.

Wakeup events due to external wakeup inputs and internal module wakeup inputs result in an interrupt flow when exiting LLS. A reset event due to $\overline{\text{RESET}}$ pin assertion results in a reset flow when exiting LLS.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit Stop mode on an LLS recovery.

16.1.2.2 VLLS modes

The LLWU module provides up to 16 external wakeup inputs and up to 8 internal module wakeup inputs. A VLLS reset event can be initiated via assertion of the $\overline{\text{RESET}}$ pin. All wakeup and reset events result in VLLS exit via a reset flow.

16.1.2.3 Non-low leakage modes

The LLWU is not active in all non-low leakage modes where detection and control logic are in a static state. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When the $\overline{\text{RESET}}$ pin filter or wakeup pin filters are enabled, filter operation begins immediately. If a low leakage mode is entered within 5 LPO clock cycles of an active edge, the edge event will be detected by the LLWU. For $\overline{\text{RESET}}$ pin filtering, this means that there is no restart to the minimum LPO cycle duration as the filtering transitions from a non-low leakage filter, which is implemented in the RCM, to the LLWU filter.

16.1.2.4 Debug mode

When the chip is in Debug mode and then enters LLS or a VLLSx mode, no debug logic works in the fully-functional low-leakage mode. Upon an exit from the LLS or VLLSx mode, the LLWU becomes inactive. If the exit is from a VLLSx mode, the wakeup did not occur via the $\overline{\text{RESET}}$ pin, and the SIM's SOPT4[VLLDBGREQ] bit is set to 1, the debug logic becomes active again upon the exit from the VLLSx mode.

16.1.3 Block diagram

The following figure is the block diagram for the LLWU module.

Figure 16-1. LLWU block diagram

16.2 LLWU signal descriptions

The signal properties of LLWU are shown in the following table. The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

Table 16-1. LLWU signal descriptions

Signal	Description	I/O
LLWU_Pn	Wakeup inputs (n = 0-15)	I

16.3 Memory map/register definition

The LLWU includes the following registers:

- Five 8-bit wakeup source enable registers
 - Enable external pin input sources
 - Enable internal peripheral sources
- Three 8-bit wakeup flag registers
 - Indication of wakeup source that caused exit from a low-leakage power mode includes external pin or internal module interrupt
- Two 8-bit wakeup pin filter enable registers
- One 8-bit RESET pin filter enable register

NOTE

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. Each register's displayed reset value represents this subset of reset types. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS. For more information about the types of reset on this chip, refer to the [Introduction](#) details.

LLWU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

16.3.6 LLWU Flag 1 register (LLWU_F1)

LLWU_F1 contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

16.3.7 LLWU Flag 2 register (LLWU_F2)

LLWU_F2 contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

16.3.8 LLWU Flag 3 register (LLWU_F3)

LLWU_F3 contains the wakeup flags indicating which internal wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

For internal peripherals that are capable of running in a low-leakage power mode, such as iRTC or CMP modules, the flag from the associated peripheral is accessible as the MWUFx bit. The flag will need to be cleared in the peripheral instead of writing a 1 to the MWUFx bit.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

1 LLRSTE	Low-Leakage Mode RESET Enable This bit must be set to allow the device to be reset while in a low-leakage power mode. On devices where Reset is not a dedicated pin, the RESET pin must also be enabled in the explicit port mux control. 0 RESET pin not enabled as a leakage mode exit source 1 RESET pin enabled as a low leakage mode exit source
0 RSTFILT	Digital Filter On RESET Pin Enables the digital filter for the RESET pin during LLS, VLLS3, VLLS2, or VLLS1 modes. 0 Filter not enabled 1 Filter enabled

16.4 Functional description

This on-chip peripheral module is called a low-leakage wakeup unit (LLWU) module because it allows internal peripherals and external input pins as a source of wakeup from low-leakage modes. It is operational only in LLS and VLLSx modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup. Type options are:

- Falling-edge
- Rising-edge
- Either-edge

When an external pin is enabled as a wakeup source, the pin must be configured as an input pin.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin, either wakeup or $\overline{\text{RESET}}$, is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. Two wakeup detect filters are available to detect up to two external pins. A separate reset filter is on the $\overline{\text{RESET}}$ pin. Glitch filtering is not provided on the internal modules.

For internal module wakeup operation, the WUMEx bit enables the associated module as a wakeup source.

16.4.1 LLS mode

Wakeup events triggered from either an external pin input or an internal module input result in a CPU interrupt flow to begin user code execution.

An LLS reset event due to RESET pin assertion causes an exit via a system reset. State retention data is lost, and the I/O states return to their reset state. The RCM_SRS[WAKEUP] and RCM_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

16.4.2 VLLS modes

In the case of a wakeup due to external pin or internal module wakeup, recovery is always via a reset flow and the RCM_SRS[WAKEUP] is set indicating the low-leakage mode was active. State retention data is lost and I/O will be restored after PMC_REGSC[ACKISO] has been written.

A VLLS exit event due to $\overline{\text{RESET}}$ pin assertion causes an exit via a system reset. State retention data is lost and the I/O states immediately return to their reset state. The RCM_SRS[WAKEUP] and RCM_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

16.4.3 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering LLS or VLLSx mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to LLS or VLLSx mode.

After enabling an external pin filter or changing the source pin, wait at least 5 LPO clock cycles before entering LLS or VLLSx mode to allow the filter to initialize.

NOTE

After recovering from a VLLS mode, user must restore chip configuration before clearing ACKISO. In particular, pin configuration for enabled LLWU wakeup pins must be restored to avoid any LLWU flag from being falsely set when ACKISO is cleared.

The signal selected as a wakeup source pin must be a digital pin, as selected in the pin mux control.

Chapter 17

Reset Control Module (RCM)

17.1 Introduction

This chapter describes the registers of the Reset Control Module (RCM). The RCM implements many of the reset functions for the chip. See the chip's reset chapter for more information.

17.2 Reset memory map and register descriptions

The Reset Control Module (RCM) registers provide reset status information and reset filter control.

RCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8110	System Reset Status Register 0 (RCM_SRS0)	8	R	82h	17.2.1/357
FFFF_8111	System Reset Status Register 1 (RCM_SRS1)	8	R	00h	17.2.2/359
FFFF_8114	Reset Pin Filter Control register (RCM_RPFC)	8	R/W	00h	17.2.3/360
FFFF_8115	Reset Pin Filter Width register (RCM_RPFW)	8	R/W	00h	17.2.4/361
FFFF_8117	Mode Register (RCM_MR)	8	R	00h	17.2.5/363

17.2.1 System Reset Status Register 0 (RCM_SRS0)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

NOTE

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x82

Reset memory map and register descriptions

- LVD (without POR) — 0x02
- LLS or VLLS mode wakeup due to $\overline{\text{RESET}}$ pin assertion — 0x41
- LLS or VLLS mode wakeup due to other wakeup sources — 0x01
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: FFFF_8110h base + 0h offset = FFFF_8110h

RCM_SRS0 field descriptions (continued)

Field	Description
	0 Reset not caused by an illegal access 1 Reset caused by an illegal access
2 LOC	Loss-of-Clock Reset Indicates a reset has been caused by a loss of external clock. The MCG clock monitor must be enabled for a loss of clock to be detected. Refer to the detailed MCG description for information on enabling the clock monitor. 0 Reset not caused by a loss of external clock. 1 Reset caused by a loss of external clock.
1 LVD	Low-Voltage Detect Reset If the LVDRE bit is set and the supply drops below the LVD trip voltage, an LVD reset occurs. This bit is also set by POR. 0 Reset not caused by LVD trip or POR 1 Reset caused by LVD trip or POR
0 WAKEUP	Low Leakage Wakeup Reset Indicates a reset has been caused by an enabled LLWU module wakeup source while the chip was in a low leakage mode. In LLS mode, the RESET pin is the only wakeup source that can cause this reset. Any enabled wakeup source in a VLLSx mode causes a reset. This bit is cleared by any reset except WAKEUP. 0 Reset not caused by LLWU module wakeup source 1 Reset caused by LLWU module wakeup source

17.2.2 System Reset Status Register 1 (RCM_SRS1)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

NOTE

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x00
- LVD (without POR) — 0x00
- LLS mode exit wakeup via RESET pin or any exit from VLLSx modes) VLLS mode wakeup — 0x00
- Other reset — a bit is set if its corresponding reset source caused the reset

0 MS	MS_B Pin State Reflects the state of the $\overline{\text{MS}}$ pin during the last Chip Reset 0 Pin deasserted (logic 1) 1 Pin asserted (logic 0)

Chapter 18

System Mode Controller (SMC)

18.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The system mode controller (SMC) is responsible for sequencing the system into and out of all low power stop and run modes. Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the system to achieve the power consumption and functionality of that mode.

This chapter describes all the available low power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The SMC is able to function during even the deepest low power modes.

18.2 Modes of operation

The V1 ColdFire CPU has two primary modes of operation: run and stop. The STOP instruction is used to invoke both stop and wait modes. The CPU does not differentiate between stop and wait modes.

In addition, Freescale MCUs also augment stop, wait, and run modes in a number of ways. The power management controller (PMC) contains a run and a stop mode regulator. Run regulation is used in normal run, wait and stop modes. Stop mode regulation is used during all very low power and low leakage modes. During stop mode regulation, the bus frequencies are limited in the very low power modes.

The SMC provides the user with multiple power options. The Very Low Power Run (VLPR) mode can drastically reduce run time power when maximum bus frequency is not required to handle the application needs. From Normal Run mode, the Run Mode

(RUNM) field can be modified to change the MCU into VLPR mode when limited frequency is sufficient for the application. From VLPR mode, a corresponding wait (VLPW) and stop (VLPS) mode can be entered.

Depending on the needs of the user application, a variety of stop modes are available that allow the state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. Several registers are used to configure the various modes of operation for the device.

The following table describes the power modes available for the device.

Table 18-1. Power modes

Mode	Description
RUN	The MCU can be run at full speed and the internal supply is fully regulated, that is, in run regulation. This mode is also referred to as Normal Run mode.
WAIT	The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate. Run regulation is maintained.
STOP	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.
VLPR	The core, system, bus, and flash clock maximum frequencies are restricted in this mode. See the Power Management chapter for details about the maximum allowable frequencies.
VLPW	The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted. See the Power Management chapter for details on the maximum allowable frequencies.
VLPS	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.
LLS	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by reducing the voltage to internal logic. Internal logic states are retained.
VLLS3	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic. All system RAM contents are retained and I/O states are held. Internal logic states are not retained.
VLLS2	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and the system RAM3 partition. The system RAM2 partition can be optionally retained using VLLSCTRL[RAM2PO]. The system RAM1 partition contents are retained in this mode. Internal logic states are not retained. ¹
VLLS1	The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained.

1. See the devices' chip configuration details for the size and location of the system RAM partitions.

18.3 Memory map and register descriptions

Details follow about the registers related to the system mode controller.

Different SMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the [Reset](#) details.

SMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8118	Power Mode Protection register (SMC_PMPROT)	8	R/W	00h	18.3.1/367
FFFF_8119	Power Mode Control register (SMC_PMCTRL)	8	R/W	00h	18.3.2/368
FFFF_811A	VLLS Control register (SMC_VLLSCTRL)	8	R/W	03h	18.3.3/370
FFFF_811B	Power Mode Status register (SMC_PMSTAT)	8	R	01h	18.3.4/371

18.3.1 Power Mode Protection register (SMC_PMPROT)

This register provides protection for entry into any low-power run or stop mode. The enabling of the low-power run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

The PMPROT register can be written only once after any system reset.

If the MCU is configured for a disallowed or reserved power mode, the MCU remains in its current power mode. For example, if the MCU is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and the RUNM bits remain 00b, indicating the MCU is still in Normal Run mode.

NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Reset](#) details for more information.

Address: FFFF_8118h base + 0h offset = FFFF_8118h

18.4 Functional description

18.4.1 Power mode transitions

The following figure shows the power mode state transitions available on the chip. Any reset always brings the MCU back to the normal run state.

Figure 18-5. Power mode state diagram

The following table defines triggers for the various state transitions shown in the previous figure.

Table 18-7. Power mode transition triggers

Transition #	From	To	Trigger conditions
1	RUN	WAIT	WAITE=1, Issue STOP instruction. See note. ¹
	WAIT	RUN	Interrupt or Reset

Table continues on the next page...

Table 18-7. Power mode transition triggers (continued)

Transition #	From	To	Trigger conditions
2	RUN	STOP	PMCTRL[RUNM]=00, PMCTRL[STOPM]=000 , STOPE=1, WAITE=0, Issue STOP instruction. See note. ¹
	STOP	RUN	Interrupt or Reset
3	RUN	VLPR	The core, system, bus and flash clock frequencies are restricted in this mode. See the Power Management chapter for the maximum allowable frequencies. Set PMPROT[AVLP]=1, PMCTRL[RUNM]=10.
	VLPR	RUN	Set PMCTRL[RUNM]=00 or Interrupt with PMCTRL[LPWUI] =1 or Reset.
4	VLPR	VLPW	WAITE=1, Issue STOP instruction. See note. ¹
	VLPW	VLPR	Interrupt with PMCTRL[LPWUI]=0
5	VLPW	RUN	Interrupt with PMCTRL[LPWUI]=1 or Reset
6	VLPR	VLPS	PMCTRL[STOPM]=000 or 010, STOPE=1, WAITE=0, Issue STOP instruction. See note. ¹
	VLPS	VLPR	Interrupt with PMCTRL[LPWUI]=0 NOTE: If VLPS was entered directly from RUN, hardware will not allow this transition and will force exit back to RUN
7	RUN	VLPS	PMPROT[AVLP]=1, PMCTRL[STOPM]=010, STOPE=1, WAITE=0, Issue STOP instruction. See note. ¹
	VLPS	RUN	Interrupt with PMCTRL[LPWUI]=1 or Interrupt with PMCTRL[LPWUI]=0 and VLPS mode was entered directly from RUN or Reset
8	RUN	VLLSx	PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, VLLSCTRL[VLLSM]=x (VLLSx), STOPE=1, WAITE=0 Issue STOP instruction.
	VLLSx	RUN	Wakeup from enabled LLWU input source or RESET pin
9	VLPR	VLLSx	PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, VLLSCTRL[VLLSM]=x (VLLSx), STOPE=1, WAITE=0 Issue STOP instruction.

Table continues on the next page...

Table 18-7. Power mode transition triggers (continued)

Transition #	From	To	Trigger conditions
10	RUN	LLS	PMPROT[ALLS]=1, PMCTRL[STOPM]=011, STOPE=1, WAITE=0 Issue STOP instruction.
	LLS	RUN	Wakeup from enabled LLWU input source or RESET pin.
11	VLPR	LLS	PMPROT[ALLS]=1, PMCTRL[STOPM]=011, STOPE=1, WAITE=0 Issue STOP instruction.

1. If debug is enabled, the core clock remains to support debug.

18.4.2 Power mode entry/exit sequencing

When entering or exiting low-power modes, the system must conform to an orderly sequence to manage transitions safely. The SMC manages the system's entry into and exit from all power modes. The following diagram illustrates the connections of the SMC with other system components in the chip that are necessary to sequence the system through all power modes.

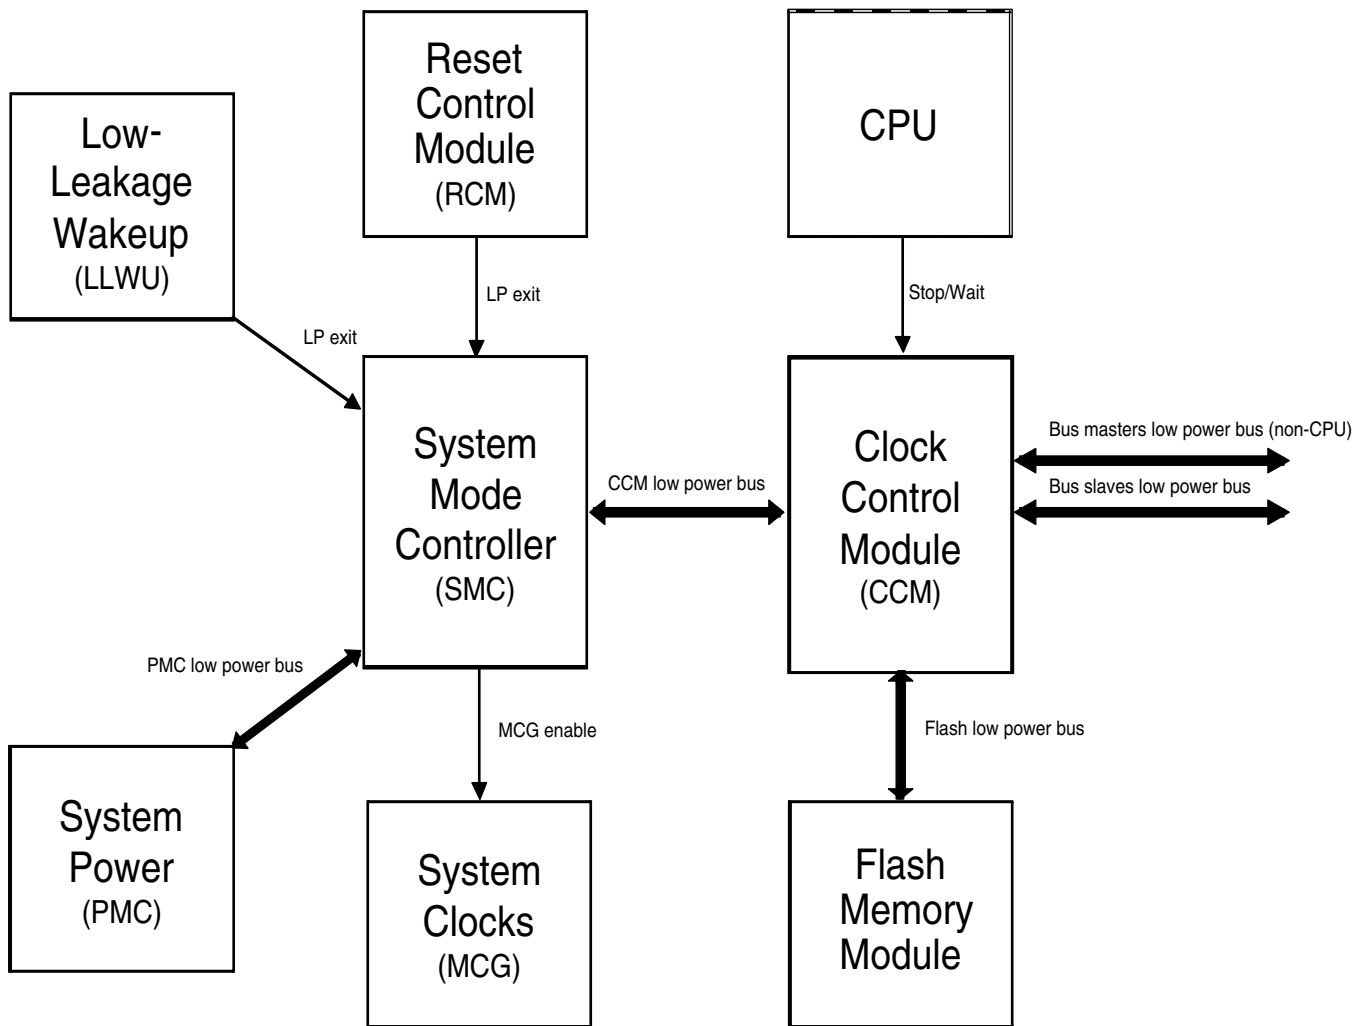

Figure 18-6. Low-power system components and connections

18.4.2.1 Stop mode entry sequence

Entry into a low-power stop mode (Stop, VLPS, LLS, VLLSx) is initiated by CPU execution of the STOP instruction. After the instruction is executed, the following sequence occurs:

1. The CPU clock is gated off immediately.
2. Requests are made to all non-CPU bus masters to enter Stop mode.
3. After all masters have acknowledged they are ready to enter Stop mode, requests are made to all bus slaves to enter Stop mode.
4. After all slaves have acknowledged they are ready to enter Stop mode, all system and bus clocks are gated off.
5. Clock generators are disabled in the MCG.
6. The on-chip regulator in the PMC and internal power switches are configured to meet the power consumption goals for the targeted low-power mode.

18.4.2.2 Stop mode exit sequence

Exit from a low-power stop mode is initiated either by a reset or an interrupt event. The following sequence then executes to restore the system to a run mode (RUN or VLPR):

1. The on-chip regulator in the PMC and internal power switches are restored.
2. Clock generators are enabled in the MCG.
3. System and bus clocks are enabled to all masters and slaves.
4. The CPU clock is enabled and the CPU begins servicing the reset or interrupt that initiated the exit from the low-power stop mode.

18.4.2.3 Aborted stop mode entry

If an interrupt or a reset occurs during a stop entry sequence, the SMC can abort the transition early and return to RUN mode without completely entering the stop mode. An aborted entry is possible only if the reset or interrupt occurs before the PMC begins the transition to stop mode regulation. After this point, the interrupt or reset is ignored until the PMC has completed its transition to stop mode regulation. When an aborted stop mode entry sequence occurs, the SMC's PMCTRL[STOPA] is set to 1.

18.4.2.4 Transition to wait modes

For wait modes (WAIT and VLPW), the CPU clock is gated off while all other clocking continues, as in RUN and VLPR mode operation. Some modules that support stop-in-wait functionality have their clocks disabled in these configurations.

18.4.2.5 Transition from stop modes to Debug mode

The debugger module supports a transition from STOP, WAIT, VLPS, and VLPW back to a Halted state when the debugger has been enabled, that is, ENBDM is 1. This transition is initiated by executing a BDC BACKGROUND command. As part of this transition, system clocking is re-established and is equivalent to the normal RUN and VLPR mode clocking configuration.

18.4.3 Run modes

The device contains two different run modes:

- Run
- Very Low-Power Run (VLPR)

18.4.3.1 RUN mode

This is the normal operating mode for the device.

This mode is selected after any internal reset including LVD and when the BKGD/MS pin is high after a POR exit or a BDM-initiated force reset. When the ColdFire processor exits reset, it fetches initial 32-bit values for the supervisor stack pointer and program counter from locations 0x00_0000 and 0x00_0004 respectively and user code execution begins.

- The processor reads the start SP (SP_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF_FFFF.

To reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

18.4.3.2 Very-Low Power Run (VLPR) mode

In VLPR mode, the on-chip voltage regulator is put into a stop mode regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

Before entering this mode, the following conditions must be met:

- The MCG must be configured in a mode which is supported during VLPR. See the Power Management details for information about these MCG modes.
- All clock monitors in the MCG must be disabled.
- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.
- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] is set to 10b to enter VLPR.
- Flash programming/erasing is not allowed.

NOTE

Do not change the clock frequency while in VLPR mode, because the regulator is slow responding and cannot manage fast load transitions. In addition, do not modify the clock source

in the MCG module, the module clock enables in the SIM, or any clock divider registers.

To reenter Normal Run mode, clear RUNM. The PMSTAT register is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system is in run regulation and the MCU can run at full speed in any clock mode. If a higher execution frequency is desired, poll the PMSTAT register until it is set to RUN when returning from VLPR mode.

VLPR mode also provides the option to return to run regulation if any interrupt occurs. Implement this option by setting Low-Power Wakeup On Interrupt (LPWUI) in the PMCTRL register. Any reset always causes an exit from VLPR and returns the device to RUN mode after the MCU exits its reset flow. The RUNM bits are cleared by hardware on any interrupt when LPWUI is set or on any reset.

18.4.3.3 BDM in Run and VLPR Mode

If the MCU is unsecure and BDM mode is enabled, then the MCU can be fully debugged using the BDM in RUN and VLPR modes. If XCSR[ENBDM] = 0, before entering active BDM mode, the host must write XCSR[ENBDM] = 1 before sending a BACKGROUND command.

18.4.4 Wait modes

This device contains two different wait modes:

- Wait
- Very-Low Power Wait (VLPW)

18.4.4.1 WAIT mode

WAIT mode is entered by executing a STOP instruction after configuring the device appropriately. Upon execution of the STOP instruction, the CPU enters a low-power state in which it is not clocked.

The V1 ColdFire core does not differentiate between STOP and WAIT modes. Both are considered STOP mode from the core's perspective. The difference between the two is at the device level. In STOP mode, most peripheral clocks are shut down. In WAIT mode, the global peripheral clocks continue to run and can be enabled or disabled on a per peripheral basis using clock gating control bits in the SIM.

When an interrupt request occurs, the CPU exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from WAIT mode, returning the device to normal RUN mode.

18.4.4.2 Very-Low-Power Wait (VLPW) mode

VLPW mode is entered by executing a STOP instruction while the MCU is in very low power run (VLPR) mode and configured as per [Table 18-7](#).

In VLPW, the on-chip voltage regulator remains in its stop regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules by clearing the peripherals' corresponding clock gating control bits in the SIM.

VLPR mode restrictions also apply to VLPW.

VLPW mode provides the option to return to fully-regulated normal RUN mode if any enabled interrupt occurs. This is done by setting PMCTRL[LPWUI]. Wait for the PMSTAT register to set to RUN before increasing the frequency.

If the LPWUI bit is clear, when an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

A system reset will cause an exit from VLPW mode, returning the device to normal RUN mode.

18.4.4.3 BDM in Wait and VLPW Mode

If the MCU is unsecure, BDM mode is enabled, and XCSR[ENBDM] is set prior to entering wait then the MCU can support debugging using the BDM.

While the MCU is in wait mode, there are some restrictions on which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available when the MCU is in wait mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode.

The BACKGROUND command can be used to wake the MCU from wait mode and enter active background mode. After entering halt mode, all background commands are available.

18.4.5 Stop modes

This device contains a variety of stop modes to meet your application needs. The stop modes range from:

- a stopped CPU, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down CPU, with only I/O and a small register file retained, very few asynchronous mode peripherals operating, while the remainder of the MCU is powered down.

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs may be traded off.

The various stop modes are selected by setting the appropriate fields in PMPROT and PMCTRL. The selected mode is entered following the execution of a STOP instruction.

The available stop modes are:

- Normal Stop (STOP)
- Very-Low Power Stop (VLPS)
- Low-Leakage Stop (LLS)
- Very-Low-Leakage Stop (VLLSx)

18.4.5.1 STOP mode

STOP mode is entered by executing a STOP instruction after configuring the device as per [Table 18-7](#). In STOP mode, the bus and CPU clocks are halted. If the ENBDM is set prior to entering stop, only the peripheral clocks are halted.

The MCG module can be configured to leave the reference clocks running.

NOTE

If neither the WAITE or STOPE bit is set when the CPU executes a STOP instruction, the MCU will not enter either of the stop modes. Executing a STOP instruction under this condition results in either a system reset if the instruction-related reset disable bit in the CPU control register is cleared (CPUCR[IRD]=0) or an illegal instruction exception if it is set (CPUCR[IRD]=1).

A module capable of providing an asynchronous interrupt to the device takes the device out of STOP mode and returns the device to normal RUN mode. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode. When an interrupt request occurs, the CPU exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from STOP mode, returning the device to normal RUN mode via an MCU reset.

18.4.5.2 Very-Low-Power Stop (VLPS) mode

VLPS mode can be entered in one of two ways:

- Executing a STOP instruction while the MCU is in VLPR mode and STOPM=010 or 000 in the PMCTRL register.
- Executing a STOP instruction while the MCU is in normal RUN mode and STOPM=010 in the PMCTRL register. Note, when VLPS is entered directly from RUN mode, exit to VLPR is disabled by hardware and the system will always exit back to RUN.

In VLPS, the on-chip voltage regulator remains in its stop regulation state as in VLPR.

A module capable of providing an asynchronous interrupt to the device takes the device out of VLPS and returns the device to VLPR mode, provided LPWUI is clear.

If LPWUI is set, the device returns to normal RUN mode upon an interrupt request. PMSTAT must be set to RUN before allowing the system to return to a frequency higher than that allowed in VLPR mode.

A system reset will also cause a VLPS exit, returning the device to normal RUN mode.

18.4.5.3 BDM in Stop and VLPS Modes

If the MCU is unsecure, BDM is enabled, XCSR[ENBDM] is set prior to entering stop, and the current mode is RUN (debug from VLPR is not supported), then the MCU can support debugging using BDM. To support debugging, the CPU clock remains running after the STOP instruction is executed. While the MCU is in stop or VLPS mode, some restrictions affect which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available when the MCU is in stop mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode.

The BACKGROUND command can wake the MCU from stop or VLPS mode and cause it to enter active background mode. After entering halt mode, all background commands are available.

NOTE

When the chip is attempting to enter VLPS mode directly from RUN mode while BDM is enabled, the MCU regulator remains in full regulation. In other words, when BDM is enabled, the regulation of the chip retains its previous state when executing STOP.

18.4.5.4 Low-Leakage Stop (LLS) mode

Low-Leakage Stop (LLS) mode can be entered from normal RUN or VLPR modes.

By executing a STOP instruction while the MCU is in RUN or VLPR mode and device configured as per [Table 18-7](#) the MCU will enter LLS mode.

In LLS, the on-chip voltage regulator is in stop regulation. Most of the peripherals are put in a state-retention mode that does not allow them to operate while in LLS.

Before entering LLS mode, the user should configure the low-leakage wakeup (LLWU) module to enable the desired wakeup sources. The available wakeup sources in LLS are detailed in the chip configuration details for this device.

After wakeup from LLS, the device returns to normal RUN mode with a pending LLWU module interrupt. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wakeup flags to determine the source of the wakeup.

NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery.

An asserted $\overline{\text{RESET}}$ pin will cause an exit from LLS mode, returning the device to normal RUN mode. When LLS is exiting via the $\overline{\text{RESET}}$ pin, the PIN and WAKEUP bits are set in the SRS0 register of the reset control module (RCM).

18.4.5.5 Very-Low-Leakage Stop (VLLSx) modes

This device contains these very low leakage modes:

- VLLS3

Functional description

- VLLS2
- VLLS1

VLLSx is often used in this document to refer to all of these modes.

All VLLSx modes can be entered from normal RUN or VLPR modes.

By executing a STOP instruction while the MCU is in a run mode and configured as per [Table 18-7](#) the MCU will enter the configured VLLS mode.

In VLLS, the on-chip voltage regulator is in its stop-regulation state while most digital logic is powered off.

Before entering VLLS mode, the user should configure the low-leakage wakeup (LLWU) module to enable the desired wakeup sources. The available wakeup sources in VLLS are detailed in the chip configuration details for this device.

After wakeup from VLLS, the device returns to normal RUN mode with a pending LLWU interrupt. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wakeup flags to determine the source of the wakeup.

When entering VLLS, each I/O pin is latched as configured before executing VLLS. Because all digital logic in the MCU is powered off, all port and peripheral data is lost during VLLS. This information must be restored before the ACKISO bit in the PMC is set.

An asserted $\overline{\text{RESET}}$ pin will cause an exit from any VLLS mode, returning the device to normal RUN mode. When exiting VLLS via the $\overline{\text{RESET}}$ pin, the PIN and WAKEUP bits are set in the SRS0 register of the reset control module (RCM).

18.4.5.6 BDM in LLS and VLLSx Modes

No debug is available while the MCU is in LLS or a VLLSx mode. LLS is a state retention mode and all debug operation can continue after wakeup from LLS, unless system wakeup is a reset event.

Entering a VLLSx mode causes all the BDM and debug controls and settings to be powered off. Therefore, any breakpoints or other debug triggers set prior to entering the VLLSx mode are lost.

To support debug immediately after a wakeup from a VLLSx mode, the VLLDBGREQ bit in the SIM's SOPT4 register can be set before entering the VLLSx mode via a BDM write. If this bit is set, the wakeup from a VLLSx mode (except for wakeup via the $\overline{\text{RESET}}$ pin) causes the CPU to enter active background mode immediately upon exiting the VLLSx mode.

Chapter 19

Power Management Controller (PMC)

19.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The power management controller (PMC) contains the internal voltage regulator, power on reset (POR), and low voltage detect system.

19.2 Features

The PMC features include:

- Internal voltage regulator
- Active POR providing brown-out detect
- Low-voltage detect supporting two low-voltage trip points with four warning levels per trip point

19.3 Low-voltage detect (LVD) system

This device includes a system to guard against low-voltage conditions. This protects memory contents and controls MCU system states during supply voltage variations. The system is comprised of a power-on reset (POR) circuit and a LVD circuit with a user-selectable trip voltage: high (V_{LVDH}) or low (V_{LVDL}). The trip voltage is selected by the LVDSC1[LVDV] bits. The LVD is disabled upon entering VLPx, LLS, and VLLSx modes.

Two flags are available to indicate the status of the low-voltage detect system:

- The low voltage detect flag (LVDF) operates in a level sensitive manner. The LVDF bit is set when the supply voltage falls below the selected trip point (VLVD). The LVDF bit is cleared by writing one to the LVDACK bit, but only if the internal supply has returned above the trip point; otherwise, the LVDF bit remains set.
- The low voltage warning flag (LVWF) operates in a level sensitive manner. The LVWF bit is set when the supply voltage falls below the selected monitor trip point (VLVW). The LVWF bit is cleared by writing one to the LVWACK bit, but only if the internal supply has returned above the trip point; otherwise, the LVWF bit remains set.

19.3.1 LVD reset operation

By setting the LVDRE bit, the LVD generates a reset upon detection of a low voltage condition. The low voltage detection threshold is determined by the LVDV bits. After an LVD reset occurs, the LVD system holds the MCU in reset until the supply voltage rises above this threshold. The LVD bit in the SRS register is set following an LVD or power-on reset.

19.3.2 LVD interrupt operation

By configuring the LVD circuit for interrupt operation (LVDIE set and LVDRE clear), LVDSC1[LVDF] is set and an LVD interrupt request occurs upon detection of a low voltage condition. The LVDF bit is cleared by writing one to the LVDSC1[LVDACK] bit.

19.3.3 Low-voltage warning (LVW) interrupt operation

The LVD system contains a low-voltage warning flag (LVWF) to indicate that the supply voltage is approaching, but is above, the LVD voltage. The LVW also has an interrupt, which is enabled by setting the LVDSC2[LVWIE] bit. If enabled, an LVW interrupt request occurs when the LVWF is set. LVWF is cleared by writing one to the LVDSC2[LVWACK] bit.

The LVDSC2[LVWV] bits select one of four trip voltages:

- Highest: V_{LVW4}
- Two mid-levels: V_{LVW3} and V_{LVW2}
- Lowest: V_{LVW1}

19.4 I/O retention

When in LLS mode, the I/O pins are held in their input or output state. Upon wakeup, the PMC is re-enabled, goes through a power up sequence to full regulation, and releases the logic from state retention mode. The I/O are released immediately after a wakeup or reset event. In the case of LLS exit via a RESET pin, the I/O default to their reset state.

When in VLLS modes, the I/O states are held on a wakeup event (with the exception of wakeup by reset event) until the wakeup has been acknowledged via a write to the ACKISO bit. In the case of VLLS exit via a RESET pin, the I/O are released and default to their reset state. In this case, no write to the ACKISO is needed.

19.5 Memory map and register descriptions

PMC register details follow.

NOTE

Different portions of PMC registers are reset only by particular reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the [Reset](#) details.

PMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8100	Low Voltage Detect Status And Control 1 register (PMC_LVDSC1)	8	R/W	10h	19.5.1/387
FFFF_8101	Low Voltage Detect Status And Control 2 register (PMC_LVDSC2)	8	R/W	00h	19.5.2/389
FFFF_8102	Regulator Status And Control register (PMC_REGSC)	8	R/W	04h	19.5.3/390

19.5.1 Low Voltage Detect Status And Control 1 register (PMC_LVDSC1)

This register contains status and control bits to support the low voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

Memory map and register descriptions

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC1 settings. To protect systems that must have LVD always on, configure the SMC's power mode protection register (PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact LVD trip voltages.

NOTE

The LVDV bits are reset solely on a POR Only event. The register's other bits are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the [Reset details](#).

11	Reserved

19.5.2 Low Voltage Detect Status And Control 2 register (PMC_LVDSC2)

This register contains status and control bits to support the low voltage warning function.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC2 settings.

See the device's data sheet for the exact LVD trip voltages.

NOTE

The LVW trip voltages depend on LVWV and LVDV bits.

NOTE

The LVWV bits are reset solely on a POR Only event. The register's other bits are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the [Reset](#) details.

19.5.3 Regulator Status And Control register (PMC_REGSC)

The PMC contains an internal voltage regulator. The voltage regulator design uses a bandgap reference that is also available through a buffer as input to certain internal peripherals, such as the CMP and ADC. The internal regulator provides a status bit (REGONS) indicating the regulator is in run regulation.

NOTE

This register is reset on Chip Reset Not VLLS and by reset types that trigger Chip Reset not VLLS. See the [Reset](#) for more information.

Address: FFFF_8100h base + 2h offset = FFFF_8102h

Bit	7	6	5	4	3	2	1	0

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved.

Table continues on the next page...

PMC_REGSC field descriptions (continued)

Field	Description
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ACKISO	Acknowledge Isolation Reading this bit indicates whether certain peripherals and the I/O pads are in a latched state as a result of having been in a VLLS mode. Writing one to this bit when it is set releases the I/O pads and certain peripherals to their normal run mode state. NOTE: After recovering from a VLLS mode, user should restore chip configuration before clearing ACKISO. In particular, pin configuration for enabled LLWU wakeup pins should be restored to avoid any LLWU flag from being falsely set when ACKISO is cleared. 0 Peripherals and I/O pads are in normal run state 1 Certain peripherals and I/O pads are in an isolated and latched state
2 REGONS	Regulator In Run Regulation Status This read-only bit provides the current status of the internal voltage regulator. 0 Regulator is in stop regulation or in transition to/from it 1 Regulator is in run regulation
1 Reserved	This field is reserved. NOTE: This reserved bit must remain cleared (set to 0).
0 BGBE	Bandgap Buffer Enable Enables the bandgap buffer. 0 Bandgap buffer not enabled 1 Bandgap buffer enabled

Chapter 20

Voltage Regulator (VREG)

20.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Voltage Regulator module is a LDO linear voltage regulator to provide 3.3V power from an input power supply varying from 2.7 V to 5.5 V. It consists of one 3.3 V power channel. When the input power supply is below 3.6 V, the regulator goes to pass-through mode. The following figure shows the ideal relation between the regulator output and input power supply.

Figure 20-1. Ideal Relation Between the Regulator Output and Input Power Supply

20.1.1 Overview

A simplified block diagram for the Voltage Regulator module is shown below.

Figure 20-2. Voltage Regulator Block Diagram

This module uses 2 regulators in parallel. In run mode, the RUN regulator with the bandgap voltage reference is enabled and can provide up to 120 mA load current. In run mode, the STANDBY regulator and the low power reference are also enabled, but a switch disconnects its output from the external pin. In STANDBY mode, the RUN regulator is disabled and the STANDBY regulator output is connected to the external pin. Internal power mode signals control whether the module is in RUN or STANDBY mode.

20.1.2 Features

- Low drop-out linear voltage regulator with one power channel (3.3V).
- Low drop-out voltage: 300 mV.
- Output current: 120 mA.
- Three different power modes: RUN, STANDBY and SHUTDOWN.
- Low quiescent current in RUN mode.
 - Typical value is around 120 uA (one thousand times smaller than the maximum load current).
- Very low quiescent current in STANDBY mode.
 - Typical value is around 1 uA.
- Automatic current limiting if the load current is greater than 290 mA.

- Automatic power-up once some voltage is applied to the regulator input.
- Pass-through mode for regulator input voltages less than 3.6 V
- Small output capacitor: 2.2 uF
- Stable with aluminum, tantalum or ceramic capacitors.

20.1.3 Modes of Operation

The regulator has these power modes:

- RUN—The regulating loop of the RUN regulator and the STANDBY regulator are active, but the switch connecting the STANDBY regulator output to the external pin is open.
- STANDBY—The regulating loop of the RUN regulator is disabled and the standby regulator is active. The switch connecting the STANDBY regulator output to the external pin is closed.
- SHUTDOWN—The module is disabled.

The regulator is enabled by default. This means that once the power supply is provided, the module power-up sequence to RUN mode starts.

20.2 Voltage Regulator Module Signal Descriptions

The following table shows the external signals for the regulator.

Table 20-1. Voltage Regulator Module Signal Descriptions

Signal	Description	I/O
reg33_in	Unregulated power supply	I
reg33_out	Regulator output voltage	O

Chapter 21

DMA Controller

21.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter describes the direct memory access (DMA) controller module. It provides an overview of the module and describes in detail its signals and programming model. The latter sections of this chapter describe operations, features, and supported data transfer modes in detail.

Note

The designation n is used throughout this section to refer to registers or signals associated with one of the four identical DMA channels: DMA0, DMA1, DMA2, or DMA3.

21.1.1 Overview

The DMA controller module enables fast transfers of data, providing an efficient way to move blocks of data with minimal processor interaction. The DMA module, shown in the following figure, has four channels that allow 8-bit, 16-bit, or 32-bit data transfers. Each channel has a dedicated source address register (SAR_n), destination address register (DAR_n), status register (DSR_n), byte count register (BCR_n), and control register (DCR_n). Collectively, the combined program-visible registers associated with each channel define a transfer control descriptor (TCD). All transfers are dual address, moving data from a source memory location to a destination memory location with the module operating as a 32-bit bus master connected to the system bus. The programming model is accessed through a 32-bit connection with the slave peripheral bus. DMA data transfers may be explicitly initiated by software or by peripheral hardware requests.

The following figure is a simplified block diagram of the 4-channel DMA controller.

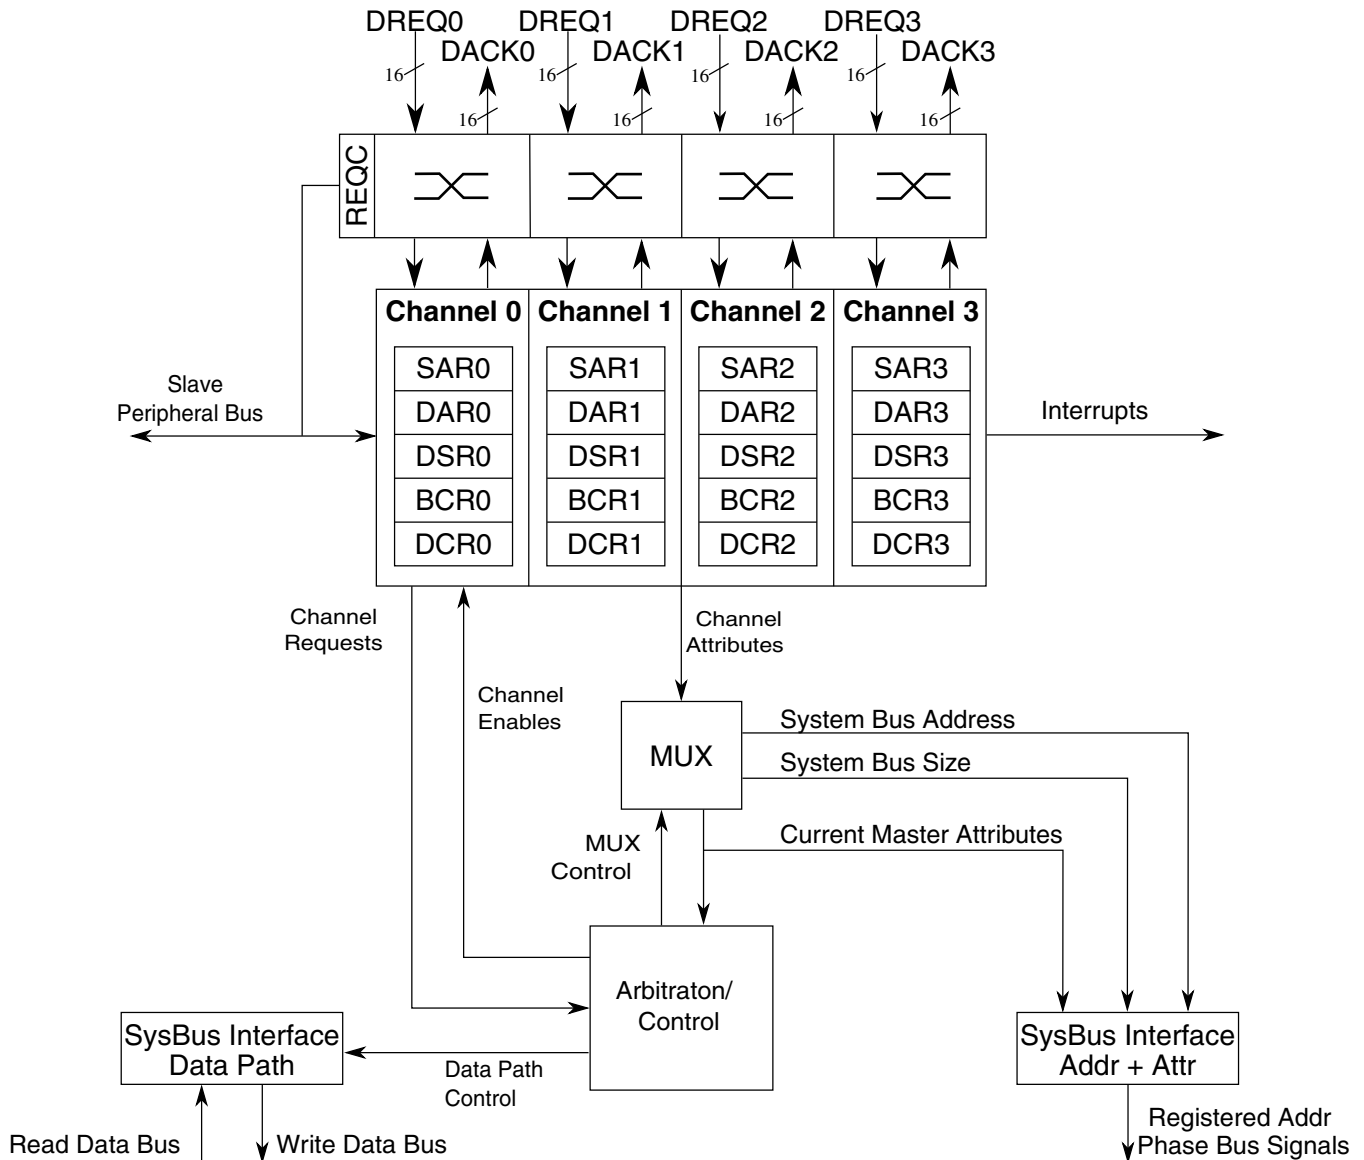

Figure 21-1. 4-Channel DMA Block Diagram

The terms *peripheral request* and *DREQ* refer to a DMA request from one of the on-chip peripherals or package pins. The DMA provides hardware handshake signals: either a DMA acknowledge (DACK) or a done indicator back to the peripheral. For details on the connections associated with DMA request inputs, see the register definition for DMA Request Control (DMAREQC).

21.1.2 Features

The DMA controller module features:

- Four independently programmable DMA controller channels
- Dual-address transfers via 32-bit master connection to the system bus
- Data transfers in 8-, 16-, or 32-bit blocks
- Continuous-mode or cycle-steal transfers from software or peripheral initiation
- One programmable input selected from 16 possible peripheral requests per channel
- Automatic hardware acknowledge/done indicator from each channel
- Independent source and destination address registers
- Optional modulo addressing and automatic updates of source and destination addresses
- Independent transfer sizes for source and destination
- Optional auto-alignment feature for source or destination accesses
- Optional automatic single or double channel linking
- Programming model accessed via 32-bit slave peripheral bus
- Channel arbitration on transfer boundaries using fixed priority scheme

21.2 DMA Transfer Overview

The DMA module can move data within system memory (including memory and peripheral devices) with minimal processor intervention, greatly improving overall system performance. The DMA module consists of four independent, functionally equivalent channels, so references to DMA in this chapter apply to any of the channels. It is not possible to address all four channels at once.

As soon as a channel has been initialized, it may be started by setting $DCRn[START]$ or a properly-selected peripheral DMA request, depending on the status of $DCRn[ERQ]$. Each channel can be programmed to select one peripheral request from a set of 16 possible request inputs.

The DMA controller supports dual-address transfers using its bus master connection to the system bus. The DMA channels support transfers up to 32 data bits in size and have the same memory map addressability as the processor.

- Dual-address transfers—A dual-address transfer consists of a read followed by a write and is initiated by a request using the DCRn[START] bit or by a peripheral DMA request. The read data is temporarily held in the DMA channel hardware until the write operation. Two types of single transfers occur: a read from a source address followed by a write to a destination address. See the following figure.

Figure 21-2. Dual-Address Transfer

Any operation involving a DMA channel follows the same three steps:

1. Channel initialization—The transfer control descriptor, contained in the channel registers, is loaded with address pointers, a byte-transfer count, and control information using accesses from the slave peripheral bus.
2. Data transfer—The DMA accepts requests for data transfers. Upon receipt of a request, it provides address and bus control for the transfers via its master connection to the system bus and temporary storage for the read data. The channel performs one or more source read and destination write data transfers.
3. Channel termination—Occurs after the operation is finished successfully or due to an error. The channel indicates the operation status in the channel's DSR, described in the definitions of the DMA Status Registers (DSRn) and Byte Count Registers (BCRn).

21.3 Memory Map and Registers

Descriptions of each register and its bit assignments follow. Modifying DMA control registers during a transfer can result in undefined operation. The following table shows the mapping of DMA controller registers. The DMA programming model is accessed via

the slave peripheral bus. The concatenation of the source and destination address registers, the status and byte count register, and the control register create a 128-bit transfer control descriptor (TCD) that defines the operation of each DMA channel.

DMA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_E400	DMA Request Control Register (DMA_REQC)	32	R/W	0000_0000h	21.3.1/401
FFFF_E500	Source Address Register (DMA_SAR0)	32	R/W	0000_0000h	21.3.2/405
FFFF_E504	Destination Address Register (DMA_DAR0)	32	R/W	0000_0000h	21.3.3/406
FFFF_E508	DMA Status Register / Byte Count Register (DMA_DSR_BCR0)	32	R/W	0000_0000h	21.3.4/406

21.3.1 DMA Request Control Register (DMA_REQC)

This register provides a software-controlled connection matrix for DMA requests and acknowledges. Each channel supports 16 possible peripheral requests. The register is programmed to select one peripheral request from the available sources for each channel of the DMA controller. Additionally, the register routes a DMA acknowledge from the channel back to the appropriate peripheral. Writing to this register determines the exact routing of the DMA requests to each of the four channels of the DMA module.

If DCRn[ERQ] is set and the channel is idle, the assertion of the appropriate DREQn signal activates channel n.

The connections of the DMA request sources to the specific channels are device-specific. Refer to the Chip Configuration details for more information.

Memory Map and Registers

DMA_SAR_n field descriptions

Field	Description
31–0 SAR	Each SAR contains the byte address used by the DMA controller to read data. The SAR _n is typically aligned on a 0-modulo-ssize boundary—that is, on the natural alignment of the source data. Because the system supports only 24-bit addresses, SAR _n [31:24] is ignored.

21.3.3 Destination Address Register (DMA_DAR_n)

Address: FFFF_E400h base + 104h offset + (16d × i), where i=0d to 3d

DMA_DAR_n field descriptions

Field	Description
31–0 DAR	Each DAR contains the byte address used by the DMA controller to write data. The DAR _n is typically aligned on a 0-modulo-dsize boundary—that is, on the natural alignment of the destination data. Because the system supports only 24-bit addresses, DAR _n [31:24] is ignored.

21.3.4 DMA Status Register / Byte Count Register (DMA_DSR_BCR_n)

DSR and BCR are two logical registers that occupy one 32-bit address. DSR_n occupies bits 31–24, and BCR_n occupies bits 23–0. DSR_n contains flags indicating the channel status, and BCR_n contains the number of bytes yet to be transferred for a given block.

On the successful completion of the write transfer, BCR_n decrements by 1, 2, or 4 for 8-bit, 16-bit, or 32-bit accesses, respectively. BCR_n is cleared if a 1 is written to DSR[DONE].

In response to an event, the DMA controller writes to the appropriate DSR_n bit. Only a write to DSR_n[DONE] results in action. DSR_n[DONE] is set when the block transfer is complete.

When a transfer sequence is initiated and BCR_n[BCR] is not a multiple of 4 or 2 when the DMA is configured for 32-bit or 16-bit transfers, respectively, DSR_n[CE] is set and no transfer occurs.

Address: FFFF_E400h base + 108h offset + (16d × i), where i=0d to 3d

DMA_DSR_BCRn field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CE	Configuration error Any of the following conditions causes a configuration error: <ul style="list-style-type: none"> • BCR, SAR, or DAR does not match the requested transfer size. • SSIZE or DSIZE is set to an unsupported value. • BCR equals 0 when the DMA receives a start condition. CE is cleared at hardware reset or by writing a 1 to the DONE bit. 0 No configuration error exists. 1 A configuration error has occurred.
29 BES	Bus error on source BES is cleared at hardware reset or by writing a 1 to the DONE bit. 0 No bus error occurred. 1 The DMA channel terminated with a bus error during the read portion of a transfer.
28 BED	Bus error on destination BED is cleared at hardware reset or by writing a 1 to the DONE bit. 0 No bus error occurred. 1 The DMA channel terminated with a bus error during the write portion of a transfer.

Table continues on the next page...

DMA_DSR_BCR_n field descriptions (continued)

Field	Description
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 REQ	Request 0 No request is pending or the channel is currently active. Cleared when the channel is selected. 1 The DMA channel has a transfer remaining and the channel is not selected.
25 BSY	Busy 0 DMA channel is inactive. Cleared when the DMA has finished the last transaction. 1 BSY is set the first time the channel is enabled after a transfer is initiated.
24 DONE	Transactions done Set when all DMA controller transactions complete as determined by transfer count, or based on error conditions. When BCR reaches zero, DONE is set when the final transfer completes successfully. DONE can also be used to abort a transfer by resetting the status bits. When a transfer completes, software must clear DONE before reprogramming the DMA. 0 DMA transfer is not yet complete. Writing a 0 has no effect. 1 DMA transfer completed. Writing a 1 to this bit clears all DMA status bits and should be used in an interrupt service routine to clear the DMA interrupt and error bits.
23–0 BCR	This field contains the number of bytes yet to be transferred for a given block.

21.3.5 DMA Control Register (DMA_DCRn)

Address: FFFF_E400h base + 10Ch offset + (16d × i), where i=0d to 3d

DMA_DCRn field descriptions

Field	Description
31 EINT	<p>Enable interrupt on completion of transfer</p> <p>Determines whether an interrupt is generated by completing a transfer or by the occurrence of an error condition.</p> <p>0 No interrupt is generated. 1 Interrupt signal is enabled.</p>
30 ERQ	<p>Enable peripheral request</p> <p>CAUTION: Be careful: a collision can occur between the START bit and D_REQ when the ERQ bit is 1.</p> <p>0 Peripheral request is ignored. 1 Enables peripheral request, defined by the appropriate REQQ[DMACn] field, to initiate transfer. A software-initiated request (setting the START bit) is always enabled.</p>
29 CS	<p>Cycle steal</p> <p>0 DMA continuously makes read/write transfers until the BCR decrements to 0. 1 Forces a single read/write transfer per request.</p>
28 AA	<p>Auto-align</p>

Table continues on the next page...

DMA_DCRn field descriptions (continued)

Field	Description
	<p>AA and SIZE bits determine whether the source or destination is auto-aligned; that is, transfers are optimized based on the address and size.</p> <p>0 Auto-align disabled</p> <p>1 If SSIZE indicates a transfer no smaller than DSIZE, source accesses are auto-aligned; otherwise, destination accesses are auto-aligned. Source alignment takes precedence over destination alignment. If auto-alignment is enabled, the appropriate address register increments, regardless of DINC or SINC.</p>
27–25 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
24 Reserved	<p>This field is reserved.</p> <p>CAUTION: Must be written as zero; otherwise, undefined behavior results.</p>
23 Reserved	<p>This field is reserved.</p> <p>CAUTION: Must be written as zero; otherwise, undefined behavior results.</p>
22 SINC	<p>Source increment</p> <p>Controls whether the source address increments after each successful transfer.</p> <p>0 No change to SAR after a successful transfer.</p> <p>1 The SAR increments by 1, 2, 4 as determined by the transfer size.</p>
21–20 SSIZE	<p>Source size</p> <p>Determines the data size of the source bus cycle for the DMA controller.</p> <p>00 32-bit</p> <p>01 8-bit</p> <p>10 16-bit</p> <p>11 Reserved (generates a configuration error (DSRn[CE]) if incorrectly specified at time of channel activation)</p>
19 DINC	<p>Destination increment</p> <p>Controls whether the destination address increments after each successful transfer.</p> <p>0 No change to the DAR after a successful transfer.</p> <p>1 The DAR increments by 1, 2, 4 depending upon the size of the transfer.</p>
18–17 DSIZE	<p>Destination size</p> <p>Determines the data size of the destination bus cycle for the DMA controller.</p> <p>00 32-bit</p> <p>01 8-bit</p> <p>10 16-bit</p> <p>11 Reserved (generates a configuration error (DSRn[CE]) if incorrectly specified at time of channel activation)</p>
16 START	<p>Start transfer</p> <p>0 DMA inactive</p> <p>1 The DMA begins the transfer in accordance to the values in the TCDn. START is cleared automatically after one module clock and always reads as logic 0.</p>

Table continues on the next page...

DMA_DCRn field descriptions (continued)

Field	Description
15–12 SMOD	<p>Source address modulo</p> <p>Defines the size of the source data circular buffer used by the DMA Controller. If enabled (SMOD is non-zero), the buffer base address is located on a boundary of the buffer size. The value of this boundary is based upon the initial source address (SAR). The base address should be aligned to a 0-modulo-(circular buffer size) boundary. Misaligned buffers are not possible. The boundary is forced to the value determined by the upper address bits in the field selection.</p> <p>0000 Buffer disabled 0001 Circular buffer size is 16 bytes 0010 Circular buffer size is 32 bytes 0011 Circular buffer size is 64 bytes 0100 Circular buffer size is 128 bytes 0101 Circular buffer size is 256 bytes 0110 Circular buffer size is 512 bytes 0111 Circular buffer size is 1 KB 1000 Circular buffer size is 2 KB 1001 Circular buffer size is 4 KB 1010 Circular buffer size is 8 KB 1011 Circular buffer size is 16 KB 1100 Circular buffer size is 32 KB 1101 Circular buffer size is 64 KB 1110 Circular buffer size is 128 KB 1111 Circular buffer size is 256 KB</p>
11–8 DMOD	<p>Destination address modulo</p> <p>Defines the size of the destination data circular buffer used by the DMA Controller. If enabled (DMOD value is non-zero), the buffer base address is located on a boundary of the buffer size. The value of this boundary depends on the initial destination address (DAR). The base address should be aligned to a 0-modulo-(circular buffer size) boundary. Misaligned buffers are not possible. The boundary is forced to the value determined by the upper address bits in the field selection.</p> <p>0000 Buffer disabled 0001 Circular buffer size is 16 bytes 0010 Circular buffer size is 32 bytes 0011 Circular buffer size is 64 bytes 0100 Circular buffer size is 128 bytes 0101 Circular buffer size is 256 bytes 0110 Circular buffer size is 512 bytes 0111 Circular buffer size is 1 KB 1000 Circular buffer size is 2 KB 1001 Circular buffer size is 4 KB 1010 Circular buffer size is 8 KB 1011 Circular buffer size is 16 KB 1100 Circular buffer size is 32 KB 1101 Circular buffer size is 64 KB 1110 Circular buffer size is 128 KB 1111 Circular buffer size is 256 KB</p>
7 D_REQ	Disable request

Table continues on the next page...

DMA_DCR_n field descriptions (continued)

Field	Description
	<p>DMA hardware automatically clears the corresponding DCR_n[ERQ] bit when the byte count register reaches zero.</p> <p>0 ERQ bit is not affected. 1 ERQ bit is cleared when the BCR is exhausted.</p>
6 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
5–4 LINKCC	<p>Link channel control</p> <p>Allows DMA channels to have their transfers linked. The current DMA channel triggers a DMA request to the linked channels (LCH1 or LCH2) depending on the condition described by the LINKCC bits.</p> <p>If not in cycle steal mode (DCR_n[CS]=0) and LINKCC equals 01 or 10, no link to LCH1 occurs.</p> <p>If LINKCC equals 01, a link to LCH1 is created after each cycle-steal transfer performed by the current DMA channel is completed. As the last cycle-steal is performed and the BCR reaches zero, then the link to LCH1 is closed and a link to LCH2 is created.</p> <p>00 No channel-to-channel linking 01 Perform a link to channel LCH1 after each cycle-steal transfer followed by a link to LCH2 after the BCR decrements to zero 10 Perform a link to channel LCH1 after each cycle-steal transfer 11 Perform a link to channel LCH1 after the BCR decrements to zero</p>
3–2 LCH1	<p>Link channel 1</p> <p>Indicates the DMA channel assigned as link channel 1. The link channel number cannot be the same as the currently executing channel, and generates a configuration error if this is attempted (DSR_n[CE] is set).</p> <p>00 DMA Channel 0 01 DMA Channel 1 10 DMA Channel 2 11 DMA Channel 3</p>

The link channel number cannot be the same as the currently executing channel, and generates a configuration error if this is attempted (DSR_n[CE] is set).</p> <p>00 DMA Channel 0 01 DMA Channel 1 10 DMA Channel 2 11 DMA Channel 3</p>

21.4 Functional Description

In the following discussion, the term DMA request implies that DCR_n[START] is set, or DCR_n[ERQ] is set and then followed by assertion of the properly selected DMA peripheral request. The START bit is cleared when the channel is activated.

Before initiating a dual-address access, the DMA module verifies that $DCR_n[SSIZE]$ and $DCR_n[DSIZE]$ are consistent with the source and destination addresses. If they are not consistent, the configuration error bit, $DSR_n[CE]$, is set. If misalignment is detected, no transfer occurs, $DSR_n[CE]$ is set, and, depending on the DCR configuration, an interrupt event may be issued. If the auto-align bit, $DCR_n[AA]$, is set, error checking is performed on the appropriate registers.

A read/write transfer sequence reads data from the source address and writes it to the destination address. The number of bytes transferred is the largest of the sizes specified by $DCR_n[SSIZE]$ and $DCR_n[DSIZE]$ in the DMA Control Registers (DCR_n).

Source and destination address registers (SAR_n and DAR_n) can be programmed in the DCR_n to increment at the completion of a successful transfer.

21.4.1 Transfer Requests (Cycle-Steal and Continuous Modes)

The DMA channel supports software-initiated or peripheral-initiated requests. A request is issued by setting $DCR_n[START]$ or when the selected peripheral request asserts and $DCR_n[ERQ]$ is set. Setting $DCR_n[ERQ]$ enables recognition of the peripheral DMA requests. Selecting between cycle-steal and continuous modes minimizes bus usage for either type of request.

- Cycle-steal mode ($DCR_n[CS] = 1$)—Only one complete transfer from source to destination occurs for each request. If $DCR_n[ERQ]$ is set, the request is peripheral initiated. A software-initiated request is enabled by setting $DCR_n[START]$.
- Continuous mode ($DCR_n[CS] = 0$)—After a software-initiated or peripheral request, the DMA continuously transfers data until BCR_n reaches zero. The DMA performs the specified number of transfers, then retires the channel.

In either mode, the crossbar switch performs independent arbitration on each slave port after each transaction.

21.4.2 Channel Initialization and Startup

Before a data transfer starts, the channel's transfer control descriptor must be initialized with information describing configuration, request-generation method, and pointers to the data to be moved.

21.4.2.1 Channel Prioritization

The four DMA channels are prioritized based on number, with channel 0 having highest priority and channel 3 having the lowest, that is, channel 0 > channel 1 > channel 2 > channel 3.

Simultaneous peripheral requests activate the channels based on this priority order. Once activated, a channel runs to completion as defined by $DCRn[CS]$ and $BCRn$.

21.4.2.2 Programming the DMA Controller Module

CAUTION

During a channel's execution, writes to programming model registers can corrupt the data transfer. The DMA module itself does not have a mechanism to prevent writes to registers during a channel's execution.

General guidelines for programming the DMA are:

- The REQC register is configured to select the peripheral DMA requests and assign them to the individual DMA channels.
- $TCDn$ is initialized.
 - $SARn$ is loaded with the source (read) address. If the transfer is from a peripheral device to memory or to another peripheral, the source address is the location of the peripheral data register. If the transfer is from memory to a peripheral device or to memory, the source address is the starting address of the data block. This can be any appropriately aligned address.
 - $DARn$ is initialized with the destination (write) address. If the transfer is from a peripheral device to memory, or from memory to memory, $DARn$ is loaded with the starting address of the data block to be written. If the transfer is from memory to a peripheral device, or from a peripheral device to a peripheral device, $DARn$ is loaded with the address of the peripheral data register. This address can be any appropriately aligned address.

- SAR_n and DAR_n change after each data transfer depending on $DCR_n[SSIZE, DSIZE, SINC, DINC, SMOD, DMOD]$ and the starting addresses. Increment values can be 1, 2, or 4 for 8-bit, 16-bit, or 32-bit transfers, respectively. If the address register is programmed to remain unchanged, the register is not incremented after the data transfer.
- $BCR_n[BCR]$ must be loaded with the total number of bytes to be transferred. It is decremented by 1, 2, or 4 at the end of each transfer, depending on the transfer size. $DSR_n[DONE]$ must be cleared for channel startup.
- After the channel has been initialized, it may be started by setting $DCR_n[START]$ or a properly selected peripheral DMA request, depending on the status of $DCR_n[ERQ]$. For a software-initiated transfer, the channel can be started by setting $DCR_n[START]$ as part of a single 32-bit write to the last 32 bits of the TCD_n ; that is, it is not required to write the DCR_n with $START$ cleared and then perform a second write to explicitly set $START$.
- Programming the channel for a software-initiated request causes the channel to request the system bus and start transferring data immediately. If the channel is programmed for peripheral-initiated request, a properly selected peripheral DMA request must be asserted before the channel begins the system bus transfers.
- The hardware can automatically clear $DCR_n[ERQ]$, disabling the peripheral request, when BCR_n reaches zero by setting $DCR_n[D_REQ]$.
- Changes to DCR_n are effective immediately while the channel is active. To avoid problems with changing a DMA channel setup, write a one to $DSR_n[DONE]$ to stop the DMA channel.

21.4.3 Dual-Address Data Transfer Mode

Each channel supports dual-address transfers. Dual-address transfers consist of a source data read and a destination data write. The DMA controller module begins a dual-address transfer sequence after a DMA request. If no error condition exists, $DSR_n[REQ]$ is set.

- Dual-address read—The DMA controller drives the SAR_n value onto the system address bus. If $DCR_n[SINC]$ is set, the SAR_n increments by the appropriate number of bytes upon a successful read cycle. When the appropriate number of read cycles complete (multiple reads if the destination size is larger than the source), the DMA initiates the write portion of the transfer.

If a termination error occurs, $DSR_n[BES, DONE]$ are set and DMA transactions stop.

- Dual-address write—The DMA controller drives the DAR_n value onto the system address bus. When the appropriate number of write cycles complete (multiple writes if the source size is larger than the destination), DAR_n increments by the appropriate number of bytes if $DCR_n[DINC]$ is set. BCR_n decrements by the appropriate number of bytes. $DSR_n[DONE]$ is set when BCR_n reaches zero. If the BCR_n is greater than zero, another read/write transfer is initiated if continuous mode is enabled ($DCR_n[CS] = 0$).

If a termination error occurs, $DSR_n[BED, DONE]$ are set and DMA transactions stop.

21.4.4 Advanced Data Transfer Controls: Auto-Alignment

Typically, auto-alignment for DMA transfers applies for transfers of large blocks of data. As a result, it does not apply for peripheral-initiated cycle-steal transfers.

Auto-alignment allows block transfers to occur at the optimal size based on the address, byte count, and programmed size. To use this feature, $DCR_n[AA]$ must be set. The source is auto-aligned if $DCR_n[SSIZE]$ indicates a transfer size larger than $DCR_n[DSIZE]$. Source alignment takes precedence over the destination when the source and destination sizes are equal. Otherwise, the destination is auto-aligned. The address register chosen for alignment increments regardless of the increment value. Configuration error checking is performed on registers not chosen for alignment.

If BCR_n is greater than 16, the address determines transfer size. Transfers of 8 bits, 16 bits, or 32 bits are transferred until the address is aligned to the programmed size boundary, at which time accesses begin using the programmed size. If BCR_n is less than 16 at the start of a transfer, the number of bytes remaining dictates transfer size.

Consider this example:

- AA equals 1.
- SAR_n equals 0x(00)80_0001.
- BCR_n equals 0x00_00F0.
- SSIZE equals 00 (32 bits).
- DSIZE equals 01 (8 bits).

Because $SSIZE > DSIZE$, the source is auto-aligned. Error checking is performed on destination registers. The access sequence is as follows:

1. Read 1 byte from 0x(00)80_0001, increment SAR_n , write 1 byte (using DAR_n).
2. Read 2 bytes from 0x(00)80_0002, increment SAR_n , write 2 bytes.

3. Read 4 bytes from 0x(00)80_0004, increment SAR_n, write 4 bytes.
4. Repeat 4-byte operations until SAR_n equals 0x(00)80_00F0.
5. Read byte from 0x(00)80_00F0, increment SAR_n, write byte.

If DSIZE is another size, data writes are optimized to write the largest size allowed based on the address, but not exceeding the configured size.

21.4.5 Termination

An unsuccessful transfer can terminate for one of the following reasons:

- Error conditions—When the DMA encounters a read or write cycle that terminates with an error condition, DSR_n[BES] is set for a read and DSR_n[BED] is set for a write before the transfer is halted. If the error occurred in a write cycle, data in the internal holding registers is lost.
- Interrupts—If DCR_n[EINT] is set, the DMA drives the appropriate interrupt request signal. The processor can read DSR_n to determine whether the transfer terminated successfully or with an error. DSR_n[DONE] is then written with a one to clear the interrupt, the DONE, and error status bits.

Chapter 22

Multipurpose Clock Generator (MCG)

22.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The multipurpose clock generator (MCG) module provides several clock source choices for the MCU. The module contains a frequency-locked loop (FLL) and a phase-locked loop (PLL). The FLL is controllable by either an internal or an external reference clock. The PLL is controllable by the external reference clock. The module can select either of the FLL or PLL output clocks, or either of the internal or external reference clocks as a source for the MCU system clock. The MCG operates in conjunction with a crystal oscillator, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock.

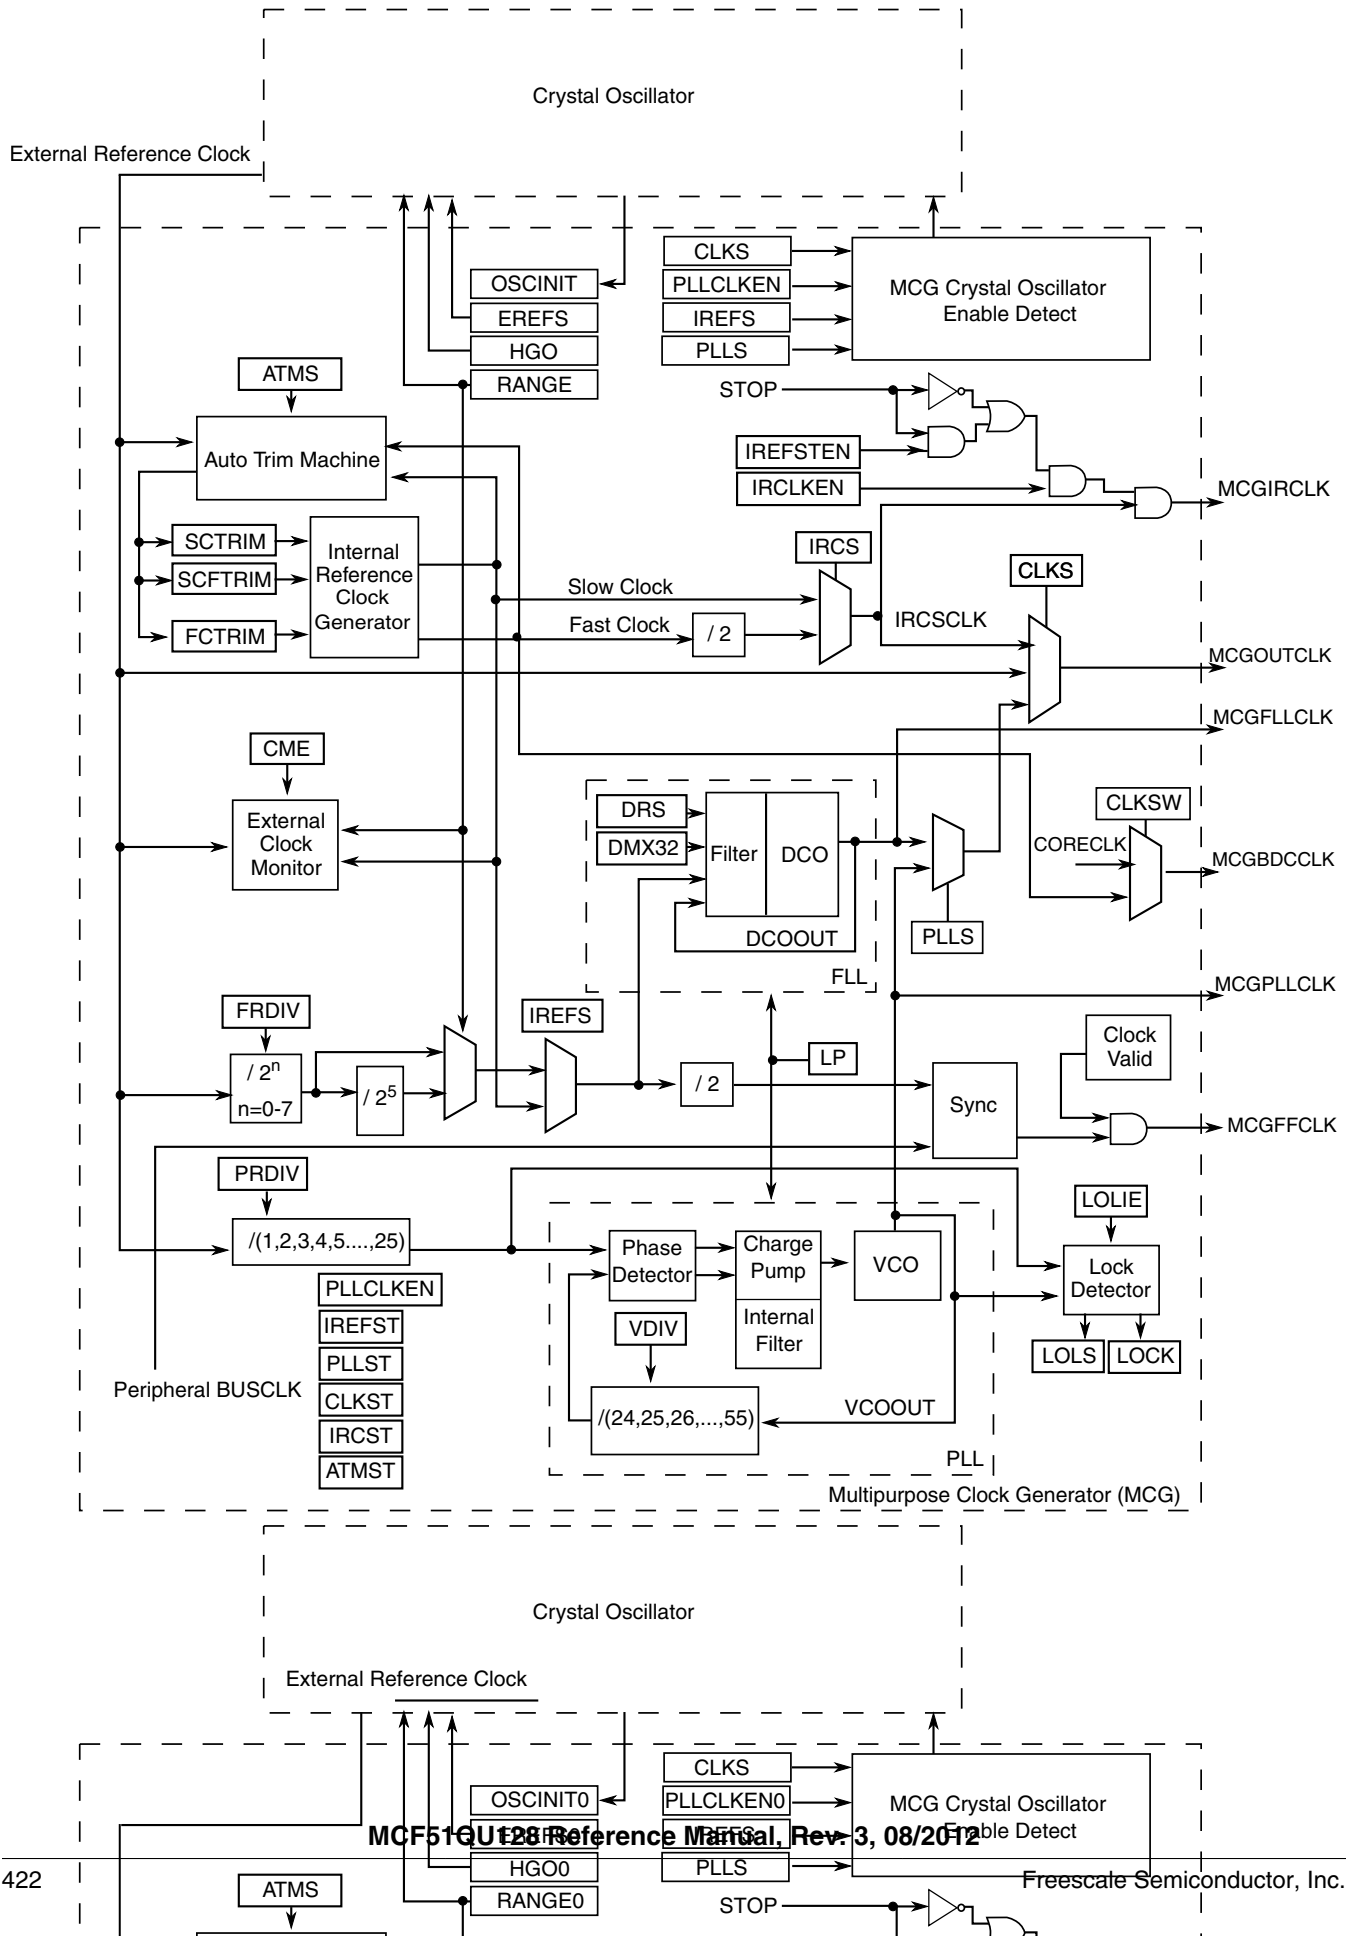

22.1.1 Features

Key features of the MCG module are:

- Frequency-locked loop (FLL):
 - Digitally-controlled oscillator (DCO)
 - DCO frequency range is programmable for up to four different frequency ranges.
 - Option to program and maximize DCO output frequency for a low frequency external reference clock source.
 - Option to prevent FLL from resetting its current locked frequency when switching clock modes if FLL reference frequency is not changed.

- Internal or external reference clock can be used as the FLL source.
- Can be used as a clock source for other on-chip peripherals.
- Phase-locked loop (PLL):
 - Voltage-controlled oscillator (VCO)
 - External reference clock is used as the PLL source.
 - Modulo VCO frequency divider
 - Phase/Frequency detector
 - Integrated loop filter
 - Can be used as a clock source for other on-chip peripherals.
- Internal reference clock generator:
 - Slow clock with nine trim bits for accuracy
 - Fast clock with four trim bits
 - Can be used as source clock for the FLL. In FEI mode, only the slow Internal Reference Clock (IRC) can be used as the FLL source.
 - Either the slow or the fast clock can be selected as the clock source for the MCU.
 - Can be used as a clock source for other on-chip peripherals.
- Control signals for the MCG external reference low power oscillator clock generators are provided:
 - HGO, RANGE, EREFS
- External clock from the Crystal Oscillator :
 - Can be used as a source for the FLL and/or the PLL.
 - Can be selected as the clock source for the MCU.
- External clock monitor with reset and interrupt request capability to check for external clock failure when running in FBE, PEE, BLPE, or FEE modes
- Lock detector with interrupt request capability for use with the PLL
- Internal Reference Clocks Auto Trim Machine (ATM) capability using an external clock as a reference
- Reference dividers for both the FLL and the PLL are provided

- Reference dividers for the Fast Internal Reference Clock are provided
- MCG Background Debug Controller Clock (MCGBDCCLK) is provided as a clock source for the Background Debug Controller (BDC)
- MCG PLL Clock (MCGPLLCLK) is provided as a clock source for other on-chip peripherals
- MCG FLL Clock (MCGFLLCLK) is provided as a clock source for other on-chip peripherals
- MCG Fixed Frequency Clock (MCGFFCLK) is provided as a clock source for other on-chip peripherals
- MCG Internal Reference Clock (MCGIRCLK) is provided as a clock source for other on-chip peripherals

22.1.2 Modes of Operation

The MCG has the following modes of operation: FEI, FEE, FBI, FBE, PBE, PEE, BLPI, BLPE, and Stop. For details, see [MCG modes of operation](#).

22.2 External Signal Description

There are no MCG signals that connect off chip.

22.3 Memory Map/Register Definition

This section includes the memory map and register definition.

MCG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

MCG_C1 field descriptions

Field	Description
7–6 CLKS	<p>Clock Source Select</p> <p>Selects the clock source for MCGOUTCLK .</p> <p>00 Encoding 0 — Output of FLL or PLL is selected (depends on PLLS control bit).</p> <p>01 Encoding 1 — Internal reference clock is selected.</p> <p>10 Encoding 2 — External reference clock is selected.</p> <p>11 Encoding 3 — Reserved.</p>
5–3 FRDIV	<p>FLL External Reference Divider</p> <p>Selects the amount to divide down the external reference clock for the FLL. The resulting frequency must be in the range 31.25 kHz to 39.0625 kHz (This is required when FLL/DCO is the clock source for MCGOUTCLK . In FBE mode, it is not required to meet this range, but it is recommended in the cases when trying to enter a FLL mode from FBE).</p> <p>000 If RANGE = 0 , Divide Factor is 1; for all other RANGE values, Divide Factor is 32.</p> <p>001 If RANGE = 0 , Divide Factor is 2; for all other RANGE values, Divide Factor is 64.</p> <p>010 If RANGE = 0 , Divide Factor is 4; for all other RANGE values, Divide Factor is 128.</p> <p>011 If RANGE = 0 , Divide Factor is 8; for all other RANGE values, Divide Factor is 256.</p> <p>100 If RANGE = 0 , Divide Factor is 16; for all other RANGE values, Divide Factor is 512.</p> <p>101 If RANGE = 0 , Divide Factor is 32; for all other RANGE values, Divide Factor is 1024.</p> <p>110 If RANGE = 0 , Divide Factor is 64; for all other RANGE values, Divide Factor is Reserved .</p> <p>111 If RANGE = 0 , Divide Factor is 128; for all other RANGE values, Divide Factor is Reserved .</p>
2 IREFS	<p>Internal Reference Select</p> <p>Selects the reference clock source for the FLL.</p> <p>0 External reference clock is selected.</p> <p>1 The slow internal reference clock is selected.</p>
1 IRCLKEN	<p>Internal Reference Clock Enable</p> <p>Enables the internal reference clock for use as MCGIRCLK.</p> <p>0 MCGIRCLK inactive.</p> <p>1 MCGIRCLK active.</p>
0 IREFSTEN	<p>Internal Reference Stop Enable</p> <p>Controls whether or not the internal reference clock remains enabled when the MCG enters Stop mode.</p> <p>0 Internal reference clock is disabled in Stop mode.</p> <p>1 Internal reference clock is enabled in Stop mode if IRCLKEN is set or if MCG is in FEI, FBI, or BLPI modes before entering Stop mode.</p>

22.3.2 MCG Control 2 Register (MCG_C2)

Address: FFFF_8400h base + 1h offset = FFFF_8401h

Bit	7	6	5	4	3	2	1	0
Read	0	0	RANGE		HGO	EREFS	LP	IRCS
Write								
Reset	0	0	0	0	0	0	0	0

MCG_C2 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 RANGE	Frequency Range Select Selects the frequency range for the crystal oscillator or external clock source. See the Oscillator (OSC) chapter for more details and the device data sheet for the frequency ranges used. 00 Encoding 0 — Low frequency range selected for the crystal oscillator . 01 Encoding 1 — High frequency range selected for the crystal oscillator . 1X Encoding 2 — Very high frequency range selected for the crystal oscillator .
3 HGO	High Gain Oscillator Select Controls the crystal oscillator mode of operation. See the Oscillator (OSC) chapter for more details. 0 Configure crystal oscillator for low-power operation. 1 Configure crystal oscillator for high-gain operation.
2 EREFS	External Reference Select Selects the source for the external reference clock. See the Oscillator (OSC) chapter for more details. 0 External reference clock requested. 1 Oscillator requested.
1 LP	Low Power Select Controls whether the FLL or PLL is disabled in BLPI and BLPE modes. In FBE or PBE modes, setting this bit to 1 will transition the MCG into BLPE mode; in FBI mode, setting this bit to 1 will transition the MCG into BLPI mode. In any other MCG mode, LP bit has no affect. 0 FLL or PLL is not disabled in bypass modes. 1 FLL or PLL is disabled in bypass modes (lower power) unless BDM is active.
0 IRCS	Internal Reference Clock Select Selects between the fast or slow internal reference clock source. 0 Slow internal reference clock selected. 1 Fast internal reference clock selected.

22.3.3 MCG Control 3 Register (MCG_C3)

Address: FFFF_8400h base + 2h offset = FFFF_8402h

* Notes:

- x = Undefined at reset.

MCG_C3 field descriptions

Field	Description
7-0 SCTRIM	<p>Slow Internal Reference Clock Trim Setting</p> <p>SCTRIM¹ controls the slow internal reference clock frequency by controlling the slow internal reference clock period. The SCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.</p> <p>An additional fine trim bit is available in C4 register as the SCFTRIM bit. Upon reset, this value is loaded with a factory trim value.</p> <p>If an SCTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.</p>

1. A value for SCTRIM is loaded during reset from a factory programmed location .

22.3.4 MCG Control 4 Register (MCG_C4)

NOTE

Reset values for DRST and DMX32 bits are 0.

Address: FFFF_8400h base + 3h offset = FFFF_8403h

* Notes:

- x = Undefined at reset.
- A value for FCTRIM is loaded during reset from a factory programmed location . x = Undefined at reset.

22.3.7 MCG Status Register (MCG_S)

Address: FFFF_8400h base + 6h offset = FFFF_8406h

Bit	7	6	5	4	3	2	1	0
Read	LOLS	LOCK0	PLLST	IREFST	CLKST		OSCINIT	IRCST
Write								
Reset	0	0	0	1	0	0	0	0

MCG_S field descriptions

Field	Description
7 LOLS	<p>Loss of Lock Status</p> <p>This bit is a sticky bit indicating the lock status for the PLL. LOLS is set if after acquiring lock, the PLL output frequency has fallen outside the lock exit frequency tolerance, D_{unl}. LOLIE determines whether an interrupt request is made when LOLS is set. This bit is cleared by reset or by writing a logic 1 to it when set. Writing a logic 0 to this bit has no effect.</p> <p>0 PLL has not lost lock since LOLS was last cleared. 1 PLL has lost lock since LOLS was last cleared.</p>

Table continues on the next page...

MCG_S field descriptions (continued)

Field	Description
6 LOCK0	<p>Lock Status</p> <p>This bit indicates whether the PLL has acquired lock. Lock detection is only enabled when the PLL is enabled (either through clock mode selection or PLLCLKEN0=1 setting). While the PLL clock is locking to the desired frequency, the MCG PLL clock (MCGPLLCLK) will be gated off until the LOCK bit gets asserted. If the lock status bit is set, changing the value of the PRDIV [4:0] bits in the C5 register or the VDIV0[4:0] bits in the C6 register causes the lock status bit to clear and stay cleared until the PLL has reacquired lock. Entry into LLS, VLPS, or regular Stop with PLLSTEN=0 also causes the lock status bit to clear and stay cleared until the Stop mode is exited and the PLL has reacquired lock. Any time the PLL is enabled and the LOCK0 bit is cleared, the MCGPLLCLK will be gated off until the LOCK0 bit is asserted again.</p> <p>0 PLL is currently unlocked. 1 PLL is currently locked.</p>
5 PLLST	<p>PLL Select Status</p> <p>This bit indicates the clock source selected by PLLS. The PLLST bit does not update immediately after a write to the PLLS bit due to internal synchronization between clock domains.</p> <p>0 Source of PLLS clock is FLL clock. 1 Source of PLLS clock is PLL output clock.</p>
4 IREFST	<p>Internal Reference Status</p> <p>This bit indicates the current source for the FLL reference clock. The IREFST bit does not update immediately after a write to the IREFS bit due to internal synchronization between clock domains.</p> <p>0 Source of FLL reference clock is the external reference clock. 1 Source of FLL reference clock is the internal reference clock.</p>
3–2 CLKST	<p>Clock Mode Status</p> <p>These bits indicate the current clock mode. The CLKST bits do not update immediately after a write to the CLKS bits due to internal synchronization between clock domains.</p> <p>00 Encoding 0 — Output of the FLL is selected (reset default). 01 Encoding 1 — Internal reference clock is selected. 10 Encoding 2 — External reference clock is selected. 11 Encoding 3 — Output of the PLL is selected.</p>
1 OSCINIT	<p>OSC Initialization</p> <p>This bit, which resets to 0, is set to 1 after the initialization cycles of the crystal oscillator clock have completed. After being set, the bit is cleared to 0 if the OSC is subsequently disabled. See the OSC module's detailed description for more information.</p>
0 IRCST	<p>Internal Reference Clock Status</p> <p>The IRCST bit indicates the current source for the internal reference clock select clock (IRCSCCLK). The IRCST bit does not update immediately after a write to the IRCS bit due to internal synchronization between clock domains. The IRCST bit will only be updated if the internal reference clock is enabled, either by the MCG being in a mode that uses the IRC or by setting the C1[IRCLKEN] bit.</p> <p>0 Source of internal reference clock is the slow clock (32 kHz IRC). 1 Source of internal reference clock is the fast clock (4 MHz IRC).</p>

22.3.8 MCG Auto Trim Control Register (MCG_ATC)

Address: FFFF_8400h base + 8h offset = FFFF_8408h

MCG_ATC field descriptions

Field	Description
7 ATME	<p>Automatic Trim Machine Enable</p> <p>Enables the Auto Trim Machine to start automatically trimming the selected Internal Reference Clock.</p> <p>NOTE: ATME deasserts after the Auto Trim Machine has completed trimming all trim bits of the IRCS clock selected by the ATMS bit.</p> <p>Writing to C1, C3, C4, and ATC registers or entering Stop mode aborts the auto trim operation and clears this bit.</p> <p>0 Auto Trim Machine disabled. 1 Auto Trim Machine enabled.</p>
6 ATMS	<p>Automatic Trim Machine Select</p> <p>Selects the IRCS clock for Auto Trim Test.</p> <p>0 32 kHz Internal Reference Clock selected. 1 4 MHz Internal Reference Clock selected.</p>
5 ATMF	<p>Automatic Trim machine Fail Flag</p> <p>Fail flag for the Automatic Trim Machine (ATM). This bit asserts when the Automatic Trim Machine is enabled (ATME=1) and a write to the C1, C3, C4, and ATC registers is detected or the MCG enters into any Stop mode. A write to ATMF clears the flag.</p> <p>0 Automatic Trim Machine completed normally. 1 Automatic Trim Machine failed.</p>
4-0 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>

22.3.9 MCG Auto Trim Compare Value High Register (MCG_ATCVH)

Address: FFFF_8400h base + Ah offset = FFFF_840Ah

MCG_ATCVH field descriptions

Field	Description
7–0 ATCVH	ATM Compare Value High Values are used by Auto Trim Machine to compare and adjust Internal Reference trim values during ATM SAR conversion.

22.3.10 MCG Auto Trim Compare Value Low Register (MCG_ATCVL)

Address: FFFF_8400h base + Bh offset = FFFF_840Bh

Bit	7	6	5	4	3	2	1	0
Read	ATCVL							
Write								
Reset	0	0	0	0	0	0	0	0

MCG_ATCVL field descriptions

Field	Description
7–0 ATCVL	ATM Compare Value Low Values are used by Auto Trim Machine to compare and adjust Internal Reference trim values during ATM SAR conversion.

22.4 Functional Description**22.4.1 MCG mode state diagram**

The nine states of the MCG are shown in the following figure and are described in [Table 22-14](#). The arrows indicate the permitted MCG mode transitions.

Figure 22-12. MCG mode state diagram

NOTE

- During exits from LLS or VLPS when the MCG is in PEE mode, the MCG will reset to PBE clock mode and the C1[CLKS] and S[CLKST] will automatically be set to 2'b10.
- If entering Normal Stop mode when the MCG is in PEE mode with C5[PLLSTEN]=0, the MCG will reset to PBE clock mode and C1[CLKS] and S[CLKST] will automatically be set to 2'b10.

22.4.1.1 MCG modes of operation

The MCG operates in one of the following modes.

Note

The MCG restricts transitions between modes. For the permitted transitions, see [Figure 22-12](#).

Table 22-14. MCG modes of operation

Mode	Description
FLL Engaged Internal (FEI)	<p>FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 00 • C1[IREFS] bit is written to 1 • C6[PLLS] bit is written to 0 <p>In FEI mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the 32 kHz Internal Reference Clock (IRC). The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FEI mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set.</p>
FLL Engaged External (FEE)	<p>FLL engaged external (FEE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 00 • C1[IREFS] bit is written to 0 • C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz • C6[PLLS] bit is written to 0 <p>In FEE mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the external reference clock. The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the external reference frequency, as specified by C1[FRDIV] and C2[RANGE]. See the C4[DMX32] bit description for more details. In FEE mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set.</p>
FLL Bypassed Internal (FBI)	<p>FLL bypassed internal (FBI) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 01 • C1[IREFS] bit is written to 1 • C6[PLLS] is written to 0 • C2[LP] is written to 0 <p>In FBI mode, the MCGOUTCLK is derived either from the slow (32 kHz IRC) or fast (2 MHz IRC) internal reference clock, as selected by the C2[IRCS] bit. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the C2[IRCS] selected internal reference clock. The FLL clock (DCOCLK) is controlled by the slow internal reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FBI mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set.</p>

Table continues on the next page...

Table 22-14. MCG modes of operation (continued)

Mode	Description
FLL Bypassed External (FBE)	<p>FLL bypassed external (FBE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 10 • C1[IREFS] bit is written to 0 • C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz. • C6[PLLS] bit is written to 0 • C2[LP] is written to 0 <p>In FBE mode, the MCGOUTCLK is derived from the external reference clock. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the external reference clock. The FLL clock (DCOCLK) is controlled by the external reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the divided external reference frequency. See the C4[DMX32] bit description for more details. In FBI mode the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set.</p>
PLL Engaged External (PEE)	<p>PLL Engaged External (PEE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 00 • C1[IREFS] bit is written to 0 • C6[PLLS] bit is written to 1 <p>In PEE mode, the MCGOUTCLK is derived from the PLL clock, which is controlled by the external reference clock. The PLL clock frequency locks to a multiplication factor, as specified by C6[VDIV], times the external reference frequency, as specified by C5[PRDIV]. The PLL's programmable reference divider must be configured to produce a valid PLL reference clock. The FLL is disabled in a low-power state.</p>
PLL Bypassed External (PBE)	<p>PLL Bypassed External (PBE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 10 • C1[IREFS] bit is written to 0 • C6[PLLS] bit is written to 1 • C2[LP] bit is written to 0 <p>In PBE mode, MCGOUTCLK is derived from the external reference clock; the PLL is operational, but its output clock is not used. This mode is useful to allow the PLL to acquire its target frequency while MCGOUTCLK is driven from the external reference clock. The PLL clock frequency locks to a multiplication factor, as specified by its [VDIV], times the PLL reference frequency, as specified by its [PRDIV]. In preparation for transition to PEE, the PLL's programmable reference divider must be configured to produce a valid PLL reference clock. The FLL is disabled in a low-power state.</p>
Bypassed Low Power Internal (BLPI) ¹	<p>Bypassed Low Power Internal (BLPI) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 01 • C1[IREFS] bit is written to 1 • C6[PLLS] bit is written to 0 • C2[LP] bit is written to 1 <p>In BLPI mode, MCGOUTCLK is derived from the internal reference clock. The FLL is disabled and PLL is disabled even if the C5[PLLCLKEN] is set to 1.</p>

Table continues on the next page...

Table 22-14. MCG modes of operation (continued)

Mode	Description
Bypassed Low Power External (BLPE)	<p>Bypassed Low Power External (BLPE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> • C1[CLKS] bits are written to 10 • C1[IREFS] bit is written to 0 • C2[LP] bit is written to 1 <p>In BLPE mode, MCGOUTCLK is derived from the external reference clock. The FLL is disabled and PLL is disabled even if the C5[PLLCLKEN] is set to 1.</p>
Stop	<p>Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the chapter that describes how modules are configured and MCG behavior during Stop recovery. Entering Stop mode, the FLL is disabled, and all MCG clock signals are static except in the following case:</p> <p>MCGPLLCLK is active in Normal Stop mode when PLLSTEN=1</p> <p>MCGIRCLK is active in Normal Stop mode when all the following conditions become true:</p> <ul style="list-style-type: none"> • C1[IRCLKEN] = 1 • C1[IREFSTEN] = 1 <p>NOTE:</p> <ul style="list-style-type: none"> • When entering Low Power Stop modes (LLS or VLPS) from PEE mode, on exit the MCG clock mode is forced to PBE clock mode. C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK] bit will be cleared without setting S[LOLS]. • When entering Normal Stop mode from PEE mode and if C5[PLLSTEN]=0, on exit the MCG clock mode is forced to PBE mode, the C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK] bit will clear without setting S[LOLS]. If C5[PLLSTEN]=1, the S[LOCK] bit will not get cleared and on exit the MCG will continue to run in PEE mode.

1. If entering VLPR mode, MCG has to be configured and enter BLPE mode or BLPI mode with the Fast IRC clock selected (C2[IRCS]=1). After it enters VLPR mode, writes to any of the MCG control registers that can cause an MCG clock mode switch to a non low power clock mode must be avoided.

NOTE

For the chip-specific modes of operation, see the power management chapter of this MCU.

22.4.1.2 MCG mode switching

The C1[IREFS] bit can be changed at any time, but the actual switch to the newly selected reference clocks is shown by the S[IREFST] bit. When switching between engaged internal and engaged external modes, the FLL will begin locking again after the switch is completed.

The C1[CLKS] bits can also be changed at any time, but the actual switch to the newly selected clock is shown by the S[CLKST] bits. If the newly selected clock is not available, the previous clock will remain selected.

The C4[DRST_DRS] write bits can be changed at any time except when C2[LP] bit is 1. If the C4[DRST_DRS] write bits are changed while in FLL engaged internal (FEI) or FLL engaged external (FEE), the MCGOUTCLK will switch to the new selected DCO range within three clocks of the selected DCO clock. After switching to the new DCO, the FLL remains unlocked for several reference cycles. DCO startup time is equal to the FLL acquisition time. After the selected DCO startup time is over, the FLL is locked. The completion of the switch is shown by the C4[DRST_DRS] read bits.

22.4.2 Low Power Bit Usage

The C2[LP] bit is provided to allow the FLL or PLL to be disabled and thus conserve power when these systems are not being used. The C4[DRST_DRS] can not be written while C2[LP] bit is 1. However, in some applications, it may be desirable to enable the FLL or PLL and allow it to lock for maximum accuracy before switching to an engaged mode. Do this by writing C2[LP] to 0.

22.4.3 MCG Internal Reference Clocks

This module supports two internal reference clocks with nominal frequencies of 32 kHz (slow IRC) and 4 MHz (fast IRC).

22.4.3.1 MCG Internal Reference Clock

The MCG Internal Reference Clock (MCGIRCLK) provides a clock source for other on-chip peripherals and is enabled when C1[IRCLKEN]=1. When enabled, MCGIRCLK is driven by either the fast internal reference clock (2 MHz IRC) or the slow internal reference clock (32 kHz IRC). The IRCS clock frequency can be re-targeted by trimming the period of its IRCS selected internal reference clock. This can be done by writing a new trim value to the C3[SCTRIM]:C4[SCFTRIM] bits when the slow IRC clock is selected or by writing a new trim value to the C4[FCTRIM] bits when the fast IRC clock is selected. The internal reference clock period is proportional to the trim value written. C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) and C4[FCTRIM] (if C2[IRCS]=1) bits affect the MCGOUTCLK frequency if the MCG is in FBI or BLPI modes. C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) bits also affect the MCGOUTCLK frequency if the MCG is in FEI mode.

Additionally, this clock can be enabled in Stop mode by setting C1[IRCLKEN] and C1[IREFSTEN], otherwise this clock is disabled in Stop mode.

22.4.4 External Reference Clock

The MCG module can support an external reference clock in all modes. See the device datasheet for external reference frequency range. When C1[IREFS] is set, the external reference clock will not be used by the FLL or PLL. In these modes, the frequency can be equal to the maximum frequency the chip-level timing specifications will support.

If the CME is asserted the slow internal reference clock is enabled along with the enabled external clock monitor. For the case when C6[CME]=1, a loss of clock is detected if the OSC external reference falls below a minimum frequency (f_{loc_high} or f_{loc_low} depending on C2[RANGE]).

All clock monitors must be disabled before VLPR or VLPW power modes are entered.

Upon detect of a loss of clock event, the MCU generates a system reset if the respective LOCRE bit is set. Otherwise the MCG sets the respective LOCS bit and the MCG generates a LOCS interrupt request.

22.4.5 MCG Fixed frequency clock

The MCG Fixed Frequency Clock (MCGFFCLK) provides a fixed frequency clock source for other on-chip peripherals; see the block diagram. This clock is driven by either the slow clock from the internal reference clock generator or the external reference clock from the Crystal Oscillator, divided by the FLL reference clock divider. The source of MCGFFCLK is selected by C1[IREFS].

This clock is synchronized to the peripheral bus clock and is valid only when its frequency is not more than 1/8 of the MCGOUTCLK frequency. When it is not valid, it is disabled and held high. The MCGFFCLK is not available when the MCG is in BLPI mode. This clock is also disabled in Stop mode. The FLL reference clock must be set within the valid frequency range for the MCGFFCLK.

22.4.6 MCG Background Debug Controller Clock

The MCG Background Debug Controller Clock (MCGBDCCLK) provides a clock source to the Background Debug Controller (BDC). This clock is driven by either the SYCLK or the 4 MHz internal reference clock (IRC), as selected by the XCSR[CLKSW] bit in the V1 ColdFire debug module.

22.4.7 MCG PLL clock

The MCG PLL Clock (MCGPLLCLK) is available depending on the device's configuration of the MCG module. For more details, see the clock distribution chapter of this MCU. The MCGPLLCLK is prevented from coming out of the MCG until it is enabled and S[LOCK] is set.

22.4.8 MCG Auto TRIM (ATM)

The MCG Auto Trim (ATM) is a MCG feature that when enabled, it configures the MCG hardware to automatically trim the MCG Internal Reference Clocks using an external clock as a reference. The selection between which MCG IRC clock gets tested and enabled is controlled by the ATC[ATMS] control bit (ATC[ATMS]=0 selects the 32 kHz IRC and ATC[ATMS]=1 selects the 4 MHz IRC). If 4 MHz IRC is selected for the ATM, a divide by 128 is enabled to divide down the 4 MHz IRC to a range of 31.250 kHz.

When MCG ATM is enabled by writing ATC[ATME] bit to 1, The ATM machine will start auto trimming the selected IRC clock. During the autotrim process, ATC[ATME] will remain asserted and will deassert after ATM is completed or an abort occurs. The MCG ATM is aborted if a write to any of the following control registers is detected : C1, C3, C4, or ATC or if Stop mode is entered. If an abort occurs, ATC[ATMF] fail flag is asserted.

The ATM machine uses the bus clock as the external reference clock to perform the IRC auto-trim. Therefore, it is required that the MCG is configured in a clock mode where the reference clock used to generate the system clock is the external reference clock such as FBE clock mode. The MCG must not be configured in a clock mode where selected IRC ATM clock is used to generate the system clock. The bus clock is also required to be running with in the range of 8–16 MHz.

To perform the ATM on the selected IRC, the ATM machine uses the successive approximation technique to adjust the IRC trim bits to generate the desired IRC trimmed frequency. The ATM SARs each of the ATM IRC trim bits starting with the MSB. For each trim bit test, the ATM uses a pulse that is generated by the ATM selected IRC clock to enable a counter that counts number of ATM external clocks. At end of each trim bit, the ATM external counter value is compared to the ATCV[15:0] register value. Based on the comparison result, the ATM trim bit under test will get cleared or stay asserted. This is done until all trim bits have been tested by ATM SAR machine.

Before the ATM can be enabled, the ATM expected count needs to be derived and stored into the ATCV register. The ATCV expected count is derived based on the required target Internal Reference Clock (IRC) frequency, and the frequency of the external reference clock using the following formula:

$$\text{ATCV Expected Count Value} = 21 * (\text{Fe} / \text{Fr})$$

- Fr = Target Internal Reference Clock (IRC) Trimmed Frequency
- Fe = External Clock Frequency

If the auto trim is being performed on the 4 MHz IRC, the calculated expected count value must be multiplied by 128 before storing it in the ATCV register. Therefore, the ATCV Expected Count Value for trimming the 4 MHz IRC is calculated using the following formula.

$$\text{Expected Count Value} = (\text{Fe} / \text{Fr}) * 21 * (128)$$

22.5 Initialization / Application information

This section describes how to initialize and configure the MCG module in an application. The following sections include examples on how to initialize the MCG and properly switch between the various available modes.

22.5.1 MCG module initialization sequence

The MCG comes out of reset configured for FEI mode. The internal reference will stabilize in t_{irefsts} microseconds before the FLL can acquire lock. As soon as the internal reference is stable, the FLL will acquire lock in $t_{\text{fll_acquire}}$ milliseconds.

22.5.1.1 Initializing the MCG

Because the MCG comes out of reset in FEI mode, the only MCG modes that can be directly switched to upon reset are FEE, FBE, and FBI modes (see [Figure 22-12](#)). Reaching any of the other modes requires first configuring the MCG for one of these three intermediate modes. Care must be taken to check relevant status bits in the MCG status register reflecting all configuration changes within each mode.

To change from FEI mode to FEE or FBE modes, follow this procedure:

1. Enable the external clock source by setting the appropriate bits in C2 register.

2. Write to C1 register to select the clock mode.
 - If entering FEE mode, set C1[FRDIV] appropriately, clear the C1[IREFS] bit to switch to the external reference, and leave the C1[CLKS] bits at 2'b00 so that the output of the FLL is selected as the system clock source.
 - If entering FBE, clear the C1[IREFS] bit to switch to the external reference and change the C1[CLKS] bits to 2'b10 so that the external reference clock is selected as the system clock source. The C1[FRDIV] bits should also be set appropriately here according to the external reference frequency to keep the FLL reference clock in the range of 31.25 kHz to 39.0625 kHz. Although the FLL is bypassed, it is still on in FBE mode.
 - The internal reference can optionally be kept running by setting the C1[IRCLKEN] bit. This is useful if the application will switch back and forth between internal and external modes. For minimum power consumption, leave the internal reference disabled while in an external clock mode.
3. Once the proper configuration bits have been set, wait for the affected bits in the MCG status register to be changed appropriately, reflecting that the MCG has moved into the proper mode.
 - If the MCG is in FEE, FBE, PEE, PBE, or BLPE mode, and C2[EREFS] was also set in step 1, wait here for S[OSCINIT] bit to become set indicating that the external clock source has finished its initialization cycles and stabilized.
 - If in FEE mode, check to make sure the S[IREFST] bit is cleared before moving on.
 - If in FBE mode, check to make sure the S[IREFST] bit is cleared and S[CLKST] bits have changed to 2'b10 indicating the external reference clock has been appropriately selected. Although the FLL is bypassed, it is still on in FBE mode.
4. Write to the C4 register to determine the DCO output (MCGFLLCLK) frequency range.
 - By default, with C4[DMX32] cleared to 0, the FLL multiplier for the DCO output is 640. For greater flexibility, if a mid-low-range FLL multiplier of 1280 is desired instead, set C4[DRST_DRS] bits to 2'b01 for a DCO output frequency of 40 MHz. If a mid high-range FLL multiplier of 1920 is desired instead, set the C4[DRST_DRS] bits to 2'b10 for a DCO output frequency of 60 MHz. If a high-range FLL multiplier of 2560 is desired instead, set the C4[DRST_DRS] bits to 2'b11 for a DCO output frequency of 80 MHz.

- When using a 32.768 kHz external reference, if the maximum low-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b00 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 732 will be 24 MHz.
 - When using a 32.768 kHz external reference, if the maximum mid-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b01 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 1464 will be 48 MHz.
 - When using a 32.768 kHz external reference, if the maximum mid high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b10 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2197 will be 72 MHz.
 - When using a 32.768 kHz external reference, if the maximum high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST_DRS] bits to 2'b11 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2929 will be 96 MHz.
5. Wait for the FLL lock time to guarantee FLL is running at new C4[DRST_DRS] and C4[DMX32] programmed frequency.

To change from FEI clock mode to FBI clock mode, follow this procedure:

1. Change C1[CLKS] bits in C1 register to 2'b01 so that the internal reference clock is selected as the system clock source.
2. Wait for S[CLKST] bits in the MCG status register to change to 2'b01, indicating that the internal reference clock has been appropriately selected.
3. Write to the C2 register to determine the IRCS output (IRCSCLK) frequency range.
 - By default, with C2[IRCS] cleared to 0, the IRCS selected output clock is the slow internal reference clock (32 kHz IRC). If the faster IRC is desired, set C2[IRCS] bit to 1 for a IRCS clock derived from the 4 MHz IRC source.

22.5.2 Using a 32.768 kHz reference

In FEE and FBE modes, if using a 32.768 kHz external reference, at the default FLL multiplication factor of 640, the DCO output (MCGFLLCLK) frequency is 20.97 MHz at low-range. If C4[DRST_DRS] bits are set to 2'b01, the multiplication factor is doubled to 1280, and the resulting DCO output frequency is 41.94 MHz at mid-low-range. If C4[DRST_DRS] bits are set to 2'b10, the multiplication factor is set to 1920, and the resulting DCO output frequency is 62.91 MHz at mid high-range. If C4[DRST_DRS] bits are set to 2'b11, the multiplication factor is set to 2560, and the resulting DCO output frequency is 83.89 MHz at high-range.

In FBI and FEI modes, setting C4[DMX32] bit is not recommended. If the internal reference is trimmed to a frequency above 32.768 kHz, the greater FLL multiplication factor could potentially push the microcontroller system clock out of specification and damage the part.

22.5.3 MCG mode switching

When switching between operational modes of the MCG, certain configuration bits must be changed in order to properly move from one mode to another. Each time any of these bits are changed (C6[PLLS], C1[IREFS], C1[CLKS], C2[IRCS], or C2[EREFS]), the corresponding bits in the MCG status register (PLLST, IREFST, CLKST, IRCST, or OSCINIT) must be checked before moving on in the application software.

Additionally, care must be taken to ensure that the reference clock divider (C1[FRDIV] and C5[PRDIV]) is set properly for the mode being switched to. For instance, in PEE mode, if using a 4 MHz crystal, C5[PRDIV] must be set to 5'b000 (divide-by-1) or 5'b001 (divide -by-2) to divide the external reference down to the required frequency between 2 and 4 MHz.

In FBE, FEE, FBI, and FEI modes, at any time, the application can switch the FLL multiplication factor between 640, 1280, 1920, and 2560 with C4[DRST_DRS] bits. Writes to C4[DRST_DRS] bits will be ignored if C2[LP]=1.

The table below shows MCGOUTCLK frequency calculations using C1[FRDIV], C5[PRDIV], and C6[VDIV] settings for each clock mode.

Table 22-15. MCGOUTCLK Frequency Calculation Options

Clock Mode	$f_{\text{MCGOUTCLK}}^1$	Note
FEI (FLL engaged internal)	$(f_{\text{int}} * F)$	Typical $f_{\text{MCGOUTCLK}} = 20$ MHz immediately after reset.
FEE (FLL engaged external)	$(f_{\text{ext}} / \text{FLL_R}) * F$	$f_{\text{ext}} / \text{FLL_R}$ must be in the range of 31.25 kHz to 39.0625 kHz

Table continues on the next page...

Table 22-15. MCGOUTCLK Frequency Calculation Options (continued)

Clock Mode	$f_{\text{MCGOUTCLK}}^1$	Note
FBE (FLL bypassed external)	f_{ext}	$f_{\text{ext}} / \text{FLL_R}$ must be in the range of 31.25 kHz to 39.0625 kHz
FBI (FLL bypassed internal)	f_{int}	Typical $f_{\text{int}} = 32$ kHz
PEE (PLL engaged external)	$(f_{\text{ext}} / \text{PLL_R}) * M$	$f_{\text{ext}} / \text{PLL_R}$ must be in the range of 2 – 4 MHz
PBE (PLL bypassed external)	f_{ext}	$f_{\text{ext}} / \text{PLL_R}$ must be in the range of 2 – 4 MHz
BLPI (Bypassed low power internal)	f_{int}	
BLPE (Bypassed low power external)	f_{ext}	

1. FLL_R is the reference divider selected by the C1[FRDIV] bits, PLL_R is the reference divider selected by C5[PRDIV] bits, F is the FLL factor selected by C4[DRST_DRS] and C4[DMX32] bits, and M is the multiplier selected by C6[VDIV] bits.

This section will include three mode switching examples using an 4 MHz external crystal. If using an external clock source less than 2 MHz, the MCG must not be configured for any of the PLL modes (PEE and PBE).

22.5.3.1 Example 1: Moving from FEI to PEE mode: External Crystal = 4 MHz, MCGOUTCLK frequency = 48 MHz

In this example, the MCG will move through the proper operational modes from FEI to PEE to achieve 48 MHz MCGOUTCLK frequency from 4 MHz external crystal reference. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, FEI must transition to FBE mode:
 - a. C2 = 0x1C
 - C2[RANGE] set to 2'b01 because the frequency of 4 MHz is within the high frequency range.
 - C2[HGO] set to 1 to configure the crystal oscillator for high gain operation.
 - C2[EREFS] set to 1, because a crystal is being used.
 - b. C1 = 0x90
 - C1[CLKS] set to 2'b10 to select external reference clock as system clock source

- C1[FRDIV] set to 3'b010, or divide-by-128 because $4 \text{ MHz} / 128 = 31.25 \text{ kHz}$ which is in the 31.25 kHz to 39.0625 kHz range required by the FLL
 - C1[IREFS] cleared to 0, selecting the external reference clock and enabling the external oscillator.
- c. Loop until S[OSCINIT] is 1, indicating the crystal selected by C2[EREFS] has been initialized.
 - d. Loop until S[IREFST] is 0, indicating the external reference is the current source for the reference clock.
 - e. Loop until S[CLKST] is 2'b10, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then configure C5[PRDIV] to generate correct PLL reference frequency.
 - a. C5 = 0x01
 - C5[PRDIV] set to 5'b001, or divide-by-2 resulting in a pll reference frequency of $4 \text{ MHz} / 2 = 2 \text{ MHz}$.
 3. Then, FBE must transition either directly to PBE mode or first through BLPE mode and then to PBE mode:
 - a. BLPE: If a transition through BLPE mode is desired, first set C2[LP] to 1.
 - b. BLPE/PBE: C6 = 0x40
 - C6[PLLS] set to 1, selects the PLL. At this time, with a C1[PRDIV] value of 2'b001, the PLL reference divider is 2 (see PLL External Reference Divide Factor table), resulting in a reference frequency of $4 \text{ MHz} / 2 = 2 \text{ MHz}$. In BLPE mode, changing the C6[PLLS] bit only prepares the MCG for PLL usage in PBE mode.
 - C6[VDIV] set to 5'b0000, or multiply-by-24 because $2 \text{ MHz reference} * 24 = 48 \text{ MHz}$. In BLPE mode, the configuration of the VDIV bits does not matter because the PLL is disabled. Changing them only sets up the multiply value for PLL usage in PBE mode.
 - c. BLPE: If transitioning through BLPE mode, clear C2[LP] to 0 here to switch to PBE mode.
 - d. PBE: Loop until S[PLLST] is set, indicating that the current source for the PLLS clock is the PLL.
 - e. PBE: Then loop until S[LOCK] is set, indicating that the PLL has acquired lock.
 4. Lastly, PBE mode transitions into PEE mode:

- a. $C1 = 0x10$
 - $C1[CLKS]$ set to $2'b00$ to select the output of the PLL as the system clock source.
- b. Loop until $S[CLKST]$ are $2'b11$, indicating that the PLL output is selected to feed $MCGOUTCLK$ in the current clock mode.
 - Now, with $PRDIV$ of divide-by-2, and $C6[VDIV]$ of multiply-by-24,
 $MCGOUTCLK = [(4 \text{ MHz} / 2) * 24] = 48 \text{ MHz}$.

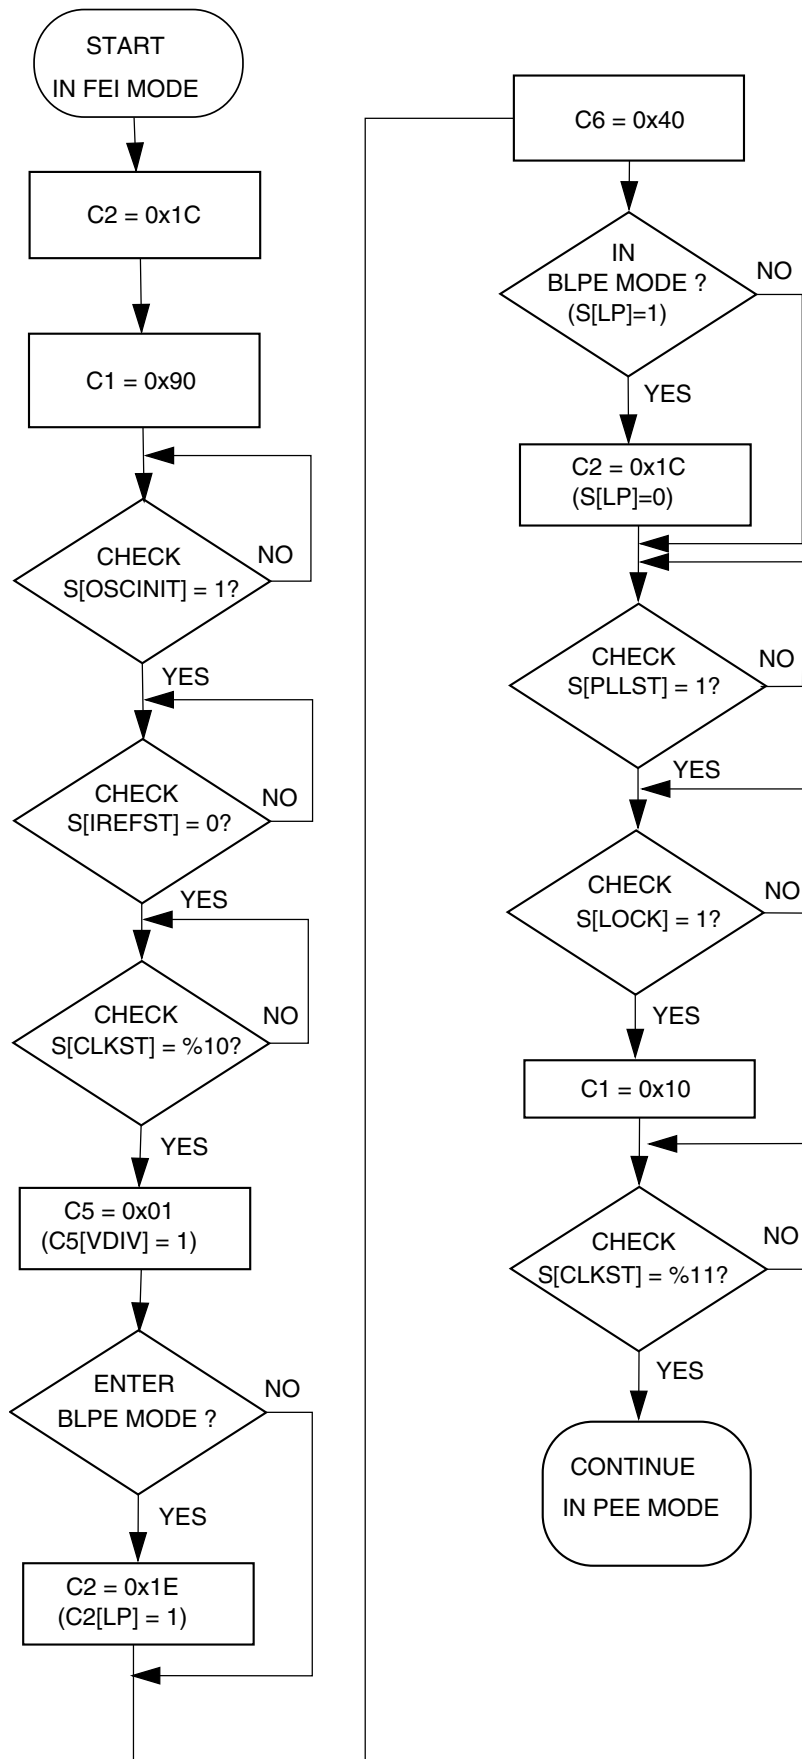

Figure 22-13. Flowchart of FEI to PEE mode transition using an 4 MHz crystal
MCF51QU128 Reference Manual, Rev. 3, 08/2012

22.5.3.2 Example 2: Moving from PEE to BLPI mode: MCGOUTCLK frequency =32 kHz

In this example, the MCG will move through the proper operational modes from PEE mode with a 4 MHz crystal configured for a 48 MHz MCGOUTCLK frequency (see previous example) to BLPI mode with a 32 kHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, PEE must transition to PBE mode:
 - a. $C1 = 0x90$
 - $C1[CLKS]$ set to $2'b10$ to switch the system clock source to the external reference clock.
 - b. Loop until $S[CLKST]$ are $2'b10$, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then, PBE must transition either directly to FBE mode or first through BLPE mode and then to FBE mode:
 - a. BLPE: If a transition through BLPE mode is desired, first set $C2[LP]$ to 1.
 - b. BLPE/FBE: $C6 = 0x00$
 - $C6[PLLS]$ clear to 0 to select the FLL. At this time, with $C1[FRDIV]$ value of $3'b010$, the FLL divider is set to 128, resulting in a reference frequency of $4\text{ MHz} / 128 = 31.25\text{ kHz}$. If $C1[FRDIV]$ was not previously set to $3'b010$ (necessary to achieve required 31.25–39.06 kHz FLL reference frequency with an 4 MHz external source frequency), it must be changed prior to clearing $C6[PLLS]$ bit. In BLPE mode, changing this bit only prepares the MCG for FLL usage in FBE mode. With $C6[PLLS] = 0$, the $C6[VDIV]$ value does not matter.
 - c. BLPE: If transitioning through BLPE mode, clear $C2[LP]$ to 0 here to switch to FBE mode.
 - d. FBE: Loop until $S[PLLST]$ is cleared, indicating that the current source for the PLLS clock is the FLL.
3. Next, FBE mode transitions into FBI mode:
 - a. $C1 = 0x54$
 - $C1[CLKS]$ set to $2'b01$ to switch the system clock to the internal reference clock.

- C1[IREFS] set to 1 to select the internal reference clock as the reference clock source.
 - C1[FRDIV] remain unchanged because the reference divider does not affect the internal reference.
- b. Loop until S[IREFST] is 1, indicating the internal reference clock has been selected as the reference clock source.
- c. Loop until S[CLKST] are 2'b01, indicating that the internal reference clock is selected to feed MCGOUTCLK.
4. Lastly, FBI transitions into BLPI mode.
- a. C2 = 0x02
- C2[LP] is 1
 - C2[RANGE], C2[HGO], C2[EREFS], C1[IRCLKEN], and C1[IREFSTEN] bits are ignored when the C1[IREFS] bit is set. They can remain set, or be cleared at this point.

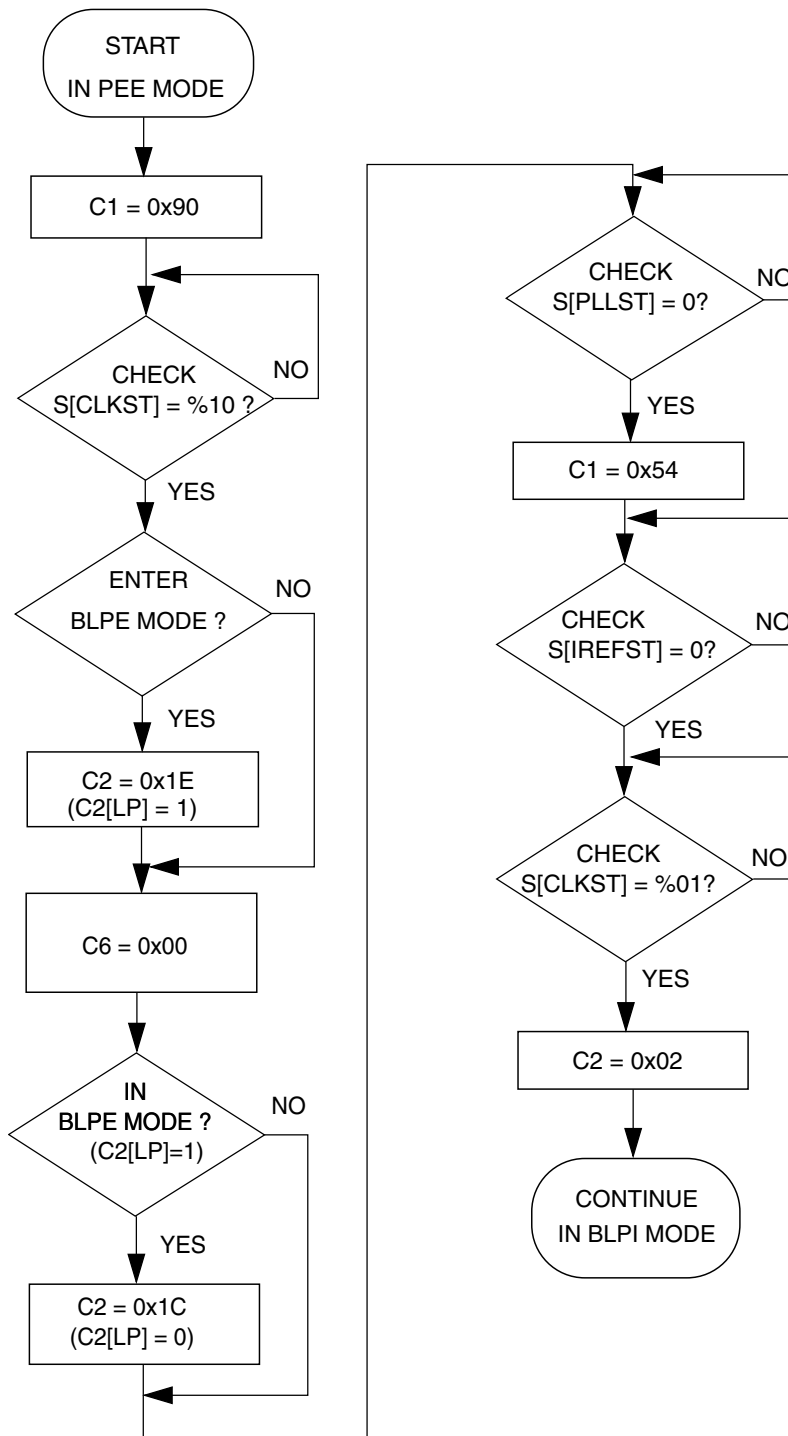

Figure 22-14. Flowchart of PEE to BLPI mode transition using an 4 MHz crystal

22.5.3.3 Example 3: Moving from BLPI to FEE mode

In this example, the MCG will move through the proper operational modes from BLPI mode at a 32 kHz MCGOUTCLK frequency running off the internal reference clock (see previous example) to FEE mode using a 4 MHz crystal configured for a 20 MHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, BLPI must transition to FBI mode.
 - a. $C2 = 0x00$
 - $C2[LP]$ is 0
2. Next, FBI will transition to FEE mode.
 - a. $C2 = 0x1C$
 - $C2[RANGE]$ set to 2'b01 because the frequency of 4 MHz is within the high frequency range.
 - $C2[HGO]$ set to 1 to configure the crystal oscillator for high gain operation.
 - $C2[EREFS]$ set to 1, because a crystal is being used.
 - b. $C1 = 0x10$
 - $C1[CLKS]$ set to 2'b00 to select the output of the FLL as system clock source.
 - $C1[FRDIV]$ remain at 3'b010, or divide-by-128 for a reference of 4 MHz / 128 = 31.25 kHz.
 - $C1[IREFS]$ cleared to 0, selecting the external reference clock.
 - c. Loop until $S[OSCINIT]$ is 1, indicating the crystal selected by the $C2[EREFS]$ bit has been initialized.
 - d. Loop until $S[IREFST]$ is 0, indicating the external reference clock is the current source for the reference clock.
 - e. Loop until $S[CLKST]$ are 2'b00, indicating that the output of the FLL is selected to feed MCGOUTCLK.
 - f. Now, with a 31.25 kHz reference frequency, a fixed DCO multiplier of 640, $MCGOUTCLK = 31.25 \text{ kHz} * 640 / 1 = 20 \text{ MHz}$.
 - g. At this point, by default, the $C4[DRST_DRS]$ bits are set to 2'b00 and $C4[DMX32]$ is cleared to 0. If the MCGOUTCLK frequency of 40 MHz is desired instead, set the $C4[DRST_DRS]$ bits to 0x01 to switch the FLL

multiplication factor from 640 to 1280. To return the MCGOUTCLK frequency to 20 MHz, set C4[DRST_DRS] bits to 2'b00 again, and the FLL multiplication factor will switch back to 640.

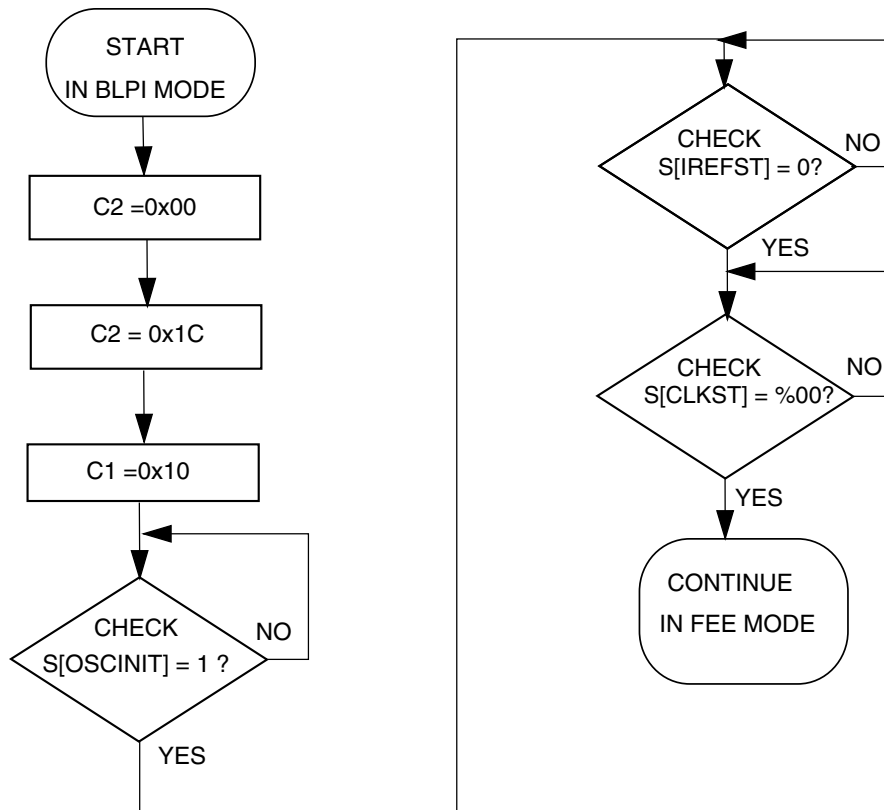

Figure 22-15. Flowchart of BLPI to FEE mode transition using a 4 MHz crystal

Chapter 23

Oscillator (OSC)

23.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The OSC module is a crystal oscillator. The module, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.

23.2 Features and Modes

Key features of the module are:

- Supports 32 kHz crystals (Low Range mode)
- Supports 1–8 MHz, crystals and resonators (High Range mode)
- Automatic Gain Control (AGC) to optimize power consumption in high frequency ranges 1–8 MHz, using low-power mode
- High gain option in frequency ranges: 32 kHz, 1–8 MHz,
- Voltage and frequency filtering to guarantee clock frequency and stability
- Optionally external input bypass clock from EXTAL signal directly
- One clock for MCU clock system
- Two clocks for on-chip peripherals that can work in Stop modes

[Functional Description](#) describes the module's operation in more detail.

23.3 Block Diagram

The OSC module uses a crystal or resonator to generate three filtered oscillator clock signals. Three clocks are output from OSC module: OSCCLK for MCU system, OSCERCLK for on-chip peripherals, and OSC32KCLK. The OSCCLK can only work in run mode. OSCERCLK and OSC32KCLK can work in low power modes. For the clock source assignments, refer to the clock distribution information of this MCU.

Refer to the chip configuration chapter for the external reference clock source in this MCU.

The following figure shows the block diagram of the OSC module.

Figure 23-1. OSC Module Block Diagram

23.4 OSC Signal Descriptions

The following table shows the user-accessible signals available for the OSC module. Refer to signal multiplexing information for this MCU for more details.

Table 23-1. OSC Signal Descriptions

Signal	Description	I/O
EXTAL	External clock/Oscillator input	I
XTAL	Oscillator output	O

23.5 External Crystal / Resonator Connections

The connections for a crystal/resonator frequency reference are shown in the following figures. When using low-frequency, low-power mode, the only external component is the crystal or ceramic resonator itself. In the other oscillator modes, load capacitors (C_x , C_y) and feedback resistor (R_F) are required. In addition, a series resistor (R_S) may be used in high-gain modes. The following table shows all possible connections.

Table 23-2. External Crystal/Resonator Connections

Oscillator Mode	Connections
Low-frequency (32 kHz), low-power	Connection 1
Low-frequency (32 kHz), high-gain	Connection 2/Connection 4 ¹ / Connection 3 ²
High-frequency (1~32 MHz), low-power	Connection 1/Connection 3 ^{2,3}
High-frequency (1~32 MHz), high-gain	Connection 2/Connection 4 ¹ / Connection 3 ²

1. When the frequency of the crystal is 32 kHz and the load capacitors (C_x , C_y) are less than 16 pF, use Connection 4.
2. When the load capacitors (C_x , C_y) are greater than 30 pF, use Connection 3.
3. With the low-power mode, the oscillator has the internal feedback resistor R_F . Therefore, the feedback resistor must not be externally with the Connection 3.

Figure 23-2. Crystal/Ceramic Resonator Connections - Connection 1

Figure 23-3. Crystal/Ceramic Resonator Connections - Connection 2

NOTE

Connection 1 and Connection 2 should use internal capacitors as the load of the oscillator by configuring the CR[SCxP] bits.

Figure 23-4. Crystal/Ceramic Resonator Connections - Connection 3

Figure 23-5. Crystal/Ceramic Resonator Connections - Connection 4

23.6 External Clock Connections

In external clock mode, the pins can be connected as shown below.

NOTE

XTAL can be used as a GPIO when the GPIO alternate function is configured for it.

Figure 23-6. External Clock Connections

23.7 Memory Map/Register Definitions

Some oscillator module register bits are typically incorporated into other peripherals such as MCG or SIM.

23.7.1 OSC Memory Map/Register Definition

OSC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8120	OSC Control Register (OSC1_CR)	8	R/W	00h	23.71.1/460

23.8 Functional Description

The following sections provide functional details of the module.

23.8.1 OSC Module States

The states of the OSC module are shown in the following figure. The states and their transitions between each other are described in this section.

Figure 23-13. OSC Module State Diagram

NOTE

XTL_CLK is the clock generated internally from OSC circuits.

23.8.1.1 Off

The OSC enters the Off state when the system does not require OSC clocks. Upon entering this state, XTL_CLK is static unless OSC is configured to select the clock from the EXTAL pad by clearing the external reference clock selection bit. For details regarding the external reference clock source in this MCU, refer to the chip configuration chapter. The EXTAL and XTAL pins are also decoupled from all other oscillator circuitry in this state. The OSC module circuitry is configured to draw minimal current.

23.8.1.2 Oscillator Start-Up

The OSC enters start-up state when it is configured to generate clocks (internally the OSC_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit. In this state, the OSC module is enabled and oscillations are starting up, but have not yet stabilized. When the oscillation amplitude becomes large enough to pass through the input buffer, XTL_CLK begins clocking the counter. When the counter reaches 4096 cycles of XTL_CLK, the oscillator is considered stable and XTL_CLK is passed to the output clock OSC_CLK_OUT.

23.8.1.3 Oscillator Stable

The OSC enters stable state when it is configured to generate clocks (internally the OSC_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit and the counter reaches 4096 cycles of XTL_CLK (when CNT_DONE_4096 is high). In this state, the OSC module is producing a stable output clock on OSC_CLK_OUT. Its frequency is determined by the external components being used.

23.8.1.4 External Clock Mode

The OSC enters external clock state when it is enabled and external reference clock selection bit is cleared. For details regarding external reference clock source in this MCU, refer to the chip configuration chapter. In this state, the OSC module is set to buffer (with hysteresis) a clock from EXTAL onto the OSC_CLK_OUT. Its frequency is determined by the external clock being supplied.

23.8.2 OSC Module Modes

The OSC is a Pierce-type oscillator that supports external crystals or resonators operating over the frequency ranges shown in [Table 23-12](#). These modes assume the following conditions: OSC is enabled to generate clocks (OSC_EN=1), configured to generate clocks internally (MCG_C2[EREFS] = 1), and some or one of the other peripherals (MCG, Timer, and so on) is configured to use the oscillator output clock (OSC_CLK_OUT).

Table 23-12. Oscillator Modes

Mode	Frequency Range
Low-frequency, high-gain	f_{osc_lo} (1 kHz) up to f_{osc_lo} (32.768 kHz)
Low-frequency, low-power (VLP)	
High-frequency mode1, high-gain	$f_{osc_hi_1}$ (1 MHz) up to $f_{osc_hi_1}$ (8 MHz)
High-frequency mode1, low-power	
High-frequency mode2, high-gain	$f_{osc_hi_2}$ (8 MHz) up to $f_{osc_hi_2}$ (32 MHz)
High-frequency mode2, low-power	

NOTE

For information about low power modes of operation used in this chip and their alignment with some OSC modes, refer to the chip's Power Management details.

23.8.2.1 Low-Frequency, High-Gain Mode

In Low-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes.

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

23.8.2.2 Low-Frequency, Low-Power Mode

In low-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

In this mode, the amplifier inputs, gain-control input, and input buffer input are all capacitively coupled for leakage tolerance (not sensitive to the DC level of EXTAL).

Also in this mode, all external components except for the resonator itself are integrated, which includes the load capacitors and feedback resistor that biases EXTAL.

23.8.2.3 High-Frequency, High-Gain Mode

In high-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

23.8.2.4 High-Frequency, Low-Power Mode

In high-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

The oscillator input buffer in this mode is differential. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

23.8.3 Counter

The oscillator output clock (OSC_CLK_OUT) is gated off until the counter has detected 4096 cycles of its input clock (XTL_CLK). After 4096 cycles are completed, the counter passes XTL_CLK onto OSC_CLK_OUT. This counting time-out is used to guarantee output clock stability.

23.8.4 Reference Clock Pin Requirements

The OSC module requires use of both the EXTAL and XTAL pins to generate an output clock in Oscillator mode, but requires only the EXTAL pin in External clock mode. The EXTAL and XTAL pins are available for I/O. For the implementation of these pins on this device, refer to the Signal Multiplexing chapter.

23.9 Reset

There is no reset state associated with the OSC module. The counter logic is reset when the OSC is not configured to generate clocks.

There are no sources of reset requests for the OSC module.

23.10 Low Power Modes Operation

When the MCU enters Stop modes, the OSC is functional depending on ERCLKEN and EREFSETN bit settings. If both these bits are set, the OSC is in operation. In Low Leakage Stop (LLS) modes, the OSC holds all register settings. If ERCLKEN and EREFSTEN bits are set before entry to Low Leakage Stop modes, the OSC is still functional in these modes. After waking up from Very Low Leakage Stop (VLLSx) modes, all OSC register bits are reset and initialization is required through software.

23.11 Interrupts

The OSC module does not generate any interrupts.

Chapter 24

Flash Memory Controller (FMC)

24.1 Introduction

The Flash Memory Controller (FMC) is a memory acceleration unit that provides:

- an interface between the chip and the 32-bit program flash memory and FlexMemory (FlexNVM and FlexRAM used as EEPROM).
- a buffer and a cache that can accelerate program flash memory data transfers.

24.1.1 Overview

The Flash Memory Controller manages the interface between the chip and the 32-bit program flash memory and FlexMemory (FlexNVM as well as FlexRAM used as EEPROM). The FMC receives status information detailing the configuration of the flash memory and FlexMemory and uses this information to ensure a proper interface. The FMC supports 8-bit, 16-bit, and 32-bit read operations from the program flash memory and FlexNVM used as data flash memory. A write operation to program flash or FlexNVM used as data flash memory results in a bus error. The FMC interface to FlexNVM and FlexRAM when they are used as EEPROM allows both read and write 8-bit, 16-bit, and 32-bit operations.

In addition, for program flash memory, the FMC provides two separate mechanisms for accelerating the interface between the device and the flash. A 32-bit speculation buffer can prefetch the next 32-bit flash memory location, and a 4-way, 4-set program flash memory cache can store previously accessed program flash memory data for quick access times.

24.1.2 Features

The FMC's features include:

- Interface between the device and the 32-bit program flash memory and FlexMemory:
 - 8-bit, 16-bit, and 32-bit read operations to nonvolatile memory (flash and FlexNVM used as data flash memory).
 - 8-bit, 16-bit, and 32-bit read and write operations to the FlexNVM and FlexRAM used as EEPROM.
 - Consecutive read accesses (such as 0x0,0x4) to program flash memory return the second read data with no wait states when the buffer or cache is enabled. The memory returns 32 bits via the 32-bit bus access.
- Acceleration of data transfer from the program flash memory to the device:
 - 32-bit prefetch speculation buffer for program flash accesses for crossbar switch master 0 (V1 ColdFire CPU) with controls for instruction/data access
 - 4-way, 4-set, 32-bit line size program flash memory cache for a total of sixteen 32-bit entries with invalidation control

24.2 Modes of operation

The FMC operates only when the chip accesses the program flash memory or FlexMemory. In terms of chip power modes:

- The FMC operates only in run and wait modes, including VLPR and VLPW modes.
- For any power mode where the program flash memory or FlexMemory cannot be accessed, the FMC is disabled.

24.3 External signal description

The FMC has no external (off-chip) signals.

24.4 Memory map and register descriptions

The ColdFire CPU's programming model provides control and configuration of the flash controller's speculation and cache functions with bits in the CPU Control Register (CPUCR). For details, see the description of the [CPUCR register](#).

NOTE

Program the Flash Memory Controller's configuration and control settings only while the Flash Memory Controller is idle. Changing settings while a flash access is in progress can lead to non-deterministic behavior.

NOTE

System software is required to maintain memory coherence when any segment of the program flash memory cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

24.5 Functional description

The FMC is a flash acceleration unit with flexible buffers for user configuration. Besides managing the interface between the chip and the program flash memory and FlexMemory, the FMC can be used to customize the program flash memory cache and buffer to provide single-cycle system clock data access times. Whenever a hit occurs for the prefetch speculation buffer or the cache (when enabled), the requested data is transferred within a single system clock. (The basic flash access time is two processor cycles.)

Upon system reset, the FMC is configured to provide buffering for transfers from the program flash memory. Prefetch support for data and instructions is enabled for program flash accesses for crossbar switch master 0 (V1 ColdFire CPU). The program flash memory cache is enabled and configured for instruction replacement.

Though the default configuration provides flash acceleration, advanced users may desire to customize the FMC buffer configurations to maximize throughput for their use cases. For example, the controls enable buffering per access type (data or instruction). When reconfiguring the FMC, do not program the control and configuration inputs to the FMC while the program flash memory or FlexMemory is being accessed. Instead, change them with a routine executing from RAM in supervisor mode.

Chapter 25

Flash Memory Module (FTFL)

25.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The flash memory module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- FlexNVM for data store and additional code store
- FlexRAM for high-endurance data store or traditional RAM

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The flash memory module includes a memory controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased with security disabled. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0')

states. Therefore, it is recommended that each flash block or sector be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

25.1.1 Features

The flash memory module includes the following features.

NOTE

See the device's Chip Configuration details for the exact amount of flash memory available on your device.

25.1.1.1 Program Flash Memory Features

- Sector size of 1 Kbyte
- Program flash protection scheme prevents accidental program or erase of stored data
- Automated, built-in, program and erase algorithms with verify
- Section programming for faster bulk programming times
- Read access to program flash memory possible while programming or erasing data in the data flash memory or FlexRAM

25.1.1.2 FlexNVM Memory Features

When FlexNVM is partitioned for data flash memory:

- Sector size of 1 Kbyte
- Protection scheme prevents accidental program or erase of stored data
- Automated, built-in program and erase algorithms with verify
- Section programming for faster bulk programming times
- Read access to data flash memory possible while programming or erasing data in the program flash memory

25.1.1.3 FlexRAM Features

- Memory that can be used as traditional RAM or as high-endurance EEPROM storage
- Up to 2 Kbytes of FlexRAM configured for EEPROM or traditional RAM operations
- When configured for EEPROM:
 - Protection scheme prevents accidental program or erase of data written for EEPROM
 - Built-in hardware emulation scheme to automate EEPROM record maintenance functions
 - Programmable EEPROM data set size and FlexNVM partition code facilitating EEPROM memory endurance trade-offs
 - Supports FlexRAM aligned writes of 1, 2, or 4 bytes at a time
 - Read access to FlexRAM possible while programming or erasing data in the program or data flash memory
- When configured for traditional RAM:
 - Read and write access possible to the FlexRAM while programming or erasing data in the program or data flash memory

25.1.1.4 Other Flash Memory Module Features

- Internal high-voltage supply generator for flash memory program and erase operations
- Optional interrupt generation upon flash command completion
- Supports MCU security mechanisms which prevent unauthorized access to the flash memory contents

25.1.2 Block Diagram

The block diagram of the flash memory module is shown in the following figure.

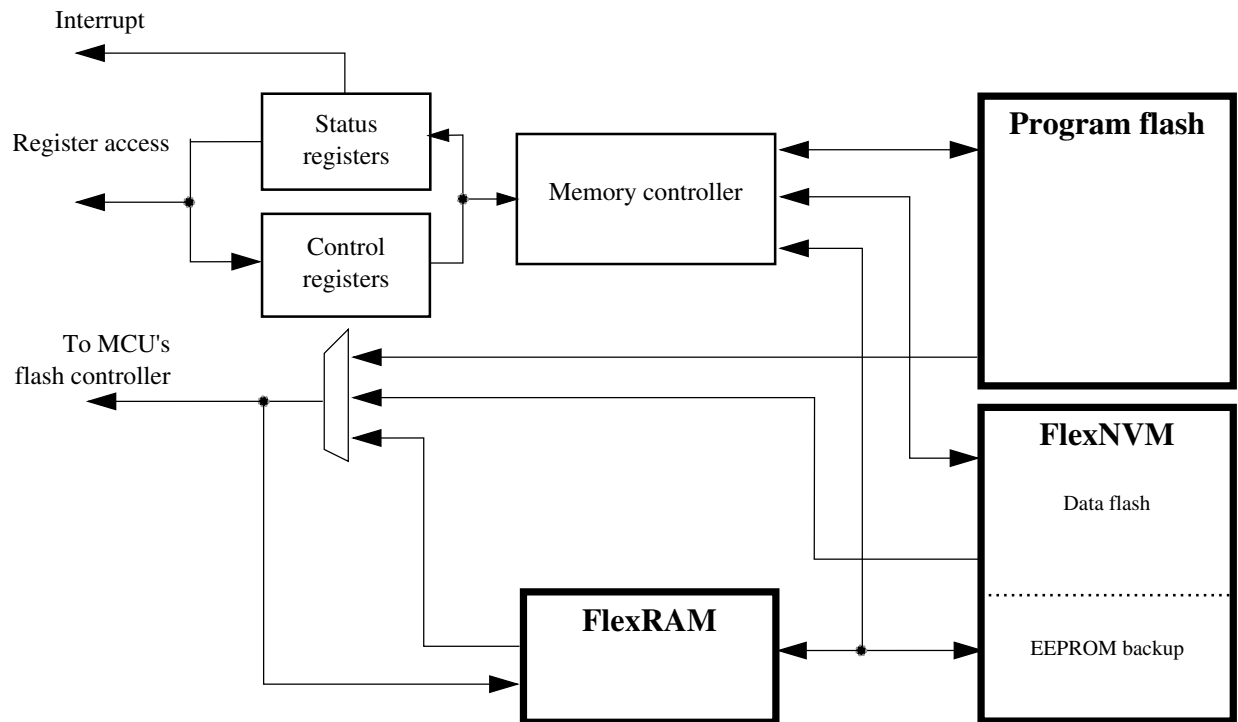

Figure 25-1. Flash Block Diagram

25.1.3 Glossary

Command write sequence — A series of MCU writes to the flash FCCOB register group that initiates and controls the execution of flash algorithms that are built into the flash memory module.

Data flash memory — Partitioned from the FlexNVM block, the data flash memory provides nonvolatile storage for user data, boot code, and additional code store.

Data flash sector — The data flash sector is the smallest portion of the data flash memory that can be erased.

EEPROM — Using a built-in filing system, the flash memory module emulates the characteristics of an EEPROM by effectively providing a high-endurance, byte-writeable (program and erase) NVM.

EEPROM backup data header — The EEPROM backup data header is comprised of a 32-bit field found in EEPROM backup data memory which contains information used by the EEPROM filing system to determine the status of a specific EEPROM backup flash sector.

EEPROM backup data record — The EEPROM backup data record is comprised of a 2-bit status field, a 14-bit address field, and a 16-bit data field found in EEPROM backup data memory which is used by the EEPROM filing system. If the status field indicates a record is valid, the data field is mirrored in the FlexRAM at a location determined by the address field.

EEPROM backup data memory — Partitioned from the FlexNVM block, EEPROM backup data memory provides nonvolatile storage for the EEPROM filing system representing data written to the FlexRAM requiring highest endurance.

EEPROM backup data sector — The EEPROM backup data sector contains one EEPROM backup data header and up to 255 EEPROM backup data records, which are used by the EEPROM filing system.

Endurance — The number of times that a flash memory location can be erased and reprogrammed.

FCCOB (Flash Common Command Object) — A group of flash registers that are used to pass command, address, data, and any associated parameters to the memory controller in the flash memory module.

Flash block — A macro within the flash memory module which provides the nonvolatile memory storage.

FlexMemory — Flash configuration that supports data flash, EEPROM, and FlexRAM.

FlexNVM Block — The FlexNVM block can be configured to be used as data flash memory, EEPROM backup flash memory, or a combination of both.

FlexRAM — The FlexRAM refers to a RAM, dedicated to the flash memory module, that can be configured to store EEPROM data or as traditional RAM. When configured for EEPROM, valid writes to the FlexRAM generate new EEPROM backup data records stored in the EEPROM backup flash memory.

Flash Memory Module — All flash blocks plus a flash management unit providing high-level control and an interface to MCU buses.

IFR — Nonvolatile information register found in each flash block, separate from the main memory array.

NVM — Nonvolatile memory. A memory technology that maintains stored data during power-off. The flash array is an NVM using NOR-type flash memory technology.

NVM Normal Mode — An NVM mode that provides basic user access to flash memory module resources. The CPU or other bus masters initiate flash program and erase operations (or other flash commands) using writes to the FCCOB register group in the flash memory module.

NVM Special Mode — An NVM mode enabling external, off-chip access to the memory resources in the flash memory module. A reduced flash command set is available when the MCU is secured. See the Chip Configuration details for information on when this mode is used.

Phrase — 64 bits of data with an aligned phrase having byte-address[2:0] = 000.

Longword — 32 bits of data with an aligned longword having byte-address[1:0] = 00.

Word — 16 bits of data with an aligned word having byte-address[0] = 0.

Program flash — The program flash memory provides nonvolatile storage for vectors and code store.

Program flash Sector — The smallest portion of the program flash memory (consecutive addresses) that can be erased.

Retention — The length of time that data can be kept in the NVM without experiencing errors upon readout. Since erased (1) states are subject to degradation just like programmed (0) states, the data retention limit may be reached from the last erase operation (not from the programming time).

RWW— Read-While-Write. The ability to simultaneously read from one memory resource while commanded operations are active in another memory resource.

Section Program Buffer — Lower half of the FlexRAM allocated for storing large amounts of data for programming via the Program Section command.

Secure — An MCU state conveyed to the flash memory module as described in the Chip Configuration details for this device. In the secure state, reading and changing NVM contents is restricted.

25.2 External Signal Description

The flash memory module contains no signals that connect off-chip.

25.3 Memory Map and Registers

This section describes the memory map and registers for the flash memory module. Data read from unimplemented memory space in the flash memory module is undefined. Writes to unimplemented or reserved memory space (registers) in the flash memory module are ignored.

25.3.1 Flash Configuration Field Description

The program flash memory contains a 16-byte flash configuration field that stores default protection settings (loaded on reset) and security information that allows the MCU to restrict access to the flash memory module.

Flash Configuration Field Byte Address	Size (Bytes)	Field Description
0x0_0400 - 0x0_0407	8	Backdoor Comparison Key. Refer to Verify Backdoor Access Key Command and Unsecuring the Chip Using Backdoor Key Access .
0x0_0408 - 0x0_040B	4	Program flash protection bytes. Refer to the description of the Program Flash Protection Registers (FPROT0-3).
0x0_040C	1	Data flash protection byte. Refer to the description of the Data Flash Protection Register (FDPROT).
0x0_040D	1	EEPROM protection byte. Refer to the description of the EEPROM Protection Register (FEPROT).
0x0_040E	1	Flash nonvolatile option byte. Refer to the description of the Flash Option Register (FOPT).
0x0_040F	1	Flash security byte. Refer to the description of the Flash Security Register (FSEC).

25.3.2 Program Flash IFR Map

The program flash IFR is nonvolatile information memory that can be read freely, but the user has no erase and limited program capabilities (see the Read Once, Program Once, and Read Resource commands in [Read Once Command](#), [Program Once Command](#) and [Read Resource Command](#)). The contents of the program flash IFR are summarized in the following table and further described in the subsequent paragraphs.

Address Range	Size (Bytes)	Field Description
0x00 – 0xBF	192	Reserved
0xC0 – 0xFF	64	Program Once Field

25.3.2.1 Program Once Field

The Program Once Field in the program flash IFR provides 64 bytes of user data storage separate from the program flash main array. The user can program the Program Once Field one time only as there is no program flash IFR erase mechanism available to the user. The Program Once Field can be read any number of times. This section of the program flash IFR is accessed in 4-Byte records using the Read Once and Program Once commands (see [Read Once Command](#) and [Program Once Command](#)).

25.3.3 Data Flash IFR Map

The data flash IFR is a 256 byte nonvolatile information memory that can be read and erased, but the user has limited program capabilities in the data flash IFR (see the Program Partition command in [Program Partition Command](#), the Erase All Blocks command in [Erase All Blocks Command](#), and the Read Resource command in [Read Resource Command](#)). The contents of the data flash IFR are summarized in the following table and further described in the subsequent paragraphs.

Address Range	Size (Bytes)	Field Description
0x00 – 0xFD	254	Reserved
0xFE	1	EEPROM data set size
0xFF	1	FlexNVM partition code

25.3.3.1 EEPROM Data Set Size

The EEPROM data set size byte in the data flash IFR supplies information which determines the amount of FlexRAM used in each of the available EEPROM subsystems. To program the EEESIZE value, see the Program Partition command described in [Program Partition Command](#).

Table 25-1. EEPROM Data Set Size

Data flash IFR: 0x00FE						
7	6	5	4	3	2	1 0
1	1	1	1	EEESIZE		
= Unimplemented or Reserved						

Table 25-2. EEPROM Data Set Size Field Description

Field	Description
7-4 Reserved	This read-only bitfield is reserved and must always be written as one.
3-0 EEESIZE	<p>EEPROM Size — Encoding of the total available FlexRAM for EEPROM use.</p> <p>NOTE: EEESIZE must be 0 bytes (1111b) when the FlexNVM partition code (FlexNVM Partition Code) is set to 'No EEPROM'.</p> <p>'0000' = Reserved '0001' = Reserved '0010' = Reserved '0011' = 2,048 Bytes '0100' = 1,024 Bytes '0101' = 512 Bytes '0110' = 256 Bytes '0111' = 128 Bytes '1000' = 64 Bytes '1001' = 32 Bytes '1010' = Reserved '1011' = Reserved '1100' = Reserved '1101' = Reserved '1110' = Reserved '1111' = 0 Bytes</p>

25.3.3.2 FlexNVM Partition Code

The FlexNVM Partition Code byte in the data flash IFR supplies a code which specifies how to split the FlexNVM block between data flash memory and EEPROM backup memory supporting EEPROM functions. To program the DEPART value, see the Program Partition command described in [Program Partition Command](#).

Table 25-3. FlexNVM Partition Code

Data Flash IFR: 0x00FF							
7	6	5	4	3	2	1	0
1	1	1	1	DEPART			
= Unimplemented or Reserved							

Table 25-4. FlexNVM Partition Code Field Description

Field	Description
7-4 Reserved	This read-only bitfield is reserved and must always be written as one.
3-0 DEPART	<p>FlexNVM Partition Code — Encoding of the data flash / EEPROM backup split within the FlexNVM memory block. FlexNVM memory not partitioned for data flash will be used to store EEPROM records.</p> <p>0000 = 32 Kbytes of data flash, No EEPROM backup (No EEPROM) 0001 = 24 Kbytes of data flash, 8 Kbytes of EEPROM backup 0010 = 16 Kbytes of data flash, 16 Kbytes of EEPROM backup 0011 = No data flash, 32 Kbytes of EEPROM backup 0100 = Reserved 0101 = Reserved 0110 = Reserved 0111 = Reserved 1000 = No data flash, 32 Kbytes of EEPROM backup 1001 = 8 Kbytes of data flash, 24 Kbytes of EEPROM backup 1010 = 16 Kbytes of data flash, 16 Kbytes of EEPROM backup 1011 = 32 Kbytes of data flash, No EEPROM backup (No EEPROM) 1100 = Reserved 1101 = Reserved 1110 = Reserved 1111 = Reserved (defaults to 32 Kbytes of data flash, No EEPROM)</p>

25.3.4 Register Descriptions

The flash memory module contains a set of memory-mapped control and status registers.

NOTE

While a command is running (FSTAT[CCIF]=0), register writes are not accepted to any register except FCNFG and FSTAT. The no-write rule is relaxed during the start-up reset sequence, prior to the initial rise of CCIF. During this initialization period the user may write any register. All register writes are also disabled (except for registers FCNFG and FSTAT) whenever an erase suspend request is active (FCNFG[ERSSUSP]=1).

FTFL memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_84E0	Flash Option Register (FTFL_FOPT)	8	R	Undefined	25.34.1/483

25.34.1 Flash Option Register (FTFL_FOPT)

The flash option register allows the MCU to customize its operations by examining the state of these read-only bits, which are loaded from NVM at reset. The function of the bits is defined in the device's Chip Configuration details.

All bits in the register are read-only .

Memory Map and Registers

During the reset sequence, the register is loaded from the flash nonvolatile option byte in the Flash Configuration Field located in program flash memory. The flash basis for the values is signified by X in the reset value.

Address: FFFF_84E0h base + 0h offset = FFFF_84E0h

Bit	7	6	5	4	3	2	1	0
Read	OPT							
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

FTFL_FOPT field descriptions

Field	Description
7-0 OPT	Nonvolatile Option These bits are loaded from flash to this register at reset. Refer to the device's Chip Configuration details for the definition and use of these bits.

25.34.2 Flash Security Register (FTFL_FSEC)

This read-only register holds all bits associated with the security of the MCU and flash memory module.

During the reset sequence, the register is loaded with the contents of the flash security byte in the Flash Configuration Field located in program flash memory. The flash basis for the values is signified by X in the reset value.

Address: FFFF_84E0h base + 1h offset = FFFF_84E1h

Bit	7	6	5	4	3	2	1	0
Read	KEYEN		MEEN		FSLACC		SEC	
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:

- x = Undefined at reset.

FTFL_FSEC field descriptions

Field	Description
7-6 KEYEN	Backdoor Key Security Enable These bits enable and disable backdoor key access to the flash memory module.

Table continues on the next page...

FTFL_FSEC field descriptions (continued)

Field	Description
	00 Backdoor key access disabled 01 Backdoor key access disabled (preferred KEYEN state to disable backdoor key access) 10 Backdoor key access enabled 11 Backdoor key access disabled
5–4 MEEN	Mass Erase Enable Bits Enables and disables mass erase capability of the flash memory module. The state of the MEEN bits is only relevant when the SEC bits are set to secure outside of NVM Normal Mode. When the SEC field is set to unsecure, the MEEN setting does not matter. 00 Mass erase is enabled 01 Mass erase is enabled 10 Mass erase is disabled 11 Mass erase is enabled
3–2 FSLACC	Freescale Failure Analysis Access Code These bits enable or disable access to the flash memory contents during returned part failure analysis at Freescale. When SEC is secure and FSLACC is denied, access to the program flash contents is denied and any failure analysis performed by Freescale factory test must begin with a full erase to unsecure the part. When access is granted (SEC is unsecure, or SEC is secure and FSLACC is granted), Freescale factory testing has visibility of the current flash contents. The state of the FSLACC bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the FSLACC setting does not matter. 00 Freescale factory access granted 01 Freescale factory access denied 10 Freescale factory access denied 11 Freescale factory access granted
1–0 SEC	Flash Security These bits define the security state of the MCU. In the secure state, the MCU limits access to flash memory module resources. The limitations are defined per device and are detailed in the Chip Configuration details. If the flash memory module is unsecured using backdoor key access, the SEC bits are forced to 10b. 00 MCU security status is secure 01 MCU security status is secure 10 MCU security status is unsecure (The standard shipping condition of the flash memory module is unsecure.) 11 MCU security status is secure

25.34.3 Flash Configuration Register (FTFL_FCNFG)

This register provides information on the current functional state of the flash memory module.

Memory Map and Registers

The erase control bits (ERSAREQ and ERSSUSP) have write restrictions. PFLSH, RAMRDY, and EEERDY are read-only status bits. The unassigned bits read as noted and are not writable. The reset values for the PFLASH, RAMRDY, and EEERDY bits are determined during the reset sequence.

Address: FFFF_84E0h base + 2h offset = FFFF_84E2h

Bit	7	6	5	4	3	2	1	0
Read	CCIE	RDCOLLIE	ERSAREQ	ERSSUSP	0	PFLSH	RAMRDY	EEERDY
Write								
Reset	0	0	0	0	0	0	0	0

FTFL_FCENFG field descriptions

Field	Description
7 CCIE	<p>Command Complete Interrupt Enable</p> <p>The CCIE bit controls interrupt generation when a flash command completes.</p> <p>0 Command complete interrupt disabled 1 Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set.</p>
6 RDCOLLIE	<p>Read Collision Error Interrupt Enable</p> <p>The RDCOLLIE bit controls interrupt generation when a flash memory read collision error occurs.</p> <p>0 Read collision error interrupt disabled 1 Read collision error interrupt enabled. An interrupt request is generated whenever a flash memory read collision error is detected (see the description of FSTAT[RDCOLERR]).</p>
5 ERSAREQ	<p>Erase All Request</p> <p>This bit issues a request to the memory controller to execute the Erase All Blocks command and release security. ERSAREQ is not directly writable but is under indirect user control. Refer to the device's Chip Configuration details on how to request this command.</p> <p>The ERSAREQ bit sets when an erase all request is triggered external to the flash memory module and CCIF is set (no command is currently being executed). ERSAREQ is cleared by the flash memory module when the operation completes.</p> <p>0 No request or request complete 1 Request to: <ol style="list-style-type: none"> 1. run the Erase All Blocks command, 2. verify the erased state, 3. program the security byte in the Flash Configuration Field to the unsecure state, and 4. release MCU security by setting the FSEC[SEC] field to the unsecure state. </p>
4 ERSSUSP	<p>Erase Suspend</p> <p>The ERSSUSP bit allows the user to suspend (interrupt) the Erase Flash Sector command while it is executing.</p> <p>0 No suspend requested 1 Suspend the current Erase Flash Sector command execution.</p>
3 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

Table continues on the next page...

FTFL_FCENFG field descriptions (continued)

Field	Description
2 PFLSH	Flash memory configuration 0 Flash memory module configured for FlexMemory that supports data flash and/or EEPROM. 1 Reserved.
1 RAMRDY	RAM Ready This flag indicates the current status of the FlexRAM . The state of the RAMRDY flag is normally controlled by the Set FlexRAM Function command. During the reset sequence, the RAMRDY flag is cleared if the FlexNVM block is partitioned for EEPROM and is set if the FlexNVM block is not partitioned for EEPROM. The RAMRDY flag is cleared if the Program Partition command is run to partition the FlexNVM block for EEPROM. The RAMRDY flag sets after completion of the Erase All Blocks command or execution of the erase-all operation triggered external to the flash memory module. 0 FlexRAM is not available for traditional RAM access. 1 FlexRAM is available as traditional RAM only; writes to the FlexRAM do not trigger EEPROM operations.
0 EEERDY	This flag indicates if the EEPROM backup data has been copied to the FlexRAM and is therefore available for read access. During the reset sequence, the EEERDY flag will remain cleared while CCIF is clear and will only set if the FlexNVM block is partitioned for EEPROM. 0 FlexRAM is not available for EEPROM operation. 1 FlexRAM is available for EEPROM operations where: <ul style="list-style-type: none"> reads from the FlexRAM return data previously written to the FlexRAM in EEPROM mode and writes to the FlexRAM clear EEERDY and launch an EEPROM operation to store the written data in the FlexRAM and EEPROM backup.

25.34.4 Flash Status Register (FTFL_FSTAT)

The FSTAT register reports the operational status of the flash memory module.

The CCIF, RDCOLERR, ACCERR, and FPVIOL bits are readable and writable. The MGSTAT0 bit is read only. The unassigned bits read 0 and are not writable.

NOTE

When set, the Access Error (ACCERR) and Flash Protection Violation (FPVIOL) bits in this register prevent the launch of any more commands or writes to the FlexRAM (when EEERDY is set) until the flag is cleared (by writing a one to it).

Address: FFFF_84E0h base + 3h offset = FFFF_84E3h

Bit	7	6	5	4	3	2	1	0
Read	CCIF	RDCOLERR	ACCERR	FPVIOL		0		MGSTAT0
Write	w1c	w1c	w1c	w1c				
Reset	0	0	0	0	0	0	0	0

FTFL_FSTAT field descriptions

Field	Description
7 CCIF	<p>Command Complete Interrupt Flag</p> <p>The CCIF flag indicates that a flash command or EEPROM file system operation has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command, and CCIF stays low until command completion or command violation. The CCIF flag is also cleared by a successful write to FlexRAM while enabled for EEE, and CCIF stays low until the EEPROM file system has created the associated EEPROM data record.</p> <p>The CCIF bit is reset to 0 but is set to 1 by the memory controller at the end of the reset initialization sequence. Depending on how quickly the read occurs after reset release, the user may or may not see the 0 hardware reset value.</p> <p>0 Flash command or EEPROM file system operation in progress 1 Flash command or EEPROM file system operation has completed</p>
6 RDCOLERR	<p>Flash Read Collision Error Flag</p> <p>The RDCOLERR error bit indicates that the MCU attempted a read from a flash memory resource that was being manipulated by a flash command (CCIF=0). Any simultaneous access is detected as a collision error by the block arbitration logic. The read data in this case cannot be guaranteed. The RDCOLERR bit is cleared by writing a 1 to it. Writing a 0 to RDCOLERR has no effect.</p> <p>0 No collision error detected 1 Collision error detected</p>
5 ACCERR	<p>Flash Access Error Flag</p> <p>The ACCERR error bit indicates an illegal access has occurred to a flash memory resource caused by a violation of the command write sequence or issuing an illegal flash command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to it. Writing a 0 to the ACCERR bit has no effect.</p> <p>0 No access error detected 1 Access error detected</p>
4 FPVIOL	<p>Flash Protection Violation Flag</p> <p>The FPVIOL error bit indicates an attempt was made to program or erase an address in a protected area of program flash or data flash memory during a command write sequence or a write was attempted to a protected area of the FlexRAM while enabled for EEPROM. While FPVIOL is set, the CCIF flag cannot be cleared to launch a command. The FPVIOL bit is cleared by writing a 1 to it. Writing a 0 to the FPVIOL bit has no effect.</p> <p>0 No protection violation detected 1 Protection violation detected</p>
3-1 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
0 MGSTAT0	<p>Memory Controller Command Completion Status Flag</p> <p>The MGSTAT0 status flag is set if an error is detected during execution of a flash command or during the flash reset sequence. As a status flag, this bit cannot (and need not) be cleared by the user like the other error flags in this register.</p> <p>The value of the MGSTAT0 bit for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the previous result is discarded and any previous error is cleared.</p>

25.34.5 Flash Common Command Object Registers (FTFL_FCCOBn)

The FCCOB register group provides 12 bytes for command codes and parameters. The individual bytes within the set append a 0-B hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOBB.

Address: FFFF_84E0h base + 4h offset + (1d × i), where i=0d to 11d

FTFL_FCCOBn field descriptions

Field	Description																						
7-0 CCOBn	<p>The FCCOB register provides a command code and relevant parameters to the memory controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command's execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes.</p> <p>Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1 by the memory controller.</p> <p>The following table shows a generic flash command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific flash command, typically an address and/or data values.</p> <p>NOTE: The command parameter table is written in terms of FCCOB Number (which is equivalent to the byte number). This number is a reference to the FCCOB register name and is not the register address.</p> <table border="1"> <thead> <tr> <th>FCCOB Number</th> <th>Typical Command Parameter Contents [7:0]</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>FCMD (a code that defines the flash command)</td> </tr> <tr> <td>1</td> <td>Flash address [23:16]</td> </tr> <tr> <td>2</td> <td>Flash address [15:8]</td> </tr> <tr> <td>3</td> <td>Flash address [7:0]</td> </tr> <tr> <td>4</td> <td>Data Byte 0</td> </tr> <tr> <td>5</td> <td>Data Byte 1</td> </tr> <tr> <td>6</td> <td>Data Byte 2</td> </tr> <tr> <td>7</td> <td>Data Byte 3</td> </tr> <tr> <td>8</td> <td>Data Byte 4</td> </tr> <tr> <td>9</td> <td>Data Byte 5</td> </tr> </tbody> </table>	FCCOB Number	Typical Command Parameter Contents [7:0]	0	FCMD (a code that defines the flash command)	1	Flash address [23:16]	2	Flash address [15:8]	3	Flash address [7:0]	4	Data Byte 0	5	Data Byte 1	6	Data Byte 2	7	Data Byte 3	8	Data Byte 4	9	Data Byte 5

9	Data Byte 5																						

FTFL_FCCOB n field descriptions (continued)

Field	Description	
	FCCOB Number	Typical Command Parameter Contents [7:0]
	A	Data Byte 6
	B	Data Byte 7
	FCCOB Endianness : The FCCOB register group uses a big endian addressing convention. For all command parameter fields larger than one byte, the most significant data resides in the lowest FCCOB register number.	

25.34.6 Program Flash Protection Registers (FTFL_FPROT n)

The FPROT registers define which logical program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any flash command. Unprotected regions can be changed by program and erase operations.

The four FPROT registers allow 32 protectable regions. Each bit protects a 1/32 region of the program flash memory . The bitfields are defined in each register as follows:

Program flash protection register	Program flash protection bits
FPROT0	PROT[31:24]
FPROT1	PROT[23:16]
FPROT2	PROT[15:8]
FPROT3	PROT[7:0]

During the reset sequence, the FPROT registers are loaded with the contents of the program flash protection bytes in the Flash Configuration Field as indicated in the following table.

Program flash protection register	Flash Configuration Field offset address
FPROT0	0x000B
FPROT1	0x000A
FPROT2	0x0009
FPROT3	0x0008

To change the program flash protection that is loaded during the reset sequence, unprotect the sector of program flash memory that contains the Flash Configuration Field. Then, reprogram the program flash protection byte.

Address: FFFF_84E0h base + 10h offset + (1d × i), where i=0d to 3d

* Notes:

- x = Undefined at reset.

FTFL_FPROTn field descriptions

Field	Description
7-0 PROT	<p>Program Flash Region Protect</p> <p>Each program flash region can be protected from program and erase operations by setting the associated PROT bit.</p> <p>In NVM Normal mode: The protection can only be increased, meaning that currently unprotected memory can be protected, but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored.</p> <p>In NVM Special mode All bits of FPROT are writable without restriction. Unprotected areas can be protected and protected areas can be unprotected.</p> <p>Restriction: The user must never write to any FPROT register while a command is running (CCIF=0). Trying to alter data in any protected area in the program flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of a program flash block is not possible if it contains any protected region.</p> <p>Each bit in the 32-bit protection register represents 1/32 of the total program flash.</p> <p>0 Program flash region is protected. 1 Program flash region is not protected</p>

25.34.7 Data Flash Protection Register (FTFL_FDPROT)

The FDPROT register defines which data flash regions are protected against program and erase operations. Protected Flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any flash command. Unprotected regions can be changed by both program and erase operations.

Address: FFFF_84E0h base + 14h offset = FFFF_84F4h

* Notes:

- x = Undefined at reset.

FTFL_FDPROT field descriptions

Field	Description
7-0 DPROT	<p>Data Flash Region Protect</p> <p>Individual data flash regions can be protected from program and erase operations by setting the associated DPROT bit. Each DPROT bit protects one-eighth of the partitioned data flash memory space. The granularity of data flash protection cannot be less than the data flash sector size. If an unused DPROT bit is set, the Erase all Blocks command does not execute and the FSTAT[FPVIOL] flag is set.</p> <p>In NVM Normal mode: The protection can only be increased, meaning that currently unprotected memory can be protected but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FDPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored.</p> <p>In NVM Special mode: All bits of the FDPROT register are writable without restriction. Unprotected areas can be protected and protected areas can be unprotected.</p> <p>Restriction: The user must never write to the FDPROT register while a command is running (CCIF=0).</p> <p>Reset: During the reset sequence, the FDPROT register is loaded with the contents of the data flash protection byte in the Flash Configuration Field located in program flash memory. The flash basis for the reset values is signified by X in the register diagram. To change the data flash protection that will be loaded during the reset sequence, unprotect the sector of program flash that contains the Flash Configuration Field. Then, erase and reprogram the data flash protection byte.</p> <p>Trying to alter data with the program and erase commands in any protected area in the data flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of the data flash memory (see the Erase Flash Block command description) is not possible if the data flash memory contains any protected region or if the FlexNVM block has been partitioned for EEPROM.</p> <p>0 Data Flash region is protected 1 Data Flash region is not protected</p>

25.34.8 EEPROM Protection Register (FTFL_FEPROT)

The FEPROT register defines which EEPROM regions of the FlexRAM are protected against program and erase operations. Protected EEPROM regions cannot have their content changed by writing to it. Unprotected regions can be changed by writing to the FlexRAM.

Address: FFFF_84E0h base + 15h offset = FFFF_84F5h

* Notes:

- x = Undefined at reset.

FTFL_FEPROT field descriptions

Field	Description
7–0 EPROT	<p>EEPROM Region Protect</p> <p>Individual EEPROM regions can be protected from alteration by setting the associated EPROT bit. The EPROT bits are not used when the FlexNVM Partition Code is set to data flash only. When the FlexNVM Partition Code is set to data flash and EEPROM or EEPROM only, each EPROT bit covers one-eighth of the configured EEPROM data (see the EEPROM Data Set Size parameter description).</p> <p>In NVM Normal mode: The protection can only be increased. This means that currently-unprotected memory can be protected, but currently-protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FEPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored.</p> <p>In NVM Special mode : All bits of the FEPROT register are writable without restriction. Unprotected areas can be protected and protected areas can be unprotected.</p> <p>Restriction: Never write to the FEPROT register while a command is running (CCIF=0).</p> <p>Reset: During the reset sequence, the FEPROT register is loaded with the contents of the FlexRAM protection byte in the Flash Configuration Field located in program flash. The flash basis for the reset values is signified by X in the register diagram. To change the EEPROM protection that will be loaded during the reset sequence, the sector of program flash that contains the Flash Configuration Field must be unprotected; then the EEPROM protection byte must be erased and reprogrammed.</p> <p>Trying to alter data by writing to any protected area in the EEPROM results in a protection violation error and sets the FPVIOL bit in the FSTAT register.</p> <p>0 EEPROM region is protected 1 EEPROM region is not protected</p>

25.4 Functional Description

The following sections describe functional details of the flash memory module.

25.4.1 Flash Protection

Individual regions within the flash memory can be protected from program and erase operations. Protection is controlled by the following registers:

- $FPROT_n$ — Four registers that protect 32 regions of the program flash memory as shown in the following figure

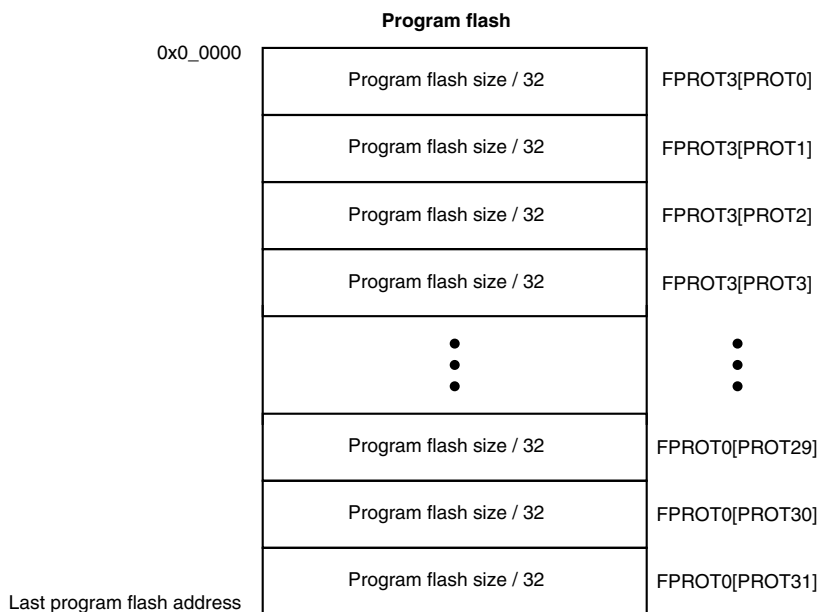

Figure 25-26. Program flash protection

- FDPROT —
 - protects eight regions of the data flash memory as shown in the following figure

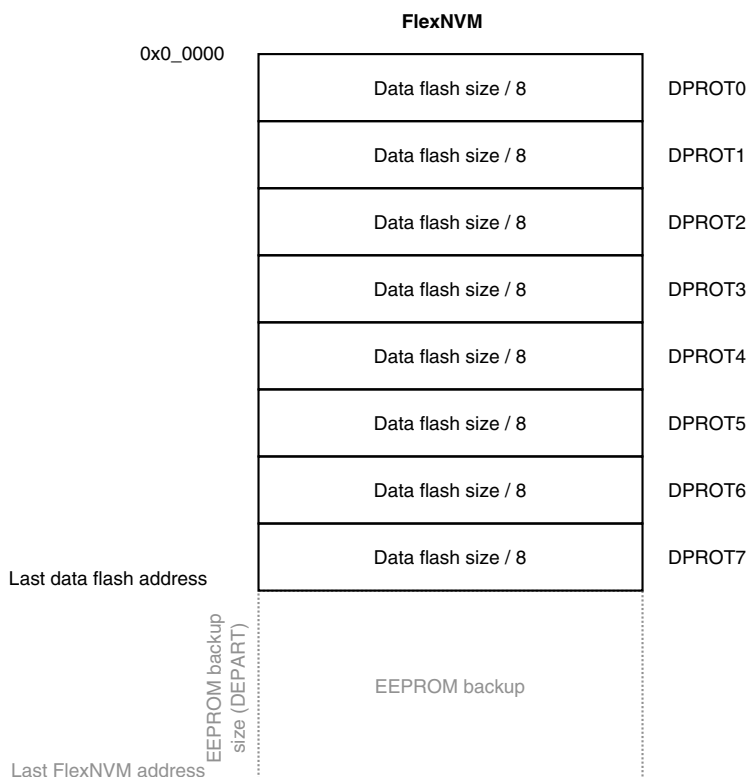

Figure 25-27. Data flash protection

- FEPROT — Protects eight regions of the EEPROM memory as shown in the following figure

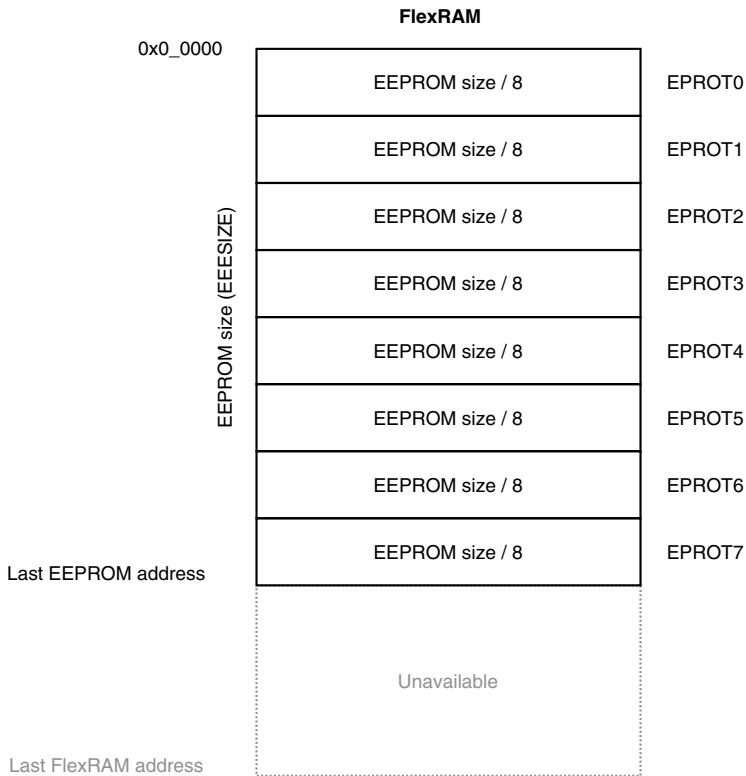

Figure 25-28. EEPROM protection

25.4.2 FlexNVM Description

This section describes the FlexNVM memory.

25.4.2.1 FlexNVM Block Partitioning for FlexRAM

The user can configure the FlexNVM block as either:

- Basic data flash,
- EEPROM flash records to support the built-in EEPROM feature, or
- A combination of both.

The user's FlexNVM configuration choice is specified using the Program Partition command described in [Program Partition Command](#).

CAUTION

While different partitions of the FlexNVM block are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM partition code choices affect the endurance and data retention characteristics of the device.

25.4.2.2 EEPROM User Perspective

The EEPROM system is shown in the following figure.

Figure 25-29. Top Level EEPROM Architecture

To handle varying customer requirements, the FlexRAM and FlexNVM blocks can be split into partitions as shown in the figure below.

1. **EEPROM partition** (EEESIZE) — The amount of FlexRAM used for EEPROM can be set from 0 Bytes (no EEPROM) to the maximum FlexRAM size (see [Table 25-2](#)). The remainder of the FlexRAM is not accessible while the FlexRAM is configured for EEPROM (see [Set FlexRAM Function Command](#)). The EEPROM partition grows upward from the bottom of the FlexRAM address space.
2. **Data flash partition** (DEPART) — The amount of FlexNVM memory used for data flash can be programmed from 0 bytes (all of the FlexNVM block is available for EEPROM backup) to the maximum size of the FlexNVM block (see [Table 25-4](#)).
3. **FlexNVM EEPROM partition** — The amount of FlexNVM memory used for EEPROM backup, which is equal to the FlexNVM block size minus the data flash memory partition size. The EEPROM backup size must be at least 16 times the EEPROM partition size in FlexRAM.

The partition information (EEESIZE, DEPART) is stored in the data flash IFR and is programmed using the Program Partition command (see [Program Partition Command](#)). Typically, the Program Partition command is executed only once in the lifetime of the device.

Data flash memory is useful for applications that need to quickly store large amounts of data or store data that is static. The EEPROM partition in FlexRAM is useful for storing smaller amounts of data that will be changed often.

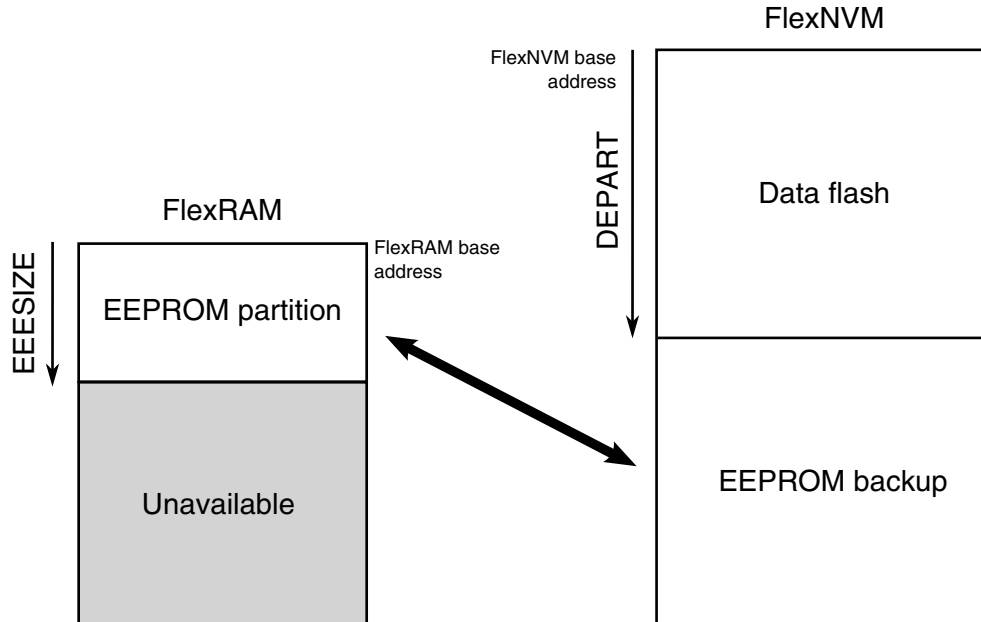

Figure 25-30. FlexRAM to FlexNVM Memory Mapping

25.4.2.3 EEPROM Implementation Overview

Out of reset with the FSTAT[CCIF] bit clear, the partition settings (EEESIZE, DEPART) are read from the data flash IFR and the EEPROM file system is initialized accordingly. The EEPROM file system locates all valid EEPROM data records in EEPROM backup and copies the newest data to FlexRAM. The FSTAT[CCIF] and FCNFG[EEERDY] bits are set after data from all valid EEPROM data records is copied to the FlexRAM. After the CCIF bit is set, the FlexRAM is available for read or write access.

When configured for EEPROM use, writes to an unprotected location in FlexRAM invokes the EEPROM file system to program a new EEPROM data record in the EEPROM backup memory in a round-robin fashion. As needed, the EEPROM file system identifies the EEPROM backup sector that is being erased for future use and partially erases that EEPROM backup sector. After a write to the FlexRAM, the FlexRAM is not accessible until the FSTAT[CCIF] bit is set. The FCNFG[EEERDY] bit will also be set. If enabled, the interrupt associated with the FSTAT[CCIF] bit can be used to determine when the FlexRAM is available for read or write access.

After a sector in EEPROM backup is full of EEPROM data records, EEPROM data records from the sector holding the oldest data are gradually copied over to a previously-erased EEPROM backup sector. When the sector copy completes, the EEPROM backup sector holding the oldest data is tagged for erase.

25.4.2.4 Write endurance to FlexRAM for EEPROM

When the FlexNVM partition code is not set to full data flash, the EEPROM data set size can be set to any of several non-zero values.

The bytes not assigned to data flash via the FlexNVM partition code are used by the flash memory module to obtain an effective endurance increase for the EEPROM data. The built-in EEPROM record management system raises the number of program/erase cycles that can be attained prior to device wear-out by cycling the EEPROM data through a larger EEPROM NVM storage space.

While different partitions of the FlexNVM are available, the intention is that a single choice for the FlexNVM partition code and EEPROM data set size is used throughout the entire lifetime of a given application. The EEPROM endurance equation and graph shown below assume that only one configuration is ever used.

$$\text{Writes_FlexRAM} = \frac{\text{EEPROM} - 2 \times \text{EESIZE}}{\text{EESIZE}} \times \text{Write_efficiency} \times n_{\text{nvmcyed}}$$

where

- **Writes_FlexRAM** — minimum number of writes to each FlexRAM location
- **EEPROM** — allocated FlexNVM based on DEPART; entered with the Program Partition command
- **EESIZE** — allocated FlexRAM based on DEPART; entered with the Program Partition command
- **Write_efficiency** —
 - 0.25 for 8-bit writes to FlexRAM
 - 0.50 for 16-bit or 32-bit writes to FlexRAM
- **n_{nvmcyed}** — data flash cycling endurance (the following graph assumes 10,000 cycles)

Figure 25-31. EEPROM backup writes to FlexRAM

25.4.3 Interrupts

The flash memory module can generate interrupt requests to the MCU upon the occurrence of various flash events. These interrupt events and their associated status and control bits are shown in the following table.

Table 25-30. Flash Interrupt Sources

Flash Event	Readable Status Bit	Interrupt Enable Bit
Flash Command Complete	FSTAT[CCIF]	FCNFG[CCIE]
Flash Read Collision Error	FSTAT[RDCOLERR]	FCNFG[RDCOLLIE]

Note

Vector addresses and their relative interrupt priority are determined at the MCU level.

25.4.4 Flash Operation in Low-Power Modes

25.4.4.1 Wait Mode

When the MCU enters wait mode, the flash memory module is not affected. The flash memory module can recover the MCU from wait via the command complete interrupt (see [Interrupts](#)).

25.4.4.2 Stop Mode

When the MCU requests stop mode, if a flash command is active (CCIF = 0) the command execution completes before the MCU is allowed to enter stop mode.

CAUTION

The MCU should never enter stop mode while any flash command is running (CCIF = 0).

NOTE

While the MCU is in very-low-power modes (VLPR, VLPW, VLPS), the flash memory module does not accept flash commands.

25.4.5 Functional Modes of Operation

The flash memory module has two operating modes: NVM Normal and NVM Special. The operating mode affects the command set availability (see [Table 25-31](#)). Refer to the Chip Configuration details of this device for how to activate each mode.

25.4.6 Flash Reads and Ignored Writes

The flash memory module requires only the flash address to execute a flash memory read.

The MCU must not read from the flash memory while commands are running (as evidenced by CCIF=0) on that block. Read data cannot be guaranteed from a flash block while any command is processing within that block. The block arbitration logic detects any simultaneous access and reports this as a read collision error (see the FSTAT[RDCOLERR] bit).

25.4.7 Read While Write (RWW)

The following simultaneous accesses are allowed:

- The user may read from the program flash memory while commands (typically program and erase operations) are active in the data flash and FlexRAM memory space.
- The MCU can fetch instructions from program flash during both data flash program and erase operations and while EEPROM backup data is maintained by the EEPROM commands.
- Conversely, the user may read from data flash and FlexRAM while program and erase commands are executing on the program flash.
- When configured as traditional RAM, writes to the FlexRAM are allowed during program and data flash operations.

Simultaneous data flash operations and FlexRAM writes, when FlexRAM is used for EEPROM, are not possible.

Simultaneous operations are further discussed in [Allowed Simultaneous Flash Operations](#).

25.4.8 Flash Program and Erase

All flash functions except read require the user to setup and launch a flash command through a series of peripheral bus writes. The user cannot initiate any further flash commands until notified that the current command has completed. The flash command structure and operation are detailed in [Flash Command Operations](#).

25.4.9 Flash Command Operations

Flash command operations are typically used to modify flash memory contents. The next sections describe:

- The command write sequence used to set flash command parameters and launch execution
- A description of all flash commands available

25.4.9.1 Command Write Sequence

Flash commands are specified using a command write sequence illustrated in [Figure 25-32](#). The flash memory module performs various checks on the command (FCCOB) content and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be zero and the CCIF flag must read 1 to verify that any previous command has completed. If CCIF is zero, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

25.4.9.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the desired flash command. The individual registers that make up the FCCOB data set can be written in any order.

25.4.9.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The CCIF flag remains zero until the flash command completes.

The FSTAT register contains a blocking mechanism that prevents a new command from launching (can't clear CCIF) if the previous command resulted in an access error (FSTAT[ACCERR]=1) or a protection violation (FSTAT[FPVIOL]=1). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write clears the error flags, the second write clears CCIF.

25.4.9.1.3 Command Execution and Error Reporting

The command processing has several steps:

1. The flash memory module reads the command code and performs a series of parameter checks and protection checks, if applicable, which are unique to each command.

If the parameter check fails, the FSTAT[ACCERR] (access error) flag is set. ACCERR reports invalid instruction codes and out-of bounds addresses. Usually, access errors suggest that the command was not set-up with valid parameters in the FCCOB register group.

Program and erase commands also check the address to determine if the operation is requested to execute on protected areas. If the protection check fails, the FSTAT[FPVIOL] (protection error) flag is set.

Command processing never proceeds to execution when the parameter or protection step fails. Instead, command processing is terminated after setting the FSTAT[CCIF] bit.

2. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to erase verify, may occur during the execution phase. Run-time errors are reported in the FSTAT[MGSTAT0] bit. A command may have access errors, protection errors, and run-time errors, but the run-time errors are not seen until all access and protection errors have been corrected.
3. Command execution results, if applicable, are reported back to the user via the FCCOB and FSTAT registers.
4. The flash memory module sets the FSTAT[CCIF] bit signifying that the command has completed.

The flow for a generic command write sequence is illustrated in the following figure.

Figure 25-32. Generic Flash Command Write Sequence Flowchart

25.4.9.2 Flash Commands

The following table summarizes the function of all flash commands. If the program flash, data flash, or FlexRAM column is marked with an 'X', the flash command is relevant to that particular memory resource.

FCMD	Command	Program flash	Data flash	FlexRAM	Function
0x00	Read 1s Block	x	x		Verify that a program flash or data flash block is erased. FlexNVM block must not be partitioned for EEPROM.

Table continues on the next page...

FCMD	Command	Program flash	Data flash	FlexRAM	Function
0x01	Read 1s Section	x	x		Verify that a given number of program flash or data flash locations from a starting address are erased.
0x02	Program Check	x	x		Tests previously-programmed locations at margin read levels.
0x03	Read Resource	IFR, ID	IFR		Read 4 bytes from program flash IFR, data flash IFR, or version ID.
0x06	Program Longword	x	x		Program 4 bytes in a program flash block or a data flash block.
0x08	Erase Flash Block	x	x		Erase a program flash block or data flash block. An erase of any flash block is only possible when unprotected. FlexNVM block must not be partitioned for EEPROM.
0x09	Erase Flash Sector	x	x		Erase all bytes in a program flash or data flash sector.
0x0B	Program Section	x	x	x	Program data from the Section Program Buffer to a program flash or data flash block.
0x40	Read 1s All Blocks	x	x		Verify that all program flash, data flash blocks, EEPROM backup data records, and data flash IFR are erased then release MCU security.
0x41	Read Once	IFR			Read 4 bytes of a dedicated 64 byte field in the program flash IFR.

Table continues on the next page...

Functional Description

FCMD	Command	Program flash	Data flash	FlexRAM	Function
0x43	Program Once	IFR			One-time program of 4 bytes of a dedicated 64-byte field in the program flash IFR.
0x44	Erase All Blocks	x	x	x	Erase all program flash blocks, data flash blocks, FlexRAM, EEPROM backup data records, and data flash IFR. Then, verify-erase and release MCU security. NOTE: An erase is only possible when all memory locations are unprotected.
0x45	Verify Backdoor Access Key	x			Release MCU security after comparing a set of user-supplied security keys to those stored in the program flash.
0x80	Program Partition		IFR	x	Program the FlexNVM Partition Code and EEPROM Data Set Size into the data flash IFR. Format all EEPROM backup data sectors allocated for EEPROM. Initialize the FlexRAM.
0x81	Set FlexRAM Function		x	x	Switches FlexRAM function between RAM and EEPROM. When switching to EEPROM, FlexNVM is not available while valid data records are being copied from EEPROM backup to FlexRAM.

NOTE

FlexRAM, or Programming Acceleration RAM, is used during PGMSEC command.

25.4.9.3 Flash Commands by Mode

The following table shows the flash commands that can be executed in each flash operating mode.

Table 25-31. Flash Commands by Mode

FCMD	Command	NVM Normal			NVM Special		
		Unsecure	Secure	MEEN=10	Unsecure	Secure	MEEN=10
0x00	Read 1s Block	x	x	x	x	—	—
0x01	Read 1s Section	x	x	x	x	—	—
0x02	Program Check	x	x	x	x	—	—
0x03	Read Resource	x	x	x	x	—	—
0x06	Program Longword	x	x	x	x	—	—
0x08	Erase Flash Block	x	x	x	x	—	—
0x09	Erase Flash Sector	x	x	x	x	—	—
0x0B	Program Section	x	x	x	x	—	—
0x40	Read 1s All Blocks	x	x	x	x	x	—
0x41	Read Once	x	x	x	x	—	—
0x43	Program Once	x	x	x	x	—	—
0x44	Erase All Blocks	x	x	x	x	x	—
0x45	Verify Backdoor Access Key	x	x	x	x	—	—
0x80	Program Partition	x	x	x	x	—	—
0x81	Set FlexRAM Function	x	x	x	x	—	—

25.4.9.4 Allowed Simultaneous Flash Operations

Only the operations marked 'OK' in the following table are permitted to run simultaneously on the program flash, data flash, and FlexRAM memories. Some operations cannot be executed simultaneously because certain hardware resources are shared by the memories. The priority has been placed on permitting program flash reads while program and erase operations execute on the FlexNVM and FlexRAM. This provides read (program flash) while write (FlexNVM, FlexRAM) functionality.

Table 25-32. Allowed Simultaneous Memory Operations

		Program Flash			Data Flash			FlexRAM		
		Read	Program	Sector Erase	Read	Program	Sector Erase	Read	E-Write ¹	R-Write ²
Program flash	Read	—				OK	OK		OK	
	Program		—		OK			OK		OK ³
	Sector Erase			—	OK			OK		OK
Data flash	Read		OK	OK	—					
	Program	OK				—		OK		OK
	Sector Erase	OK					—	OK		OK
FlexRAM	Read		OK	OK		OK	OK	—		
	E-Write ¹	OK							—	
	R-Write ²		OK	OK		OK	OK			—

1. When FlexRAM configured for EEPROM (writes are effectively multi-cycle operations).
2. When FlexRAM configured as traditional RAM (writes are single-cycle operations).
3. When FlexRAM configured as traditional RAM, writes to the RAM are ignored while the Program Section command is active (CCIF = 0).

25.4.10 Margin Read Commands

The Read-1s commands (Read 1s All Blocks, Read 1s Block, and Read 1s Section) and the Program Check command have a margin choice parameter that allows the user to apply non-standard read reference levels to the program flash and data flash array reads performed by these commands. Using the preset 'user' and 'factory' margin levels, these commands perform their associated read operations at tighter tolerances than a 'normal' read. These non-standard read levels are applied only during the command execution. All simple (uncommanded) flash array reads to the MCU always use the standard, un-margined, read reference level.

Only the 'normal' read level should be employed during normal flash usage. The non-standard, 'user' and 'factory' margin levels should be employed only in special cases. They can be used during special diagnostic routines to gain confidence that the device is not suffering from the end-of-life data loss customary of flash memory devices.

Erased ('1') and programmed ('0') bit states can degrade due to elapsed time and data cycling (number of times a bit is erased and re-programmed). The lifetime of the erased states is relative to the last erase operation. The lifetime of the programmed states is measured from the last program time.

The 'user' and 'factory' levels become, in effect, a minimum safety margin; i.e. if the reads pass at the tighter tolerances of the 'user' and 'factory' margins, then the 'normal' reads have at least this much safety margin before they experience data loss.

The 'user' margin is a small delta to the normal read reference level. 'User' margin levels can be employed to check that flash memory contents have adequate margin for normal level read operations. If unexpected read results are encountered when checking flash memory contents at the 'user' margin levels, loss of information might soon occur during 'normal' readout.

The 'factory' margin is a bigger deviation from the norm, a more stringent read criteria that should only be attempted immediately (or very soon) after completion of an erase or program command, early in the cycling life. 'Factory' margin levels can be used to check that flash memory contents have adequate margin for long-term data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at 'factory' margin levels, the flash memory contents should be erased and reprogrammed.

CAUTION

Factory margin levels must only be used during verify of the initial factory programming.

25.4.11 Flash Command Description

This section describes all flash commands that can be launched by a command write sequence. The flash memory module sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in a FCCOB field for the specific commands. Refer to the error handling table provided for each command.

Ensure that the ACCERR and FPVIOL bits in the FSTAT register are cleared prior to starting the command write sequence. As described in [Launch the Command by Clearing CCIF](#), a new command cannot be launched while these error flags are set.

Do not attempt to read a flash block while the flash memory module is running a command (CCIF = 0) on that same block. The flash memory module may return invalid data to the MCU with the collision error flag (FSTAT[RDCOLERR]) set.

When required by the command, address bit 23 selects between:

Functional Description

- program flash (=0)
- data flash (=1)

CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

25.4.11.1 Read 1s Block Command

The Read 1s Block command checks to see if an entire program flash or data flash block has been erased to the specified margin level. The FCCOB flash address bits determine which logical block is erase-verified.

Table 25-33. Read 1s Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x00 (RD1BLK)
1	Flash address [23:16] in the flash block to be verified
2	Flash address [15:8] in the flash block to be verified
3	Flash address [7:0] ¹ in the flash block to be verified
4	Read-1 Margin Choice

1. Must be longword aligned (Flash address [1:0] = 00).

After clearing CCIF to launch the Read 1s Block command, the flash memory module sets the read margin for 1s according to [Table 25-34](#) and then reads all locations within the selected program flash or data flash block.

When the data flash is targeted, DEPART must be set for no EEPROM, else the Read 1s Block command aborts setting the FSTAT[ACCERR] bit. If the flash memory module fails to read all 1s (i.e. the flash block is not fully erased), the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Read 1s Block operation has completed.

Table 25-34. Margin Level Choices for Read 1s Block

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 25-35. Read 1s Block Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin choice is specified	FSTAT[ACCERR]
Program flash is selected and the address is out of program flash range	FSTAT[ACCERR]
Data flash is selected and the address is out of data flash range	FSTAT[ACCERR]
Data flash is selected with EEPROM enabled	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

25.4.11.2 Read 1s Section Command

The Read 1s Section command checks if a section of program flash or data flash memory is erased to the specified read margin level. The Read 1s Section command defines the starting address and the number of longwords to be verified.

Table 25-36. Read 1s Section Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x01 (RD1SEC)
1	Flash address [23:16] of the first longword to be verified
2	Flash address [15:8] of the first longword to be verified
3	Flash address [7:0] ¹ of the first longword to be verified
4	Number of longwords to be verified [15:8]
5	Number of longwords to be verified [7:0]
6	Read-1 Margin Choice

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Read 1s Section command, the flash memory module sets the read margin for 1s according to [Table 25-37](#) and then reads all locations within the specified section of flash memory. If the flash memory module fails to read all 1s (i.e. the flash section is not erased), the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Read 1s Section operation completes.

Table 25-37. Margin Level Choices for Read 1s Section

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 25-38. Read 1s Section Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid margin code is supplied	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
The requested section crosses a Flash block boundary	FSTAT[ACCERR]
The requested number of longwords is zero	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

25.4.11.3 Program Check Command

The Program Check command tests a previously programmed program flash or data flash longword to see if it reads correctly at the specified margin level.

Table 25-39. Program Check Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x02 (PGMCHK)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Margin Choice
8	Byte 0 expected data
9	Byte 1 expected data
A	Byte 2 expected data
B	Byte 3 expected data

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Check command, the flash memory module sets the read margin for 1s according to [Table 25-40](#), reads the specified longword, and compares the actual read data to the expected data provided by the FCCOB. If the comparison at margin-1 fails, the FSTAT[MGSTAT0] bit is set.

The flash memory module then sets the read margin for 0s, re-reads, and compares again. If the comparison at margin-0 fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Program Check operation completes.

The supplied address must be longword aligned (the lowest two bits of the byte address must be 00):

- Byte 0 data is written to the supplied byte address ('start'),

- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10,
- Byte 3 data is programmed to byte address start+0b11.

NOTE

See the description of margin reads, [Margin Read Commands](#)

Table 25-40. Margin Level Choices for Program Check

Read Margin Choice	Margin Level Description
0x01	Read at 'User' margin-1 and 'User' margin-0
0x02	Read at 'Factory' margin-1 and 'Factory' margin-0

Table 25-41. Program Check Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
An invalid margin choice is supplied	FSTAT[ACCERR]
Either of the margin reads does not match the expected data	FSTAT[MGSTAT0]

25.4.11.4 Read Resource Command

The Read Resource command allows the user to read data from special-purpose memory resources located within the flash memory module. The special-purpose memory resources available include program flash IFR space, data flash IFR space, and the Version ID field. Each resource is assigned a select code as shown in [Table 25-43](#).

Table 25-42. Read Resource Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x03 (RDRSRC)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
Returned Values	
4	Read Data [31:24]
5	Read Data [23:16]
6	Read Data [15:8]
7	Read Data [7:0]
User-provided values	
8	Resource Select Code (see Table 25-43)

Functional Description

1. Must be longword aligned (Flash address [1:0] = 00).

Table 25-43. Read Resource Select Codes

Resource Select Code	Description	Resource Size	Local Address Range
0x00	Program Flash 0 IFR	256 Bytes	0x00_0000 - 0x00_00FF
0x00	Data Flash 0 IFR	256 Bytes	0x80_0000 - 0x80_00FF
0x01 ¹	Version ID	8 Bytes	0x00_0000 - 0x00_0007

1. Located in program flash 0 reserved space.

After clearing CCIF to launch the Read Resource command, four consecutive bytes are read from the selected resource at the provided relative address and stored in the FCCOB register. The CCIF flag sets after the Read Resource operation completes. The Read Resource command exits with an access error if an invalid resource code is provided or if the address for the applicable area is out-of-range.

Table 25-44. Read Resource Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid resource code is entered	FSTAT[ACCERR]
Flash address is out-of-range for the targeted resource.	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]

25.4.11.5 Program Longword Command

The Program Longword command programs four previously-erased bytes in the program flash memory or in the data flash memory using an embedded algorithm.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

Table 25-45. Program Longword Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x06 (PGM4)
1	Flash address [23:16]

Table continues on the next page...

Table 25-45. Program Longword Command FCCOB Requirements (continued)

FCCOB Number	FCCOB Contents [7:0]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Byte 0 program value
5	Byte 1 program value
6	Byte 2 program value
7	Byte 3 program value

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Longword command, the flash memory module programs the data bytes into the flash using the supplied address. The targeted flash locations must be currently unprotected (see the description of the FPROT and FDPROT registers) to permit execution of the Program Longword operation.

The programming operation is unidirectional. It can only move NVM bits from the erased state ('1') to the programmed state ('0'). Erased bits that fail to program to the '0' state are flagged as errors in FSTAT[MGSTAT0]. The CCIF flag is set after the Program Longword operation completes.

The supplied address must be longword aligned (flash address [1:0] = 00):

- Byte 0 data is written to the supplied byte address ('start'),
- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10, and
- Byte 3 data is programmed to byte address start+0b11.

Table 25-46. Program Longword Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
Flash address points to a protected area	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.6 Erase Flash Block Command

The Erase Flash Block operation erases all addresses in a single program flash or data flash block.

Table 25-47. Erase Flash Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x08 (ERSBLK)
1	Flash address [23:16] in the flash block to be erased
2	Flash address [15:8] in the flash block to be erased
3	Flash address [7:0] ¹ in the flash block to be erased

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Erase Flash Block command, the flash memory module erases the main array of the selected flash block and verifies that it is erased. When the data flash is targeted, DEPART must be set for no EEPROM (see [Table 25-4](#)) else the Erase Flash Block command aborts setting the FSTAT[ACCERR] bit. The Erase Flash Block command aborts and sets the FSTAT[FPVIOL] bit if any region within the block is protected (see the description of the FPROT and FDPROT registers). If the erase verify fails, FSTAT[MGSTAT0] is set. The CCIF flag will set after the Erase Flash Block operation has completed.

Table 25-48. Erase Flash Block Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Program flash is selected and the address is out of program flash range	FSTAT[ACCERR]
Data flash is selected and the address is out of data flash range	FSTAT[ACCERR]
Data flash is selected with EEPROM enabled	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
Any area of the selected flash block is protected	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.7 Erase Flash Sector Command

The Erase Flash Sector operation erases all addresses in a flash sector.

Table 25-49. Erase Flash Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x09 (ERSSCR)
1	Flash address [23:16] in the flash sector to be erased
2	Flash address [15:8] in the flash sector to be erased
3	Flash address [7:0] ¹ in the flash sector to be erased

1. Must be longword aligned (flash address [1:0] = 00).

After clearing CCIF to launch the Erase Flash Sector command, the flash memory module erases the selected program flash or data flash sector and then verifies that it is erased. The Erase Flash Sector command aborts if the selected sector is protected (see the description of the FPROT and FDPROT registers). If the erase-verify fails the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase Flash Sector operation completes. The Erase Flash Sector command is suspendable (see the FCNFG[ERSSUSP] bit and [Figure 25-33](#)).

Table 25-50. Erase Flash Sector Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid Flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
The selected program flash or data flash sector is protected	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.7.1 Suspending an Erase Flash Sector Operation

To suspend an Erase Flash Sector operation set the FCNFG[ERSSUSP] bit (see [Flash Configuration Field Description](#)) when CCIF is clear and the CCOB command field holds the code for the Erase Flash Sector command. During the Erase Flash Sector operation (see [Erase Flash Sector Command](#)), the flash memory module samples the state of the ERSSUSP bit at convenient points. If the flash memory module detects that the ERSSUSP bit is set, the Erase Flash Sector operation is suspended and the flash memory module sets CCIF. While ERSSUSP is set, all writes to flash registers are ignored except for writes to the FSTAT and FCNFG registers.

If an Erase Flash Sector operation effectively completes before the flash memory module detects that a suspend request has been made, the flash memory module clears the ERSSUSP bit prior to setting CCIF. When an Erase Flash Sector operation has been successfully suspended, the flash memory module sets CCIF and leaves the ERSSUSP bit set. While CCIF is set, the ERSSUSP bit can only be cleared to prevent the withdrawal of a suspend request before the flash memory module has acknowledged it.

25.4.11.7.2 Resuming a Suspended Erase Flash Sector Operation

If the ERSSUSP bit is still set when CCIF is cleared to launch the next command, the previous Erase Flash Sector operation resumes. The flash memory module acknowledges the request to resume a suspended operation by clearing the ERSSUSP bit. A new suspend request can then be made by setting ERSSUSP. A single Erase Flash Sector operation can be suspended and resumed multiple times.

There is a minimum elapsed time limit between the request to resume the Erase Flash Sector operation (CCIF is cleared) and the request to suspend the operation again (ERSSUSP is set). This minimum time period is required to ensure that the Erase Flash Sector operation will eventually complete. If the minimum period is continually violated, i.e. the suspend requests come repeatedly and too quickly, no forward progress is made by the Erase Flash Sector algorithm. The resume/suspend sequence runs indefinitely without completing the erase.

25.4.11.7.3 Aborting a Suspended Erase Flash Sector Operation

The user may choose to abort a suspended Erase Flash Sector operation by clearing the ERSSUSP bit prior to clearing CCIF for the next command launch. When a suspended operation is aborted, the flash memory module starts the new command using the new FCCOB contents.

While FCNFG[ERSSUSP] is set, a write to the FlexRAM while FCNFG[EEERDY] is set clears ERSSUSP and aborts the suspended operation. The FlexRAM write operation is executed by the flash memory module.

Note

Aborting the erase leaves the bitcells in an indeterminate, partially-erased state. Data in this sector is not reliable until a new erase command fully completes.

The following figure shows how to suspend and resume the Erase Flash Sector operation.

Figure 25-33. Suspend and Resume of Erase Flash Sector Operation

25.4.11.8 Program Section Command

The Program Section operation programs the data found in the section program buffer to previously erased locations in the flash memory using an embedded algorithm. Data is preloaded into the section program buffer by writing to the FlexRAM while it is set to function as traditional RAM or the programming acceleration RAM (see [Flash Sector Programming](#)).

The section program buffer is limited to the lower half of the RAM. Data written to the upper half of the RAM is ignored and may be overwritten during Program Section command execution.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

Table 25-51. Program Section Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x0B (PGMSEC)
1	Flash address [23:16]
2	Flash address [15:8]
3	Flash address [7:0] ¹
4	Number of longwords to program [15:8]
5	Number of longwords to program [7:0]

1. Must be longword aligned (Flash address [1:0] = 00).

After clearing CCIF to launch the Program Section command, the flash memory module blocks access to the FlexRAM and programs the data residing in the section program buffer into the flash memory starting at the flash address provided.

The starting address must be unprotected (see the description of the FPROT and FDPROT registers) to permit execution of the Program Section operation. Programming, which is not allowed to cross a flash sector boundary, continues until all requested longwords have been programmed. The Program Section command also verifies that after programming, all bits requested to be programmed are programmed.

After the Program Section operation completes, the CCIF flag is set and normal access to the RAM is restored. The contents of the section program buffer may be changed by the Program Section operation.

Table 25-52. Program Section Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid flash address is supplied	FSTAT[ACCERR]
Flash address is not longword aligned	FSTAT[ACCERR]
The requested section crosses a program flash sector boundary	FSTAT[ACCERR]
The requested number of longwords is zero	FSTAT[ACCERR]
The space required to store data for the requested number of longwords is more than half the size of the FlexRAM	FSTAT[ACCERR]
The FlexRAM is not set to function as a traditional RAM, i.e. set if RAMRDY=0	FSTAT[ACCERR]
The flash address falls in a protected area	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.8.1 Flash Sector Programming

The process of programming an entire flash sector using the Program Section command is as follows:

1. If required, for FlexNVM devices, execute the Set FlexRAM Function command to make the FlexRAM available as traditional RAM and initialize the FlexRAM to all ones.
2. Launch the Erase Flash Sector command to erase the flash sector to be programmed.
3. Beginning with the starting address of the FlexRAM, sequentially write enough data to the RAM to fill an entire flash sector or half the FlexRAM, whichever is less. This area of the RAM serves as the section program buffer.

NOTE

In step 1, the section program buffer was initialized to all ones, the erased state of the flash memory.

The section program buffer can be written to while the operation launched in step 2 is executing, i.e. while CCIF = 0.

4. Execute the Program Section command to program the contents of the section program buffer into the selected flash sector.
5. If a flash sector is larger than half the RAM, repeat steps 3 and 4 until the sector is completely programmed.
6. To program additional flash sectors, repeat steps 2 through 4.
7. To restore EEPROM functionality for FlexNVM devices, execute the Set FlexRAM Function command to make the FlexRAM available as EEPROM.

25.4.11.9 Read 1s All Blocks Command

The Read 1s All Blocks command checks if the program flash blocks, data flash blocks, EEPROM backup records, and data flash IFR have been erased to the specified read margin level, if applicable, and releases security if the readout passes, i.e. all data reads as '1'.

Table 25-53. Read 1s All Blocks Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x40 (RD1ALL)
1	Read-1 Margin Choice

After clearing CCIF to launch the Read 1s All Blocks command, the flash memory module :

- sets the read margin for 1s according to [Table 25-54](#),
- checks the contents of the program flash, data flash, EEPROM backup records, and data flash IFR are in the erased state.

If the flash memory module confirms that these memory resources are erased, security is released by setting the FSEC[SEC] field to the unsecure state. The security byte in the flash configuration field (see [Flash Configuration Field Description](#)) remains unaffected by the Read 1s All Blocks command. If the read fails, i.e. all memory resources are not in the fully erased state, the FSTAT[MGSTAT0] bit is set.

The EEERDY and RAMRDY bits are clear during the Read 1s All Blocks operation and are restored at the end of the Read 1s All Blocks operation.

The CCIF flag sets after the Read 1s All Blocks operation has completed.

Table 25-54. Margin Level Choices for Read 1s All Blocks

Read Margin Choice	Margin Level Description
0x00	Use the 'normal' read level for 1s
0x01	Apply the 'User' margin to the normal read-1 level
0x02	Apply the 'Factory' margin to the normal read-1 level

Table 25-55. Read 1s All Blocks Command Error Handling

Error Condition	Error Bit
An invalid margin choice is specified	FSTAT[ACCERR]
Read-1s fails	FSTAT[MGSTAT0]

25.4.11.10 Read Once Command

The Read Once command provides read access to a reserved 64-byte field located in the program flash IFR (see [Program Flash IFR Map](#) and [Program Once Field](#)). Access to this field is via 16 records, each 4 bytes long. The Read Once field is programmed using the Program Once command described in [Program Once Command](#).

Table 25-56. Read Once Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x41 (RDONCE)
1	Read Once record index (0x00 - 0x0F)
2	Not used
3	Not used
Returned Values	
4	Read Once byte 0 value
5	Read Once byte 1 value
6	Read Once byte 2 value
7	Read Once byte 3 value

After clearing CCIF to launch the Read Once command, a 4-byte Read Once record is read from the program flash IFR and stored in the FCCOB register. The CCIF flag is set after the Read Once operation completes. Valid record index values for the Read Once command range from 0x00 to 0x0F. During execution of the Read Once command, any attempt to read addresses within the program flash block containing this 64-byte field returns invalid data. The Read Once command can be executed any number of times.

Table 25-57. Read Once Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid record index is supplied	FSTAT[ACCERR]

25.4.11.11 Program Once Command

The Program Once command enables programming to a reserved 64-byte field in the program flash IFR (see [Program Flash IFR Map](#) and [Program Once Field](#)). Access to the Program Once field is via 16 records, each 4 bytes long. The Program Once field can be

Functional Description

read using the Read Once command (see [Read Once Command](#)) or using the Read Resource command (see [Read Resource Command](#)). Each Program Once record can be programmed only once since the program flash IFR cannot be erased.

Table 25-58. Program Once Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x43 (PGMONCE)
1	Program Once record index (0x00 - 0x0F)
2	Not Used
3	Not Used
4	Program Once Byte 0 value
5	Program Once Byte 1 value
6	Program Once Byte 2 value
7	Program Once Byte 3 value

After clearing CCIF to launch the Program Once command, the flash memory module first verifies that the selected record is erased. If erased, then the selected record is programmed using the values provided. The Program Once command also verifies that the programmed values read back correctly. The CCIF flag is set after the Program Once operation has completed.

The reserved program flash IFR location accessed by the Program Once command cannot be erased and any attempt to program one of these records when the existing value is not Fs (erased) is not allowed. Valid record index values for the Program Once command range from 0x00 to 0x0F. During execution of the Program Once command, any attempt to read addresses within the program flash block containing this 64-byte field returns invalid data.

Table 25-59. Program Once Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
An invalid record index is supplied	FSTAT[ACCERR]
The requested record has already been programmed to a non-FFFF value ¹	FSTAT[ACCERR]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

1. If a Program Once record is initially programmed to 0xFFFF_FFFF, the Program Once command is allowed to execute again on that same record.

25.4.11.12 Erase All Blocks Command

The Erase All Blocks operation erases all flash memory, initializes the FlexRAM, verifies all memory contents, and releases MCU security.

Table 25-60. Erase All Blocks Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x44 (ERSALL)

After clearing CCIF to launch the Erase All Blocks command, the flash memory module erases all program flash memory, data flash memory, data flash IFR space, EEPROM backup memory, and FlexRAM, then verifies that all are erased.

If the flash memory module verifies that all flash memories and the FlexRAM were properly erased, security is released by setting the FSEC[SEC] field to the unsecure state and the FCNFG[RAMRDY] bit is set. The Erase All Blocks command aborts if any flash or FlexRAM region is protected. The security byte and all other contents of the flash configuration field (see [Flash Configuration Field Description](#)) are erased by the Erase All Blocks command. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks operation completes.

Table 25-61. Erase All Blocks Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
Any region of the program flash memory, data flash memory, or FlexRAM is protected	FSTAT[FPVIOL]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.12.1 Triggering an Erase All External to the Flash Memory Module

The functionality of the Erase All Blocks command is also available in an uncommanded fashion outside of the flash memory. Refer to the device's Chip Configuration details for information on this functionality.

Before invoking the external erase all function, the FSTAT[ACCERR and PVIOL] flags must be cleared and the FCCOB0 register must not contain 0x44. When invoked, the erase-all function erases all program flash memory, data flash memory, data flash IFR space, EEPROM backup, and FlexRAM regardless of the protection settings. If the post-erase verify passes, the routine then releases security by setting the FSEC[SEC] field register to the unsecure state and the FCNFG[RAMRDY] bit sets. The security byte in the Flash Configuration Field is also programmed to the unsecure state. The status of the erase-all request is reflected in the FCNFG[ERSAREQ] bit. The FCNFG[ERSAREQ] bit is cleared once the operation completes and the normal FSTAT error reporting is available as described in [Erase All Blocks Command](#).

25.4.11.13 Verify Backdoor Access Key Command

The Verify Backdoor Access Key command only executes if the mode and security conditions are satisfied (see [Flash Commands by Mode](#)). Execution of the Verify Backdoor Access Key command is further qualified by the FSEC[KEYEN] bits. The Verify Backdoor Access Key command releases security if user-supplied keys in the FCCOB match those stored in the Backdoor Comparison Key bytes of the Flash Configuration Field (see [Flash Configuration Field Description](#)). The column labelled Flash Configuration Field offset address shows the location of the matching byte in the Flash Configuration Field.

Table 25-62. Verify Backdoor Access Key Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]	Flash Configuration Field Offset Address
0	0x45 (VFYKEY)	
1-3	Not Used	
4	Key Byte 0	0x0_0000
5	Key Byte 1	0x0_0001
6	Key Byte 2	0x0_0002
7	Key Byte 3	0x0_0003
8	Key Byte 4	0x0_0004
9	Key Byte 5	0x0_0005
A	Key Byte 6	0x0_0006
B	Key Byte 7	0x0_0007

After clearing CCIF to launch the Verify Backdoor Access Key command, the flash memory module checks the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the flash memory module sets the FSTAT[ACCERR] bit and terminates. If the command is enabled, the flash memory module compares the key provided in FCCOB to the backdoor comparison key in the Flash Configuration Field. If the backdoor keys match, the FSEC[SEC] field is changed to the unsecure state and security is released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are immediately aborted and the FSTAT[ACCERR] bit is (again) set to 1 until a reset of the flash memory module occurs. If the entire 8-byte key is all zeros or all ones, the Verify Backdoor Access Key command fails with an access error. The CCIF flag is set after the Verify Backdoor Access Key operation completes.

Table 25-63. Verify Backdoor Access Key Command Error Handling

Error Condition	Error Bit
The supplied key is all-0s or all-Fs	FSTAT[ACCERR]
An incorrect backdoor key is supplied	FSTAT[ACCERR]

Table continues on the next page...

Table 25-63. Verify Backdoor Access Key Command Error Handling (continued)

Error Condition	Error Bit
Backdoor key access has not been enabled (see the description of the FSEC register)	FSTAT[ACCERR]
This command is launched and the backdoor key has mismatched since the last power down reset	FSTAT[ACCERR]

25.4.11.14 Program Partition Command

The Program Partition command prepares the FlexNVM block for use as data flash, EEPROM backup, or a combination of both and initializes the FlexRAM. The Program Partition command must not be launched from flash memory, since flash memory resources are not accessible during Program Partition command execution.

CAUTION

While different partitions of the FlexNVM are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM Partition Code choices affect the endurance and data retention characteristics of the device.

Table 25-64. Program Partition Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x80 (PGMPART)
1	Not Used
2	Not Used
3	Not Used
4	EEPROM Data Size Code ¹
5	FlexNVM Partition Code ²

1. See [Table 25-65](#) and [EEPROM Data Set Size](#)

2. See [Table 25-66](#) and

Table 25-65. Valid EEPROM Data Set Size Codes

EEPROM Data Size Code (FCCOB4) ¹		EEPROM Data Set Size (Bytes)
FCCOB4[5:4]	FCCOB4[EEEEIZE]	
11	0xF	0 ²
11	0x9	32
11	0x8	64
11	0x7	128
11	0x6	256

Table continues on the next page...

Table 25-65. Valid EEPROM Data Set Size Codes (continued)

EEPROM Data Size Code (FCCOB4) ¹		EEPROM Data Set Size (Bytes)
FCCOB4[5:4]	FCCOB4[EEESIZE]	
11	0x5	512
11	0x4	1024
11	0x3	2048

1. FCCOB4[7:6] = 00
2. EEPROM Data Set Size must be set to 0 bytes when the FlexNVM Partition Code is set for no EEPROM.

Table 25-66. Valid FlexNVM Partition Codes

FlexNVM Partition Code (FCCOB5[DEPART]) ¹	Data flash Size (Kbytes)	EEPROM backup Size (Kbytes)
0000	32	0
0001	24	8
0010	16	16
0011	0	32
1000	0	32
1001	8	24
1010	16	16
1011	32	0

1. FCCOB5[7:4] = 0000

After clearing CCIF to launch the Program Partition command, the flash memory module first verifies that the EEPROM Data Size Code and FlexNVM Partition Code in the data flash IFR are erased. If erased, the Program Partition command erases the contents of the FlexNVM memory. If the FlexNVM is to be partitioned for EEPROM backup, the allocated EEPROM backup sectors are formatted for EEPROM use. Finally, the partition codes are programmed into the data flash IFR using the values provided. The Program Partition command also verifies that the partition codes read back correctly after programming. If the FlexNVM is partitioned for EEPROM backup, the EEERDY flag will set with RAMRDY clear. If the FlexNVM is not partitioned for EEPROM backup, the RAMRDY flag will set with EEERDY clear. The CCIF flag is set after the Program Partition operation completes.

Prior to launching the Program Partition command, the data flash IFR must be in an erased state, which can be accomplished by executing the Erase All Blocks command or by an external request (see [Erase All Blocks Command](#)). The EEPROM Data Size Code and FlexNVM Partition Code are read using the Read Resource command (see [Read Resource Command](#)).

Table 25-67. Program Partition Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
The EEPROM data size and FlexNVM partition code bytes are not initially 0xFFFF	FSTAT[ACCERR]
Invalid EEPROM Data Size Code is entered (see Table 25-65 for valid codes)	FSTAT[ACCERR]
Invalid FlexNVM Partition Code is entered (see Table 25-66 for valid codes)	FSTAT[ACCERR]
FlexNVM Partition Code = full data flash (no EEPROM) and EEPROM Data Size Code allocates FlexRAM for EEPROM	FSTAT[ACCERR]
FlexNVM Partition Code allocates space for EEPROM backup, but EEPROM Data Size Code allocates no FlexRAM for EEPROM	FSTAT[ACCERR]
FCCOB4[7:6] != 00	FSTAT[ACCERR]
FCCOB5[7:4] != 0000	FSTAT[ACCERR]
Any errors have been encountered during the verify operation	FSTAT[MGSTAT0]

25.4.11.15 Set FlexRAM Function Command

The Set FlexRAM Function command changes the function of the FlexRAM:

- When not partitioned for EEPROM, the FlexRAM is typically used as traditional RAM.
- When partitioned for EEPROM, the FlexRAM is typically used to store EEPROM data.

Table 25-68. Set FlexRAM Function Command FCCOB Requirements

FCCOB Number	FCCOB Contents [7:0]
0	0x81 (SETRAM)
1	FlexRAM Function Control Code (see Table 25-69)

Table 25-69. FlexRAM Function Control

FlexRAM Function Control Code	Action
0xFF	Make FlexRAM available as RAM: <ul style="list-style-type: none"> • Clear the FCNFG[EEERDY] and FCNFG[RAMRDY] flags • Write a background of ones to all FlexRAM locations • Set the FCNFG[RAMRDY] flag
0x00	Make FlexRAM available for EEPROM: <ul style="list-style-type: none"> • Clear the FCNFG[EEERDY] and FCNFG[RAMRDY] flags • Write a background of ones to all FlexRAM locations • Copy-down existing EEPROM data to FlexRAM • Set the FCNFG[EEERDY] flag

After clearing CCIF to launch the Set FlexRAM Function command, the flash memory module sets the function of the FlexRAM based on the FlexRAM Function Control Code.

When making the FlexRAM available as traditional RAM, the flash memory module clears the FCNFG[EEERDY] and FCNFG[RAMRDY] flags, overwrites the contents of the entire FlexRAM with a background pattern of all ones, and sets the FCNFG[RAMRDY] flag. The state of the FEPROT register does not prevent the FlexRAM from being overwritten. When the FlexRAM is set to function as a RAM, normal read and write accesses to the FlexRAM are available. When large sections of flash memory need to be programmed, e.g. during factory programming, the FlexRAM can be used as the Section Program Buffer for the Program Section command (see [Program Section Command](#)).

When making the FlexRAM available for EEPROM, the flash memory module clears the FCNFG[EEERDY] and FCNFG[RAMRDY] flags, overwrites the contents of the FlexRAM allocated for EEPROM with a background pattern of all ones, and copies the existing EEPROM data from the EEPROM backup record space to the FlexRAM. After completion of the EEPROM copy-down, the FCNFG[EEERDY] flag is set. When the FlexRAM is set to function as EEPROM, normal read and write access to the FlexRAM is available, but writes to the FlexRAM also invoke EEPROM activity. The CCIF flag is set after the Set FlexRAM Function operation completes.

Table 25-70. Set FlexRAM Function Command Error Handling

Error Condition	Error Bit
Command not available in current mode/security	FSTAT[ACCERR]
FlexRAM Function Control Code is not defined	FSTAT[ACCERR]
FlexRAM Function Control Code is set to make the FlexRAM available for EEPROM, but FlexNVM is not partitioned for EEPROM	FSTAT[ACCERR]

25.4.12 Security

The flash memory module provides security information to the MCU based on contents of the FSEC security register. The MCU then limits access to flash memory resources as defined in the device's Chip Configuration details. During reset, the flash memory module initializes the FSEC register using data read from the security byte of the Flash Configuration Field (see [Flash Configuration Field Description](#)).

The following fields are available in the FSEC register. The settings are described in the [Flash Security Register \(FTFL_FSEC\)](#) details.

Table 25-71. FSEC register fields

FSEC field	Description
KEYEN	Backdoor Key Access
MEEN	Mass Erase Capability
FSLACC	Freescale Factory Access
SEC	MCU security

25.4.12.1 Flash Memory Access by Mode and Security

The following table summarizes how access to the flash memory module is affected by security and operating mode.

Table 25-72. Flash Memory Access Summary

Operating Mode	Chip Security State	
	Unsecure	Secure
NVM Normal	Full command set	
NVM Special	Full command set	Only the Erase All Blocks and Read 1s All Blocks commands.

25.4.12.2 Changing the Security State

The security state out of reset can be permanently changed by programming the security byte of the flash configuration field. This assumes that you are starting from a mode where the necessary program flash erase and program commands are available and that the region of the program flash containing the flash configuration field is unprotected. If the flash security byte is successfully programmed, its new value takes affect after the next chip reset.

25.4.12.2.1 Unsecuring the Chip Using Backdoor Key Access

The chip can be unsecured by using the backdoor key access feature, which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash Configuration Field Description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key Command](#)) can be run; it allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the chip. The entire 8-byte key cannot be all 0s or all 1s; that is, 0000_0000_0000_0000h and FFFF_FFFF_FFFF_FFFFh are not accepted by the Verify

Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the chip can be unsecured by the following backdoor key access sequence:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key Command](#)
2. If the Verify Backdoor Access Key command is successful, the chip is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits further use of the Verify Backdoor Access Key command. A reset of the chip is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the chip is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash Configuration Field Description](#)). After the next reset of the chip, the security state of the flash memory module reverts back to the flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured chip has full control of the contents of the Flash Configuration Field. The chip may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

25.4.13 Reset Sequence

On each system reset the flash memory module executes a sequence which establishes initial values for the flash block configuration parameters, FPROT, FDPROT, FEPROT, FOPT, and FSEC registers and the FCNFG[RAMRDY, EEERDY] bits.

FSTAT[CCIF] is cleared throughout the reset sequence. The flash memory module holds off CPU access during the reset sequence. Flash reads are possible when the hold is removed. Completion of the reset sequence is marked by setting CCIF which enables flash user commands.

If a reset occurs while any flash command is in progress, that command is immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed. Commands and operations do not automatically resume after exiting reset.

Chapter 26

External Bus Interface (Mini-FlexBus)

26.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

Mini-FlexBus is a subset of the FlexBus module found on other ColdFire microprocessors. The Mini-FlexBus minimizes package pin-outs while maintaining a high level of configurability and functionality.

26.1.1 Definition

The Mini-FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:
 - External ROMs
 - Flash memories

Signal descriptions

- Programmable logic devices
- Other simple target (slave) devices

26.1.2 Features

Mini-FlexBus offers the following features:

- Two independent, user-programmable chip-select signals ($\overline{\text{FB_CS1}}$ – $\overline{\text{FB_CS0}}$)
- 8-bit and 16-bit port sizes with configuration for multiplexed or nonmultiplexed address and data buses
- 8-bit, 16-bit, and 32-bit transfers
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction

26.2 Signal descriptions

This table describes the external signals involved in data-transfer operations.

NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

Table 26-1. Mini-FlexBus signal descriptions

Signal	I/O	Function
FB_A19–FB_A0	I/O	Address Bus When FlexBus is used in a nonmultiplexed configuration, this is the address bus, FB_A. When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD. When FlexBus is used in a multiplexed configuration, the full 20-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD19–FB_AD16, and in 8-bit mode, the lower address is driven on FB_AD19–FB_AD8.
FB_D7–FB_D0	I/O	Data Bus When FlexBus is used in a nonmultiplexed configuration, this is the data bus. When FlexBus is used in a multiplexed configuration, this bus is not used.

Table continues on the next page...

Table 26-1. Mini-FlexBus signal descriptions (continued)

Signal	I/O	Function
FB_CS1–FB_CS0	O	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].
FB_OE	O	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.
FB_R/W	O	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low).
FB_TS	O	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. When FlexBus is used in a multiplexed configuration, an inverted $\overline{\text{FB_TS}}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus. $\overline{\text{FB_TS}}$ /FB_ALE is asserted for one bus clock cycle.
FB_ALE	O	Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of $\overline{\text{FB_TS}}$).

26.3 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

FB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_E800	Chip Select Address Register (FB_CSAR0)	32	R/W	0000_0000h	26.3.1/538
FFFF_E804	Chip Select Mask Register (FB_CSMR0)	32	R/W	0000_0000h	26.3.2/539

Table continues on the next page...

FB memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_E808	Chip Select Control Register (FB_CSCR0)	32	R/W	0000_0000h	26.3.3/540

FFFF_E810	Chip Select Mask Register (FB_CSMR1)	32	R/W	0000_0000h	26.3.2/539
FFFF_E814	Chip Select Control Register (FB_CSCR1)	32	R/W	0000_0000h	26.3.3/540

26.3.1 Chip Select Address Register (FB_CSARn)

Specifies the associated chip-select's base address.

Address: FFFF_E800h base + 0h offset + (12d × i), where i=0d to 1d

FB_CSARn field descriptions

Field	Description
31–16 BA	<p>Base Address</p> <p>Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed.</p> <p>NOTE: See the chip memory map for the only applicable Mini-FlexBus "expansion" address range for which the chip-selects can be active. Set the CSARn and CSMRn registers appropriately before accessing this region.</p>
15–0 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

26.3.2 Chip Select Mask Register (FB_CSMR_n)

Specifies the address mask and allowable access types for the associated chip-select.

Address: FFFF_E800h base + 4h offset + (12d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	BAM																
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	0							WP	0							V	
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

FB_CSMR_n field descriptions

Field	Description
31–16 BAM	<p>Base Address Mask</p> <p>Defines the associated chip-select's block size by masking address bits.</p> <p>0 The corresponding address bit in CSAR is used in the chip-select decode. 1 The corresponding address bit in CSAR is a don't care in the chip-select decode.</p>
15–9 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
8 WP	<p>Write Protect</p> <p>Controls write accesses to the address range in the corresponding CSAR.</p> <p>0 Write accesses are allowed. 1 Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle.</p>
7–1 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
0 V	<p>Valid</p> <p>Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select).</p> <p>NOTE: At reset, $\overline{\text{FB_CS0}}$ will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.</p> <p>0 Chip-select is invalid. 1 Chip-select is valid.</p>

26.3.3 Chip Select Control Register (FB_CSCRn)

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

NOTE

The CSCR0 reset value differs from the other CSCRs:

- Bits 31–23 are 0b
- Bit 22 is chip-dependent
- Bits 21–10 are 1b
- Bits 9–5 are chip-dependent
- Bits 4–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: FFFF_E800h base + 8h offset + (12d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Address information is driven on FB_An and data is read/written on FB_Dn. 1 Multiplexed configuration. Address information is driven on FB_ADn, and low-order address lines (FB_AD[7:0] for an 8-bit port size or FB_AD[15:0] for a 16-bit port size) must be latched using the falling edge of FB_ALE as the latch enable. Data is read/written on FB_AD[7:0] for an 8-bit port size and FB_AD[15:0] for a 16-bit port size.</p>
8 AA	<p>Auto-Acknowledge Enable</p> <p>Determines the assertion of the internal transfer acknowledge for accesses specified by the chip-select address.</p> <p>NOTE: This field must be 1b, since only internal termination is supported by the Mini-FlexBus.</p> <p>0 Reserved 1 Enabled. Internal transfer acknowledge is asserted as specified by WS.</p>
7–6 PS	<p>Port size</p> <p>Specifies the data port width associated with the associated chip-select and determines where data is driven during write cycles and where data is sampled during read cycles.</p> <p>00 Reserved 01 8-bit port size. Valid data is sampled and driven on FB_D[7:0] .</p>

Table continues on the next page...

FB_CSCR_n field descriptions (continued)

Field	Description
10	16-bit port size. Valid data is sampled and driven on FB_D[15:0]. Only supported in multiplexed mode.
11	16-bit port size. Valid data is sampled and driven on FB_AD[15:0]. Only supported in multiplexed mode.
5–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

26.4 Functional description

26.4.1 Modes of operation

Mini-FlexBus supports the following modes of operation:

- Up to a 20-bit address (non-multiplexed) with 8-bit data
- Up to a 20-bit address (multiplexed) with 16-bit data (write masking of upper/lower bytes not supported)
- Up to a 20-bit address (multiplexed) with 8-bit data

26.4.2 Address comparison

When a bus cycle is routed to Mini-FlexBus, Mini-FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how Mini-FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

When the transfer address	Then Mini-FlexBus
Matches one address register configuration	Asserts the appropriate chip-select, generating a Mini-FlexBus bus cycle as defined in the appropriate CSCR. If CSMR[WP] is set and a write access is performed, Mini-FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle.
Does not match an address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a Mini-FlexBus cycle.
Matches more than one address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a Mini-FlexBus cycle.

26.4.3 Address driven on address bus

Mini-FlexBus always drives a 20-bit address on the FB_AD bus regardless of the external memory's or peripheral's address size.

26.4.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
 - FB_AD from FB_AD0 upward
- Data lines
 - In multiplexed mode (CSCR[MUX] = 1)
 - If CSCR[PS] = 10 or 11, FB_AD15–FB_AD0
 - If CSCR[PS] = 01, FB_AD7–FB_AD0
 - In non-multiplexed mode (CSCR[MUX] = 0), FB_AD7–FB_AD0

26.4.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB_AD16–FB_AD1 and data15–data0 to FB_AD15–FB_AD0. See [Data-byte alignment and physical connections](#) for a graphical connection.

26.4.6 Data transfer signals

Data transfers between Mini-FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB_AD19–FB_AD0)
- Control signals ($\overline{\text{FB_TS}}$ / $\overline{\text{FB_ALE}}$, $\overline{\text{FB_CS}}_n$, $\overline{\text{FB_OE}}$)
- Attribute signals ()

26.4.7 Signal transitions

These signals change on the rising edge of the Mini-FlexBus clock (FB_CLK):

- Address

Functional description

- Write data
- $\overline{\text{FB_TS}}/\overline{\text{FB_ALE}}$
- $\overline{\text{FB_CSn}}$
- All attribute signals

Mini-FlexBus latches the read data on the rising edge of the clock.

26.4.8 Data-byte alignment and physical connections

The device aligns data transfers in Mini-FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane $\text{FB_AD7}–\text{FB_AD0}$. A 32-bit transfer through this 8-bit port takes four transfers, starting with the MSB to the LSB.

Non-multiplexed Mode

Figure 26-10. Connections for external memory port sizes (nonmultiplexed configuration)

Multiplexed Mode

Figure 26-11. Connections for external memory port sizes (multiplexed configuration)

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

Figure 26-12. Connections for external memory port sizes ($\text{CSCRn}[\text{BLS}] = 1$)

26.4.9 Address/data bus multiplexing

Mini-FlexBus supports a single 20-bit wide multiplexed address and data bus ($\text{FB_AD}_{19}\text{--}\text{FB_AD}_0$). Mini-FlexBus always drives the full 20-bit address on the first clock of a bus cycle. During the data phase, the $\text{FB_AD}_{19}\text{--}\text{FB_AD}_0$ lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. Mini-FlexBus continues to drive the address on any $\text{FB_AD}_{19}\text{--}\text{FB_AD}_0$ lines not used for data.

26.4.9.1 Mini-FlexBus multiplexed operating modes

This table shows the supported combinations of address and data bus widths.

Port size and phase		FB_AD		
		19–16	15–8	7–0
16-bit	Address phase	Address		
	Data phase	Address	Data	
8-bit	Address phase	Address		
	Data phase	Address		Data

26.4.10 Data transfer states

Basic data transfers occur in four clocks or states. (See [Figure 26-14](#) and [Figure 26-16](#) for examples of basic data transfers.) The Mini-FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

The states are described in this table.

State	Cycle	Description
S0	All	The read or write cycle is initiated. On the rising clock edge, Mini-FlexBus: <ul style="list-style-type: none"> Places a valid address on FB_ADn Asserts FB_TS/FB_ALE Drives FB_R/W high for a read and low for a write
S1	All	Mini-FlexBus: <ul style="list-style-type: none"> Negates $\overline{\text{FB_TS}}/\text{FB_ALE}$ on the rising edge of FB_CLK Asserts FB_CS_n Drives the data on FB_ADX–FB_AD0 for writes Tristates FB_ADX–FB_AD0 for reads Continues to drive the address on FB_AD pins that are unused for data
	Read	The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2).
S2	All	$\overline{\text{FB_CS}}_n$ and the transfer is complete.
	Read	Mini-FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.
S3	All	Mini-FlexBus invalidates the address, data, and FB_R/W on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.

26.4.11 Mini-FlexBus Timing Examples

Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

Also, ignore the AA=0 portions of the diagrams, since this setting is not supported in the Mini-FlexBus.

Note

Throughout this section:

- FB_D[X] indicates a 16-, or 8-bit wide data bus
- FB_A[Y] indicates an address bus that can be 20 bits wide.

26.4.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

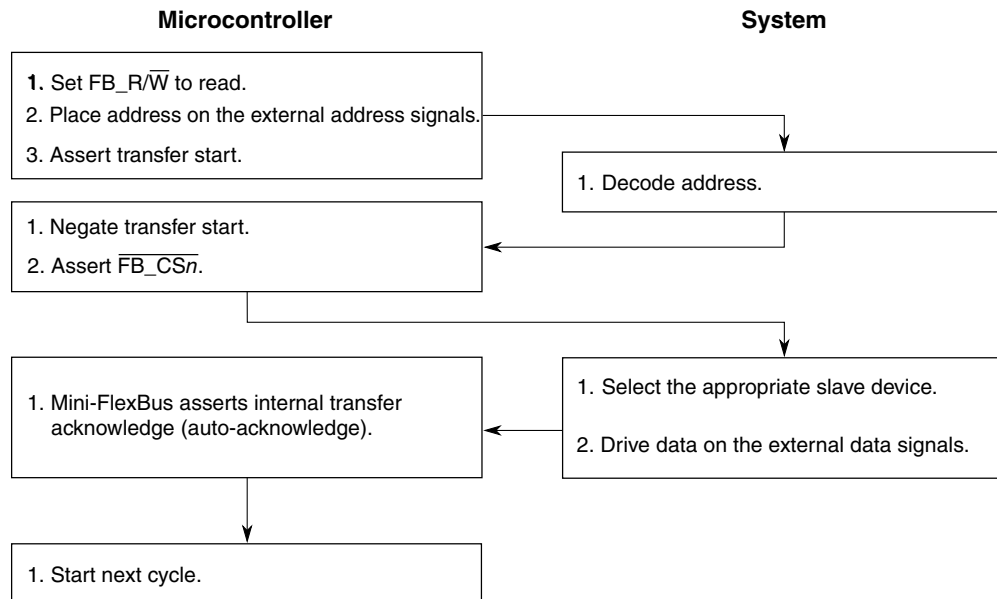

Figure 26-13. Read Cycle Flowchart

The read cycle timing diagram is shown in the following figure.

Note

The processor drives the data lines during the first clock cycle of the transfer with the full 20-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

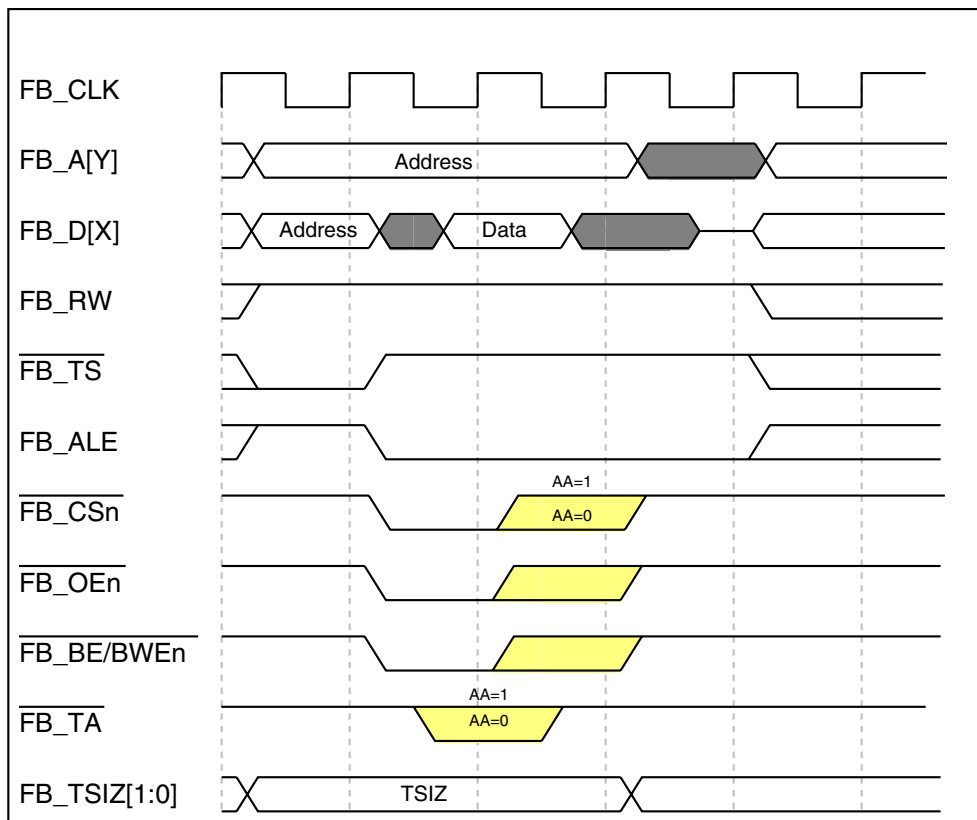

Figure 26-14. Basic Read-Bus Cycle

26.4.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

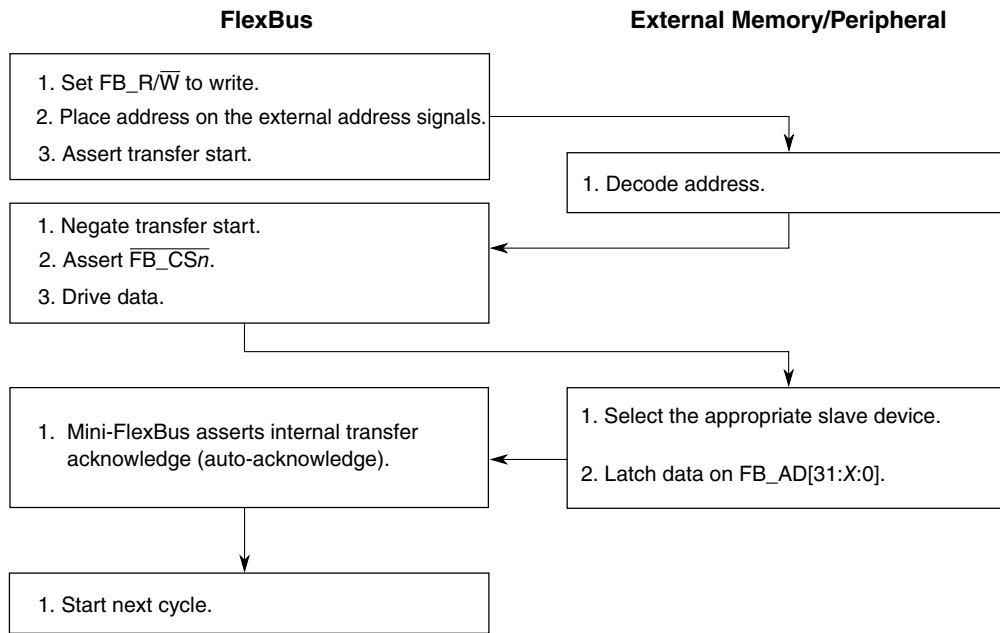

Figure 26-15. Write-Cycle Flowchart

The following figure shows the write cycle timing diagram.

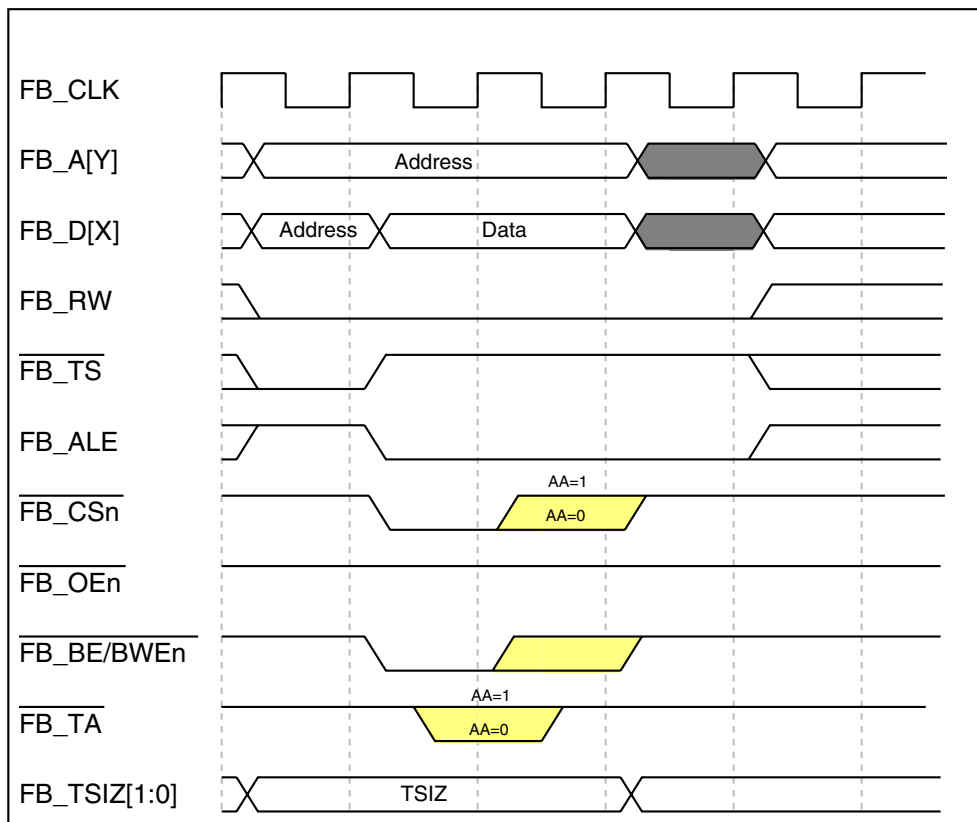

Figure 26-16. Basic Write-Bus Cycle

26.4.11.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

26.4.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The following figure illustrates the basic byte read transfer to an 8-bit device with no wait states:

- The address is driven on the full FB_AD[19:8] bus in the first clock.
- The device tristates FB_AD[7:0] on the second clock and continues to drive address on FB_AD[19:8] throughout the bus cycle.
- The external device returns the read data on FB_AD[7:0].

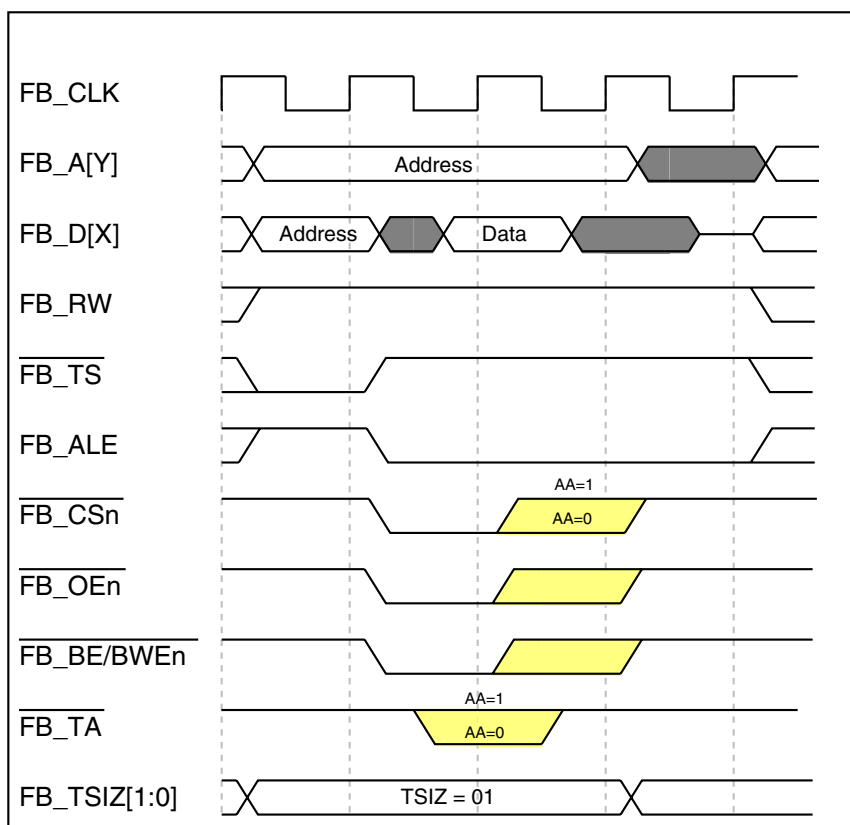

Figure 26-17. Single Byte-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[7:0].

Figure 26-18. Single Byte-Write Transfer

26.4.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB_AD[19:8] bus in the first clock.
- The device tristates FB_AD[15:0] on the second clock and continues to drive address on FB_AD[19:16] throughout the bus cycle.
- The external device returns the read data on FB_AD[15:0].

Note

In non-multiplexed mode, the Mini-FlexBus does not support connection to a 16-bit device.

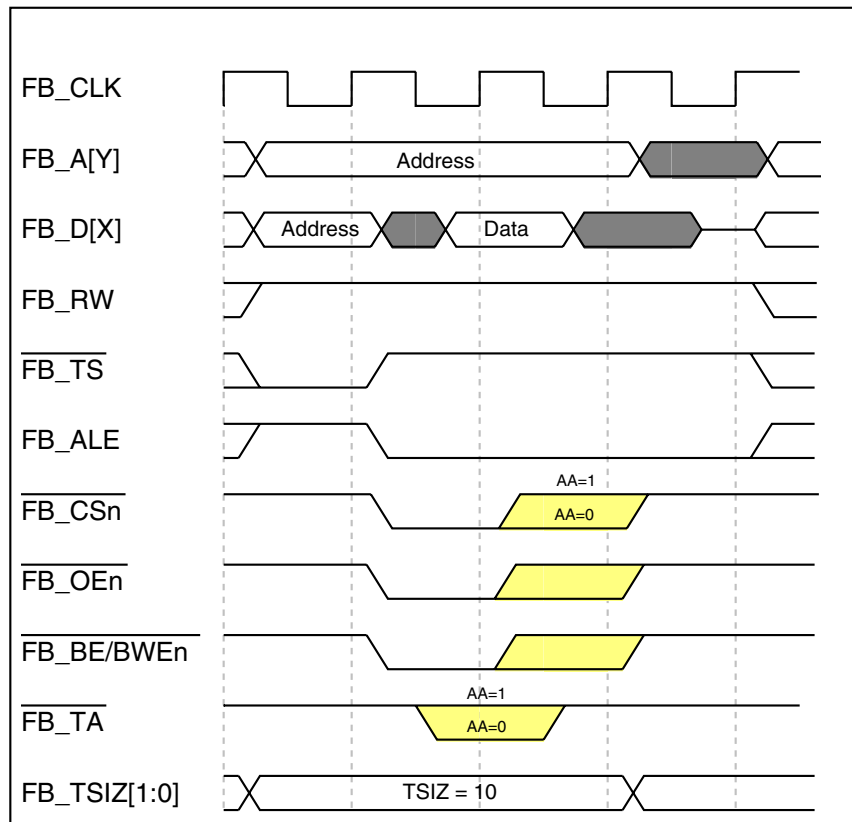

Figure 26-19. Single Word-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[15:0].

Note

In non-multiplexed mode, the Mini-FlexBus does not support connection to a 16-bit device.

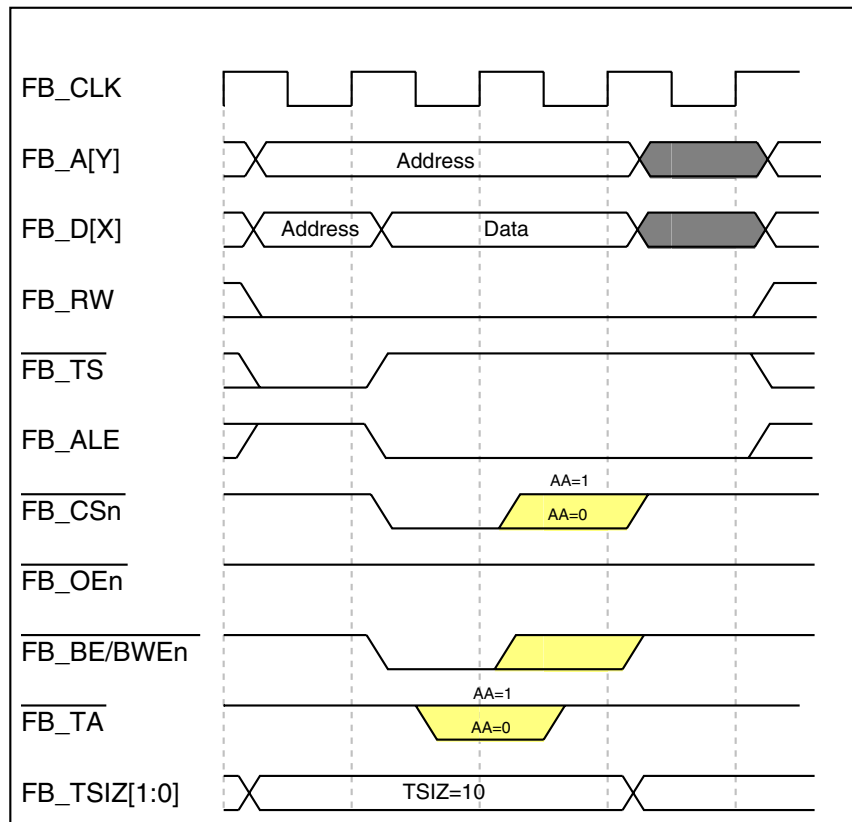

Figure 26-20. Single Word-Write Transfer

26.4.11.4 Timing Variations

The Mini-FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

26.4.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the $CSCR_n$ registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in [Figure 26-14](#) and [Figure 26-19](#)) with the default of no wait states respectively.

Functional description

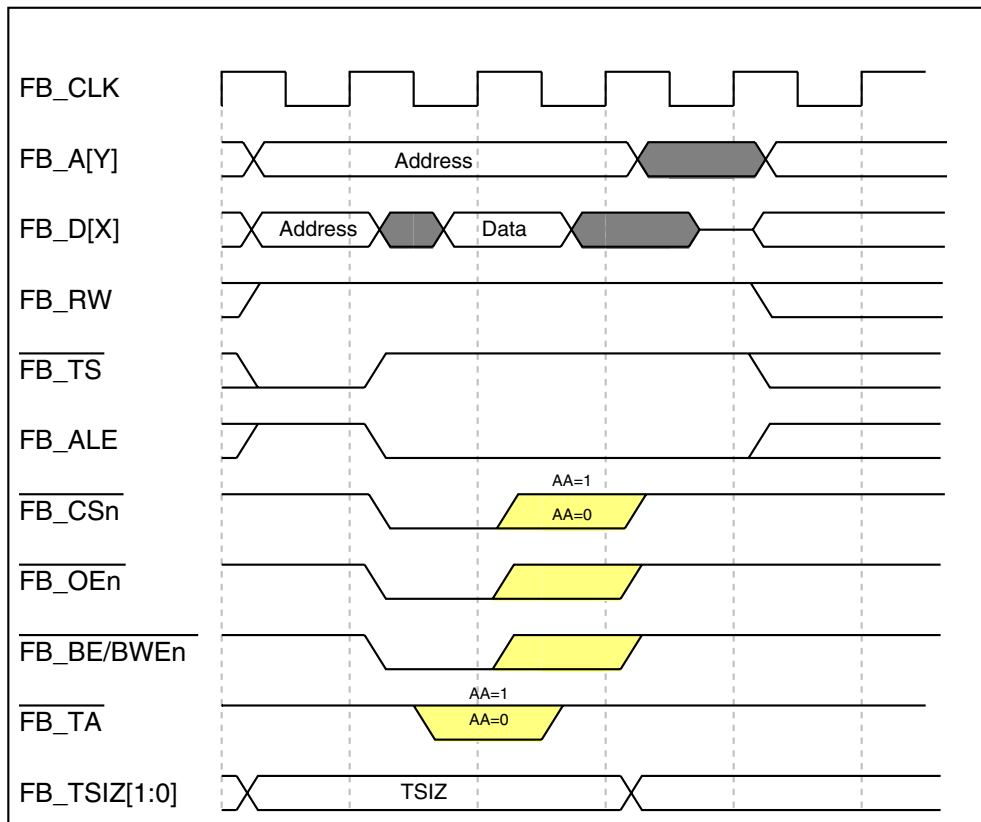

Figure 26-21. Basic Read-Bus Cycle (No Wait States)

Figure 26-22. Basic Write-Bus Cycle (No Wait States)

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge. The following figures show a read and write cycle with one wait state respectively.

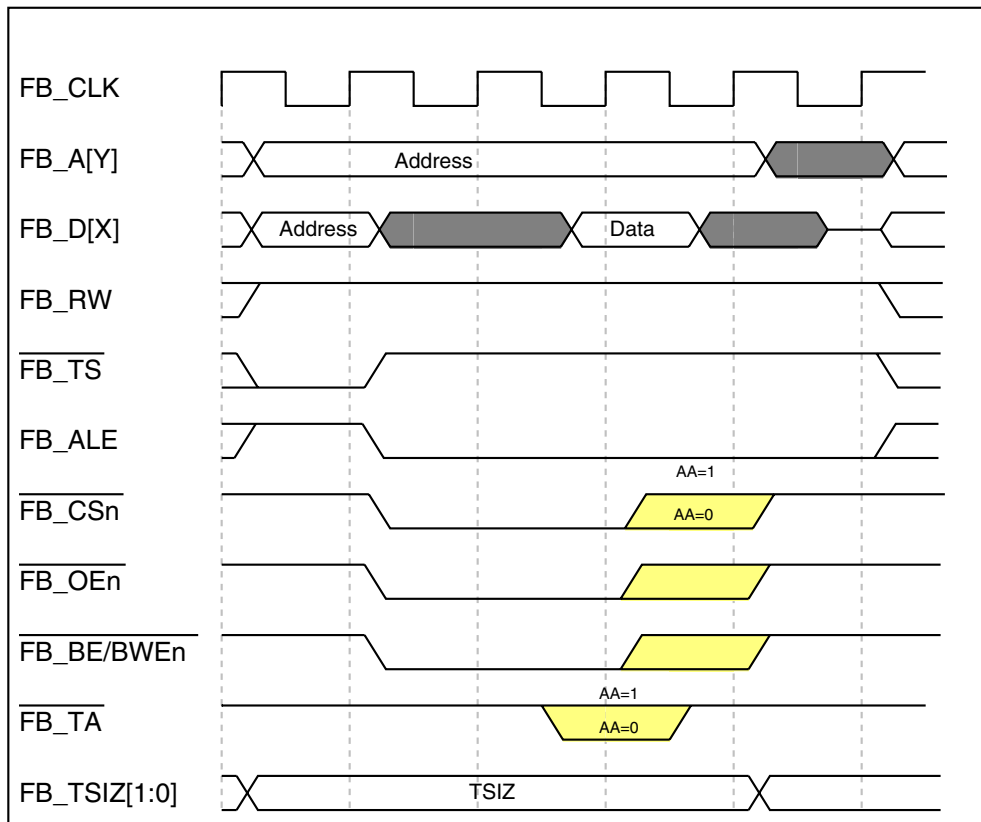

Figure 26-23. Read-Bus Cycle (One Wait State)

Figure 26-24. Write-Bus Cycle (One Wait State)

26.4.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable ($\overline{\text{FB_TS}}$ / $\overline{\text{FB_ALE}}$) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

Functional description

Figure 26-25. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)

Figure 26-26. Write-Bus Cycle with Two Clock Address Setup (No Wait States)

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

Figure 26-27. Read Cycle with Two-Clock Address Hold (No Wait States)

Figure 26-28. Write Cycle with Two-Clock Address Hold (No Wait States)

The following figure shows a bus cycle using address setup, wait states, and address hold.

Figure 26-29. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)

26.4.12 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- CSCR_n[AA] is cleared
- The clock to Mini-Flexbus is disabled
- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects

There are certain accesses to Mini-FlexBus that cause the system bus to hang. It is important to have an access-error handler to manage these conditions.

26.5 Initialization/Application Information

26.5.1 Initializing a chip-select

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

26.5.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

Chapter 27

EzPort

27.1 Overview

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The EzPort module is a serial flash programming interface that allows In-System Programming (ISP) of flash memory contents on a 32 bit general-purpose microcontroller. Memory contents can be read, erased, and programmed from an external source in a format that is compatible with many stand-alone flash memory chips, without necessitating the removal of the microcontroller from the system.

27.1.1 Introduction

The following figure is a high level block diagram of the EzPort.

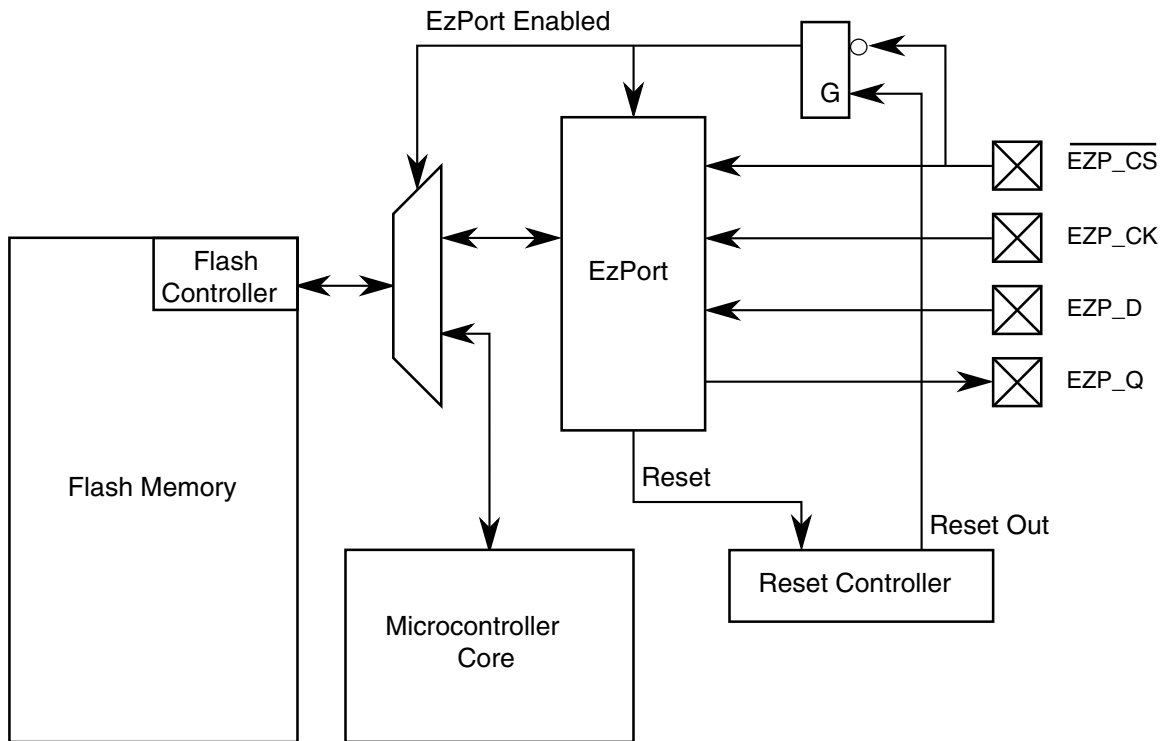

Figure 27-1. EzPort block diagram

27.1.2 Features

EzPort includes the following features:

- Serial interface that is compatible with a subset of the SPI format.
- Ability to read, erase, and program flash memory.
- Ability to reset the microcontroller, allowing it to boot from the flash memory after the memory has been configured.

27.1.3 Modes of operation

The EzPort can operate in one of two modes, enabled or disabled.

- Enabled — When enabled, the EzPort steals access to the flash memory, preventing access from other cores or peripherals. The rest of the microcontroller is disabled to avoid conflicts. The flash is configured for NVM Special mode.
- Disabled — When the EzPort is disabled, the rest of the microcontroller can access flash memory as normal.

The EzPort provides a simple interface to connect an external device to the flash memory on board a 32 bit microcontroller. The interface itself is compatible with the SPI interface, with the EzPort operating as a slave, running in either of the two following modes. The data is transmitted with the most significant bit first.

- CPOL = 0, CPHA = 0
- CPOL = 1, CPHA = 1

Commands are issued by the external device to erase, program, or read the contents of the flash memory. The serial data out from the EzPort is tri-stated unless data is being driven. This allows the signal to be shared among several different EzPort (or compatible) devices in parallel, as long as they have different chip-selects.

27.2 External signal description

The following table contains a list of EzPort external signals, and the following sections explain the signals in detail.

Table 27-1. EzPort external signal description

Name	Description	I/O
EZP_CK	EzPort Clock	Input
$\overline{\text{EZP_CS}}$	EzPort Chip Select	Input
EZP_D	EzPort Serial Data In	Input
EZP_Q	EzPort Serial Data Out	Output

27.2.1 EzPort Clock (EZP_CK)

EZP_CK is the serial clock for data transfers. The serial data in (EZP_D) and chip select ($\overline{\text{EZP_CS}}$) are registered on the rising edge of EZP_CK, while serial data out (EZP_Q) is driven on the falling edge of EZP_CK.

The maximum frequency of the EzPort clock is half the system clock frequency for all commands except when executing the Read Data or Read FlexRAM commands. When executing these commands, the EzPort clock has a maximum frequency of one-eighth the system clock frequency.

27.2.2 EzPort Chip Select ($\overline{\text{EZP_CS}}$)

$\overline{\text{EZP_CS}}$ is the chip select for signaling the start and end of serial transfers. If, while $\overline{\text{EZP_CS}}$ is asserted, the microcontroller's reset out signal is negated, EzPort is enabled out of reset; otherwise it is disabled. After EzPort is enabled, asserting $\overline{\text{EZP_CS}}$ commences a serial data transfer, which continues until $\overline{\text{EZP_CS}}$ is negated again. The negation of $\overline{\text{EZP_CS}}$ indicates the current command is finished and resets the EzPort state machine so that it is ready to receive the next command.

27.2.3 EzPort Serial Data In (EZP_D)

EZP_D is the serial data in for data transfers. EZP_D is registered on the rising edge of EZP_CK. All commands, addresses, and data are shifted in most significant bit first. When the EzPort is driving output data on EZP_Q, the data shifted in EZP_D is ignored.

27.2.4 EzPort Serial Data Out (EZP_Q)

EZP_Q is the serial data out for data transfers. EZP_Q is driven on the falling edge of EZP_CK. It is tri-stated unless $\overline{\text{EZP_CS}}$ is asserted and the EzPort is driving data out. All data is shifted out most significant bit first.

27.3 Command definition

The EzPort receives commands from an external device and translates the commands into flash memory accesses. The following table lists the supported commands.

Table 27-2. EzPort commands

Command	Description	Code	Address Bytes	Data Bytes	Accepted when secure?
WREN	Write Enable	0x06	0	0	Yes
WRDI	Write Disable	0x04	0	0	Yes
RDSR	Read Status Register	0x05	0	1	Yes
READ	Flash Read Data	0x03	3 ¹	1+	No
FAST_READ	Flash Read Data at High Speed	0x0B	3 ¹	1+ ²	No
SP	Flash Section Program	0x02	3 ³	4 - SECTION ⁴	No
SE	Flash Sector Erase	0xD8	3 ³	0	No
BE	Flash Bulk Erase	0xC7	0	0	Yes ⁵
RESET	Reset Chip	0xB9	0	0	Yes
WRFCOB	Write FCCOB Registers	0xBA	0	12	Yes ⁶

Table continues on the next page...

Table 27-2. EzPort commands (continued)

Command	Description	Code	Address Bytes	Data Bytes	Accepted when secure?
FAST_RDFCCOB	Read FCCOB registers at high speed	0xBB	0	1 - 12 ²	No
WRFLEXRAM	Write FlexRAM	0xBC	3 ¹	4	No
RDFLEXRAM	Read FlexRAM	0xBD	3 ¹	1+	No
FAST_RDFLEXRAM	Read FlexRAM at high speed	0xBE	3 ¹	1+ ²	No

1. Address must be 32-bit aligned (two LSBs must be zero).
2. One byte of dummy data must be shifted in before valid data is shifted out.
3. Address must be 32-bit aligned (two LSBs must be zero).
4. Please see the Flash Memory chapter for a definition of section size. Total number of data bytes programmed must be a multiple of 4.
5. Bulk Erase is accepted when security is set and only when the BEDIS status field is not set.
6. The flash will be in NVM Special mode, restricting the type of commands that can be executed through WRITE_FCCOB when security is enabled.

27.3.1 Command descriptions

This section describes the module commands.

27.3.1.1 Write Enable

The Write Enable (WREN) command sets the write enable register field in the EzPort status register. The write enable field must be set for a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) to be accepted. The write enable register field clears on reset, on a Write Disable command, and at the completion of write command. This command must not be used if a write is already in progress.

27.3.1.2 Write Disable

The Write Disable (WRDI) command clears the write enable register field in the status register. This command must not be used if a write is already in progress.

27.3.1.3 Read Status Register

The Read Status Register (RDSR) command returns the contents of the EzPort status register.

Table 27-3. EzPort status register

	7	6	5	4	3	2	1	0
R	FS	WEF			FLEXRAM	BEDIS	WEN	WIP
W								
Reset:	0/1 ¹	0	0	0	0/1 ²	0/1 ³	0	1 ⁴

1. Reset value reflects the status of flash security out of reset.
2. Reset value reflects FlexNVM flash partitioning. If FlexNVM flash has been partitioned for EEPROM, this field is set immediately after reset. Note that FLEXRAM is cleared after the EzPort initialization sequence completes, as indicated by clearing of WIP.
3. Reset value reflects whether bulk erase is enabled or disabled out of reset.
4. Initial value of WIP is 1, but the value clears to 0 after EzPort initialization is complete.

Table 27-4. EzPort status register field description

Field	Description
0 WIP	Write in progress. Sets after a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) is accepted and clears after the flash memory has completed all operations associated with the write command, as indicated by the Command Complete Interrupt Flag (CCIF) inside the flash. This field is also asserted on reset and cleared when EzPort initialization is complete. Only the Read Status Register (RDSR) command is accepted while a write is in progress. 0 = Write is not in progress. Accept any command. 1 = Write is in progress. Only accept RDSR command.
1 WEN	Write enable Enables the write command that follows. It is a control field that must be set before a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) is accepted. Is set by the Write Enable (WREN) command and cleared by reset or a Write Disable (WRDI) command. This field also clears when the flash memory has completed all operations associated with the command. 0 = Disables the following write command. 1 = Enables the following write command.
2 BEDIS	Bulk erase disable Indicates whether bulk erase (BE) is disabled when flash is secure. 0 = BE is enabled. 1 = BE is disabled if FS is also set. Attempts to issue a BE command will result in the WEF flag being set.
3 FLEXRAM	FlexRAM mode Indicates the current mode of the FlexRAM. Valid only when WIP is cleared. 0 = FlexRAM is in RAM mode. RD/WRFLEXRAM command can be used to read/write data in FlexRAM. 1 = FlexRAM is in EEPROM mode. SP command is not accepted. RD/WRFLEXRAM command can be used to read/write data in the FlexRAM.

Table continues on the next page...

Table 27-4. EzPort status register field description (continued)

Field	Description
6 WEF	<p>Write error flag</p> <p>Indicates whether there has been an error while executing a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM). The WEF flag will set if Flash Access Error Flag (ACCERR), Flash Protection Violation (FPVIOL), or Memory Controller Command Completion Status (MGSTAT0) inside the flash memory is set at the completion of the write command. See the flash memory chapter for further description of these flags and their sources. The WEF flag clears after a Read Status Register (RDSR) command.</p> <p>0 = No error on previous write command. 1 = Error on previous write command.</p>
7 FS	<p>Flash security</p> <p>Indicates whether the flash is secure. See Table 27-2 for the list of commands that will be accepted when flash is secure. Flash security can be disabled by performing a BE command.</p> <p>0 = Flash is not secure. 1 = Flash is secure.</p>

27.3.1.4 Read Data

The Read Data (READ) command returns data from the flash memory or FlexNVM, depending on the initial address specified in the command word. The initial address must be 32-bit aligned with the two LSBs being zero.

Data continues being returned for as long as the EzPort chip select ($\overline{\text{EzP_CS}}$) is asserted, with the address automatically incrementing. In this way, the entire contents of flash can be returned by one command. Attempts to read from an address which does not fall within the valid address range for the flash memory regions returns unknown data. See [Flash memory map for EzPort access](#).

For this command to return the correct data, the EzPort clock (EzP_CK) must run at the internal system clock divided by eight or slower. This command is not accepted if the WEF, WIP, or FS field in the EzPort status register is set.

27.3.1.5 Read Data at High Speed

The Read Data at High Speed (FAST_READ) command is identical to the READ command, except for the inclusion of a dummy byte following the address bytes and before the first data byte is returned.

This command can be run with an EzPort clock (EzP_CK) frequency of half the internal system clock frequency of the microcontroller or slower. This command is not accepted if the WEF, WIP, or FS field in the EzPort status register is set.

27.3.1.6 Section Program

The Section Program (SP) command programs up to one section of flash memory that has previously been erased. Please see the Flash Memory chapter for a definition of section size. The starting address of the memory to program is sent after the command word and must be a 32-bit aligned address with the two LSBs being zero.

As data is shifted in, the EzPort buffers the data in FlexRAM before executing an SP command within the flash. For this reason, the number of bytes to be programmed must be a multiple of 4 and up to one flash section can be programmed at a time. For more details, see the Flash Block Guide.

Attempts to program more than one section, across a sector boundary or from an initial address which does not fall within the valid address range for the flash causes the WEF flag to set. See [Flash memory map for EzPort access](#).

This command requires the FlexRAM to be configured for traditional RAM operation. By default, after entering EzPort mode, the FlexRAM is configured for traditional RAM operation. If the user reconfigures FlexRAM for EEPROM operation, then the user should use the WRFCCOB command to configure FlexRAM back to traditional RAM operation before issuing an SP command. See the Flash Memory chapter for details on how the FlexRAM function is modified.

This command is not accepted if the WEF, WIP, FLEXRAM, or FS field is set or if the WEN field is not set in the EzPort status register.

27.3.1.7 Sector Erase

The Sector Erase (SE) command erases the contents of one sector of flash memory. The three byte address sent after the command byte can be any address within the sector to erase, but must be a 32-bit aligned address (the two LSBs must be zero). Attempts to erase from an initial address which does not fall within the valid address range (see [Flash memory map for EzPort access](#)) for the flash results in the WEF flag being set.

This command is not accepted if the WEF, WIP or FS field is set or if the WEN field is not set in the EzPort status register.

27.3.1.8 Bulk Erase

The Bulk Erase (BE) command erases the entire contents of flash memory, ignoring any protected sectors or flash security. Flash security is disabled upon successful completion of the BE command.

Attempts to issue a BE command while the BEDIS and FS fields are set results in the WEF flag being set in the EzPort status register. Also, this command is not accepted if the WEF or WIP field is set or if the WEN field is not set in the EzPort status register.

27.3.1.9 EzPort Reset Chip

The Reset Chip (RESET) command forces the chip into the reset state. If the EzPort chip select ($\overline{\text{EZP_CS}}$) pin is asserted at the end of the reset period, EzPort is enabled; otherwise, it is disabled. This command allows the chip to boot up from flash memory after being programmed by an external source.

This command is not accepted if the WIP field is set in the EzPort status register.

27.3.1.10 Write FCCOB Registers

The Write FCCOB Registers (WRFCCOB) command allows the user to write to the flash common command object registers and execute any command allowed by the flash.

NOTE

When security is enabled, the flash is configured in NVM Special mode, restricting the commands that can be executed by the flash.

After receiving 12 bytes of data, EzPort writes the data to the FCCOB 0-B registers in the flash and then automatically launches the command within the flash. If greater or less than 12 bytes of data is received, this command has unexpected results and may result in the WEF flag being set.

This command is not accepted if the WEF or WIP field is set or if the WEN field is not set in the EzPort status register.

27.3.1.11 Read FCCOB Registers at High Speed

The Read FCCOB Registers at High Speed (FAST_RDFCCOB) command allows the user to read the contents of the flash common command object registers. After receiving the command, EzPort waits for one dummy byte of data before returning FCCOB register data starting at FCCOB 0 and ending with FCCOB B.

This command can be run with an EzPort clock (EZP_CK) frequency half the internal system clock frequency of the microcontroller or slower. Attempts to read greater than 12 bytes of data returns unknown data. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are 1.

27.3.1.12 Write FlexRAM

The Write FlexRAM (WRFLEXRAM) command allows the user to write four bytes of data to the FlexRAM. If the FlexRAM is configured for EEPROM operation, the WRFLEXRAM command can effectively be used to create data records in the EEPROM flash memory.

By default, after entering EzPort mode, the FlexRAM is configured for traditional RAM operation and functions as direct RAM. The user can alter the FlexRAM configuration by using WRFCCOB to execute a Set FlexRAM or Program Partition command within the flash.

The address of the FlexRAM location to be written is sent after the command word and must be a 32-bit aligned address (the two LSBs must be zero). Attempts to write an address which does not fall within the valid address range for the FlexRAM results in the value of the WEF flag being 1. See [Flash memory map for EzPort access](#) for more information.

After receiving four bytes of data, EzPort writes the data to the FlexRAM. If greater or less than four bytes of data is received, this command has unexpected results and may result in the value of the WEF flag being 1.

This command is not accepted if the WEF, WIP or FS fields are 1 or if the WEN field is 0 in the EzPort status register.

27.3.1.13 Read FlexRAM

The Read FlexRAM (RDFLEXRAM) command returns data from the FlexRAM. If the FlexRAM is configured for EEPROM operation, the RDFLEXRAM command can effectively be used to read data from EEPROM flash memory.

Data continues being returned for as long as the EzPort chip select ($\overline{\text{EzP_CS}}$) is asserted, with the address automatically incrementing. In this way, the entire contents of FlexRAM can be returned by one command.

The initial address must be 32-bit aligned (the two LSBs must be zero). Attempts to read from an address which does not fall within the valid address range for the FlexRAM returns unknown data. See [Flash memory map for EzPort access](#) for more information.

For this command to return the correct data, the EzPort clock (EzP_CK) must run at the internal system clock divided by eight or slower. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are set.

27.3.1.14 Read FlexRAM at High Speed

The Read FlexRAM at High Speed (FAST_RDFLEXRAM) command is identical to the RDFLEXRAM command, except for the inclusion of a dummy byte following the address bytes and before the first data byte is returned.

This command can be run with an EzPort clock (EzP_CK) frequency up to and including half the internal system clock frequency of the microcontroller. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are set.

27.4 Flash memory map for EzPort access

The following table shows the flash memory map for access through EzPort.

NOTE

The flash block address map for access through EzPort may not conform to the system memory map. Changes are made to allow the EzPort address width to remain 24 bits.

Table 27-5. Flash Memory Map for EzPort Access

Valid start address	Size	Flash block	Valid commands
0x0000_0000	See device's chip configuration details	Flash	READ, FAST_READ, SP, SE, BE
0x0080_0000	See device's chip configuration details	FlexNVM	READ, FAST_READ, SP, SE, BE
0x0000_0000	See device's chip configuration details	FlexRAM	RDFLEXRAM, FAST_RDFLEXRAM, WRFLEXRAM, BE

Chapter 28

Cyclic Redundancy Check (CRC)

28.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial, WAS, and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

28.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or byte-wise. This option is required for certain CRC standards. A byte-wise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the byte-wise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

28.1.2 Block diagram

The following is a block diagram of the CRC.

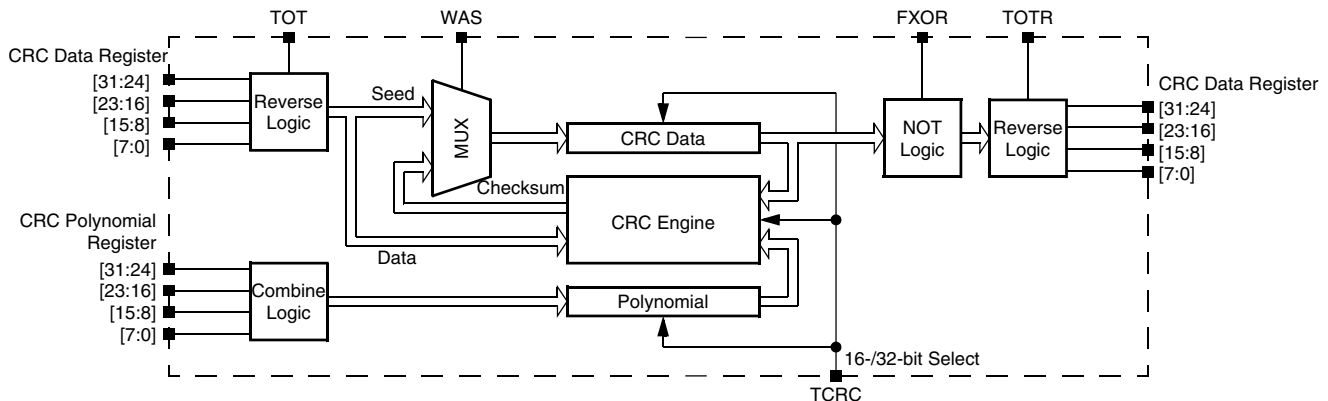

Figure 28-1. Programmable cyclic redundancy check (CRC) block diagram

28.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

28.1.3.1 Run mode

This is the basic mode of operation.

28.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is MCU dependent.

28.2 Memory map and register descriptions

CRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
FFFF_8570	CRC Data Register (CRC_CRC)	32	R/W	FFFF_FFFFh	28.2.1/579
FFFF_8574	CRC Polynomial Register (CRC_GPOLY)	32	R/W	0000_1021h	28.2.2/580
FFFF_8578	CRC Control Register (CRC_CTRL)	16	R/W	0000h	28.2.3/580

28.2.1 CRC Data Register (CRC_CRC)

The CRC data register contains the value of the seed, data, and checksum. When the CTRL[WAS] bit is set, any write to the data register is regarded as the seed value. When the CTRL[WAS] bit is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: FFFF_8570h base + 0h offset = FFFF_8570h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	

CRC_CRC field descriptions

Field	Description
31–24 HU	CRC High Upper Byte In 16-bit CRC mode (the CTRL[TCRC] bit is 0), this field is not used for programming a seed value. In 32-bit CRC mode (the CTRL[TCRC] bit is 1), values written to this field are part of the seed value when the CTRL[WAS] bit is 1. When the CTRL[WAS] bit is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23–16 HL	CRC High Lower Byte In 16-bit CRC mode (the CTRL[TCRC] bit is 0), this field is not used for programming a seed value. In 32-bit CRC mode (the CTRL[TCRC] bit is 1), values written to this field are part of the seed value when the CTRL[WAS] bit is 1. When the CTRL[WAS] bit is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15–8 LU	CRC Low Upper Byte When the CTRL[WAS] bit is 1, values written to this field are part of the seed value. When the CTRL[WAS] bit is 0, data written to this field is used for CRC checksum generation.
7–0 LL	CRC Low Lower Byte When the CTRL[WAS] bit is 1, values written to this field are part of the seed value. When the CTRL[WAS] bit is 0, data written to this field is used for CRC checksum generation.

28.2.2 CRC Polynomial Register (CRC_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: FFFF_8570h base + 4h offset = FFFF_8574h

CRC_GPOLY field descriptions

Field	Description
31–16 HIGH	High polynomial half-word This field is writable and readable in 32-bit CRC mode (the CTRL[TCRC] bit is 1). This field is not writable in 16-bit CRC mode (the CTRL[TCRC] bit is 0).
15–0 LOW	Low polynomial half-word This field is writable and readable in both 32-bit and 16-bit CRC modes.

28.2.3 CRC Control Register (CRC_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting the CTRL[WAS] bit and then writing the seed into the CRC data register.

Address: FFFF_8570h base + 8h offset = FFFF_8578h

CRC_CTRL field descriptions

Field	Description
15–14 TOT	<p>Type of Transpose for Writes</p> <p>These bits define the transpose configuration of the data written to the CRC data register. Refer to the description of the transpose feature for the available transpose options.</p> <p>00 No transposition. 01 Bits in bytes are transposed; bytes are not transposed. 10 Both bits in bytes and bytes are transposed. 11 Only bytes are transposed; no bits in a byte are transposed.</p>
13–12 TOTR	<p>Type of Transpose for Read</p> <p>These bits identify the transpose configuration of the value read from the CRC data register. Refer to the description of the transpose feature for the available transpose options.</p> <p>00 No transposition. 01 Bits in bytes are transposed; bytes are not transposed. 10 Both bits in bytes and bytes are transposed. 11 Only bytes are transposed; no bits in a byte are transposed.</p>
11 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
10 FXOR	<p>Complement Read of CRC data register</p> <p>Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables "on the fly" complementing of read data.</p> <p>0 No XOR on reading. 1 Invert or complement the read value of the CRC data register.</p>
9 WAS	<p>Write CRC data register as seed</p> <p>When this bit is asserted, a value written to the CRC data register is considered a seed value. When this bit is de-asserted, a value written to the CRC data register is taken as data for CRC computation.</p> <p>0 Writes to the CRC data register are data values. 1 Writes to the CRC data register are seed values.</p>
8 TCRC	<p>Width of CRC protocol.</p> <p>0 16-bit CRC protocol. 1 32-bit CRC protocol.</p>
7–0 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>

28.3 Functional description

28.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program the WAS, POLYNOMIAL, and necessary parameters for transpose and CRC result inversion in the applicable registers. Asserting CTRL[WAS] enables the programming of the seed value into the CRC data register.

After a completed CRC calculation, reasserting CTRL[WAS] and programming a seed, whether the value is new or a previously used seed value, reinitialize the CRC module for a new CRC computation. All other parameters must be set before programming the seed value and subsequent data values.

28.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

28.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 16-bit polynomial to the GPOLY[LOW] field. The GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC[LU:LL]. CRC[HU:HL] are not used.
6. Clear CTRL[WAS] to start writing data values.
7. Write data values into CRC[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC[LU:LL].
8. When all values have been written, read the final CRC result from CRC[LU:LL].

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

28.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 32-bit polynomial to GPOLY[HIGH:LOW].
4. Set CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC[HU:HL:LU:LL].
6. Clear CTRL[WAS] to start writing data values.
7. Write data values into CRC[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC[HU:HL:LU:LL]. The CRC is calculated bitwise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

28.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

28.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00
No transposition occurs.
2. CTRL[TOT] or CTRL[TOTR] is 01

Functional description

Bits in a byte are transposed, while bytes are not transposed.

reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

Figure 28-5. Transpose type 01

3. CTRL[TOT] or CTRL[TOTR] is 10

Both bits in bytes and bytes are transposed.

reg[31:0] becomes = {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}

Figure 28-6. Transpose type 10

4. CTRL[TOT] or CTRL[TOTR] is 11

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

Figure 28-7. Transpose type 11

NOTE

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[**HU:HL**] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

28.3.4 CRC result complement

When CTRL[**FXOR**] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[**FXOR**] is cleared, reading the CRC data register accesses the raw checksum value.

Chapter 29

Analog-to-Digital Converter (ADC)

29.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The 12-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

NOTE

For the chip specific modes of operation, see the power management information of the device.

29.1.1 Features

Features of the ADC module include:

- Linear successive approximation algorithm with up to 12-bit resolution
- Up to 24 single-ended external analog inputs
- Output modes:
 - single-ended 12-bit, 10-bit, and 8-bit modes
- Output in right-justified unsigned format for single-ended
- Single or continuous conversion, that is, automatic return to idle after single conversion
- Configurable sample time and conversion speed/power
- Conversion complete/hardware average complete flag and interrupt

- Input clock selectable from up to four sources
- Operation in Low-Power modes for lower noise
- Asynchronous clock source for lower noise operation with option to output the clock
- Selectable hardware conversion trigger with hardware channel select
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Temperature sensor
- Hardware average function
- Selectable voltage reference: external or alternate
- Self-Calibration mode

29.1.2 Block diagram

The following figure is the ADC module block diagram.

Figure 29-1. ADC block diagram

29.2 ADC Signal Descriptions

The ADC module supports up to 24 single-ended inputs. The ADC also requires four supply/reference/ground connections.

NOTE

Refer to ADC configuration section in chip configuration chapter for the number of channels supported on this device.

Table 29-1. ADC Signal Descriptions

Signal	Description	I/O
ADn	Single-Ended Analog Channel Inputs	I
V_{REFSH}	Voltage Reference Select High	I
V_{REFSL}	Voltage Reference Select Low	I
V_{DDA}	Analog Power Supply	I
V_{SSA}	Analog Ground	I

29.2.1 Analog Power (V_{DDA})

The ADC analog portion uses V_{DDA} as its power connection. In some packages, V_{DDA} is connected internally to V_{DD} . If externally available, connect the V_{DDA} pin to the same voltage potential as V_{DD} . External filtering may be necessary to ensure clean V_{DDA} for good results.

29.2.2 Analog Ground (V_{SSA})

The ADC analog portion uses V_{SSA} as its ground connection. In some packages, V_{SSA} is connected internally to V_{SS} . If externally available, connect the V_{SSA} pin to the same voltage potential as V_{SS} .

29.2.3 Voltage Reference Select

V_{REFSH} and V_{REFSL} are the high and low reference voltages for the ADC module.

The ADC can be configured to accept one of two voltage reference pairs for V_{REFSH} and V_{REFSL} . Each pair contains a positive reference that must be between the minimum Ref Voltage High and V_{DDA} , and a ground reference that must be at the same potential as V_{SSA} . The two pairs are external (V_{REFH} and V_{REFL}) and alternate (V_{ALTH} and V_{ALTL}). These voltage references are selected using $SC2[REFSEL]$. The alternate V_{ALTH} and V_{ALTL} voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the Voltage References specific to this MCU.

In some packages, V_{REFH} is connected in the package to V_{DDA} and V_{REFL} to V_{SSA} . If externally available, the positive reference(s) may be connected to the same potential as V_{DDA} or may be driven by an external source to a level between the minimum Ref Voltage High and the V_{DDA} potential. V_{REFH} must never exceed V_{DDA} . Connect the ground references to the same voltage potential as V_{SSA} .

29.2.4 Analog Channel Inputs (ADx)

The ADC module supports up to 24 single-ended analog inputs. A single-ended input is selected for conversion through the $SC1[ADCH]$ channel select bits.

29.3 Register definition

This section describes the ADC registers.

ADC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

FFFF_864C	ADC Plus-Side General Calibration Value Register (ADC0_CLP0)	32	R/W	0000_0020h	29.3.16/607

29.3.1 ADC Status and Control Registers 1 (ADCx_SC1n)

SC1A is used for both software and hardware trigger modes of operation.

To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC can have more than one status and control register: one for each conversion. The SC1B–SC1n registers indicate potentially multiple SC1 registers for use only in hardware trigger mode. See the chip configuration information about the number of SC1n registers specific to this device. The SC1n registers have identical fields, and are used in a "ping-pong" approach to control ADC operation.

At any one point in time, only one of the SC1n registers is actively controlling ADC conversions. Updating SC1A while SC1n is actively controlling a conversion is allowed, and vice-versa for any of the SC1n registers specific to this MCU.

Writing SC1A while SC1A is actively controlling a conversion aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, writes to SC1A subsequently initiate a new conversion, if SC1[ADCH] contains a value other than all 1s.

Writing any of the SC1n registers while that specific SC1n register is actively controlling a conversion aborts the current conversion. None of the SC1B–SC1n registers are used for software trigger operation and therefore writes to the SC1B–SC1n registers do not initiate a new conversion.

Address: FFFF_8600h base + 0h offset + (4d × i), where i=0d to 1d

ADCx_SC1n field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 COCO	<p>Conversion Complete Flag</p> <p>This is a read-only field that is set each time a conversion is completed when the compare function is disabled, or SC2[ACFE]=0 and the hardware average function is disabled, or SC3[AVGE]=0. When the compare function is enabled, or SC2[ACFE]=1, COCO is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled, or SC3[AVGE]=1, COCO is set upon completion of the selected number of conversions (determined by AVGS). COCO in SC1A is also set at the completion of a calibration sequence. COCO is cleared when the respective SC1n register is written or when the respective Rn register is read.</p> <p>0 Conversion is not completed. 1 Conversion is completed.</p>
6 AIEN	<p>Interrupt Enable</p> <p>Enables conversion complete interrupts. When COCO becomes set while the respective AIEN is high, an interrupt is asserted.</p> <p>0 Conversion complete interrupt is disabled. 1 Conversion complete interrupt is enabled.</p>
5 Reserved	This field is reserved. This reserved bit should not be changed.
4–0 ADCH	<p>Input channel select</p> <p>Selects one of the input channels.</p> <p>NOTE: Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the actual ADC channel assignments for your device, see the Chip Configuration details.</p> <p>The successive approximation converter subsystem is turned off when the channel select bits are all set, that is, ADCH = 11111. This feature allows explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional single conversion from being performed. It is not necessary to set ADCH to all 1s to place the ADC in a low-power state when continuous conversions are not enabled because the module automatically enters a low-power state when a conversion completes.</p> <p>00000 AD0 is selected as input. 00001 AD1 is selected as input. 00010 AD2 is selected as input. 00011 AD3 is selected as input. 00100 AD4 is selected as input. 00101 AD5 is selected as input. 00110 AD6 is selected as input. 00111 AD7 is selected as input. 01000 AD8 is selected as input. 01001 AD9 is selected as input. 01010 AD10 is selected as input. 01011 AD11 is selected as input. 01100 AD12 is selected as input. 01101 AD13 is selected as input.</p>

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADCx_CFG1 field descriptions (continued)

Field	Description
7 ADLPC	<p>Low-Power Configuration</p> <p>Controls the power configuration of the successive approximation converter. This optimizes power consumption when higher sample rates are not required.</p> <p>0 Normal power configuration. 1 Low-power configuration. The power is reduced at the expense of maximum clock speed.</p>
6–5 ADIV	<p>Clock Divide Select</p> <p>ADIV selects the divide ratio used by the ADC to generate the internal clock ADCK.</p> <p>00 The divide ratio is 1 and the clock rate is input clock. 01 The divide ratio is 2 and the clock rate is (input clock)/2. 10 The divide ratio is 4 and the clock rate is (input clock)/4. 11 The divide ratio is 8 and the clock rate is (input clock)/8.</p>
4 ADLSMP	<p>Sample time configuration</p> <p>ADLSMP selects between different sample times based on the conversion mode selected. This bit adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption if continuous conversions are enabled and high conversion rates are not required. When ADLSMP=1, the long sample time select bits, (ADLSTS[1:0]), can select the extent of the long sample time.</p> <p>0 Short sample time. 1 Long sample time.</p>
3–2 MODE	<p>Conversion mode selection</p> <p>Selects the ADC resolution mode.</p> <p>00 It is single-ended 8-bit conversion. 01 It is single-ended 12-bit conversion . 10 It is single-ended 10-bit conversion . 11 Reserved. Do not set the bitfield to this value.</p>
1–0 ADICK	<p>Input Clock Select</p> <p>Selects the input clock source to generate the internal clock, ADCK. Note that when the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start, when CFG2[ADACKEN]=0, the asynchronous clock is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated.</p> <p>00 Bus clock 01 (Bus clock)/2 10 Alternate clock (ALTCLK) 11 Asynchronous clock (ADACK)</p>

29.3.3 ADC Configuration Register 2 (ADCx_CFG2)

Configuration Register 2 (CFG2) selects the special high-speed configuration for very high speed conversions and selects the long sample time duration during long sample mode.

Address: FFFF_8600h base + Ch offset = FFFF_860Ch

ADCx_CFG2 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved.
3 ADACKEN	Asynchronous Clock Output Enable Enables the asynchronous clock source and the clock source output regardless of the conversion and status of CFG1[ADICLK]. Based on MCU configuration, the asynchronous clock may be used by other modules. See chip configuration information. Setting this field allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced because the ADACK clock is already operational.

Table continues on the next page...

ADCx_CFG2 field descriptions (continued)

Field	Description
	0 Asynchronous clock output disabled; Asynchronous clock is enabled only if selected by ADICLK and a conversion is active. 1 Asynchronous clock and clock output is enabled regardless of the state of the ADC.
2 ADHSC	High-Speed Configuration Configures the ADC for very high-speed operation. The conversion sequence is altered with 2 ADCK cycles added to the conversion time to allow higher speed conversion clocks. 0 Normal conversion sequence selected. 1 High-speed conversion sequence selected with 2 additional ADCK cycles to total conversion time.
1–0 ADLSTS	Long Sample Time Select Selects between the extended sample times when long sample time is selected, that is, when CFG1[ADLSMP]=1. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required. 00 Default longest sample time; 20 extra ADCK cycles; 24 ADCK cycles total. 01 12 extra ADCK cycles; 16 ADCK cycles total sample time. 10 6 extra ADCK cycles; 10 ADCK cycles total sample time. 11 2 extra ADCK cycles; 6 ADCK cycles total sample time.

29.3.4 ADC Data Result Register (ADCx_Rn)

The data result registers (Rn) contain the result of an ADC conversion of the channel selected by the corresponding status and channel control register (SC1A:SC1n). For every status and channel control register, there is a corresponding data result register.

Unused bits in Rn are cleared in unsigned right-justified modes and carry the sign bit (MSB) in sign-extended 2's complement modes.

The following table describes the behavior of the data result registers in the different modes of operation.

Table 29-35. Data result register description

Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
12-bit single-ended	0	0	0	0	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned right-justified
10-bit single-ended	0	0	0	0	0	0	D	D	D	D	D	D	D	D	D	D	Unsigned right-justified
8-bit single-ended	0	0	0	0	0	0	0	0	D	D	D	D	D	D	D	D	Unsigned right-justified

NOTE

S: Sign bit or sign bit extension;

29.3.5 Compare Value Registers (ADCx_CVn)

The compare value registers (CV1 and CV2) contain a compare value used to compare the conversion result when the compare function is enabled, that is, SC2[ACFE]=1. This register is formatted in the same way as the Rn registers in different modes of operation for both bit position definition and value format using unsigned or sign-extended 2's complement. Therefore, the compare function uses only the CVn fields that are related to the ADC mode of operation.

The compare value 2 register (CV2) is used only when the compare range function is enabled, that is, SC2[ACREN]=1.

Address: FFFF_8600h base + 18h offset + (4d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

29.3.7 Status and Control Register 3 (ADCx_SC3)

The Status and Control Register 3 (SC3) controls the calibration, continuous convert, and hardware averaging functions of the ADC module.

Address: FFFF_8600h base + 24h offset = FFFF_8624h

ADCx_SC3 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CAL	Calibration Begins the calibration sequence when set. This field stays set while the calibration is in progress and is cleared when the calibration sequence is completed. CALF must be checked to determine the result of the calibration sequence. Once started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and CALF will set. Setting CAL will abort any current conversion.
6 CALF	Calibration Failed Flag Displays the result of the calibration sequence. The calibration sequence will fail if SC2[ADTRG] = 1, any ADC register is written, or any stop mode is entered before the calibration sequence completes. Writing 1 to CALF clears it.

Table continues on the next page...

ADCx_SC3 field descriptions (continued)

Field	Description
	0 Calibration completed normally. 1 Calibration failed. ADC accuracy specifications are not guaranteed.
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ADCO	Continuous Conversion Enable Enables continuous conversions. 0 One conversion or one set of conversions if the hardware average function is enabled, that is, AVGE=1, after initiating a conversion. 1 Continuous conversions or sets of conversions if the hardware average function is enabled, that is, AVGE=1, after initiating a conversion.
2 AVGE	Hardware Average Enable Enables the hardware average function of the ADC. 0 Hardware average function disabled. 1 Hardware average function enabled.
1–0 AVGS	Hardware Average Select Determines how many ADC conversions will be averaged to create the ADC average result. 00 4 samples averaged. 01 8 samples averaged. 10 16 samples averaged. 11 32 samples averaged.

29.3.8 ADC Offset Correction Register (ADCx_OFS)

The ADC Offset Correction Register (OFS) contains the user-selected or calibration-generated offset error correction value. This register is a 2's complement, left-justified, 16-bit value. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

Address: FFFF_8600h base + 28h offset = FFFF_8628h

29.4 Functional description

The ADC module is disabled during reset, in Low-Power Stop mode, or when SC1n[ADCH] are all high; see the power management information for details. The module is idle when a conversion has completed and another conversion has not been initiated. When it is idle and the asynchronous clock output enable is disabled, or CFG2[ADACKEN]= 0, the module is in its lowest power state. The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications, the ADC module must be calibrated using the on-chip calibration function. See [Calibration function](#) for details on how to perform calibration.

When the conversion is completed, the result is placed in the Rn data registers. The respective SC1n[COCO] is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, or, when SC1n[AIEN]=1.

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the CV1 and CV2 registers. The compare function is enabled by setting SC2[ACFE] and operates in any of the conversion modes and configurations.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting SC3[AVGE] and operates in any of the conversion modes and configurations.

NOTE

For the chip specific modes of operation, see the power management information of this MCU.

29.4.1 Clock select and divide control

One of four clock sources can be selected as the clock source for the ADC module. This clock source is then divided by a configurable value to generate the input clock ADCK, to the module. The clock is selected from one of the following sources by means of CFG1[ADICLK].

- Bus clock. This is the default selection following reset.
- Bus clock divided by two. For higher bus clock rates, this allows a maximum divide-by-16 of the bus clock using CFG1[ADIV].

- ALTCLK: As defined for this MCU. See the chip configuration information.
- Asynchronous clock (ADACK): This clock is generated from a clock source within the ADC module. When the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start $CFG2[ADACKEN]=0$, ADACK is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated. To avoid the conversion time variability and latency associated with the ADACK clock startup, set $CFG2[ADACKEN]=1$ and wait the worst-case startup time of 5 μ s prior to initiating any conversions using the ADACK clock source. Conversions are possible using ADACK as the input clock source while the MCU is in Normal Stop mode. See [Power Control](#) for more information.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by $CFG1[ADIV]$ and can be divide-by 1, 2, 4, or 8.

29.4.2 Voltage reference selection

The ADC can be configured to accept one of the two voltage reference pairs as the reference voltage (V_{REFSH} and V_{REFSL}) used for conversions. Each pair contains a positive reference that must be between the minimum Ref Voltage High and V_{DDA} , and a ground reference that must be at the same potential as V_{SSA} . The two pairs are external (V_{REFH} and V_{REFL}) and alternate (V_{ALTH} and V_{ALTL}). These voltage references are selected using $SC2[REFSEL]$. The alternate (V_{ALTH} and V_{ALTL}) voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

29.4.3 Hardware trigger and channel selects

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when $SC2[ADTRG]$ is set and a hardware trigger select event, ADHWTSn, has occurred. This source is not available on all MCUs. See the Chip Configuration chapter for information on the ADHWT source and the ADHWTSn configurations specific to this MCU.

When an ADHWT source is available and hardware trigger is enabled, that is $SC2[ADTRG]=1$, a conversion is initiated on the rising-edge of ADHWT after a hardware trigger select event, that is, ADHWTSn, has occurred. If a conversion is in progress when a rising-edge of a trigger occurs, the rising-edge is ignored. In continuous convert configuration, only the initial rising-edge to launch continuous conversions is observed, and until conversion is aborted, the ADC continues to do conversions on the same SCn register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The hardware trigger select event, that is, ADHWTSn, must be set prior to the receipt of the ADHWT signal. If these conditions are not met, the converter may ignore the trigger or use the incorrect configuration. If a hardware trigger select event is asserted during a conversion, it must stay asserted until the end of current conversion and remain set until the receipt of the ADHWT signal to trigger a new conversion. The channel and status fields selected for the conversion depend on the active trigger select signal:

- ADHWTSa active selects SC1A
- ADHWTSn active selects SC1n

Note

Asserting more than one hardware trigger select signal (ADHWTSn) at the same time results in unknown results. To avoid this, select only one hardware trigger select signal (ADHWTSn) prior to the next intended conversion.

When the conversion is completed, the result is placed in the Rn registers associated with the ADHWTSn received. For example:

- ADHWTSa active selects RA register
- ADHWTSn active selects Rn register

The conversion complete flag associated with the ADHWTSn received, that is, $SC1n[COCO]$, is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, that is, $SC1[AIEN]=1$.

29.4.4 Conversion control

Conversions can be performed as determined by $CFG1[MODE]$ as shown in the description of $CFG1[MODE]$.

Conversions can be initiated by a software or hardware trigger. In addition, the ADC module can be configured for:

- Low-power operation
- Long sample time

- Continuous conversion
- Hardware average
- Automatic compare of the conversion result to a software determined compare value

29.4.4.1 Initiating conversions

A conversion is initiated:

- Following a write to SC1A, with SC1n[ADCH] not all 1's, if software triggered operation is selected, that is, when SC2[ADTRG]=0.
- Following a hardware trigger, or ADHWT event, if hardware triggered operation is selected, that is, SC2[ADTRG]=1, and a hardware trigger select event, ADHWTSn, has occurred. The channel and status fields selected depend on the active trigger select signal:
 - ADHWTSn active selects SC1n
 - if neither is active, the off condition is selected

Note

Selecting more than one ADHWTSn prior to a conversion completion will result in unknown results. To avoid this, select only one ADHWTSn prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled, that is, when ADCO=1.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion, by:.. In software triggered operation, that is, when ADTRG=0, continuous conversions begin after SC1A is written and continue until aborted. In hardware triggered operation, that is, when ADTRG=1 and one ADHWTSn event has occurred, continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions are completed. In software triggered operation, conversions begin after SC1A is written. In hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions are also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

29.4.4.2 Completing conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, Rn. If the compare functions are disabled, this is indicated by setting of SC1n[COCO]. If hardware averaging is enabled, the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed. If the compare function is enabled, the respective SC1n[COCO] sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed and the compare condition is true. An interrupt is generated if the respective SC1n[AIEN] is high at the time that the respective SC1n[COCO] is set.

29.4.4.3 Aborting conversions

Any conversion in progress is aborted when:

- Writing to SC1A while it is actively controlling a conversion, aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, a write to SC1A initiates a new conversion if SC1A[ADCH] is equal to a value other than all 1s. Writing to any of the SC1B–SC1n registers while that specific SC1B–SC1n register is actively controlling a conversion aborts the current conversion. The SC1(B-n) registers are not used for software trigger operation and therefore writes to the SC1(B-n) registers do not initiate a new conversion.
- A write to any ADC register besides the SC1A-SC1n registers occurs. This indicates that a change in mode of operation has occurred and the current conversion is therefore invalid.
- The MCU is reset or enters Low-Power Stop modes.
- The MCU enters Normal Stop mode with ADACK not enabled.

When a conversion is aborted, the contents of the data registers, Rn, are not altered. The data registers continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset or Low-Power Stop modes, RA and Rn return to their reset states.

29.4.4.4 Power control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, but the asynchronous clock output is disabled, that is $CFG2[ADACKEN]=0$, the ADACK clock generator also remains in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled, that is, $CFG2[ADACKEN]=1$, it remains active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting $CFG1[ADLPC]$. This results in a lower maximum value for f_{ADCK} .

29.4.4.5 Sample time and total conversion time

For short sample, that is, when $CFG1[ADLSMP]=0$, there is a 2-cycle adder for first conversion over the base sample time of four ADCK cycles. For high speed conversions, that is, when $CFG2[ADHSC]=1$, there is an additional 2-cycle adder on any conversion. The table below summarizes sample times for the possible ADC configurations.

ADC configuration			Sample time (ADCK cycles)	
CFG1[ADLSMP]	CFG2[ADLSTS]	CFG2[ADHSC]	First or Single	Subsequent
0	X	0	6	4
1	00	0	24	
1	01	0	16	
1	10	0	10	
1	11	0	6	
0	X	1	8	6
1	00	1	26	
1	01	1	18	
1	10	1	12	
1	11	1	8	

The total conversion time depends upon:

- The sample time as determined by $CFG1[ADLSMP]$ and $CFG2[ADLSTS]$
- The MCU bus frequency
- The conversion mode, as determined by $CFG1[MODE]$
- The high speed configuration, that is, $CFG2[ADHSC]$
- The frequency of the conversion clock, that is, f_{ADCK} .

Functional description

CFG2[ADHSC] is used to configure a higher clock input frequency. This will allow faster overall conversion times. To meet internal ADC timing requirements, CFG2[ADHSC] adds additional ADCK cycles. Conversions with CFG2[ADHSC]=1 take two more ADCK cycles. CFG2[ADHSC] must be used when the ADCLK exceeds the limit for CFG2[ADHSC]=0.

After the module becomes active, sampling of the input begins.

1. CFG1[ADLSMP] and CFG2[ADLSTS] select between sample times based on the conversion mode that is selected.
2. When sampling is completed, the converter is isolated from the input channel and a successive approximation algorithm is applied to determine the digital value of the analog signal.
3. The result of the conversion is transferred to Rn upon completion of the conversion algorithm.

If the bus frequency is less than f_{ADCK} , precise sample time for continuous conversions cannot be guaranteed when short sample is enabled, that is, when CFG1[ADLSMP]=0.

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by CFG1[ADICLK], and the divide ratio is specified by CFG1[ADIV].

The maximum total conversion time for all configurations is summarized in the equation below. See the following tables for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder} + \text{HSCAdder})$$

Figure 29-46. Conversion time equation

Table 29-54. Single or first continuous time adder (SFCAdder)

CFG1[ADLSMP]	CFG2[ADACKEN]	CFG1[ADICLK]	Single or first continuous time adder (SFCAdder)
1	x	0x, 10	3 ADCK cycles + 5 bus clock cycles
1	1	11	3 ADCK cycles + 5 bus clock cycles ¹
1	0	11	5 μ s + 3 ADCK cycles + 5 bus clock cycles
0	x	0x, 10	5 ADCK cycles + 5 bus clock cycles
0	1	11	5 ADCK cycles + 5 bus clock cycles ¹
0	0	11	5 μ s + 5 ADCK cycles + 5 bus clock cycles

1. To achieve this time, CFG2[ADACKEN] must be 1 for at least 5 μ s prior to the conversion is initiated.

Table 29-55. Average number factor (AverageNum)

SC3[AVGE]	SC3[AVGS]	Average number factor (AverageNum)
0	xx	1

Table continues on the next page...

Table 29-55. Average number factor (AverageNum) (continued)

SC3[AVGE]	SC3[AVGS]	Average number factor (AverageNum)
1	00	4
1	01	8

1	01	12 ADCK cycles
1	10	6 ADCK cycles
1	11	2 ADCK cycles

Table 29-58. High-speed conversion time adder (HSCAdder)

CFG2[ADHSC]	High-speed conversion time adder (HSCAdder)
0	0 ADCK cycles
1	2 ADCK cycles

Note

The ADCK frequency must be between f_{ADCK} minimum and f_{ADCK} maximum to meet ADC specifications.

29.4.4.6 Conversion time examples

The following examples use the [Figure 29-46](#), and the information provided in [Table 29-54](#) through [Table 29-58](#).

29.4.4.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is:

- 10-bit mode, with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 8 MHz
- Long sample time disabled
- High-speed conversion disabled

The conversion time for a single conversion is calculated by using the [Figure 29-46](#), and the information provided in [Table 29-54](#) through [Table 29-58](#). The table below lists the variables of [Figure 29-46](#).

Table 29-59. Typical conversion time

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	20 ADCK cycles
LSTAdder	0
HSCAdder	0

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for a bus clock and an ADCK frequency equal to 8 MHz, the resulting conversion time is 3.75 μ s.

29.4.4.6.2 Short conversion time configuration

A configuration for short ADC conversion is:

- 8-bit Single-Ended mode with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 20 MHz
- Long sample time disabled
- High-speed conversion enabled

The conversion time for this conversion is calculated by using the [Figure 29-46](#), and the information provided in [Table 29-54](#) through [Table 29-58](#). The table below lists the variables of [Figure 29-46](#).

Table 29-60. Typical conversion time

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	17 ADCK cycles

Table continues on the next page...

Table 29-60. Typical conversion time (continued)

Variable	Time
LSTAdder	0 ADCK cycles
HSCAdder	2

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock and ADCK frequency equal to 20 MHz, the resulting conversion time is 1.45 μ s.

29.4.4.7 Hardware average function

The hardware average function can be enabled by setting SC3[AVGE]=1 to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which can select 4, 8, 16, or 32 conversions to be averaged. While the hardware average function is in progress, SC2[ADACT] will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions have been completed. When hardware averaging is selected, the completion of a single conversion will not set SC1n[COCO].

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, Rn, and SC1n[COCO] is set. An ADC interrupt is generated upon the setting of SC1n[COCO] if the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

Note

The hardware average function can perform conversions on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the hardware average is completed if SC1n[AIEN] was set.

29.4.5 Automatic compare function

The compare function can be configured to check whether the result is less than or greater-than-or-equal-to a single compare value, or, if the result falls within or outside a range determined by two compare values. The compare mode is determined by SC2[ACFGT], SC2[ACREN], and the values in the compare value registers, CV1 and

CV2. After the input is sampled and converted, the compare values in CV1 and CV2 are used as described in the following table. There are six Compare modes as shown in the following table.

Table 29-61. Compare modes

SC2[ACFGT]	SC2[ACREN]	ADCCV1 relative to ADCCV2	Function	Compare mode description
0	0	—	Less than threshold	Compare true if the result is less than the CV1 registers.
1	0	—	Greater than or equal to threshold	Compare true if the result is greater than or equal to CV1 registers.
0	1	Less than or equal	Outside range, not inclusive	Compare true if the result is less than CV1 Or the result is greater than CV2.
0	1	Greater than	Inside range, not inclusive	Compare true if the result is less than CV1 And the result is greater than CV2.
1	1	Less than or equal	Inside range, inclusive	Compare true if the result is greater than or equal to CV1 And the result is less than or equal to CV2.
1	1	Greater than	Outside range, inclusive	Compare true if the result is greater than or equal to CV1 Or the result is less than or equal to CV2.

With SC2[ACREN] =1, and if the value of CV1 is less than or equal to the value of CV2, then setting SC2[ACFGT] will select a trigger-if-inside-compare-range inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than CV2, setting SC2[ACFGT] will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, SC1n[COCO] is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, SC1n[COCO] is not set and the conversion result data will not be transferred to the result register, Rn. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated when SC1n[COCO] is set and the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

Note

The compare function can monitor the voltage on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the compare condition is met.

29.4.6 Calibration function

The ADC contains a self-calibration function that is required to achieve the specified accuracy. Calibration must be run, or valid calibration values written, after any reset and before a conversion is initiated. The calibration function sets the offset calibration value and the plus-side calibration values. The offset calibration value is automatically stored in the ADC offset correction register (OFS), and the plus-side calibration values are automatically stored in the ADC plus-side calibration registers, CLPx. The user must configure the ADC correctly prior to calibration, and must generate the plus-side gain calibration results and store them in the ADC plus-side gain register (PG) after the calibration function completes.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, and high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. For best calibration results:

- Set hardware averaging to maximum, that is, SC3[AVGE]=1 and SC3[AVGS]=11 for an average of 32
- Set ADC clock frequency f_{ADCK} less than or equal to 4 MHz
- $V_{REFH}=V_{DDA}$
- Calibrate at nominal voltage and temperature

The input channel, conversion mode continuous function, compare function, resolution mode, and single-ended mode are all ignored during the calibration function.

To initiate calibration, the user sets SC3[CAL] and the calibration will automatically begin if the SC2[ADTRG] is 0. If SC2[ADTRG] is 1, SC3[CAL] will not get set and SC3[CALF] will be set. While calibration is active, no ADC register can be written and no stop mode may be entered, or the calibration routine will be aborted causing SC3[CAL] to clear and SC3[CALF] to set. At the end of a calibration sequence, SC1n[COCO] will be set. SC1n[AIEN] can be used to allow an interrupt to occur at the end of a calibration sequence. At the end of the calibration routine, if SC3[CALF] is not set, the automatic calibration routine is completed successfully.

To complete calibration, the user must generate the gain calibration values using the following procedure:

1. Initialize or clear a 16-bit variable in RAM.

Functional description

2. Add the plus-side calibration results CLP0, CLP1, CLP2, CLP3, CLP4, and CLPS to the variable.
3. Divide the variable by two.
4. Set the MSB of the variable.
5. The previous two steps can be achieved by setting the carry bit, rotating to the right through the carry bit on the high byte and again on the low byte.
6. Store the value in the plus-side gain calibration register PG.

When calibration is complete, the user may reconfigure and use the ADC as desired. A second calibration may also be performed, if desired, by clearing and again setting SC3[CAL].

Overall, the calibration routine may take as many as 14k ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen. For an 8 MHz clock source, this length amounts to about 1.7 ms. To reduce this latency, the calibration values, which are offset, plus-side gain, and plus-side calibration values, may be stored in flash memory after an initial calibration and recovered prior to the first ADC conversion. This method can reduce the calibration latency to 20 register store operations on all subsequent power, reset, or Low-Power Stop mode recoveries.

29.4.7 User-defined offset function

OFS contains the user-selected or calibration-generated offset error correction value. This register is a 2's complement, left-justified. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

The formatting of the OFS is different from the data result register, Rn, to preserve the resolution of the calibration value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8-bit single-ended mode, OFS[14:7] are subtracted from D[7:0]; OFS[15] indicates the sign (negative numbers are effectively added to the result) and OFS[6:0] are ignored.

OFS is automatically set according to calibration requirements once the self-calibration sequence is done, that is, SC3[CAL] is cleared. The user may write to OFS to override the calibration result if desired. If the OFS is written by the user to a value that is different from the calibration value, the ADC error specifications may not be met. Storing the value generated by the calibration function in memory before overwriting with a user-specified value is recommended.

Note

There is an effective limit to the values of offset that can be set by the user. If the magnitude of the offset is too high, the results of the conversions will cap off at the limits.

The offset calibration function may be employed by the user to remove application offsets or DC bias values. OFS may be written with a number in 2's complement format and this offset will be subtracted from the result, or hardware averaged value. To add an offset, store the negative offset in 2's complement format and the effect will be an addition. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value. The minimum value for single-ended conversions is 0x0000.

To preserve accuracy, the calibrated offset value initially stored in OFS must be added to the user-defined offset. For applications that may change the offset repeatedly during operation, store the initial offset calibration value in flash so it can be recovered and added to any user offset adjustment value and the sum stored in OFS.

29.4.8 Temperature sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs. The following equation provides an approximate transfer function of the temperature sensor.

$$\text{Temp} = 25 - \left(\left(V_{\text{TEMP}} - V_{\text{TEMP25}} \right) \div m \right)$$

Figure 29-47. Approximate transfer function of the temperature sensor

where:

- V_{TEMP} is the voltage of the temperature sensor channel at the ambient temperature.
- V_{TEMP25} is the voltage of the temperature sensor channel at 25 °C.
- m is referred as temperature sensor slope in the device data sheet. It is the hot or cold voltage versus temperature slope in V/°C.

For temperature calculations, use the V_{TEMP25} and temperature sensor slope values from the ADC Electricals table.

In application code, the user reads the temperature sensor channel, calculates V_{TEMP} , and compares to V_{TEMP25} . If V_{TEMP} is greater than V_{TEMP25} the cold slope value is applied in the preceding equation. If V_{TEMP} is less than V_{TEMP25} , the hot slope value is applied in

the preceding equation. ADC Electricals table may only specify one temperature sensor slope value. In that case, the user could use the same slope for the calculation across the operational temperature range.

For more information on using the temperature sensor, see the application note titled *Temperature Sensor for the HCS08 Microcontroller Family* (document AN3031).

29.4.9 MCU wait mode operation

Wait mode is a lower-power consumption Standby mode from which recovery is fast because the clock sources remain active. If a conversion is in progress when the MCU enters Wait mode, it continues until completion. Conversions can be initiated while the MCU is in Wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in Wait mode. The use of ALTCLK as the conversion clock source in Wait is dependent on the definition of ALTCLK for this MCU. See the Chip Configuration information on ALTCLK specific to this MCU.

If the compare and hardware averaging functions are disabled, a conversion complete event sets SC1n[COCO] and generates an ADC interrupt to wake the MCU from Wait mode if the respective ADC interrupt is enabled, that is, when SC1n[AIEN]=1. If the hardware averaging function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from Wait mode unless a new conversion is initiated by the hardware trigger.

29.4.10 MCU Normal Stop mode operation

Stop mode is a low-power consumption Standby mode during which most or all clock sources on the MCU are disabled.

29.4.10.1 Normal Stop mode with ADACK disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its Idle state. The contents of the ADC registers, including Rn, are unaffected by Normal Stop mode. After exiting from Normal Stop mode, a software or hardware trigger is required to resume conversions.

29.4.10.2 Normal Stop mode with ADACK enabled

If ADACK is selected as the conversion clock, the ADC continues operation during Normal Stop mode. See the chip configuration chapter for configuration information for this MCU.

If a conversion is in progress when the MCU enters Normal Stop mode, it continues until completion. Conversions can be initiated while the MCU is in Normal Stop mode by means of the hardware trigger or if continuous conversions are enabled.

If the compare and hardware averaging functions are disabled, a conversion complete event sets SC1n[COCO] and generates an ADC interrupt to wake the MCU from Normal Stop mode if the respective ADC interrupt is enabled, that is, when SC1n[AIEN]=1. The result register, Rn, will contain the data from the first completed conversion that occurred during Normal Stop mode. If the hardware averaging function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare is not true, the ADC will return to its Idle state and cannot wake the MCU from Normal Stop mode unless a new conversion is initiated by another hardware trigger.

29.4.11 MCU Low-Power Stop mode operation

The ADC module is automatically disabled when the MCU enters Low-Power Stop mode. All module registers contain their reset values following exit from Low-Power Stop mode. Therefore, the module must be re-enabled and re-configured following exit from Low-Power Stop mode.

NOTE

For the chip specific modes of operation, see the power management information for the device.

29.5 Initialization information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. The user can configure the module for 12-bit, 10-bit, or 8-bit single-ended resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. For information used in this example, refer to [Table 29-57](#), [Table 29-58](#), and [Table 29-59](#).

Note

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

29.5.1 ADC module initialization example

29.5.1.1 Initialization sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is:

1. Calibrate the ADC by following the calibration instructions in [Calibration function](#).
2. Update CFG to select the input clock source and the divide ratio used to generate ADCK. This register is also used for selecting sample time and low-power configuration.
3. Update SC2 to select the conversion trigger, hardware or software, and compare function options, if enabled.
4. Update SC3 to select whether conversions will be continuous or completed only once (ADCO) and whether to perform hardware averaging.
5. Update SC1:SC1n registers to enable or disable conversion complete interrupts. Also, select the input channel which can be used to perform conversions.

29.5.1.2 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low-power with a long sample time on input channel 1, where ADCK is derived from the bus clock divided by 1.

CFG1 = 0x98 (%10011000)

Bit 7	ADLPC	1	Configures for low power, lowers maximum clock speed.
Bit 6:5	ADIV	00	Sets the ADCK to the input clock ÷ 1.
Bit 4	ADLSMP	1	Configures for long sample time.
Bit 3:2	MODE	10	Selects the single-ended 10-bit conversion.
Bit 1:0	ADICLK	00	Selects the bus clock.

SC2 = 0x00 (%00000000)

Bit 7	ADACT	0	Flag indicates if a conversion is in progress.
Bit 6	ADTRG	0	Software trigger selected.
Bit 5	ACFE	0	Compare function disabled.
Bit 4	ACFGT	0	Not used in this example.
Bit 3	ACREN	0	Compare range disabled.
Bit 2	DMAEN	0	DMA request disabled.
Bit 1:0	REFSEL	00	Selects default voltage reference pin pair (External pins V_{REFH} and V_{REFL}).

SC1A = 0x41 (%01000001)

Bit 7	COCO	0	Read-only flag which is set when a conversion completes.
Bit 6	AIEN	1	Conversion complete interrupt enabled.
Bit 4:0	ADCH	00001	Input channel 1 selected as ADC input channel.

RA = 0xxx

Holds results of conversion.

CV = 0xxx

Holds compare value when compare function enabled.

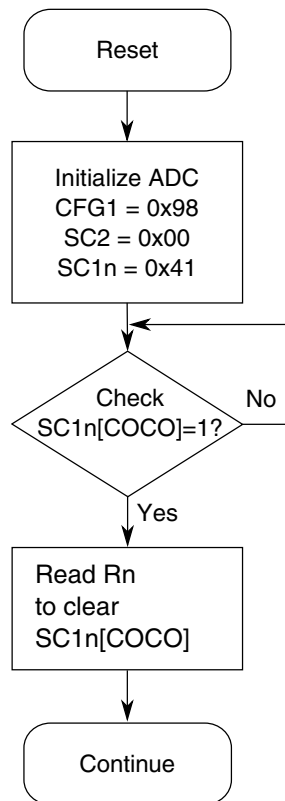

Figure 29-48. Initialization flowchart example

29.6 Application information

The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an ADC.

29.6.1 External pins and routing

29.6.1.1 Analog supply pins

Depending on the device, the analog power and ground supplies, V_{DDA} and V_{SSA} , of the ADC module are available as:

- V_{DDA} and V_{SSA} available as separate pins—When available on a separate pin, both V_{DDA} and V_{SSA} must be connected to the same voltage potential as their corresponding MCU digital supply, V_{DD} and V_{SS} , and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

- V_{SSA} is shared on the same pin as the MCU digital V_{SS} .
- V_{SSA} and V_{DDA} are shared with the MCU digital supply pins—In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the V_{SSA} pin. This must be the only ground connection between these supplies, if possible. V_{SSA} makes a good single point ground location.

29.6.1.2 Analog voltage reference pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs used by the converter:

- V_{REFSH} is the high reference voltage for the converter.
- V_{REFSL} is the low reference voltage for the converter.

The ADC can be configured to accept one of two voltage reference pairs for V_{REFSH} and V_{REFSL} . Each pair contains a positive reference and a ground reference. The two pairs are external, V_{REFH} and V_{REFL} and alternate, V_{ALTH} and V_{ALTTL} . These voltage references are selected using $SC2[REFSEL]$. The alternate voltage reference pair, V_{ALTH} and V_{ALTTL} , may select additional external pins or internal sources based on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

In some packages, the external or alternate pairs are connected in the package to V_{DDA} and V_{SSA} , respectively. One of these positive references may be shared on the same pin as V_{DDA} on some devices. One of these ground references may be shared on the same pin as V_{SSA} on some devices.

If externally available, the positive reference may be connected to the same potential as V_{DDA} or may be driven by an external source to a level between the minimum Ref Voltage High and the V_{DDA} potential. The positive reference must never exceed V_{DDA} . If externally available, the ground reference must be connected to the same voltage potential as V_{SSA} . The voltage reference pairs must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the V_{REFH} and V_{REFL} loop. The best external component to meet this current demand is a 0.1 μF capacitor with good high-frequency characteristics. This capacitor is connected between V_{REFH} and V_{REFL} and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum, that is, parasitic only.

29.6.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01 μF capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used, they must be placed as near as possible to the package pins and be referenced to V_{SSA} .

For proper conversion, the input voltage must fall between V_{REFH} and V_{REFL} . If the input is equal to or exceeds V_{REFH} , the converter circuit converts the signal to 0xFFF, which is full scale 12-bit representation, 0x3FF, which is full scale 10-bit representation, or 0xFF, which is full scale 8-bit representation. If the input is equal to or less than V_{REFL} , the converter circuit converts it to 0x000. Input voltages between V_{REFH} and V_{REFL} are straight-line linear conversions. There is a brief current associated with V_{REFL} when the sampling capacitor is charging.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins must not be transitioning during conversions.

29.6.2 Sources of error

29.6.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy.

$$RAS + RADIN = SC / (FMAX * NUMTAU * CADIN)$$

Figure 29-49. Sampling equation

Where:

RAS = External analog source resistance

SC = Number of ADCK cycles used during sample window

CADIN = Internal ADC input capacitance

NUMTAU = $-\ln(\text{LSBERR} / 2^N)$

LSBERR = value of acceptable sampling error in LSBs

N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode

Higher source resistances or higher-accuracy sampling is possible by setting CFG1[ADLSMP] and changing CFG2[ADLSTS] to increase the sample window, or decreasing ADCK frequency to increase sample time.

29.6.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance, R_{AS} , is high. If this error cannot be tolerated by the application, keep R_{AS} lower than $V_{REFH} / (4 \times I_{LEAK} \times 2^N)$ for less than 1/4 LSB leakage error, where N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode.

29.6.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1 μ F low-ESR capacitor from V_{REFH} to V_{REFL} .
- There is a 0.1 μ F low-ESR capacitor from V_{DDA} to V_{SSA} .
- If inductive isolation is used from the primary supply, an additional 1 μ F capacitor is placed from V_{DDA} to V_{SSA} .
- V_{SSA} , and V_{REFL} , if connected, is connected to V_{SS} at a quiet point in the ground plane.
- Operate the MCU in Wait or Normal Stop mode before initiating (hardware-triggered conversions) or immediately after initiating (hardware- or software-triggered conversions) the ADC conversion.
 - For software triggered conversions, immediately follow the write to SC1 with a Wait instruction or Stop instruction.
 - For Normal Stop mode operation, select ADACK as the clock source. Operation in Normal Stop reduces V_{DD} noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive V_{DD} noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in Wait or Normal Stop mode, or I/O activity cannot be halted, the following actions may reduce the effect of noise on the accuracy:

- Place a 0.01 μF capacitor (C_{AS}) on the selected input channel to V_{REFL} or V_{SSA} . This improves noise issues, but affects the sample rate based on the external analog source resistance.
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1 LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock, that is, ADACK, and averaging. Noise that is synchronous to ADCK cannot be averaged out.

29.6.2.4 Code width and quantization error

The ADC quantizes the ideal straight-line transfer function into 4096 steps in the 12-bit mode). Each step ideally has the same height, that is, 1 code, and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N-bit converter, where N can be 12, 10, or 8, defined as 1 LSB, is:

$$1\text{LSB} = (V_{REFH}) / 2^N$$

Figure 29-50. Ideal code width for an N-bit converter

There is an inherent quantization error due to the digitization of the result. For 8-bit, 10-bit, or 12-bit conversions, the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be $\pm 1/2$ LSB in 8-bit, 10-bit, or 12-bit modes. As a consequence, however, the code width of the first (0x000) conversion is only $1/2$ LSB and the code width of the last (0xFF or 0x3FF) is 1.5 LSB.

29.6.2.5 Linearity errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors, but the system designers must be aware of these errors because they affect overall accuracy:

- Zero-scale error (E_{ZS}), sometimes called offset: This error is defined as the difference between the actual code width of the first conversion and the ideal code width. This is 1/2 LSB in 8-bit, 10-bit, or 12-bit modes. If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 LSB) is used.
- Full-scale error (E_{FS}): This error is defined as the difference between the actual code width of the last conversion and the ideal code width. This is 1.5 LSB in 8-bit, 10-bit, or 12-bit modes. If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1 LSB) is used.
- Differential non-linearity (DNL): This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL): This error is defined as the highest-value or absolute value that the running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE): This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

29.6.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error:

- Code jitter: Code jitter is when, at certain points, a given input voltage converts to one of the two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code, and vice-versa. However, even small amounts of system noise can cause the converter to be indeterminate, between two codes, for a range of input voltages around the transition voltage.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally, the techniques discussed in [Noise-induced errors](#) reduces this error.

- Non-monotonicity: Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage.
- Missing codes: Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

Chapter 30

Comparator (CMP)

30.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference V_{in} into 64 voltage levels. A 6-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/64$. V_{in} can be selected from two voltage sources, V_{in1} and V_{in2} . The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

30.2 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control

6-bit DAC key features

- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
 - Sampled
 - Windowed, which is ideal for certain PWM zero-crossing-detection applications
 - Digitally filtered:
 - Filter can be bypassed
 - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
 - Shorter propagation delay at the expense of higher power
 - Low power, with longer propagation delay
- DMA transfer support
 - A comparison event can be selected to trigger a DMA transfer
- Functional in all modes of operation
- The window and filter functions are not available in the following modes:
 - Stop
 - VLPS
 - LLS
 - VLLSx

30.3 6-bit DAC key features

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

30.4 ANMUX key features

- Two 8-to-1 channel mux
- Operational over the entire supply range

30.5 CMP, DAC and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

Figure 30-1. CMP, DAC and ANMUX block diagram

30.6 CMP block diagram

The following figure shows the block diagram for the CMP module.

Figure 30-2. Comparator module block diagram

In the CMP block diagram:

- The Window Control block is bypassed when $CR1[WE] = 0$
- If $CR1[WE] = 1$, the comparator output will be sampled on every bus clock when $WINDOW=1$ to generate $COUTA$. Sampling does NOT occur when $WINDOW = 0$.
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and $CR0[FILTER_CNT]$ is set to $0x01$.
- The Filter block filters based on multiple samples when the filter is bypassed and $CR0[FILTER_CNT]$ is set greater than $0x01$.
 - If $CR1[SE] = 1$, the external $SAMPLE$ input is used as sampling clock
 - IF $CR1[SE] = 0$, the divided bus clock is used as sampling clock

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.
- CR1[WE] and CR1[SE] are mutually exclusive.

30.7 Memory map/register definitions

Address offsets are in terms of bytes for the ColdFire V1 architecture.

The ColdFire V1 IP Bus interface is designed such that a single 16-bit access by the MCU is serialized into two 8-bit accesses onto the bus. Similarly, a single 32-bit access by the MCU is serialized into four 8-bit accesses onto the bus. The register order defined above is such that a single 32-bit access by the ColdFire MCU could (in this order):

1. Initialize the mux and delay block settings
2. Configure and enable the analog comparator
3. Configure filtering
4. Clear edge detection status and enable interrupts

CMP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8530	CMP Control Register 0 (CMP0_CR0)	8	R/W	00h	30.7.1/638
FFFF_8531	CMP Control Register 1 (CMP0_CR1)	8	R/W	00h	30.7.2/639
FFFF_8532	CMP Filter Period Register (CMP0_FPR)	8	R/W	00h	30.7.3/641
FFFF_8533	CMP Status and Control Register (CMP0_SCR)	8	R/W	00h	30.7.4/641
FFFF_8534	DAC Control Register (CMP0_DACCR)	8	R/W	00h	30.7.5/643

30.7.1 CMP Control Register 0 (CMPx_CR0)

Address: FFFF_8530h base + 0h offset = FFFF_8530h

Bit	7	6	5	4	3	2	1	0
Read	0	FILTER_CNT			0	0	HYSTCTR	
Write	[Shaded]				[Shaded]		[Shaded]	
Reset	0	0	0	0	0	0	0	0

CMPx_CR0 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 FILTER_CNT	Filter Sample Count Represents the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state. For information regarding filter programming and latency, see the Functional description . 000 Filter is disabled. If SE = 1, then COUT is a logic 0. This is not a legal state, and is not recommended. If SE = 0, COUT = COUTA. 001 One sample must agree. The comparator output is simply sampled. 010 2 consecutive samples must agree. 011 3 consecutive samples must agree. 100 4 consecutive samples must agree. 101 5 consecutive samples must agree. 110 6 consecutive samples must agree. 111 7 consecutive samples must agree.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–0 HYSTCTR	Comparator hard block hysteresis control Defines the programmable hysteresis level. The hysteresis values associated with each level are device-specific. See the Data Sheet of the device for the exact values. 00 Level 0 01 Level 1 10 Level 2 11 Level 3

30.7.2 CMP Control Register 1 (CMPx_CR1)

Address: FFFF_8530h base + 1h offset = FFFF_8531h

Bit	7	6	5	4	3	2	1	0
Read	SE	WE	0	PMODE	INV	COS	OPE	EN
Write								
Reset	0	0	0	0	0	0	0	0

CMPx_CR1 field descriptions

Field	Description
7 SE	Sample Enable At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations.

Table continues on the next page...

CMPx_CR1 field descriptions (continued)

Field	Description
	0 Sampling mode is not selected. 1 Sampling mode is selected.
6 WE	Windowing Enable At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing 1s to both field locations because this "11" case is reserved and may change in future implementations. 0 Windowing mode is not selected. 1 Windowing mode is selected.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PMODE	Power Mode Select See the electrical specifications table in the device Data Sheet for details. 0 Low-Speed (LS) Comparison mode selected. In this mode, CMP has slower output propagation delay and lower current consumption. 1 High-Speed (HS) Comparison mode selected. In this mode, CMP has faster output propagation delay and higher current consumption.
3 INV	Comparator INVERT Allows selection of the polarity of the analog comparator function. It is also driven to the COUT output, on both the device pin and as SCR[COUT], when OPE=0. 0 Does not invert the comparator output. 1 Inverts the comparator output.
2 COS	Comparator Output Select 0 Set the filtered comparator output (CMPO) to equal COUT. 1 Set the unfiltered comparator output (CMPO) to equal COUTA.
1 OPE	Comparator Output Pin Enable 0 CMPO is not available on the associated CMPO output pin. If the comparator does not own the pin, this field has no effect. 1 CMPO is available on the associated CMPO output pin. The comparator output (CMPO) is driven out on the associated CMPO output pin if the comparator owns the pin. If the comparator does not own the field, this bit has no effect.
0 EN	Comparator Module Enable Enables the Analog Comparator module. When the module is not enabled, it remains in the off state, and consumes no power. When the user selects the same input from analog mux to the positive and negative port, the comparator is disabled automatically. 0 Analog Comparator is disabled. 1 Analog Comparator is enabled.

30.7.3 CMP Filter Period Register (CMPx_FPR)

Address: FFFF_8530h base + 2h offset = FFFF_8532h

Bit	7	6	5	4	3	2	1	0
Read	FILT_PER							
Write	FILT_PER							
Reset	0	0	0	0	0	0	0	0

CMPx_FPR field descriptions

Field	Description
7–0 FILT_PER	<p>Filter Sample Period</p> <p>Specifies the sampling period, in bus clock cycles, of the comparator output filter, when CR1[SE]=0. Setting FILT_PER to 0x0 disables the filter. Filter programming and latency details appear in the Functional description.</p> <p>This field has no effect when CR1[SE]=1. In that case, the external SAMPLE signal is used to determine the sampling period.</p>

30.7.4 CMP Status and Control Register (CMPx_SCR)

Address: FFFF_8530h base + 3h offset = FFFF_8533h

Bit	7	6	5	4	3	2	1	0
Read	0	DMAEN	SMELB	IER	IEF	CFR	CFF	COUT
Write		DMAEN	SMELB	IER	IEF	w1c	w1c	
Reset	0	0	0	0	0	0	0	0

CMPx_SCR field descriptions

Field	Description
7 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
6 DMAEN	<p>DMA Enable Control</p> <p>Enables the DMA transfer triggered from the CMP module. When this field is set, a DMA request is asserted when CFR or CFF is set.</p> <p>0 DMA is disabled. 1 DMA is enabled.</p>
5 SMELB	<p>Stop Mode Edge/Level Interrupt Control</p> <p>Controls whether CFR and CFF are edge sensitive or level sensitive in Stop mode.</p> <p>NOTE: This field must always be programmed to 0 to keep the comparator working and to wake up the MCU.</p>

Table continues on the next page...

CMPx_SCR field descriptions (continued)

Field	Description
	<p>0 CFR/CFF are level sensitive in Stop mode. CFR will be asserted when COUT is high. CFF will be asserted when COUT is low.</p> <p>1 CFR/CFF are edge sensitive in Stop mode. An active low-to-high transition must be seen on COUT to assert CFR, and an active high-to-low transition must be seen on COUT to assert CFF.</p>
4 IER	<p>Comparator Interrupt Enable Rising</p> <p>Enables the CFR interrupt from the CMP. When this field is set, an interrupt will be asserted when CFR is set.</p> <p>0 Interrupt is disabled. 1 Interrupt is enabled.</p>
3 IEF	<p>Comparator Interrupt Enable Falling</p> <p>Enables the CFF interrupt from the CMP. When this field is set, an interrupt will be asserted when CFF is set.</p> <p>0 Interrupt is disabled. 1 Interrupt is enabled.</p>
2 CFR	<p>Analog Comparator Flag Rising</p> <p>Detects a rising-edge on COUT, when set, during normal operation. CFR is cleared by writing 1 to it. During Stop modes, CFR can be programmed as either edge or level sensitive via the SMELB bit .</p> <p>NOTE: Edge detection during Stop mode is only supported on platforms that allow peripherals to be clocked during Stop modes. If the CFR flag is active during Stop mode, then SMELB must be set to 0 for cases where it is not receiving a clock during Stop mode.</p> <p>0 Rising-edge on COUT has not been detected. 1 Rising-edge on COUT has occurred.</p>
1 CFF	<p>Analog Comparator Flag Falling</p> <p>Detects a falling-edge on COUT, when set, during normal operation. CFF is cleared by writing 1 to it. During Stop modes, CFF can be programmed as either edge or level sensitive via the SMELB bit .</p> <p>NOTE: Edge detection during Stop mode is only supported on platforms that allow peripherals to be clocked during Stop modes. If the CFF flag is active during Stop mode, then SMELB must be set to 0 for cases where it is not receiving a clock during Stop mode.</p> <p>0 Falling-edge on COUT has not been detected. 1 Falling-edge on COUT has occurred.</p>
0 COUT	<p>Analog Comparator Output</p> <p>Returns the current value of the Analog Comparator output, when read. The field is reset to 0 and will read as CR1[INV] when the Analog Comparator module is disabled, that is, when CR1[EN] = 0. Writes to this field are ignored.</p>

30.7.5 DAC Control Register (CMPx_DACCR)

Address: FFFF_8530h base + 4h offset = FFFF_8534h

Bit	7	6	5	4	3	2	1	0
Read	DACEN	VRSEL	VOSEL					
Write								
Reset	0	0	0	0	0	0	0	0

CMPx_DACCR field descriptions

Field	Description
7 DACEN	<p>DAC Enable</p> <p>Enables the DAC. When the DAC is disabled, it is powered down to conserve power.</p> <p>0 DAC is disabled. 1 DAC is enabled.</p>
6 VRSEL	<p>Supply Voltage Reference Source Select</p> <p>0 V_{in1} is selected as resistor ladder network supply reference V_{in1}.</p> <p>1 V_{in2} is selected as resistor ladder network supply reference V_{in2}.</p>
5–0 VOSEL	<p>DAC Output Voltage Select</p> <p>Selects an output voltage from one of 64 distinct levels.</p> <p>$DACO = (V_{in} / 64) * (VOSEL[5:0] + 1)$, so the DACO range is from V_{in}/64 to V_{in}.</p>

30.7.6 MUX Control Register (CMPx_MUXCR)

PEN and MEN bits should be enabled or disabled together with CR1[EN] bit.

Address: FFFF_8530h base + 5h offset = FFFF_8535h

Bit	7	6	5	4	3	2	1	0
Read	PEN	MEN	PSEL			MSEL		
Write								
Reset	0	0	0	0	0	0	0	0

CMPx_MUXCR field descriptions

Field	Description
7 PEN	<p>PMUX Enable</p> <p>This bit is used to enable positive MUX. When the PMUX is disabled, the PMUX output is in a high impedance state. When software selects the same input for plus and minus inputs of the comparator, both PMUX and MMUX are disabled automatically.</p>

Table continues on the next page...

CMPx_MUXCR field descriptions (continued)

Field	Description
	0 PMUX is disabled. 1 PMUX is enabled.
6 MEN	MMUX Enable This bit is used to enable negative MUX. When the MMUX is disabled, the MMUX output is in a high impedance state. When software selects the same input for plus and minus inputs of the comparator, both PMUX and MMUX are disabled automatically. 0 MMUX is disabled. 1 MMUX is enabled.
5-3 PSEL	Plus Input Mux Control Determines which input is selected for the plus input of the comparator. For INx inputs, see CMP, DAC, and ANMUX block diagrams. NOTE: When an inappropriate operation selects the same input for both muxes, the comparator automatically shuts down to prevent itself from becoming a noise generator. 000 IN0 001 IN1 010 IN2 011 IN3 100 IN4 101 IN5 110 IN6 111 IN7
2-0 MSEL	Minus Input Mux Control Determines which input is selected for the minus input of the comparator. For INx inputs, see CMP, DAC, and ANMUX block diagrams. NOTE: When an inappropriate operation selects the same input for both muxes, the comparator automatically shuts down to prevent itself from becoming a noise generator. 000 IN0 001 IN1 010 IN2 011 IN3 100 IN4 101 IN5 110 IN6 111 IN7

30.8 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM. CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] and SCR[SMELB] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].

30.8.1 CMP functional modes

There are three main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

Table 30-15. Comparator sample/filter controls

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation
1	0	X	X	X	X	Disabled See the Disabled mode (# 1) .

Table 30-15. Comparator sample/filter controls (continued)

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation
5A	1	1	0	0x00	X	Windowed mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the Windowed mode (#s 5A & 5B) .
5B	1	1	0	X	0x00	
6	1	1	0	0x01	0x01–0xFF	Windowed/Resampled mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by FILT_PER to generate COUT. See the Windowed/Resampled mode (# 6) .
7	1	1	0	> 0x01	0x01–0xFF	Windowed/Filtered mode Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the Windowed/Filtered mode (#7) .
All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER_CNT], and FPR[FILT_PER] are illegal.						

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

Note

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER_CNT]=0x00. This resets the filter to a known state.

30.8.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

30.8.1.2 Continuous mode (#s 2A & 2B)

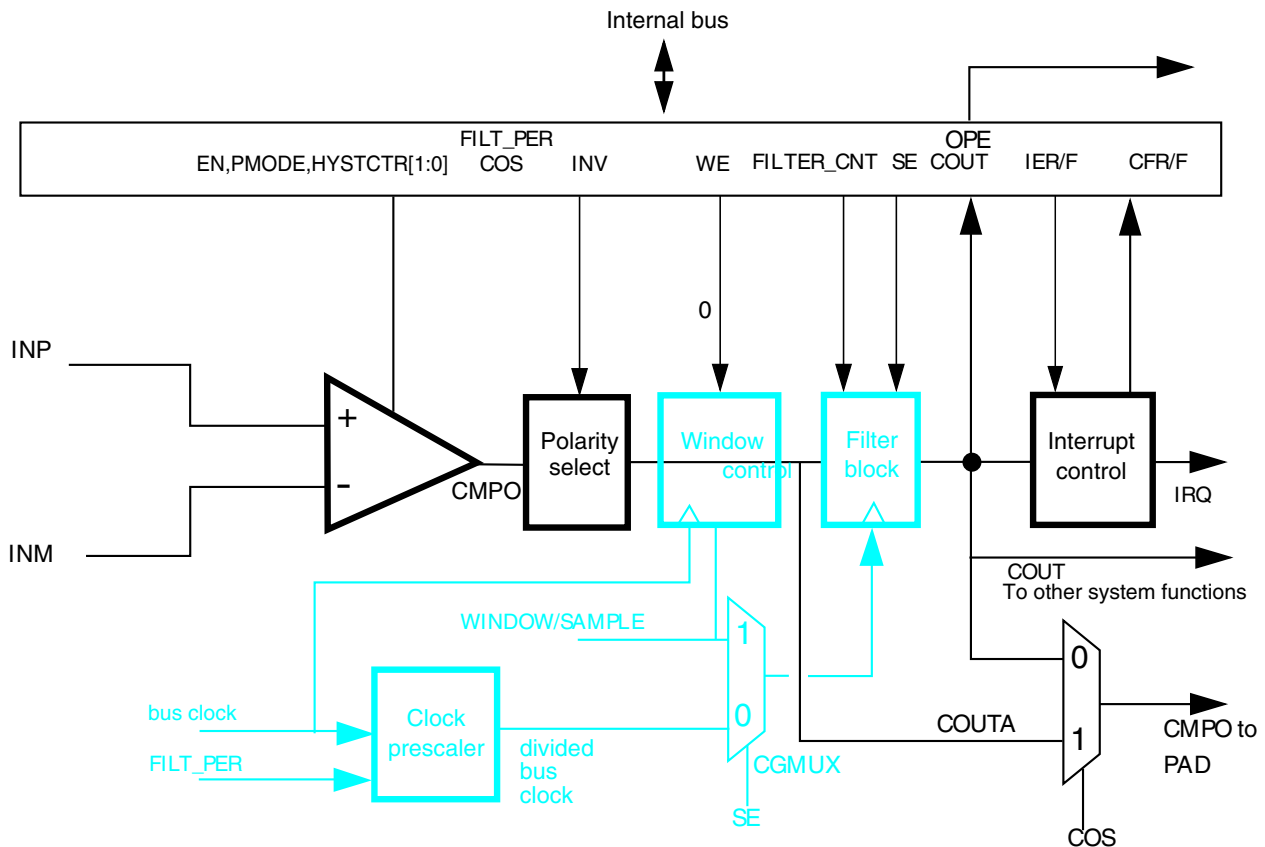

Figure 30-15. Comparator operation in Continuous mode

NOTE

See the chip configuration section for the source of sample/window input.

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unlocked mode. COUT and COUTA are identical.

For control configurations which result in disabling the filter block, see the [Filter Block Bypass Logic](#) diagram.

30.8.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

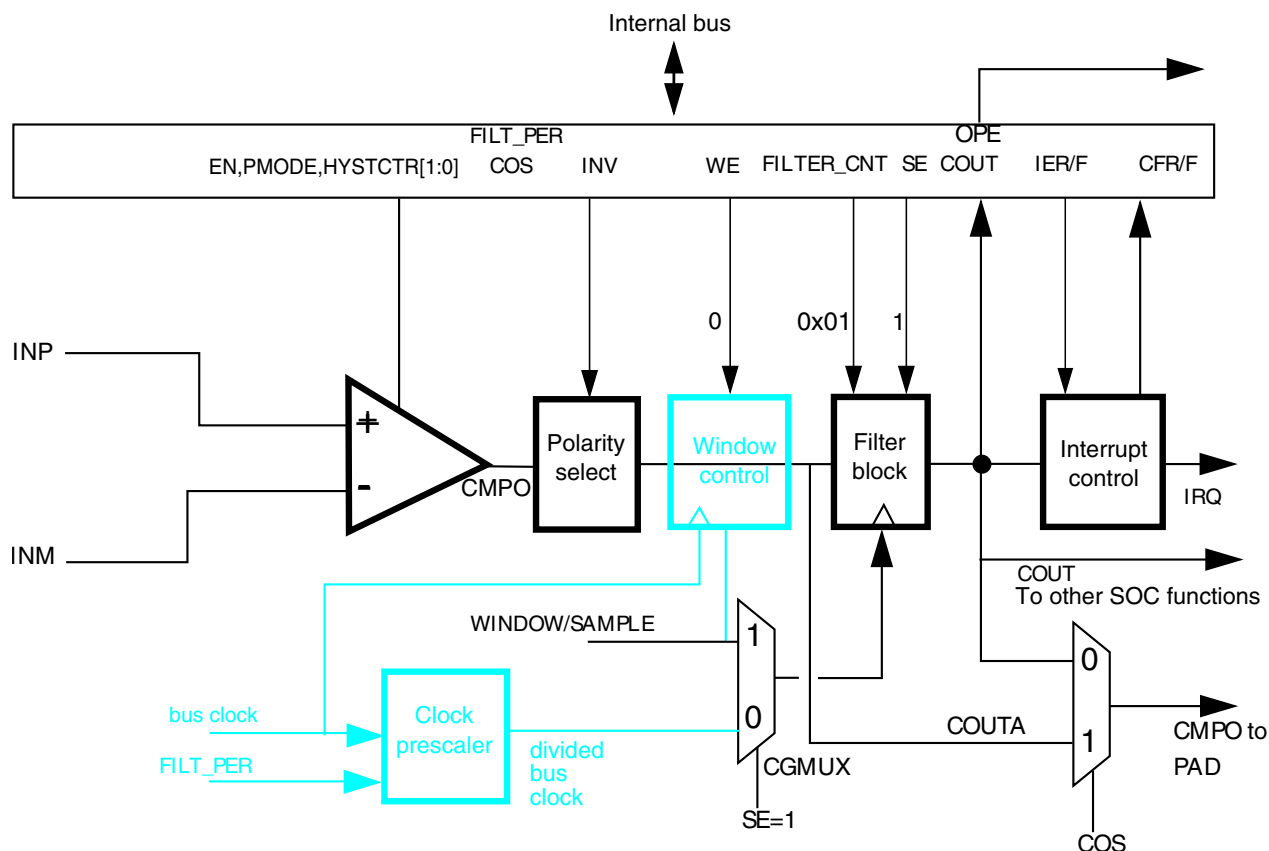

Figure 30-16. Sampled, Non-Filtered (# 3A): sampling point externally driven

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

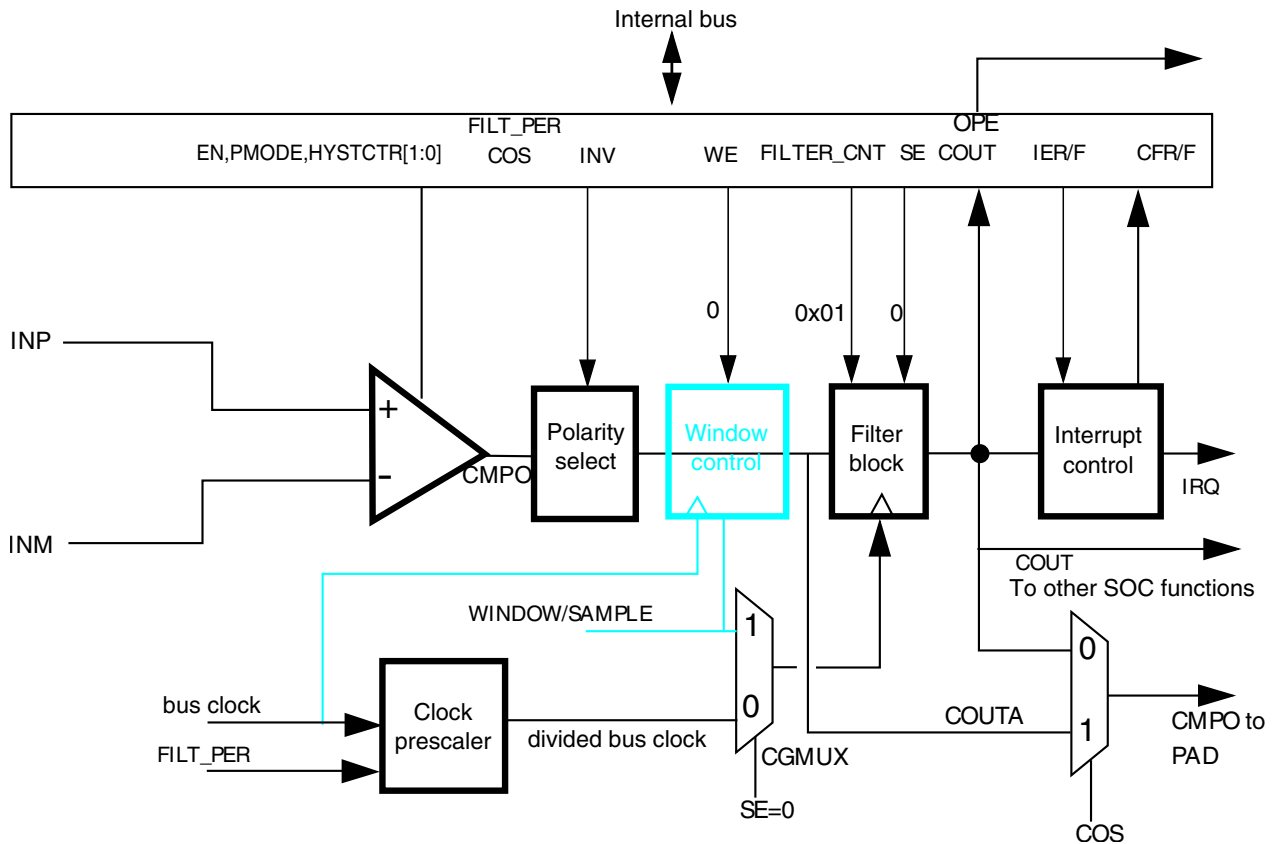

Figure 30-17. Sampled, Non-Filtered (# 3B): sampling interval internally derived

30.8.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, $CR0[FILTER_CNT] > 1$, which activates filter operation.

Functional description

Figure 30-18. Sampled, Filtered (# 4A): sampling point externally driven

Figure 30-19. Sampled, Filtered (# 4B): sampling point internally derived

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, $CR0[FILTER_CNT] > 1$, which activates filter operation.

30.8.1.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

Figure 30-20. Windowed mode operation

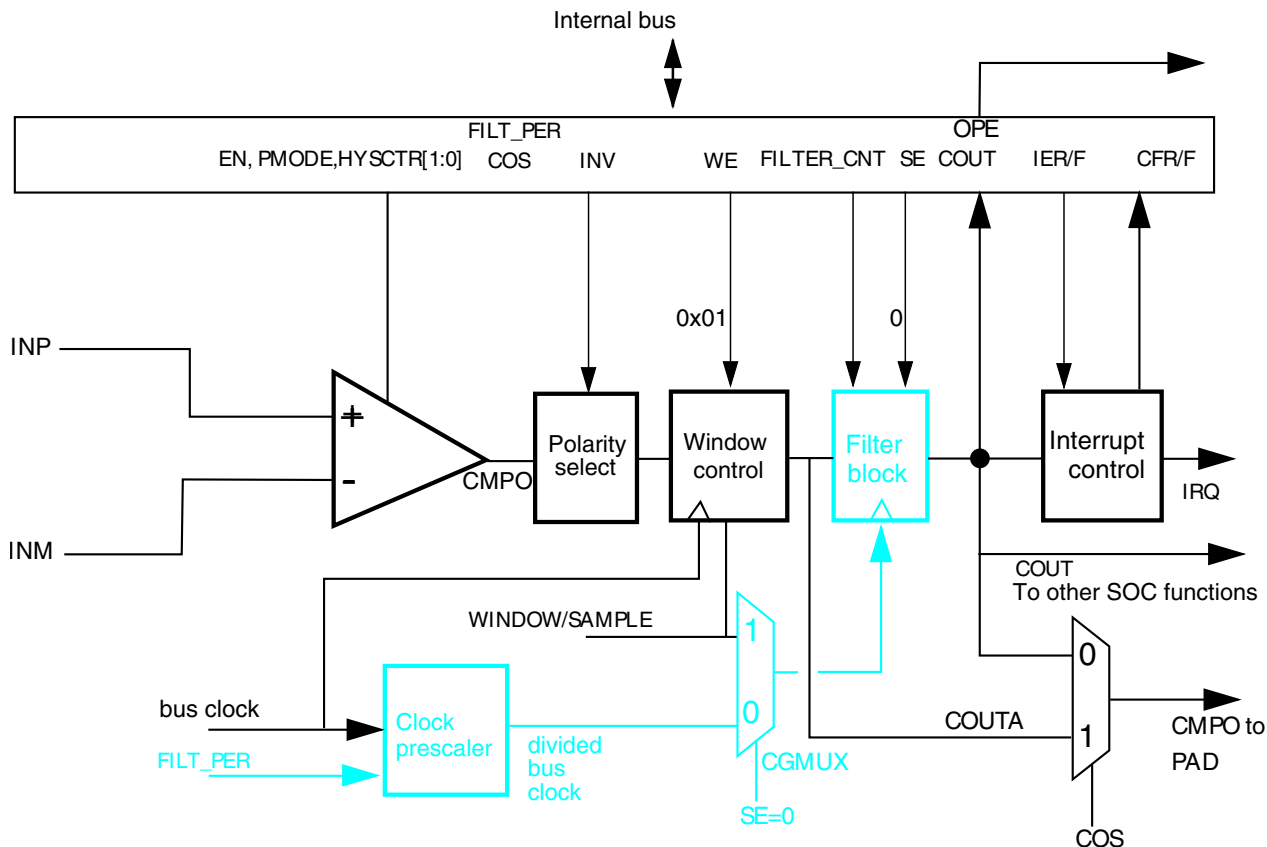

Figure 30-21. Windowed mode

For control configurations which result in disabling the filter block, see [Filter Block Bypass Logic](#) diagram.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

30.8.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 30-20, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

Figure 30-22. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of CR0[FILTER_CNT] must be 1.

30.8.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + $((CR0[FILTER_CNT] * FPR[FILT_PER]) + 1) * \text{bus clock}$ for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

Figure 30-23. Windowed/Filtered mode

30.8.2 Power modes

30.8.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.

30.8.2.2 Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

30.8.2.3 Low-Leakage mode operation

When the chip is in Low-Leakage modes:

- The CMP module is partially functional and is limited to Low-Speed mode, regardless of CR1[PMODE] setting
- Windowed, Sampled, and Filtered modes are not supported
- The CMP output pin is latched and does not reflect the compare output state.

The positive- and negative-input voltage can be supplied from external pins or the DAC output. The MCU can be brought out of the Low-Leakage mode if a compare event occurs and the CMP interrupt is enabled. After wakeup from low-leakage modes, the CMP module is in the reset state except for SCR[CFF] and SCR[CFR].

30.8.2.4 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the CMP continues to operate normally.

30.8.3 Startup and operation

A typical startup sequence is as follows.

The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the [Low-pass filter](#).

During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

30.8.4 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

30.8.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER_CNT] > 0x01 and
- Setting FPR[FILT_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed. In other words, SCR[COUTA] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CR0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed.

30.8.4.2 Latency issues

The value of FPR[FILT_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER_CNT].

The values of FPR[FILT_PER] or SAMPLE period and CR0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

Table 30-16. Comparator sample/filter maximum latencies

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation	Maximum latency ¹
1	0	X	X	X	X	Disabled	N/A

Table continues on the next page...

Table 30-16. Comparator sample/filter maximum latencies (continued)

Mode #	CR1[EN]	CR1[WE]	CR1[SE]	CR0[FILTER_CNT]	FPR[FILT_PER]	Operation	Maximum latency ¹
2A	1	0	0	0x00	X	Continuous Mode	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FPR[FILT_PER] * T_{per}) + T_{per}$
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	$T_{PD} + (CR0[FILTER_CNT] * T_{SAMPLE}) + T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (CR0[FILTER_CNT] * FPR[FILT_PER] * T_{per}) + T_{per}$
5A	1	1	0	0x00	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	0x00		$T_{PD} + T_{per}$
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	$T_{PD} + (FPR[FILT_PER] * T_{per}) + 2T_{per}$
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	$T_{PD} + (CR0[FILTER_CNT] * FPR[FILT_PER] * T_{per}) + 2T_{per}$

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

30.9 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both. The following table gives the conditions in which the interrupt request is asserted and deasserted.

When	Then
SCR[IER] and SCR[CFR] are set	The interrupt request is asserted
SCR[IEF] and SCR[CFF] are set	The interrupt request is asserted
SCR[IER] and SCR[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

30.10 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA

transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

30.11 Digital-to-analog converter

The following figure shows the block diagram of the DAC module. It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DACCR). Its supply reference source can be selected from two sources V_{in1} and V_{in2} . The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

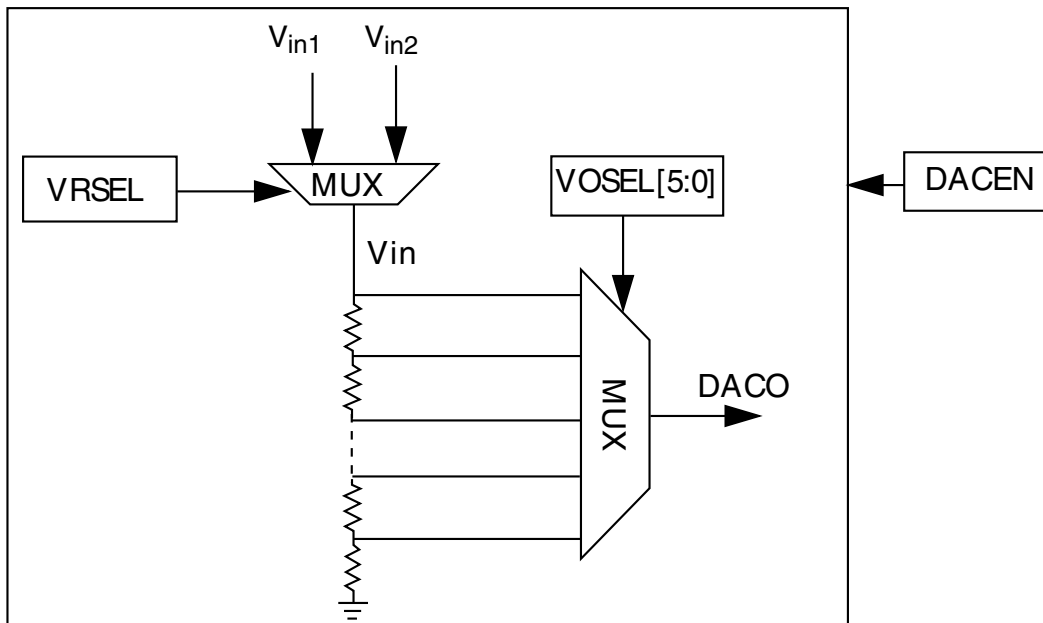

Figure 30-24. 6-bit DAC block diagram

30.12 DAC functional description

This section provides DAC functional description.

30.12.1 Voltage reference source select

- V_{in1} connects to the primary voltage source as supply reference of 64 tap resistor ladder
- V_{in2} connects to an alternate voltage source

30.13 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

30.14 DAC clocks

This module has a single clock input, the bus clock.

30.15 DAC interrupts

This module has no interrupts.

Chapter 31

12-bit Digital-to-Analog Converter (DAC)

31.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The 12-bit digital-to-analog converter (DAC) is a low-power general-purpose DAC. The output of this DAC can be placed on an external pin or set as one of the inputs to the analog comparator, analog-to-digital converter (ADC), or other peripherals.

31.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from $1/4096 V_{in}$ to V_{in} , and the step is $1/4096 V_{in}$, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

31.3 Block diagram

The block diagram of the DAC module is as follows:

Block diagram

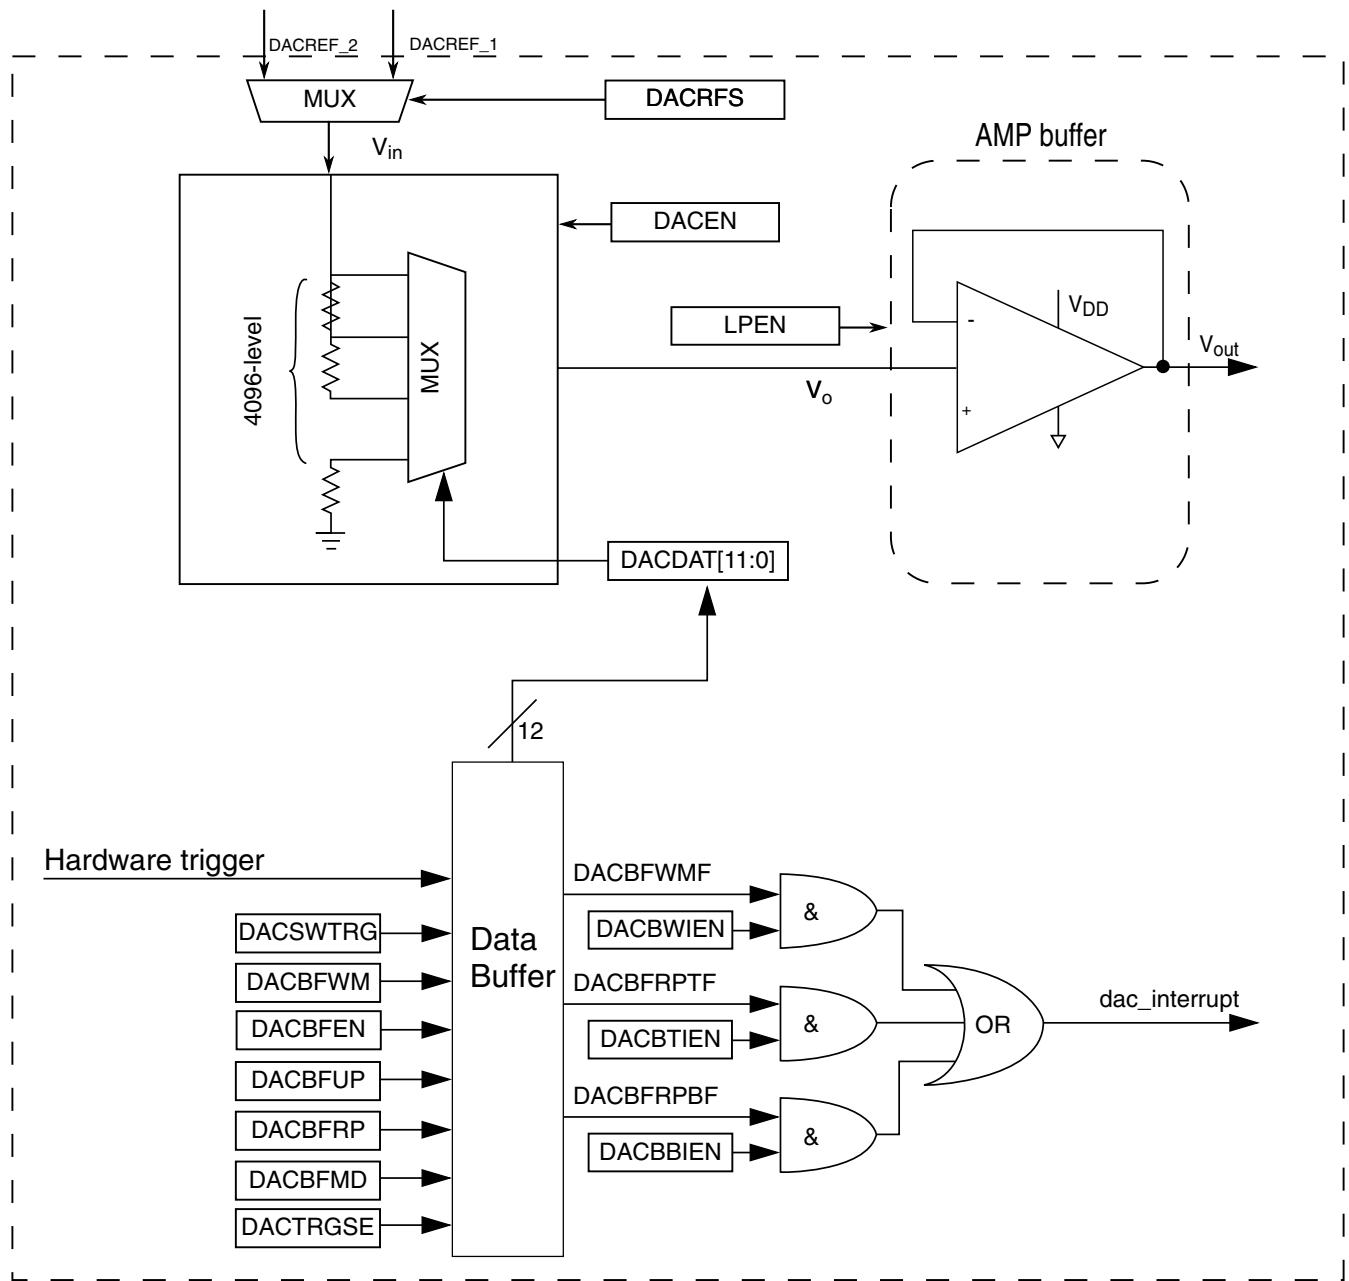

Figure 31-1. DAC block diagram

31.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level. The address offset is defined at the module level.

DAC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8500	DAC Data High Register (DAC0_DAT0H)	8	R/W	00h	31.4.1/664

31.4.1 DAC Data High Register (DACx_DATnH)

Address: FFFF_8500h base + 0h offset + (2d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	0				DATA1			
Write	0				0			
Reset	0	0	0	0	0	0	0	0

DACx_DATnH field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 DATA1	When the DAC Buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula. $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$ When the DAC buffer is enabled, DATA[11:0] is mapped to the 16-word buffer.

31.4.2 DAC Data Low Register (DACx_DATnL)

Address: FFFF_8500h base + 1h offset + (2d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	DATA0							
Write	0							
Reset	0	0	0	0	0	0	0	0

DACx_DATnL field descriptions

Field	Description
7–0 DATA0	When the DAC buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$

DACx_DATnL field descriptions (continued)

Field	Description
	When the DAC buffer is enabled, DATA is mapped to the 16-word buffer.

31.4.3 DAC Status Register (DACx_SR)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: FFFF_8500h base + 20h offset = FFFF_8520h

Bit	7	6	5	4	3	2	1	0
Read	0					DACBFWM	DACBFRPT	DACBFRPB

31.4.5 DAC Control Register 1 (DACx_C1)

Address: FFFF_8500h base + 22h offset = FFFF_8522h

DACx_C1 field descriptions

Field	Description
7 DMAEN	DMA Enable Select 0 DMA is disabled. 1 DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 DACBFWM	DAC Buffer Watermark Select Controls when SR[DACBFWMF] will be set. When the DAC buffer read pointer reaches the word defined by this field, which is 1–4 words away from the upper limit (DACBUP), SR[DACBFWMF] will be set. This allows user configuration of the watermark interrupt. 00 1 word 01 2 words 10 3 words 11 4 words
2–1 DACBFMD	DAC Buffer Work Mode Select 00 Normal mode 01 Swing mode 01 Reserved 10 One-Time Scan mode 11 Reserved
0 DACBFEN	DAC Buffer Enable 0 Buffer read pointer is disabled. The converted data is always the first word of the buffer. 1 Buffer read pointer is enabled. The converted data is the word that the read pointer points to. It means converted data can be from any word of the buffer.

31.4.6 DAC Control Register 2 (DACx_C2)

Address: FFFF_8500h base + 23h offset = FFFF_8523h

DACx_C2 field descriptions

Field	Description
7–4 DACBFRP	DAC Buffer Read Pointer Keeps the current value of the buffer read pointer.
3–0 DACBFUP	DAC Buffer Upper Limit Selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it.

31.5 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by C0[DACRFS]. See the module introduction for information on the source for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to $V_{in}/4096$, and the step is $V_{in}/4096$.

31.5.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever any hardware or software trigger event occurs. Refer to [Introduction](#) for the hardware trigger connection.

The data buffer can be configured to operate in Normal mode, Swing mode, or One-Time Scan mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and C2[DACBFUP] by writing C2[DACBFRP].

31.5.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. SR[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, $C2[DACBFRP] = C2[DACBFUP]$. SR[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, SR[DACBFWMF] is

set when the DAC buffer read pointer has reached the position defined by C1[DACBFWM]. C1[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from C2[DACBFUP].

31.5.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

Table 31-79. Modes of DAC data buffer operation

Modes	Description
Buffer Normal mode	This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.
Buffer Swing mode	This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.
Buffer One-time Scan mode	The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again. NOTE: If the software set the read pointer to the upper limit, the read pointer will not advance in this mode.

31.5.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

31.5.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

31.5.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 31-80. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	<p>If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop.</p> <p>In low-power stop modes, the DAC is fully shut down.</p>

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

31.5.5 Background Mode Operation

When the MCU is in active background mode, the DAC will operate normally.

Chapter 32

Voltage Reference (VREF)

32.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Voltage Reference(VREF) is intended to supply an accurate voltage output that can be trimmed in 0.5 mV steps. The VREF can be used in applications to provide a reference voltage to external devices or used internally as a reference to analog peripherals such as the ADC, DAC, or CMP. The voltage reference has three operating modes that provide different levels of supply rejection and power consumption..

The following figure is a block diagram of the Voltage Reference.

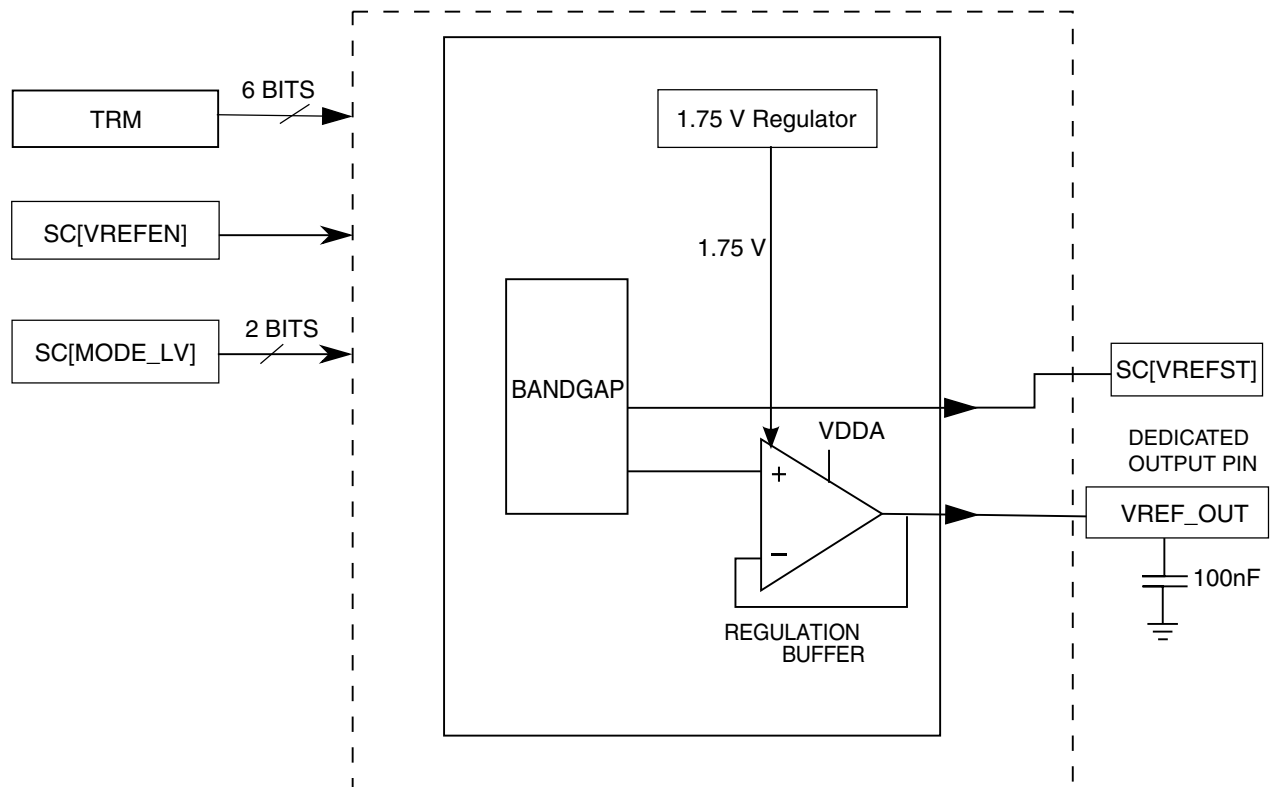

Figure 32-1. Voltage reference block diagram

32.1.1 Overview

The Voltage Reference provides a buffered reference voltage for use as an external reference. In addition, the buffered reference is available internally for use with on chip peripherals such as ADCs and DACs. Refer to the chip configuration chapter for a description of these options. The reference voltage is output on a dedicated output pin when the VREF is enabled. The Voltage Reference output can be trimmed with a resolution of 0.5mV by means of the TRM register TRIM[5:0] bitfield.

32.1.2 Features

The Voltage Reference has the following features:

- Programmable trim register with 0.5 mV steps, automatically loaded with factory trimmed value upon reset
- Programmable buffer mode selection:
 - Off

- Bandgap enabled/standby (output buffer disabled)
- High power buffer mode (output buffer enabled)
- 1.2 V output at room temperature
- Dedicated output pin, VREF_OUT

32.1.3 Modes of Operation

The Voltage Reference continues normal operation in Run, Wait, and Stop modes. The Voltage Reference can also run in Very Low Power Run (VLPR), Very Low Power Wait (VLPW) and Very Low Power Stop (VLPS). If it is desired to use the VREF regulator in the very low power modes, the system reference voltage must be enabled in these modes. Refer to the chip configuration chapter for information on enabling this mode of operation. Having the VREF regulator enabled does increase current consumption. In very low power modes it may be desirable to disable the VREF regulator to minimize current consumption. Note however that the accuracy of the output voltage will be reduced (by as much as several mVs) when the VREF regulator is not used. .

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

32.1.4 VREF Signal Descriptions

The following table shows the Voltage Reference signals properties.

Table 32-1. VREF Signal Descriptions

Signal	Description	I/O
VREF_OUT	Internally-generated Voltage Reference output	O

NOTE

When the VREF output buffer is disabled, the status of the VREF_OUT signal is high-impedence.

32.2 Memory Map and Register Definition

VREF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8670	VREF Trim Register (VREF_TRM)	8	R/W	See section	32.2.1/674
FFFF_8671	VREF Status and Control Register (VREF_SC)	8	R/W	00h	32.2.2/675

32.2.1 VREF Trim Register (VREF_TRM)

This register contains bits that contain the trim data for the Voltage Reference.

Address: FFFF_8670h base + 0h offset = FFFF_8670h

* Notes:

- x = Undefined at reset.

VREF_TRM field descriptions

Field	Description
7 Reserved	This field is reserved. Upon reset this value is loaded with a factory trim value.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 TRIM	Trim bits These bits change the resulting VREF by approximately ± 0.5 mV for each step. NOTE: Min = minimum and max = maximum voltage reference output. For minimum and maximum voltage reference output values, refer to the Data Sheet for this chip. 000000 Min 111111 Max

32.2.2 VREF Status and Control Register (VREF_SC)

This register contains the control bits used to enable the internal voltage reference and to select the buffer mode to be used.

Address: FFFF_8670h base + 1h offset = FFFF_8671h

Bit	7	6	5	4	3	2	1	0

1–0 MODE_LV	Buffer Mode selection These bits select the buffer modes for the Voltage Reference module. 00 Bandgap on only, for stabilization and startup 01 High power buffer mode enabled 10 Reserved 11 Reserved

32.3 Functional Description

The Voltage Reference is a bandgap buffer system. Unity gain amplifiers are used.

The VREF_OUT signal can be used by both internal and external peripherals in high power buffer mode, A 100 nF capacitor must be connected between VREF_OUT and VSSA.

The following table shows all possible function configurations of the Voltage Reference.

Table 32-5. Voltage Reference function configurations

SC[VREFEN]	SC[MODE_LV]	Configuration	Functionality
0	X	Voltage Reference disabled	Off
1	00	Voltage Reference enabled, bandgap on only	Startup and standby
1	01	Reserved	Reserved
1	10	Voltage Reference enabled, low power buffer on	VREF_OUT available for internal and external use. 100 nF capacitor is required.
1	11	Reserved	Reserved

32.3.1 Voltage Reference Disabled, SC[VREFEN] = 0

When SC[VREFEN] = 0, the Voltage Reference is disabled, the VREF bandgap and the output buffers are disabled. The Voltage Reference is in off mode.

32.3.2 Voltage Reference Enabled, SC[VREFEN] = 1

When SC[VREFEN] = 1, the Voltage Reference is enabled, and different modes should be set by the SC[MODE_LV] bits.

32.3.2.1 SC[MODE_LV]=00

The internal VREF bandgap is enabled to generate an accurate 1.2 V output that can be trimmed with the TRM register's TRIM[5:0] bitfield. The bandgap requires some time for startup and stabilization. SC[VREFST] can be monitored to determine if the stabilization and startup is complete.

The output buffer is disabled in this mode, and there is no buffered voltage output. The Voltage Reference is in standby mode. If this mode is first selected and the low power or high power buffer mode is subsequently enabled, there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (T_{stap}) and the value is specified in the appropriate device data sheet.

32.3.2.2 SC[MODE_LV] = 01

Reserved

32.3.2.3 SC[MODE_LV] = 10

The internal VREF bandgap is on. The low power buffer is enabled to generate a buffered 1.2 V voltage to VREF_OUT. It can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from the standby mode (SC[MODE_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (T_{stap}) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of T_{stap} or until SC[VREFST] = 1.

In this mode, a 100 nF capacitor is required to connect between the VREF_OUT pin and VSSA.

32.3.2.4 SC[MODE_LV] = 11

Reserved

32.4 Initialization/Application Information

The Voltage Reference requires some time for startup and stabilization. After SC[VREFEN] = 1, SC[VREFST] can be monitored to determine if the stabilization and startup is completed. The settling time of internal bandgap reference is typically 35ms, which means there is 35ms delay after the bandgap is enabled, the SC[VREFST] can only be useful after the bandgap is stable after the settling time.

When the Voltage Reference is already enabled and stabilized, changing SC[MODE_LV] will not clear SC[VREFST] but there will be some startup time before the output voltage at the VREF_OUT pin has settled. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. Also, there will be some settling time when a step change of the load current is applied to the VREF_OUT pin. When the 1.75V VREF regulator is disabled, the VREF_OUT voltage will be more sensitive to supply voltage variation. It is recommended to use this regulator to achieve optimum VREF_OUT performance.

The SC[REGEN] and SC[ICOMPEN] bits are written to 1 during factory trimming of the VREF voltage. These bits should be written to 1 to achieve the performance stated in the device data sheet.

Chapter 33

Programmable Delay Block (PDB)

33.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved. The PDB can optionally provide pulse outputs (Pulse-Out's) that are used as the sample window in the CMP block.

33.1.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to eight configurable PDB channels for ADC hardware trigger
 - One PDB channel is associated with one ADC.
 - One trigger output for ADC hardware trigger and up to eight pre-trigger outputs for ADC trigger select per PDB channel
 - Trigger outputs can be enabled or disabled independently.
 - One 16-bit delay register per pre-trigger output
 - Optional bypass of the delay registers of the pre-trigger outputs
 - Operation in One-Shot or Continuous modes

- Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel
- One programmable delay interrupt
- One sequence error interrupt
- One channel flag and one sequence error flag per pre-trigger
- DMA support
- Up to eight DAC interval triggers
 - One interval trigger output per DAC
 - One 16-bit delay interval register per DAC trigger output
 - Optional bypass of the delay interval trigger registers
 - Optional external triggers
- Up to eight pulse outputs (pulse-out's)
 - Pulse-out's can be enabled or disabled independently.
 - Programmable pulse width

NOTE

The number of PDB input and output triggers are chip-specific. See the chip configuration information for details.

33.1.2 Implementation

In this section, the following letters refer to the number of output triggers:

- N — Total available number of PDB channels.
- n — PDB channel number, valid from 0 to $N-1$.
- M — Total available pre-trigger per PDB channel.
- m — Pre-trigger number, valid from 0 to $M-1$.
- X — Total number of DAC interval triggers.
- x — DAC interval trigger output number, valid from 0 to $X-1$.

- Y — Total number of Pulse-Out's.
- y — Pulse-Out number, valid value is from 0 to $Y-1$.

NOTE

The number of module output triggers to core is chip-specific. For module to core output triggers implementation, see the chip configuration information.

33.1.3 Back-to-back acknowledgment connections

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

33.1.4 DAC External Trigger Input Connections

The implementation of DAC external trigger inputs is chip-specific. See the chip configuration information for details.

33.1.5 Block diagram

This diagram illustrates the major components of the PDB.

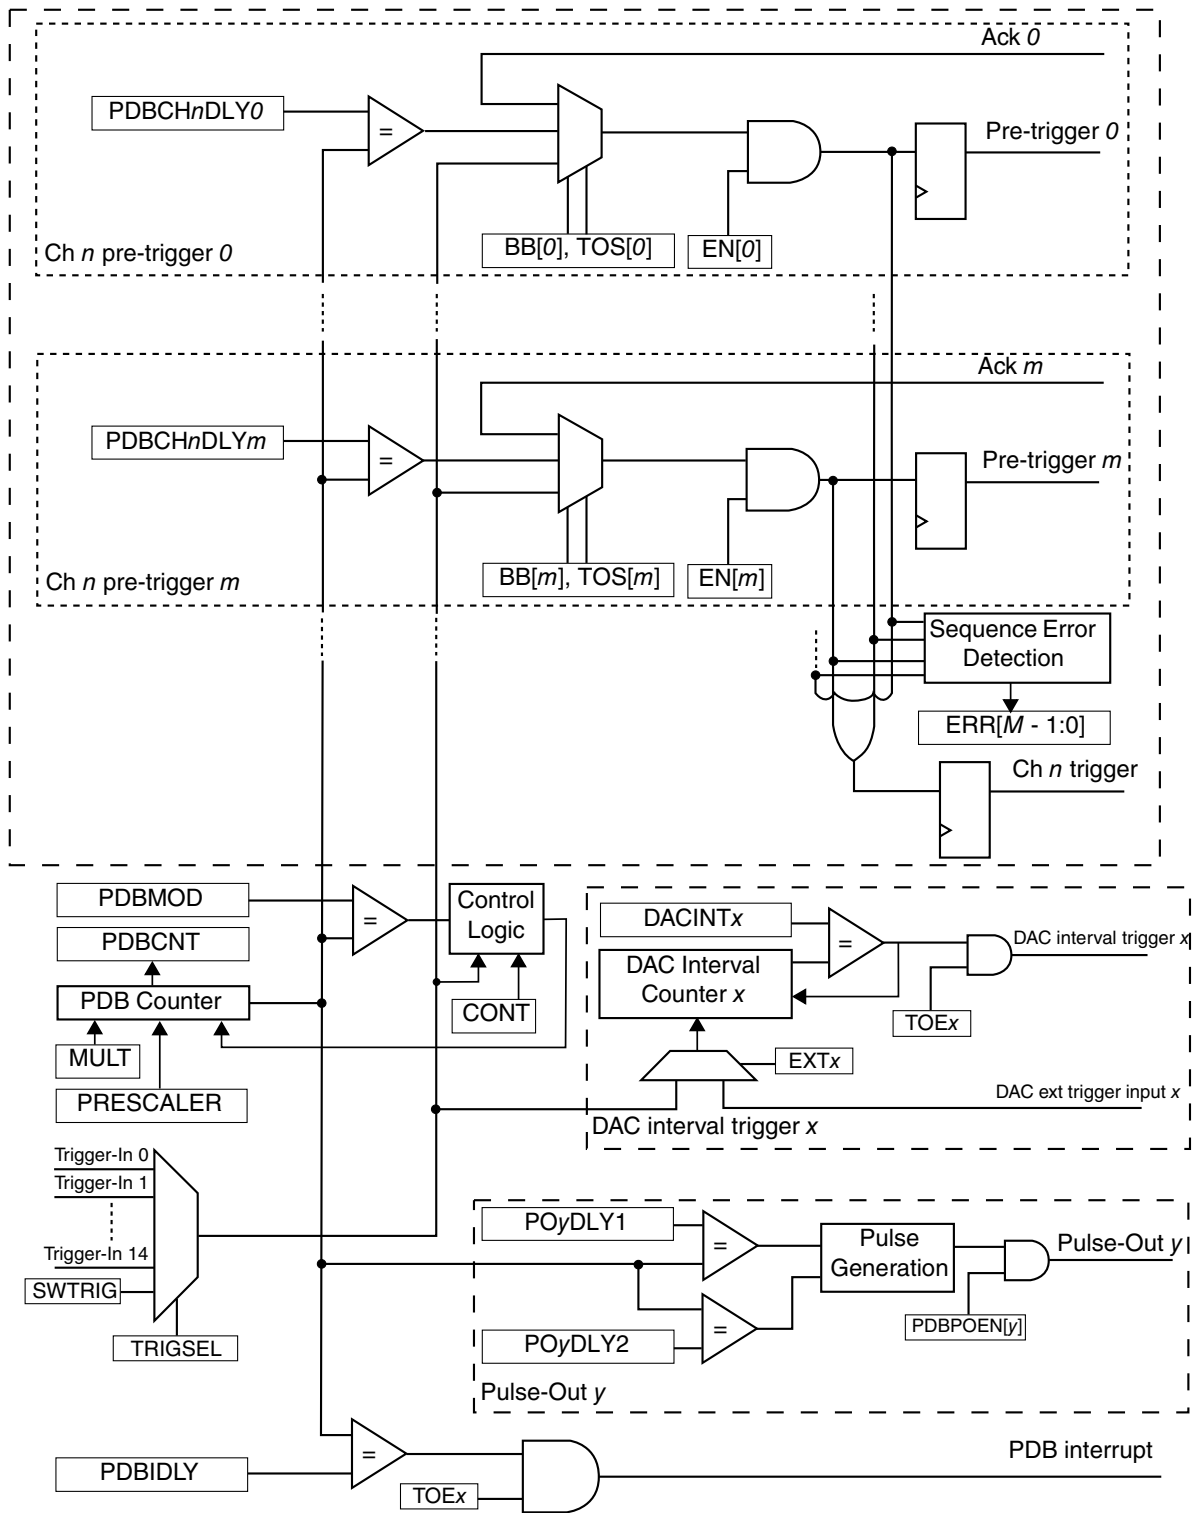

Figure 33-1. PDB block diagram

In this diagram, only one PDB channel n , one DAC interval trigger x , and one Pulse-Out y is shown. The PDB enable control logic and the sequence error interrupt logic is not shown.

33.1.6 Modes of operation

PDB ADC trigger operates in the following modes.

Disabled: Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.

Debug: Counter is paused when processor is in Debug mode, and the counter for dac trigger is also paused in Debug mode.

Enabled One-Shot: Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.

Enabled Continuous: Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.

Enabled Bypassed: The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

33.2 PDB signal descriptions

This table shows the detailed description of the external signal.

Table 33-1. PDB signal descriptions

Signal	Description	I/O
EXTRG	External Trigger Input Source If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter.	I

33.4 Functional description

33.4.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared against several different digital values. If the PDB is enabled, a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on selected trigger input source or software trigger being selected and SC[SWTRIG] is written with 1. For each channel, delay m determines the time between assertion of the trigger input event to the point at which changes in the pre-trigger m output signal is initiated. The time is defined as:

- Trigger input event to pre-trigger $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$ peripheral clock cycles
- Add one additional peripheral clock cycle to determine the time at which the channel trigger output change.

Functional description

Each channel is associated with one ADC block. PDB channel n pre-trigger outputs 0 to M and trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block prior to the actual trigger. The ADC contains M sets of configuration and result registers, allowing it to operate in a ping-pong fashion, alternating conversions between M different analog sources. The pre-trigger outputs are used to specify which signal will be sampled next. When pre-trigger m is asserted, the ADC conversion is triggered with set m of the configuration and result registers.

The waveforms shown in the following diagram illustrate the pre-trigger and trigger outputs of PDB channel n . The delays can be independently set via the $CHnDLYm$ registers. And the pre-triggers can be enabled or disabled in $CHnC1[EN[m]]$.

Figure 33-42. Pre-trigger and trigger outputs

The delay in $CHnDLYm$ register can be optionally bypassed, if $CHnC1[TOS[m]]$ is cleared. In this case, when the trigger input event occurs, the pre-trigger m is asserted after two peripheral clock cycles.

The PDB can be configured in back-to-back operation. Back-to-back operation enables the ADC conversions complete to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on next set of configuration and results registers. When back-to-back is enabled by setting $CHnC1[BB[m]]$, the delay m is ignored and the pre-trigger m is asserted two peripheral cycles after the acknowledgment m is received. The acknowledgment connections in this MCU is described in [Back-to-back acknowledgment connections](#).

When an ADC conversion, which is triggered by one of the pre-triggers from PDB channel n , is in progress and $ADCnSC1[COCO]$ is not set, a new trigger from PDB channel n pre-trigger m cannot be accepted by $ADCn$. Therefore every time when one PDB channel n pre-trigger and trigger output starts an ADC conversion, an internal lock associated with the corresponding pre-trigger is activated. The lock becomes inactive when the corresponding $ADCnSC1[COCO]$ is set, or the corresponding PDB pre-trigger is disabled, or the PDB is disabled. The channel n trigger output is suppressed when any of the locks of the pre-triggers in channel n is active. If a new pre-trigger m asserts when

there is active lock in the PDB channel n , a register flag bit, $CHnS[ERR[m]]$, associated with the pre-trigger m is set. If $SC[PDBEIE]$ is set, the sequence error interrupt is generated. Sequence error is typically happened because the delay m is set too short and the pre-trigger m asserts before the previously triggered ADC conversion is completed.

When the PDB counter reaches the value set in $IDLY$ register, the $SC[PDBIF]$ flag is set. A PDB interrupt can be generated if $SC[PDBIE]$ is set and $SC[DMAEN]$ is cleared. If $SC[DMAEN]$ is set, PDB requests a DMA transfer when $SC[PDBIF]$ is set.

The modulus value in MOD register, is used to reset the counter back to zero at the end of the count. If $SC[CONT]$ bit is set, the counter will then resume a new count. Otherwise, the counter operation will cease until the next trigger input event occurs.

33.4.2 PDB trigger input source selection

The PDB has up to 15 trigger input sources, namely Trigger-In 0 to 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through the $SC[SWTRIG]$. $SC[TRIGSEL]$ bits select the active trigger input source or software trigger.

For the trigger input sources implemented in this MCU, see chip configuration information.

33.4.3 DAC interval trigger outputs

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter x is reset and started when a trigger input event occurs if $DACINTCx[EXT]$ is cleared. When the interval counter x is equal to the value set in $DACINTx$ register, the DAC interval trigger x output generates a pulse of one peripheral clock cycle width to update the $DACx$. If $DACINTCx[EXT]$ is set, the DAC interval counter is bypassed and the interval trigger output x generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the $DACINTCx[TOE]$.

DAC interval counters are also reset when the PDB counter reaches the MOD register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

Together, the DAC interval trigger pulse and the ADC pre-trigger/trigger pulses allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

Functional description

Figure 33-43. PDB ADC triggers and DAC interval triggers use case

NOTE

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

33.4.4 Pulse-Out's

PDB can generate pulse outputs of configurable width. When PDB counter reaches the value set in POyDLY[DLY1], the Pulse-Out goes high; when the counter reaches POyDLY[DLY2], it goes low. POyDLY[DLY2] can be set either greater or less than POyDLY[DLY1].

Because the PDB counter is shared by both ADC pre-trigger/trigger outputs and Pulse-Out generation, they have the same time base.

The pulse-out connections implemented in this MCU are described in the device's chip configuration details.

33.4.5 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus Register (MOD)
- PDB Interrupt Delay Register (IDLY)
- PDB Channel n Delay m Register (CH n DLY m)
- DAC Interval x Register (DACINT x)
- PDB Pulse-Out y Delay Register (PO y DLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized as shown in the table below.

Table 33-44. Circumstances of update to the delay registers

SC[LDMOD]	Update to the delay registers
00	The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].
01	The PDB counter reaches the MOD register value after 1 is written to SC[LDOK].
10	A trigger input event is detected after 1 is written to SC[LDOK].
11	Either the PDB counter reaches the MOD register value, or a trigger input event is detected, after 1 is written to SC[LDOK].

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

Figure 33-44. Registers Update with SC[LDMOD] = 00

Figure 33-45. Registers update with SC[LDMOD] = x1

33.4.6 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 33-45. PDB interrupt summary

Interrupt	Flags	Enable bit
PDB Interrupt	SC[PDBIF]	SC[PDBIE] = 1 and SC[DMAEN] = 0
PDB Sequence Error Interrupt	CHnS[ERRm]	SC[PDBEIE] = 1

33.4.7 DMA

If SC[DMAEN] is set, PDB can generate DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt will not be issued.

33.5 Application information

33.5.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only

values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

Chapter 34

Modulo Timer (MTIM)

34.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The MTIM (or MTIM16) module is a simple 16-bit timer with several software selectable clock sources and a programmable interrupt.

34.2 Features

Timer system features include:

- 16-bit up-counter
 - Free-running or 16-bit modulo limit
 - Software controllable interrupt on overflow
 - Counter reset bit (TRST)
 - Counter stop bit (TSTP)
- Four software selectable clock sources for input to prescaler:
 - System bus clock — rising edge
 - Fixed frequency clock (XCLK) — rising edge
 - External clock source on the TCLK pin — rising edge
 - External clock source on the TCLK pin — falling edge
- Nine selectable clock prescale values:

Features

- Clock source divide by 1, 2, 4, 8, 16, 32, 64, 128, or 256
- Modulo compare matched can be an output

34.2.1 Block Diagram

The following figure is a block diagram of the modulo timer module.

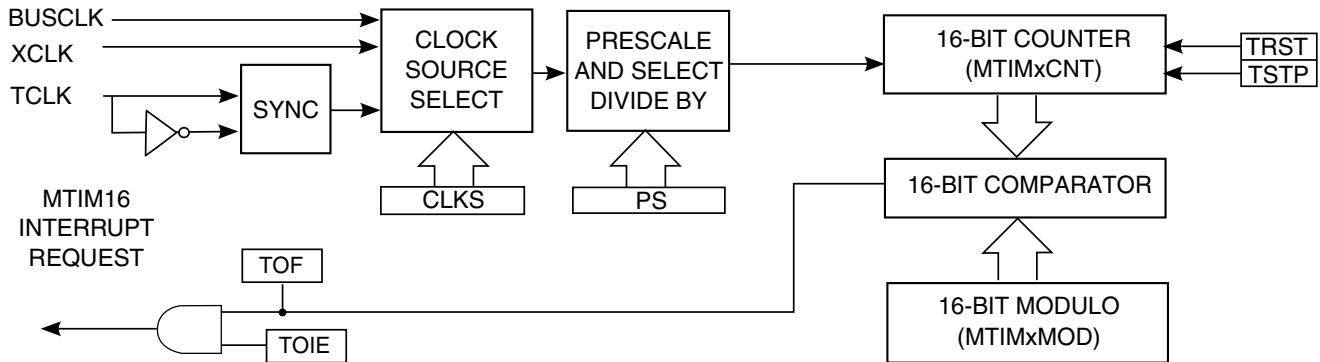

Figure 34-1. Modulo Timer (MTIM16) Block Diagram

34.2.2 Modes of Operation

This section defines MTIM16 operation in stop, wait, and background debug modes.

34.2.2.1 MTIM16 in Wait Mode

The MTIM16 continues to run in wait mode if enabled prior to the execution of the WAIT instruction. The timer overflow interrupt brings the MCU out of wait mode if it is enabled. For lowest possible current consumption, the MTIM16 should be stopped by software if it is not needed as an interrupt source during wait mode.

34.2.2.2 MTIM16 in Stop Modes

MTIM operation in stop modes is chip-specific. See details about MCU power modes and clocking.

- If the MTIM is unlocked in any MCU stop mode, it is disabled in that mode, regardless of the module settings before the STOP instruction was executed. It cannot be used as a wakeup source in that mode.
- If the MTIM is clocked and enabled in an MCU stop mode, it can be used as a wakeup source in that mode.

Upon waking from very low-power stop modes, the MTIM enters its reset state.

For low-power stop modes:

- If the device exits any of these modes with a reset, the MTIM module enters its reset state.
- If the device exits any of these modes with an interrupt, the MTIM module continues from its state in the low-power stop mode.
- If the counter was active upon entering any of these modes, the count resumes from the current value.

34.2.2.3 MTIM16 in Active Background Mode

The MTIM16 stops all counting until the microcontroller returns to normal user operating mode. Counting resumes from the suspended value as long as an MTIM16 reset did not occur (TRST written to a 1).

34.3 External Signal Description

This section describes the module external signals.

34.3.1 TCLK — External Clock Source Input into MTIM16

The MTIM16 includes one external signal, TCLK, used to input an external clock when selected as the MTIM16 clock source. The signal properties of TCLK are shown in the following table.

Table 34-1. Signal Properties

Signal	Function	I/O
TCLK	External clock source input into MTIM16	I

The TCLK input must be synchronized by the bus clock. Also, variations in duty cycle and clock jitter must be accommodated. As a result, the TCLK signal must be limited to one-fourth of the bus frequency.

The TCLK pin can be muxed with a general-purpose port pin. Refer to the chip-level signal multiplexing and pin assignment details for more information.

34.4 Memory Map and Register Descriptions

Each MTIM16 module includes six registers.

If a chip has more than one MTIM16 module, register names include placeholder characters.

MTIM memory map

Address offset (hex)	Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	FFFF_8410	MTIM16 status and control register (MTIM0_SC)	8	R/W	10h	34.4.1/704

34.4.3 MTIM16 counter register high (MTIMx_CNTH)

This register is the read-only value of the high byte of the current MTIM16 16-bit counter.

When either the CNTH or CNTL register is read, the content of the two registers is latched into a buffer where they remain latched until the other register is read. This allows the coherent 16-bit value to be read in both big-endian and little-endian compile environments and ensures the 16-bit counter is unaffected by the read operation. The coherency mechanism is automatically restarted by an MCU reset or by setting the TRST bit of the SC register (whether BDM mode is active or not).

When BDM is active, the coherency mechanism is frozen such that the buffer latches remain in the state they were in when BDM became active, even if one or both halves of the counter register are read while BDM is active. This assures that if the user was in the middle of reading a 16-bit register when BDM became active, the appropriate value from the other half of the 16-bit value is read after returning to normal execution. The value read from the CNTH and CNTL registers in BDM mode is the value of these registers and not the value of their read buffer.

Address: FFFF_8410h base + 2h offset = FFFF_8412h

**MTIM0_CNTH field descriptions**

Field	Description
7–0 CNTH	MTIM16 count (high byte) These 8 read-only bits contain the current high byte value of the 16-bit counter. Writing has no effect on this register. Reset clears the register to 0x00.

34.4.4 MTIM16 counter register low (MTIMx_CNTRL)

This register is the read-only value of the low byte of the current MTIM16 16-bit counter.

When either the CNTH or CNTRL register is read, the content of the two registers is latched into a buffer where they remain latched until the other register is read. This allows the coherent 16-bit value to be read in both big-endian and little-endian compile environments and ensures the 16-bit counter is unaffected by the read operation. The coherency mechanism is automatically restarted by an MCU reset or by setting the TRST bit of the SC register (whether BDM mode is active or not).

When BDM is active, the coherency mechanism is frozen such that the buffer latches remain in the state they were in when BDM became active, even if one or both halves of the counter register are read while BDM is active. This assures that if the user was in the middle of reading a 16-bit register when BDM became active, the appropriate value from the other half of the 16-bit value is read after returning to normal execution. The value read from the CNTH and CNTRL registers in BDM mode is the value of these registers and not the value of their read buffer.

Address: FFFF_8410h base + 3h offset = FFFF_8413h

**MTIM0_CNTRL field descriptions**

7–0 CNTRL	MTIM16 count (low byte)

MTIMO_CNTL field descriptions (continued)

Field	Description
	These 8 read-only bits contain the current low byte value of the 16-bit counter. Writing has no effect on this register. Reset clears the register to 0x00.

34.4.5 MTIM16 modulo register high (MTIMx_MODH)

A value of 0x0000 in MODH:MODL puts the MTIM16 in free-running mode. Writing to either MODH or MODL latches the value into a buffer and the latched buffers are updated after the second byte writing. The updated values take effect and reload to the MODH:MODL registers in the next MTIM16 counter cycle, except for the first writing of modulo after a chip reset or in BDM mode. However, after a software reset, the MODH:MODL takes effect at once even if it did not take effect before the reset. On the first writing of MODH:MODL after chip reset, the counter is reset and the modulo takes effect immediately. The latching mechanism may be manually reset by setting the TRST bit of the SC register (whether BDM is active or not).

When BDM is active, the coherency mechanism is frozen so that the buffer latches remain in the state they were in when the BDM became active, even if one or both halves of the modulo register are written while BDM is active. Any writing to the modulo registers bypasses the buffer latches and writes directly to the modulo register while BDM is active, and also the counter is cleared at the same time.

Reading MODH:MODL returns the modulo values that are taking effect whenever in normal run mode or in BDM mode.

Address: FFFF_8410h base + 4h offset = FFFF_8414h

MTIMO_MODH field descriptions

Field	Description
7-0 MODH	MTIM16 modulo (high byte) These 8 read/write bits contain the modulo high byte value used to reset the counter and set TOF. Reset sets the register to 0x00.

34.4.6 MTIM16 modulo register low (MTIMx_MODL)

A value of 0x0000 in MODH:MODL puts the MTIM16 in free-running mode. Writing to either MODH or MODL latches the value into a buffer and the latched buffers are updated after the second byte writing. The updated values take effect and reload to the MODH:MODL registers in the next MTIM16 counter cycle, except for the first writing of modulo after a chip reset or in BDM mode. However, after a software reset, the MODH:MODL takes effect at once even if it did not take effect before the reset. On the first writing of MODH:MODL after chip reset, the counter is reset and the modulo takes effect immediately. The latching mechanism may be manually reset by setting the TRST bit of the SC register (whether BDM is active or not).

When BDM is active, the coherency mechanism is frozen so that the buffer latches remain in the state they were in when the BDM became active, even if one or both halves of the modulo register are written while BDM is active. Any writing to the modulo registers bypasses the buffer latches and writes directly to the modulo register while BDM is active, and also the counter is cleared at the same time.

Reading MODH:MODL returns the modulo values that are taking effect whenever in normal run mode or in BDM mode.

Address: FFFF_8410h base + 5h offset = FFFF_8415h

MTIM0_MODL field descriptions

Field	Description
7-0 MODL	MTIM16 modulo (low byte) These 8 read/write bits contain the modulo low byte value used to reset the counter and set TOF. Reset sets the register to 0x00.

34.5 Functional Description

The MTIM16 is composed of a main 16-bit up-counter with 16-bit modulo register, a clock source selector, and a prescaler block with nine selectable values. The module also contains software selectable interrupt logic.

The MTIM16 counter (CNTH:CNTH registers) has three modes of operation: stopped, free-running, and modulo. The counter is stopped out of reset. If the counter starts without writing a new value to the modulo registers, it will be in free-running mode. The counter is in modulo mode when a value other than 0x0000 is in the modulo registers.

After an MCU reset, the counter stops and resets to 0x0000, and the modulo also resets to 0x0000. The bus clock functions as the default clock source, and the prescale value is divided by 1. To start the MTIM16 in free-running mode, write to the MTIM16 status and control (SC) register and clear the MTIM16 stop (TSTP) bit.

Clock sources are software selectable:

- the internal bus clock
- the fixed frequency clock (XCLK)
- an external clock on the TCLK pin that is selectable as incrementing on either rising or falling edges

The MTIM16 clock select (CLKS) field in the CLK register selects the desired clock source. If the counter is active (the TSTP bit is 0) when a new clock source is selected, the counter continues counting from the previous value using the new clock source.

Nine prescale values are software selectable: clock source divided by 1, 2, 4, 8, 16, 32, 64, 128, or 256. The prescaler select bits (PS[3:0]) in the CLK register select the desired prescale value. If the counter is active (TSTP = 0) when a new prescaler value is selected, the counter continues counting from the previous value using the new prescaler value.

The MTIM16 modulo register (MODH:MODL) allows the overflow compare value to be set to any value from 0x0001 to 0xFFFF. Reset clears the modulo value to 0x0000, which results in a free-running counter.

When the counter is active (the TSTP bit is 0), it increases at the selected rate until the count matches the modulo value. When these values match, the counter overflows to 0x0000 and continues counting. The MTIM16 overflow flag (TOF) is set whenever the counter overflows. The flag sets on the transition from the modulo value to 0x0000.

Clearing TOF is a two-step process. The first step is to read the SC register while TOF is set. The second step is to write a 0 to TOF. If another overflow occurs between the first and second steps, the clearing process is reset and TOF stays set after the second step is performed. This will prevent the second occurrence from being missed. TOF is also cleared when a 1 is written to TRST.

The MTIM16 module allows for an optional interrupt to be generated whenever TOF is set. To enable the MTIM16 overflow interrupt, set the MTIM16 overflow interrupt enable (TOIE) bit in the SC register. The TOIE bit should never be written to be 1 while TOF is 1. Instead, TOF should be cleared first, and then the TOIE bit can be set to 1.

34.5.1 MTIM16 Operation Example

This section shows an example of the MTIM16 module's operation as the counter reaches a matching value from the modulo register.

Figure 34-14. MTIM16 Counter Overflow Example

In this figure, the selected clock source could be any of the four possible choices. The prescaler is set to divide-by-4 (the PS field is 0010). The modulo value in the MODH:MODL register is set to 01AAh. When the counter (CNTH:CNTH registers) reaches the modulo value of 01AAh, the counter overflows to 0000h and continues counting. The timer overflow flag, TOF, sets when the counter value changes from 01AAh to 0000h. An MTIM16 overflow interrupt is generated when TOF is set, if the TOIE bit is 1.

Chapter 35

Low Power Timer (LPTMR)

35.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

35.1.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
 - Optional interrupt can generate asynchronous wakeup from any low-power mode
 - Hardware trigger output
 - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
 - Rising-edge or falling-edge

35.1.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

Table 35-1. Modes of operation

Modes	Description
Run	The LPTMR operates normally.
Wait	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Stop	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Low-Leakage	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Debug	The LPTMR operates normally.

35.2 LPTMR signal descriptions

Table 35-2. LPTMR signal descriptions

Signal	I/O	Description
LPTMR_ALT <i>n</i>	I	Pulse Counter Input pin

35.2.1 Detailed signal descriptions

Table 35-3. LPTMR interface—detailed signal descriptions

Signal	I/O	Description
LPTMR_ALT <i>n</i>	I	Pulse Counter Input The LPTMR can select one of the input pins to be used in Pulse Counter mode.
		State meaning Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment. Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment.
		Timing Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.

35.3 Memory map and register definition

NOTE

All LPTMR registers are reset by the Chip POR not VLLS reset type and by POR Only, which triggers Chip POR not VLLS. Each register's displayed reset value represents this subset of reset types. LPTMR registers are unaffected by other reset types. For more information about the types of reset on this chip, refer to the Reset details.

LPTMRx_CMCR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 COMPARE	Compare Value When the LPTMR is enabled and the CNR equals the value in the CMR and increments, TCF is set and the hardware trigger asserts until the next time the CNR increments. If the CMR is 0, the hardware trigger will remain asserted until the LPTMR is disabled. If the LPTMR is enabled, the CMR must be altered only when TCF is set.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency f_{LPTMR} defined in the device datasheet.

35.4.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

35.4.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every 2^2 to 2^{16} prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

35.4.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

35.4.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output will also deassert.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising-edges	The glitch filter output will also assert.

NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every 2^2 to 2^{16} prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

35.4.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

35.4.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

35.4.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

35.4.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

When	Then
The CMR is set to 0 with CSR[TFC] clear	The LPTMR hardware trigger will assert on the first compare and does not deassert.
The CMR is set to a nonzero value, or, if CSR[TFC] is set	The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR.

35.4.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

Chapter 36

Carrier Modulator Transmitter (CMT)

36.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The carrier modulator transmitter (CMT) module provides the means to generate the protocol timing and carrier signals for a wide variety of encoding schemes. The CMT incorporates hardware to off-load the critical and/or lengthy timing requirements associated with signal generation from the CPU, releasing much of its bandwidth to handle other tasks such as:

- Code data generation
- Data decompression, or,
- Keyboard scanning

. The CMT does not include dedicated hardware configurations for specific protocols, but is intended to be sufficiently programmable in its function to handle the timing requirements of most protocols with minimal CPU intervention.

When the modulator is disabled, certain CMT registers can be used to change the state of the infrared output (IRO) signal directly. This feature allows for the generation of future protocol timing signals not readily producible by the current architecture.

36.2 Features

The features of this module include:

- Four modes of operation:
 - Time; with independent control of high and low times

Block diagram

- Baseband
- Frequency-shift key (FSK)
- Direct software control of the IRO signal
- Extended space operation in Time, Baseband, and FSK modes
- Selectable input clock divider
- Interrupt on end-of-cycle
 - Ability to disable the IRO signal and use as timer interrupt

36.3 Block diagram

The following figure presents the block diagram of the CMT module.

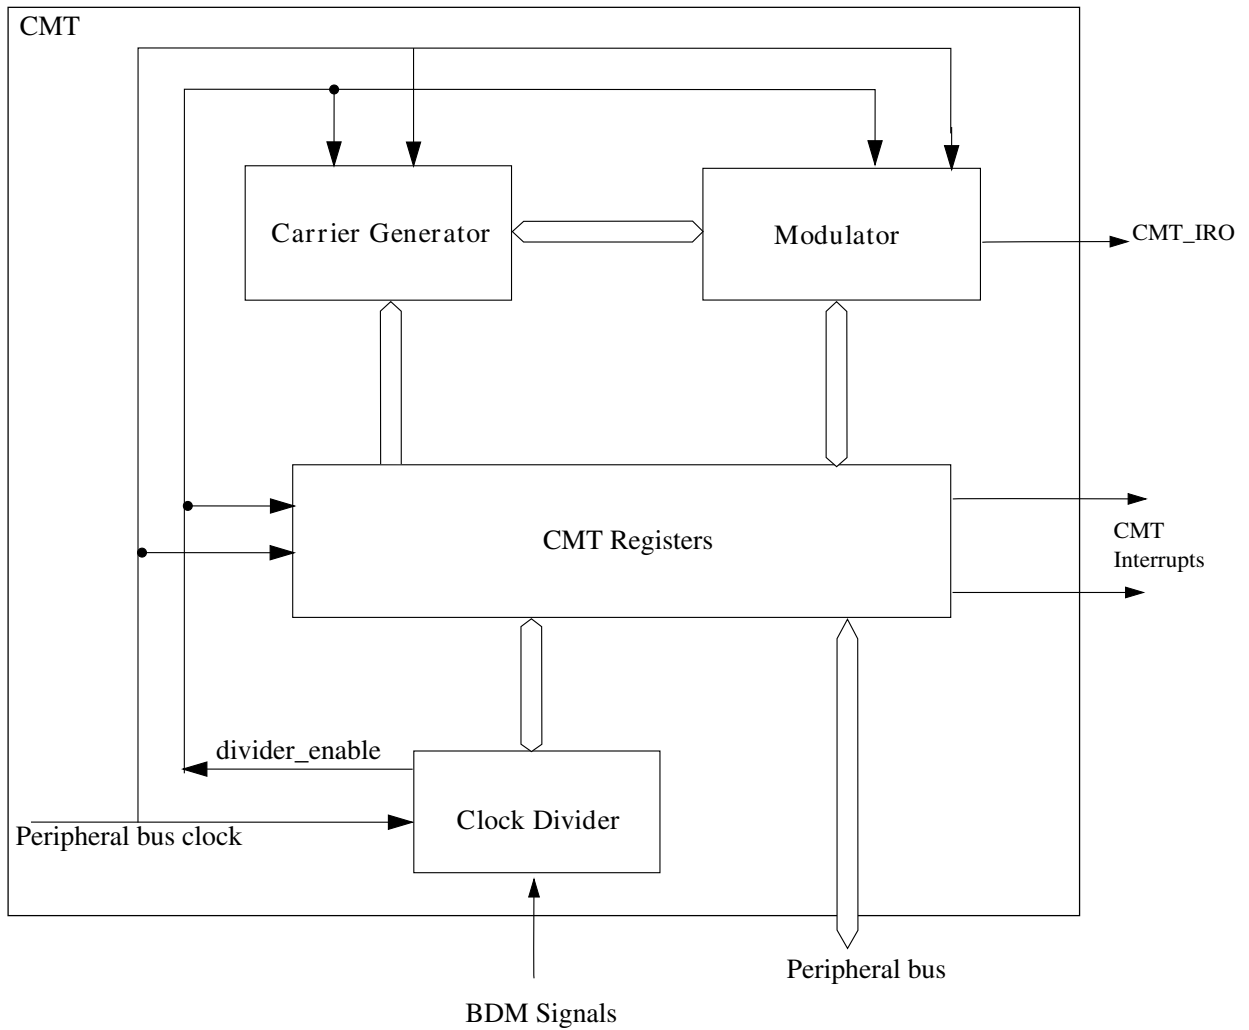

Figure 36-1. CMT module block diagram

36.4 Modes of operation

The following table describes the operation of the CMT module operates in various modes.

Table 36-1. Modes of operation

Modes	Description
Time	In Time mode, the user independently defines the high and low times of the carrier signal to determine both period and duty cycle
Baseband	When MSC[BASE] is set, the carrier output (f_{cg}) to the modulator is held high continuously to allow for the generation of baseband protocols.

Table continues on the next page...

Table 36-1. Modes of operation (continued)

Modes	Description
Frequency-shift key	This mode allows the carrier generator to alternate between two sets of high and low times. When operating in FSK mode, the generator will toggle between the two sets when instructed by the modulator, allowing the user to dynamically switch between two carrier frequencies without CPU intervention.

The following table summarizes the modes of operation of the CMT module.

Table 36-2. CMT modes of operation

Mode	MSC[MCGEN] ¹	MSC[BASE] ²	MSC[FSK] ²	MSC[EXSPC]	Comment
Time	1	0	0	0	f _{cg} controlled by primary high and low registers. f _{cg} transmitted to the IRO signal when modulator gate is open.
Baseband	1	1	X	0	f _{cg} is always high. The IRO signal is high when the modulator gate is open.
FSK	1	0	1	0	f _{cg} control alternates between primary high/low registers and secondary high/low registers. f _{cg} transmitted to the IRO signal when modulator gate is open.
Extended Space	1	X	X	1	Setting MSC[EXSPC] causes subsequent modulator cycles to be spaces (modulator out not asserted) for the duration of the modulator period (mark and space times).
IRO Latch	0	X	X	X	OC[IROL] controls the state of the IRO signal.

1. To prevent spurious operation, initialize all data and control registers before beginning a transmission when MSC[MCGEN]=1.
2. This field is not double-buffered and must not be changed during a transmission while MSC[MCGEN]=1.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

36.4.1 Wait mode operation

During Wait mode, the CMT if enabled, will continue to operate normally. However, there is no change in operating modes of CMT during Wait mode, because the CPU is not operating.

36.4.2 Stop mode operation

This section describes the CMT Stop mode operations.

36.4.2.1 Normal Stop mode operation

During Normal Stop mode, clocks to the CMT module are halted. No registers are affected.

The CMT module will resume upon exit from Normal Stop mode because the clocks are halted. Software must ensure that the Normal Stop mode is not entered while the modulator is still in operation so as to prevent the IRO signal from being asserted while in Normal Stop mode. This may require a timeout period from the time that MSC[MCGEN] is cleared to allow the last modulator cycle to complete.

36.4.2.2 Low-Power Stop mode operation

During Low-Power Stop mode, the CMT module is completely powered off internally and the IRO signal state is latched and held at the time when the CMT enters this mode. To prevent the IRO signal from being asserted during Low-Power Stop mode, the software must assure that the signal is not active when entering Low-Power Stop mode. Upon wakeup from Low-Power Stop mode, the CMT module will be in the reset state.

36.4.3 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the CMT temporarily suspends all counting until the microcontroller returns to normal user mode.

36.5 CMT external signal descriptions

The following table shows the description of the external signal.

Table 36-3. CMT signal description

Signal	Description	I/O
CMT_IRO	Infrared Output	O

36.5.1 CMT_IRO — Infrared Output

This output signal is driven by the modulator output when MSC[MCGEN] and OC[IROPEN] are set. The IRO signal starts a valid transmission with a delay, after MSC[MCGEN] bit be asserted to high, that can be calculated based on two register bits. [Table 36-5](#) shows how to calculate this delay.

The following table describes conditions for the IRO signal to be active.

If	Then
MSC[MCGEN] is cleared and OC[IROPEN] is set	The signal is driven by OC[IROL] . This enables user software to directly control the state of the IRO signal by writing to OC[IROL] .
OC[IROPEN] is cleared	The signal is disabled and is not driven by the CMT module. Therefore, CMT can be configured as a modulo timer for generating periodic interrupts without causing signal activity.

Table 36-5. CMT_IRO signal delay calculation

Condition	Delay (bus clock cycles)
MSC[CMTDIV] = 0	PPS[PPSDIV] + 2
MSC[CMTDIV] > 0	(PPS[PPSDIV] *2) + 3

36.6 Memory map/register definition

The following registers control and monitor the CMT operation.

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level. The address offset is defined at the module level.

CMT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8420	CMT Carrier Generator High Data Register 1 (CMT_CGH1)	8	R/W	Undefined	36.6.1/731

When operating in FSK mode, this register and the primary register pair are alternately selected under the control of the modulator. The secondary carrier low time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled when operating in FSK mode.

36.6.5 CMT Output Control Register (CMT_OC)

This register is used to control the IRO signal of the CMT module.

Address: FFFF_8420h base + 4h offset = FFFF_8424h

Bit	7	6	5	4	3	2	1	0
Read	IROL	CMPOL	IROPEN	0				
Write	IROL	CMPOL	IROPEN	0				
Reset	0	0	0	0	0	0	0	0

CMT_OC field descriptions

Field	Description
7 IROL	IRO Latch Control Reads the state of the IRO latch. Writing to IROL changes the state of the IRO signal when MSC[MCGEN] is cleared and IROPEN is set.
6 CMTPOL	CMT Output Polarity Controls the polarity of the IRO signal. 0 The IRO signal is active-low. 1 The IRO signal is active-high.
5 IROPEN	IRO Pin Enable Enables and disables the IRO signal. When the IRO signal is enabled, it is an output that drives out either the CMT transmitter output or the state of IROL depending on whether MSC[MCGEN] is set or not. Also, the state of output is either inverted or non-inverted, depending on the state of CMTPOL. When the IRO signal is disabled, it is in a high-impedance state and is unable to draw any current. This signal is disabled during reset. 0 The IRO signal is disabled. 1 The IRO signal is enabled as output.
4–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.6.6 CMT Modulator Status and Control Register (CMT_MSC)

This register contains the modulator and carrier generator enable (MCGEN), end of cycle interrupt enable (EOCIE), FSK mode select (FSK), baseband enable (BASE), extended space (EXSPC), prescaler (CMTDIV) bits, and the end of cycle (EOCF) status bit.

Address: FFFF_8420h base + 5h offset = FFFF_8425h

36.6.12 CMT Direct Memory Access Register (CMT_DMA)

This register is used to enable/disable direct memory access (DMA).

Address: FFFF_8420h base + Bh offset = FFFF_842Bh

Bit	7	6	5	4	3	2	1	0
Read	0							DMA
Write								
Reset	0	0	0	0	0	0	0	0

CMT_DMA field descriptions

Field	Description
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable Enables the DMA protocol. 0 DMA transfer request and done are disabled. 1 DMA transfer request and done are enabled.

36.7 Functional description

The CMT module primarily consists of clock divider, carrier generator, and modulator.

36.7.1 Clock divider

The CMT was originally designed to be based on an 8 MHz bus clock that could be divided by 1, 2, 4, or 8 according to the specification. To be compatible with higher bus frequency, the primary prescaler (PPS) was developed to receive a higher frequency and generate a clock enable signal called intermediate frequency (IF). This IF must be approximately equal to 8 MHz and will work as a clock enable to the secondary prescaler. The following figure shows the clock divider block diagram.

Figure 36-14. Clock divider block diagram

For compatibility with previous versions of CMT, when bus clock = 8 MHz, the PPS must be configured to zero. The PPS counter is selected according to the bus clock to generate an intermediate frequency approximately equal to 8 MHz.

36.7.2 Carrier generator

The carrier generator resolution is 125 ns when operating with an 8 MHz intermediate frequency signal and the secondary prescaler is set to divide by 1, or, when $MSC[CMTDIV] = 00$. The carrier generator can generate signals with periods between 250 ns (4 MHz) and 127.5 μ s (7.84 kHz) in steps of 125 ns. The following table shows the relationship between the clock divide bits and the carrier generator resolution, minimum carrier generator period, and minimum modulator period.

Table 36-19. Clock divider

Bus clock (MHz)	MSC[CMTDIV]	Carrier generator resolution (μ s)	Min. carrier generator period (μ s)	Min. modulator period (μ s)
8	00	0.125	0.25	1.0
8	01	0.25	0.5	2.0
8	10	0.5	1.0	4.0
8	11	1.0	2.0	8.0

The possible duty cycle options depend upon the number of counts required to complete the carrier period. For example, 1.6 MHz signal has a period of 625 ns and will therefore require 5 x 125 ns counts to generate. These counts may be split between high and low times, so the duty cycles available will be:

- 20% with one high and four low times
- 40% with two high and three low times
- 60% with three high and two low times, and
- 80% with four high and one low time

For low-frequency signals with large periods, high-resolution duty cycles as a percentage of the total period, are possible.

The carrier signal is generated by counting a register-selected number of input clocks (125 ns for an 8 MHz bus) for both the carrier high time and the carrier low time. The period is determined by the total number of clocks counted. The duty cycle is determined by the ratio of high-time clocks to total clocks counted. The high and low time values are user-programmable and are held in two registers.

An alternate set of high/low count values is held in another set of registers to allow the generation of dual-frequency FSK protocols without CPU intervention.

Note

Only nonzero data values are allowed. The carrier generator will not work if any of the count values are equal to zero.

MSC[MCGEN] must be set and MSC[BASE] must be cleared to enable carrier generator clocks. When MSC[BASE] is set, the carrier output to the modulator is held high continuously. The following figure represents the block diagram of the clock generator.

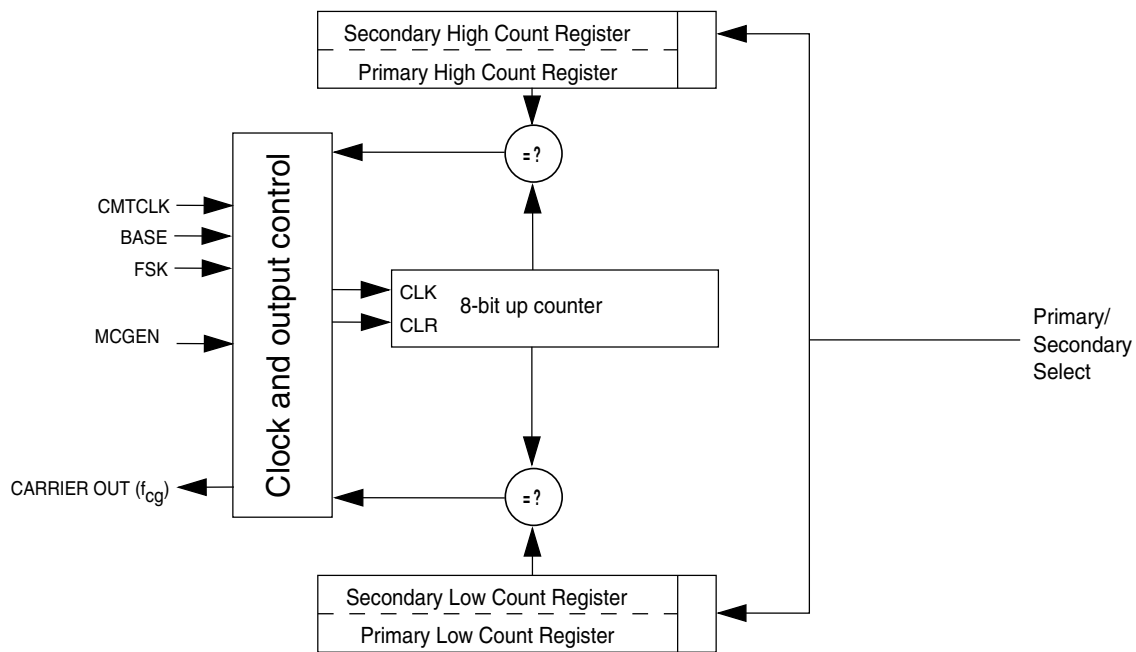

Figure 36-15. Carrier generator block diagram

The high/low time counter is an 8-bit up counter. After each increment, the contents of the counter are compared with the appropriate high or low count value register. When the compare value is reached, the counter is reset to a value of 0x01, and the compare is redirected to the other count value register.

Assuming that the high time count compare register is currently active, a valid compare will cause the carrier output to be driven low. The counter will continue to increment starting at the reset value of 0x01. When the value stored in the selected low count value register is reached, the counter will again be reset and the carrier output will be driven high.

The cycle repeats, automatically generating a periodic signal which is directed to the modulator. The lower frequency with maximum period, f_{\max} , and highest frequency with minimum period, f_{\min} , which can be generated, are defined as:

$$f_{\max} = f_{\text{CMTCLK}} \div (2 * 1) \text{ Hz}$$

$$f_{\min} = f_{\text{CMTCLK}} \div (2 * (2^8 - 1)) \text{ Hz}$$

In the general case, the carrier generator output frequency is:

$$f_{\text{cg}} = f_{\text{CMTCLK}} \div (\text{High count} + \text{Low count}) \text{ Hz}$$

Where: $0 < \text{High count} < 256$ and

$$0 < \text{Low count} < 256$$

The duty cycle of the carrier signal is controlled by varying the ratio of high time to low + high time. As the input clock period is fixed, the duty cycle resolution will be proportional to the number of counts required to generate the desired carrier period.

$$\text{DutyCycle} = \frac{\text{Highcount}}{\text{Highcount} + \text{Lowcount}}$$

36.7.3 Modulator

The modulator block controls the state of the infrared out signal (IRO). The modulator output is gated on to the IRO signal when the modulator/carrier generator is enabled. . When the modulator/carrier generator is disabled, the IRO signal is controlled by the state of the IRO latch. OC[CMTPOL] enables the IRO signal to be active-high or active-low.

The following table describes the functions of the modulators in different modes:

Table 36-20. Mode functions

Mode	Function
Time	The modulator can gate the carrier onto the modulator output.
Baseband	The modulator can control the logic level of the modulator output.
FSK	The modulator can count carrier periods and instruct the carrier generator to alternate between two carrier frequencies whenever a modulation period consisting of mark and space counts, expires.

The modulator provides a simple method to control protocol timing. The modulator has a minimum resolution of 1.0 μs with an 8 MHz. It can count bus clocks to provide real-time control, or carrier clocks for self-clocked protocols.

The modulator includes a 17-bit down counter with underflow detection. The counter is loaded from the 16-bit modulation mark period buffer registers, CMD1 and CMD2. The most significant bit is loaded with a logic 0 and serves as a sign bit.

When	Then
The counter holds a positive value	The modulator gate is open and the carrier signal is driven to the transmitter block.
The counter underflows	The modulator gate is closed and a 16-bit comparator is enabled which compares the logical complement of the value of the down counter with the contents of the modulation space period register which has been loaded from the registers, CMD3 and CMD4.

Functional description

When a match is obtained, the cycle repeats by opening the modulator gate, reloading the counter with the contents of CMD1 and CMD2, and reloading the modulation space period register with the contents of CMD3 and CMD4.

The modulation space period is activated when the carrier signal is low to prohibit cutting off the high pulse of a carrier signal. If the carrier signal is high, the modulator extends the mark period until the carrier signal becomes low. To deassert the space period and assert the mark period, the carrier signal must have gone low to ensure that a space period is not erroneously shortened.

If the contents of the modulation space period register are all zeroes, the match will be immediate and no space period will be generated, for instance, for FSK protocols that require successive bursts of different frequencies).

MSC[MCGEN] must be set to enable the modulator timer.

The following figure presents the block diagram of the modulator.

Figure 36-16. Modulator block diagram

36.7.3.1 Time mode

When the modulator operates in Time mode, or, when MSC[MCGEN] is set, and MSC[BASE] and MSC[FSK] are cleared:

- The modulation mark period consists of an integer number of $(\text{CMTCLK} \div 8)$ clock periods.
- The modulation space period consists of 0 or an integer number of $(\text{CMTCLK} \div 8)$ clock periods.

With an 8 MHz IF and $\text{MSC}[\text{CMTDIV}] = 00$, the modulator resolution is 1 μs and has a maximum mark and space period of about 65.535 μs each. See Figure 36-17 for an example of the Time and Baseband mode outputs.

The mark and space time equations for Time and Baseband mode are:

$$t_{\text{mark}} = (\text{CMD1}:\text{CMD2} + 1) \div (f_{\text{CMTCLK}} \div 8)$$

$$t_{\text{space}} = \text{CMD3}:\text{CMD4} \div (f_{\text{CMTCLK}} \div 8)$$

where $\text{CMD1}:\text{CMD2}$ and $\text{CMD3}:\text{CMD4}$ are the decimal values of the concatenated registers.

Figure 36-17. Example: CMT output in Time and Baseband modes with $\text{OC}[\text{CMTPOL}] = 0$

36.7.3.2 Baseband mode

Baseband mode, that is, when $\text{MSC}[\text{MCGEN}]$ and $\text{MSC}[\text{BASE}]$ are set, is a derivative of Time mode, where the mark and space period is based on $(\text{CMTCLK} \div 8)$ counts. The mark and space calculations are the same as in Time mode.

In this mode, the modulator output will be at a logic 1 for the duration of the mark period and at a logic 0 for the duration of a space period. See [Figure 36-17](#) for an example of the output for both Baseband and Time modes. In the example, the carrier out frequency (f_{cg}) is generated with a high count of 0x01 and a low count of 0x02 that results in a divide of 3 of CMTCLK with a 33% duty cycle. The modulator down counter was loaded with the value 0x0003 and the space period register with 0x0002.

Note

The waveforms in [Figure 36-17](#) and [Figure 36-18](#) are for the purpose of conceptual illustration and are not meant to represent precise timing relationships between the signals shown.

36.7.3.3 FSK mode

When the modulator operates in FSK mode, that is, when MSC[MCGEN] and MSC[FSK] are set, and MSC[BASE] is cleared:

- The modulation mark and space periods consist of an integer number of carrier clocks (space period can be zero).
- When the mark period expires, the space period is transparently started as in Time mode.
- The carrier generator toggles between primary and secondary data register values whenever the modulator space period expires.

The space period provides an interpulse gap (no carrier). If CMD3:CMD4 = 0x0000, then the modulator and carrier generator will switch between carrier frequencies without a gap or any carrier glitches (zero space).

Using timing data for carrier burst and interpulse gap length calculated by the CPU, FSK mode can automatically generate a phase-coherent, dual-frequency FSK signal with programmable burst and interburst gaps.

The mark and space time equations for FSK mode are:

$$t_{\text{mark}} = (\text{CMD1:CMD2} + 1) \div f_{cg}$$

$$t_{\text{space}} = (\text{CMD3:CMD4}) \div f_{cg}$$

Where f_{cg} is the frequency output from the carrier generator. The example in [Figure 36-18](#) shows what the IRO signal looks like in FSK mode with the following values:

- CMD1:CMD2 = 0x0003
- CMD3:CMD4 = 0x0002
- Primary carrier high count = 0x01
- Primary carrier low count = 0x02

- Secondary carrier high count = 0x03
- Secondary carrier low count = 0x01

Figure 36-18. Example: CMT output in FSK mode

36.7.4 Extended space operation

In either Time, Baseband, or FSK mode, the space period can be made longer than the maximum possible value of the space period register. Setting MSC[EXSPC] will force the modulator to treat the next modulation period beginning with the next load of the counter and space period register, as a space period equal in length to the mark and space counts combined. Subsequent modulation periods will consist entirely of these extended space periods with no mark periods. Clearing MSC[EXSPC] will return the modulator to standard operation at the beginning of the next modulation period.

36.7.4.1 EXSPC operation in Time mode

To calculate the length of an extended space in Time or Baseband mode, add the mark and space times and multiply by the number of modulation periods when MSC[EXSPC] is set.

$$t_{\text{exspace}} = (t_{\text{mark}} + t_{\text{space}}) * (\text{number of modulation periods})$$

For an example of extended space operation, see [Figure 36-19](#).

Note

The extended space enable feature can be used to emulate a zero mark event.

Figure 36-19. Extended space operation

36.7.4.2 EXSPC operation in FSK mode

In FSK mode, the modulator continues to count carrier out clocks, alternating between the primary and secondary registers at the end of each modulation period.

To calculate the length of an extended space in FSK mode, it is required to know whether MSC[EXSPC] was set on a primary or secondary modulation period, and the total number of both primary and secondary modulation periods completed while MSC[EXSPC] is high. A status bit for the current modulation is not accessible to the CPU. If necessary, software must maintain tracking of the current primary or secondary modulation cycle. The extended space period ends at the completion of the space period time of the modulation period during which MSC[EXSPC] is cleared.

The following table depicts the equations which can be used to calculate the extended space period depending on when MSC[EXSPC] is set.

If	Then
MSC[EXSPC] was set during a primary modulation cycle	Use the equation: $t_{\text{exspace}} = (t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + \dots$
MSC[EXSPC] bit was set during a secondary modulation cycle	Use the equation: $t_{\text{exspace}} = (t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + \dots$

Where the subscripts p and s refer to mark and space times for the primary and secondary modulation cycles.

36.8 CMT interrupts and DMA

The CMT generates an interrupt request or a DMA transfer request according to MSC[EOCIE], MSC[EOCF], DMA[DMA] bits.

Table 36-23. DMA transfer request x CMT interrupt request

MSC[EOCF]	DMA[DMA]	MSC[EOCIE]	DMA transfer request	CMT interrupt request
0	X	X	0	0
1	X	0	0	0
1	0	1	0	1
1	1	1	1	0

MSC[EOCF] is set:

- When the modulator is not currently active and MSC[MCGEN] is set to begin the initial CMT transmission.
- At the end of each modulation cycle when the counter is reloaded from CMD1:CMD2, while MSC[MCGEN] is set.

When MSC[MCGEN] is cleared and then set before the end of the modulation cycle, MSC[EOCF] will not be set when MSC[MCGEN] is set, but will become set at the end of the current modulation cycle.

When MSC[MCGEN] becomes disabled, the CMT module does not set MSC[EOCF] at the end of the last modulation cycle.

If MSC[EOCIE] is high when MSC[EOCF] is set, the CMT module will generate an interrupt request or a DMA transfer request.

MSC[EOCF] must be cleared to prevent from being generated by another event like interrupt or DMA request, after exiting the service routine. See the following table.

Table 36-24. How to clear MSC[EOCF]

DMA[DMA]	MSC[EOCIE]	Description
0	X	MSC[EOCF] is cleared by reading MSC followed by an access of CMD2 or CMD4.
1	X	MSC[EOCF] is cleared by the CMT DMA transfer done.

The EOC interrupt is coincident with:

- Loading the down-counter with the contents of CMD1:CMD2
- Loading the space period register with the contents of CMD3:CMD4

The EOC interrupt provides a means for the user to reload new mark/space values into the modulator data registers. Modulator data register updates will take effect at the end of the current modulation cycle.

NOTE

The down-counter and space period register are updated at the end of every modulation cycle, irrespective of interrupt handling and the state of MSC[EOCF].

Chapter 37

FlexTimer (FTM)

37.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The FlexTimer module is a two to eight channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

37.1.1 FlexTimer philosophy

The FlexTimer is built upon a very simple timer used for many years on Freescale's 8-bit microcontrollers, the HCS08 Timer PWM Module – TPM. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made: signed up-counter, dead time insertion hardware, fault control inputs, enhanced triggering functionality and initialization, and polarity control.

All of the features common with the TPM module have fully backwards compatible register assignments and the FlexTimer can use code on the same core platform without change to perform the same functions. A small exception to this is when the FlexTimer clock frequency is twice bus clock frequency to provide extra resolution for high speed PWM applications.

Motor control and power conversion features have been added through a dedicated set of registers. The new features, such as hardware dead time insertion, polarity, fault control, and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers. All of the new features are disabled after reset by default.

FlexTimer input triggers can come directly from other modules integrated on the chip, such as comparators or ADCs, to automatically initiate timer functions. These triggers can be linked in a variety of ways during integration of the modules so please note carefully the options available for used FlexTimer configuration.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

37.1.2 Features

The FTM features include:

- Selectable FTM source clock:
 - Source clock can be the system clock, the fixed frequency clock, or an external clock
 - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
 - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- FTM has a 16-bit counter
 - It can be a free-running counter or a counter with initial and final value
 - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In input capture mode:
 - The capture can occur on rising edges, falling edges or both edges
 - An input filter can be selected for some channels

- In output compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of triggers (match trigger)
- Software control of PWM outputs
- Up to four fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- For instances of the module that support it: Quadrature decoder with input filters, relative position counting and interrupt on position count or capture of position count on external event

37.1.3 Modes of operation

When the MCU is in active BDM background or BDM foreground mode, the FTM temporarily suspends all counting until the MCU returns to normal user operating mode. During stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During wait mode, the FTM continues to operate normally. If the

FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the MCU from wait mode, the power can then be saved by disabling FTM functions before entering wait mode.

37.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CH_n (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

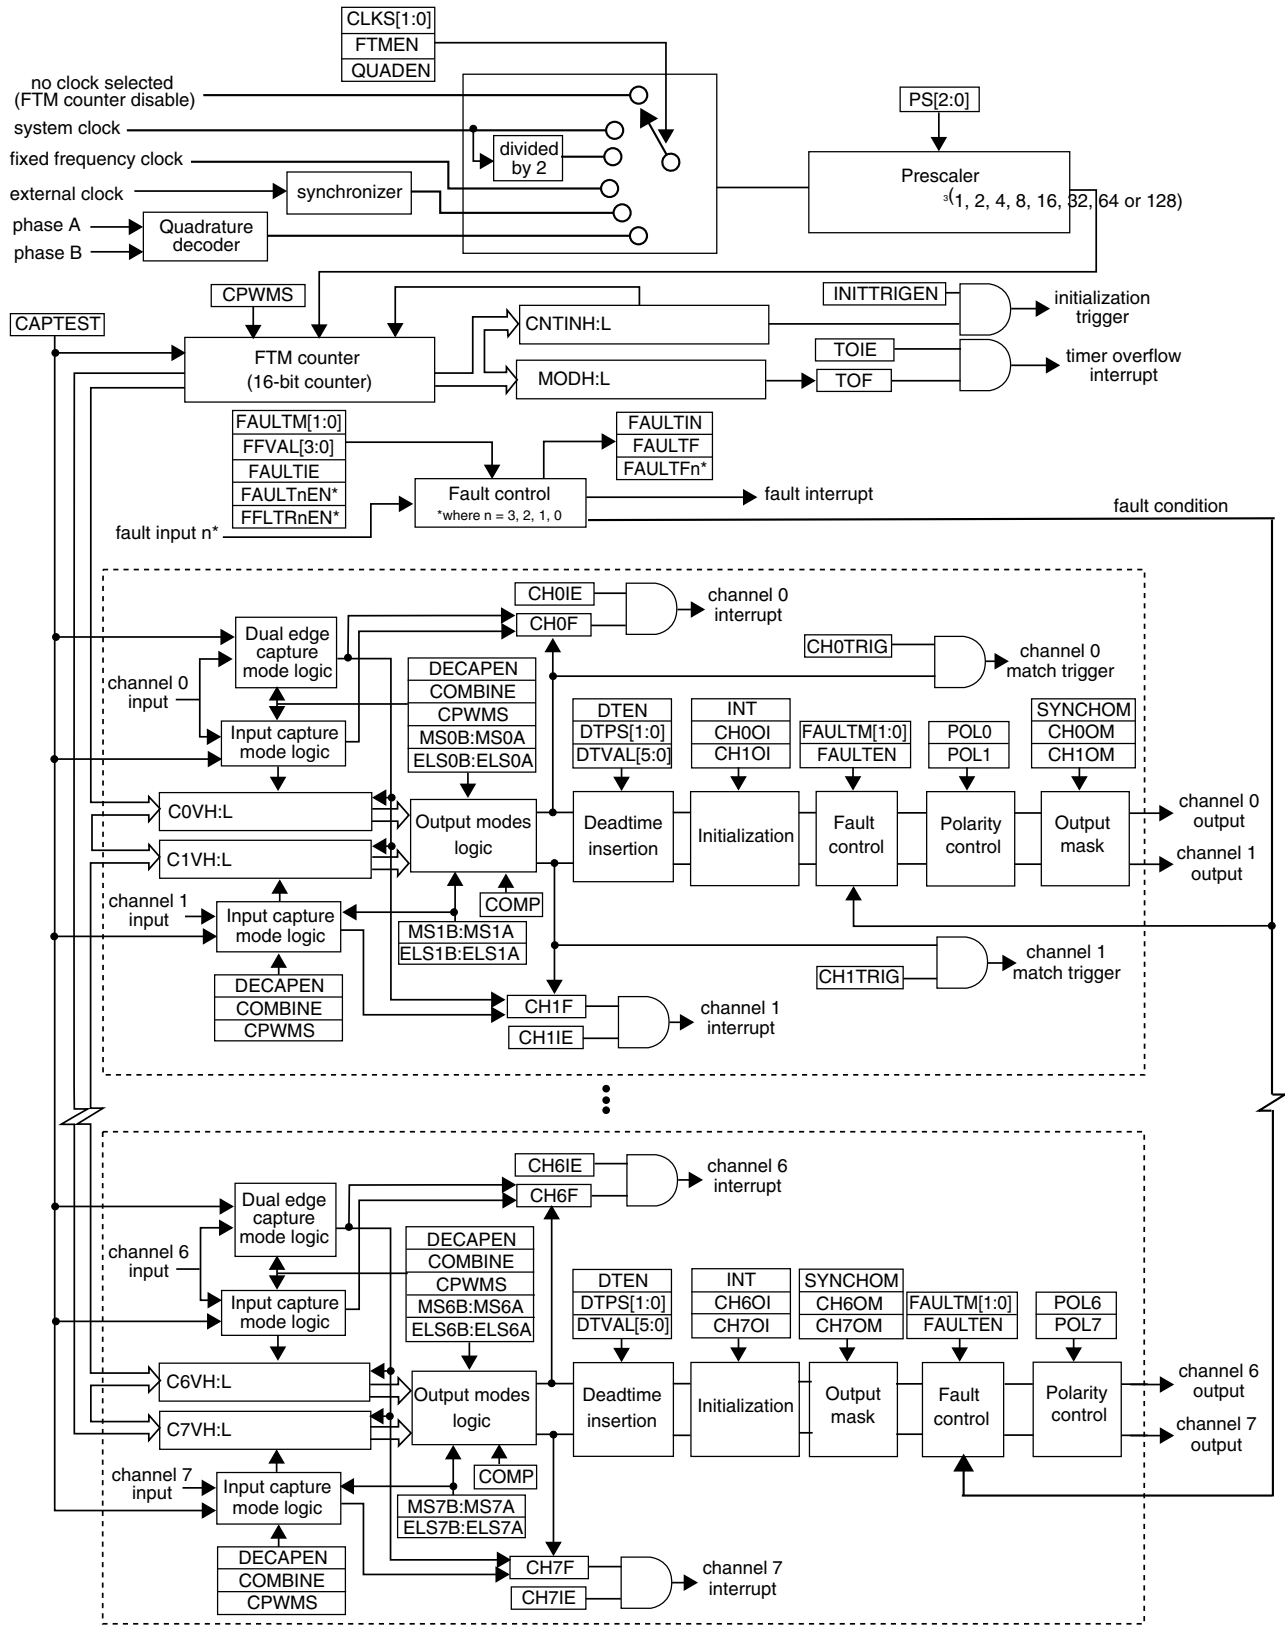

Figure 37-1. FTM block diagram

37.2 Signal description

The following table shows the user-accessible signals for the FTM.

NOTE

The PHA and PHB signals are user accessible if the quadrature decoder feature is supported.

Table 37-1. Signal properties

Name	Function
EXTCLK	External clock – FTM external clock can be selected to drive the FTM counter.
CHn ¹	Channel (n) – I/O pin associated with FTM channel (n).
FAULTj ²	Fault input (j) – input pin associated with fault input (j).
PHA	Quadrature decoder phase A input – input pin associated with quadrature decoder phase A.
PHB	Quadrature decoder phase B input – input pin associated with quadrature decoder phase B.

1. n = channel number (0 to 7)
2. j = fault input (0 to 3)

37.2.1 EXTCLK — FTM external clock

The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.

37.2.2 CHn — FTM channel (n) I/O pin

Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.

37.2.3 FAULTj — FTM fault input

The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input

may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Each FAULTj input is activated by its corresponding FAULTjEN bit in the FLTCTRL register.

37.2.4 PHA — FTM Quadrature Decoder Phase A Input

The quadrature decoder phase A input is used when the quadrature decoder mode is selected (if the quadrature decoder feature is supported). The phase A input signal is one of the signals that control the FTM counter increment or decrement in the quadrature decoder mode ([Quadrature Decoder Mode](#)).

37.2.5 PHB — FTM Quadrature Decoder Phase B Input

The quadrature decoder phase B input is used when the quadrature decoder mode is selected (if the quadrature decoder feature is supported). The phase B input signal is one of the signals that control the FTM counter increment or decrement in the quadrature decoder mode ([Quadrature Decoder Mode](#)).

37.3 Memory map and register definition

This section provides a detailed description of all FTM registers.

37.3.1 Module memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The FTM memory map can be split into two sets of registers. The first set has the original TPM registers.

Starting with Counter Initial Value High (CNTINH), the second set has the FTM specific registers. Any second set registers, or bits within these registers, that are used by an unavailable function in the FTM configuration remain in the memory map and in the reset value even though they have no active function.

Note

Do not write to the FTM specific registers (second set registers) when FTMEN = 0.

37.3.2 Register descriptions

This section consists of register descriptions in address order.

It can be written only when MODE[WPDIS] = 1.</p> <p>00 No clock selected (this in effect disables the FTM counter). 01 If MODE[FTMEN] = 0, the System clock divided by 2 is selected. If MODE[FTMEN] = 1, the System clock is selected. 10 Fixed frequency clock 11 External clock</p>
2–0 PS	<p>Prescale Factor Selection</p> <p>Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. PS is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128</p>

37.3.4 Counter High (FTMx_CNTH)

The Counter registers contain the high and low bytes of the counter value. Reading either byte latches the contents of both bytes into a buffer where they remain latched until the other half is read. This allows coherent 16-bit reads in either big-endian or little-endian order which makes this more friendly to various compiler implementations. The coherency mechanism is automatically restarted by an MCU reset or any write to the Status and Control register.

Writing any value to COUNT_H or COUNT_L updates the FTM counter with its initial 16-bit value (contained in the Counter Initial Value registers) and resets the read coherency mechanism, regardless of the data involved in the write.

When BDM is active, the FTM counter is frozen (this is the value that you may read); the read coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both counter bytes are read while BDM is active. This assures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution.

Address: Base address + 1h offset

FTMx_CNTH field descriptions

Field	Description
7-0 COUNT_H	Counter value high byte

37.3.5 Counter Low (FTMx_CNTL)

See the description for the Counter High register.

Address: Base address + 2h offset

FTMx_CNTL field descriptions

Field	Description
7-0 COUNT_L	Counter value low byte

37.3.6 Modulo High (FTMx_MODH)

The Modulo registers contain the high and low bytes of the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method ([Counter](#)).

Writing to either byte latches the value into a buffer. The register is updated with the value of their write buffer according to [Update of the registers with write buffers](#).

If MODE[FTMEN] = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

When BDM is active, this write coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both bytes of the modulo register are written while BDM is active. Any write to the modulo register bypasses the buffer latches and directly writes to the modulo register while BDM is active.

It is recommended to initialize the FTM counter, by writing to CNTH or CNTL, before writing to the FTM modulo register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 3h offset

FTMx_MODH field descriptions

Field	Description
7-0 MOD_H	High byte of the modulo value

37.3.7 Modulo Low (FTMx_MODL)

FTMx_CnSC field descriptions (continued)

Field	Description
	The functionality of ELSB and ELSA depends on the channel mode. See the table in the register description. ELSA is write protected. It can be written only when MODE[WPDIS] = 1.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable Enables DMA transfers for the channel. 0 Disable DMA transfers. 1 Enable DMA transfers.

37.3.9 Channel Value High (FTMx_CnVH)

These registers contain the captured FTM counter value of the input capture function or the match value for the output modes.

In input capture, capture test, and dual edge capture modes, reading a single byte in CnV latches the contents into a buffer where they remain latched until the other byte is read. This latching mechanism also resets, or becomes unlatched, when the CnSC register is written whether BDM mode is active or not. Any write to the channel registers is ignored during these input modes.

When BDM is active, the read coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both bytes of the channel value register are read while BDM is active. This ensures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution. Any read of the CnV registers in BDM mode bypasses the buffer latches and returns the value of these registers and not the value of their read buffer.

In output modes, writing to CnV latches the value into a buffer. The registers are updated with the value of their write buffer according to [Update of the registers with write buffers](#).

If MODE[FTMEN] = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not. This latching mechanism allows coherent 16-bit writes in either big-endian or little-endian order, which is friendly to various compiler implementations.

When BDM is active, the write coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active even if one or both bytes of the channel value register are written while BDM is active. Any write to the CnV registers bypasses the buffer latches and writes directly to the register while BDM is active. The values written to the channel value registers while BDM is active are used in output modes operation after normal execution resumes. Writes to the channel value registers while BDM is active do not interfere with the partial completion of a coherency sequence. After the write coherency mechanism has been fully exercised, the channel value registers are updated using the buffered values while BDM was not active.

Address: Base address + 6h offset + (3d × i), where i=0d to 5d

FTMx_CnVH field descriptions

Field	Description
7–0 VAL_H	Channel Value High Byte Captured FTM counter value of the input capture function or the match value for the output modes

37.3.10 Channel Value Low (FTMx_CnVL)

See the description for the Channel Value High register.

Address: Base address + 7h offset + (3d × i), where i=0d to 5d

FTMx_CnVL field descriptions

Field	Description
7–0 VAL_L	Channel Value Low Byte Captured FTM counter value of the input capture function or the match value for the output modes

37.3.11 Counter Initial Value High (FTMx_CNTINH)

The Counter Initial Value registers contain the high and low bytes of the initial value for the FTM counter.

Writing to either byte latches the value into a buffer. The registers are updated with the value of their write buffer.

When BDM is active, the write coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both bytes of the counter initial value register are written while BDM is active. Any write to the counter initial value registers bypasses the buffer latches and writes directly to the counter initial value register while BDM is active.

The first time that the FTM clock is selected (first write to change the CLKS bits to a non-zero value), FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the Counter Initial Value registers and then initialize the FTM counter by writing any value to CNT).

37.3.12 Counter Initial Value Low (FTMx_CNTINL)

See the description for the Counter Initial Value High register.

Address: Base address + 21h offset

FTMx_CNTINL field descriptions

Field	Description
7-0 INIT_L	Counter Initial Value Low Byte

37.3.13 Capture and Compare Status (FTMx_STATUS)

STATUS contains a copy of the status flag CHnF bit, in CnSC, for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case, a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

NOTE

The use of STATUS register is available only when (MODE[FTMEN] = 1), (COMBINE = 1), and (CPWMS = 0). The use of this register with (MODE[FTMEN] = 0), (COMBINE = 0), or (CPWMS = 1) is not recommended and its results are not guaranteed.

37.3.14 Features Mode Selection (FTMx_MODE)

This register contains the control bits used to configure the fault interrupt and fault control, capture test mode, PWM synchronization, write protection, channel output initialization, and enable the enhanced features of the FTM. These controls relate to all channels within this module.

Address: Base address + 23h offset

Bit	7	6	5	4	3	2	1	0
Read	FAULTIE	FAULTM		CAPTEST	PWMSYNC	WPDIS	INIT	FTMEN
Write								
Reset	0	0	0	0	0	1	0	0

FTMx_MODE field descriptions

Field	Description
7 FAULTIE	<p>Fault Interrupt Enable</p> <p>Enables the generation of an interrupt when a fault is detected by FTM and the FTM fault control is enabled.</p> <p>0 Fault control interrupt is disabled. 1 Fault control interrupt is enabled.</p>
6–5 FAULTM	<p>Fault Control Mode</p> <p>Defines the FTM fault control mode.</p> <p>FAULTM is write protected. These bits can be written only if MODE[WPDIS] = 1.</p> <p>00 Fault control is disabled for all channels. 01 Fault control is enabled for even channels only (channels 0, 2, 4, and 6), and the selected mode is the manual fault clearing. 10 Fault control is enabled for all channels, and the selected mode is the manual fault clearing. 11 Fault control is enabled for all channels, and the selected mode is the automatic fault clearing.</p>
4 CAPTEST	<p>Capture Test Mode Enable</p> <p>Enables the capture test mode. CAPTEST bit is write protected. This bit can be written only if WPDIS = 1.</p> <p>0 Capture test mode is disabled. 1 Capture test mode is enabled.</p>
3 PWMSYNC	<p>PWM Synchronization Mode</p> <p>Selects which triggers can be used by MOD, CV, CHnOM, and FTM counter synchronization (PWM synchronization).</p> <p>0 No restrictions. Software and hardware triggers can be used by MOD, CV, CHnOM, and FTM counter synchronization. 1 Software trigger can be used only by MOD and CV synchronization, and hardware triggers can be used only by CHnOM and FTM counter synchronization.</p>
2 WPDIS	<p>Write Protection Disable</p> <p>When write protection is enabled (MODE[WPDIS] = 0), write protected bits can not be written. When write protection is disabled (MODE[WPDIS] = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect.</p> <p>0 Write protection is enabled. 1 Write protection is disabled.</p>
1 INIT	<p>Initialize the Output Channels</p> <p>When a 1 is written to INIT bit the output channels are initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect.</p> <p>The INIT bit is always read as 0.</p>
0 FTMEN	<p>FTM Enable</p> <p>This bit is write protected, and can be written only if WPDIS = 1.</p>

Table continues on the next page...

FTMx_MODE field descriptions (continued)

Field	Description
0	Only the TPM-compatible registers (first set of registers) can be used without any restriction. Do not use the FTM-specific registers.
1	All registers including the FTM-specific registers (second set of registers) are available for use with no restrictions.

37.3.15 Synchronization (FTMx_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

NOTE

The software trigger (SWSYNC bit) and hardware triggers (TRIG0, TRIG1, and TRIG2 bits) have a potential conflict if used together. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the boundary cycle (CNTMAX and CNTMIN bits) is intended to provide the update of MOD, CNTIN, and CV across all enabled channels simultaneously. The use of the boundary cycle selection together with TRIG0, TRIG1, or TRIG2 bits is likely to result in unpredictable behavior.

The MODE[PWMSYNC] bit determines which type of trigger event controls the functions enabled by the SYNC register.

Address: Base address + 24h offset

Bit	7	6	5	4	3	2	1	0
Read	SWSYNC	TRIG2	TRIG1	TRIG0	SYNCHOM	REINIT	CNTMAX	CNTMIN
Write								
Reset	0	0	0	0	0	0	0	0

FTMx_SYNC field descriptions

Field	Description
7 SWSYNC	PWM Synchronization Software Trigger Selects the software trigger as the PWM synchronization trigger. The software trigger occurs when a 1 is written to SWSYNC bit.

Table continues on the next page...

FTMx_SYNC field descriptions (continued)

Field	Description
	0 Software trigger is not selected. 1 Software trigger is selected.
6 TRIG2	PWM Synchronization External Trigger 2 Selects external trigger 2 as the PWM synchronization trigger. External trigger 2 occurs when the FTM detects a rising edge in the trigger 2 input signal. 0 External trigger 2 is not selected. 1 External trigger 2 is selected.
5 TRIG1	PWM Synchronization External Trigger 1 Selects external trigger 1 as the PWM synchronization trigger. External trigger 1 occurs when the FTM detects a rising edge in the trigger 1 input signal. 0 External trigger 1 is not selected. 1 External trigger 1 is selected.
4 TRIG0	PWM Synchronization External Trigger 0 Selects external trigger 0 as the PWM synchronization trigger. External trigger 0 occurs when the FTM detects a rising edge in the trigger 0 input signal. 0 External trigger 0 is not selected. 1 External trigger 0 is selected.
3 SYNCHOM	Output Mask Synchronization Selects when the CHnOM bits in register OUTMASK are updated with the value of their write buffer. 0 CHnOM bits are updated with the value of the OUTMASK write buffer in all rising edges of the system clock. 1 CHnOM bits are updated with the value of the OUTMASK write buffer only by the PWM synchronization.
2 REINIT	FTM Counter Reinitialization by Synchronization (See “FTM Counter Synchronization”) Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected. 0 FTM counter continues to count normally. 1 FTM counter is updated with its initial value when the selected trigger is detected.
1 CNTMAX	Maximum Boundary Cycle Enable Determines when the MOD, CNTIN, and CV registers are updated with their write buffer contents following a PWM synchronization event. If CNTMAX is enabled, the registers are updated when the FTM counter reaches its maximum value MOD. 0 The maximum boundary cycle is disabled. 1 The maximum boundary cycle is enabled.
0 CNTMIN	Minimum Boundary Cycle Enable Determines when the MOD and CV registers are updated with their write buffer contents after a PWM synchronization event. If CNTMIN is enabled, the registers are updated when the FTM counter reaches its minimum value CNTIN.

Table continues on the next page...

FTMx_SYNC field descriptions (continued)

Field	Description
0	The minimum boundary cycle is disabled.
1	The minimum boundary cycle is enabled.

37.3.16 Initial State for Channel Output (FTMx_OUTINIT)

Address: Base address + 25h offset

Bit	7	6	5	4	3	2	1	0

FTMx_OUTINIT field descriptions

Field	Description
7 CH7OI	Channel 7 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
6 CH6OI	Channel 6 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
5 CH5OI	Channel 5 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
4 CH4OI	Channel 4 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
3 CH3OI	Channel 3 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
2 CH2OI	Channel 2 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs.

Table continues on the next page...

FTMx_OUTINIT field descriptions (continued)

Field	Description
	0 The initialization value is 0. 1 The initialization value is 1.
1 CH1OI	Channel 1 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
0 CH0OI	Channel 0 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.

37.3.17 Output Mask (FTMx_OUTMASK)

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control applications where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register stores the value into a write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

Address: Base address + 26h offset

Bit	7	6	5	4	3	2	1	0
Read	CH7OM	CH6OM	CH5OM	CH4OM	CH3OM	CH2OM	CH1OM	CH0OM
Write								
Reset	0	0	0	0	0	0	0	0

FTMx_OUTMASK field descriptions

Field	Description
7 CH7OM	Channel 7 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
6 CH6OM	Channel 6 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally).

Table continues on the next page...

FTMx_OUTMASK field descriptions (continued)

Field	Description
	0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
5 CH5OM	Channel 5 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
4 CH4OM	Channel 4 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
3 CH3OM	Channel 3 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
2 CH2OM	Channel 2 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
1 CH1OM	Channel 1 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
0 CH0OM	Channel 0 Output Mask Defines if the channel output is masked (forced to its inactive state) or unmasked (it continues to operate normally). 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.

37.3.18 Function for Linked Channels (FTMx_COMBINEn)

This register contains the control bits used to configure the fault control, synchronization, deadtime, dual edge capture mode, complementary, and combine features of channels (n) and (n+1).

- COMBINE0 supports channels 0 and 1.
- COMBINE1 supports channels 2 and 3.
- COMBINE2 supports channels 4 and 5.

NOTE

The channel (n) is the even channel and the channel (n+1) is the odd channel of a pair of channels.

Address: Base address + 27h offset + (1d × i), where i=0d to 2d

Bit	7	6	5	4	3	2	1	0
Read	0	FAULTEN	SYNCEN	DTEN	DECAP	DECAPEN	COMP	COMBINE
Write								
Reset	0	0	0	0	0	0	0	0

FTMx_COMBINEn field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FAULTEN	Fault Control Enable Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
5 SYNCEN	Synchronization Enable Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
4 DTEN	Deadtime Enable Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
3 DECAP	Dual Edge Capture Mode Captures

Table continues on the next page...

FTMx_COMBINEn field descriptions (continued)

Field	Description
	<p>Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.</p> <p>This field applies only when MODE[FTMEN] = 1 and DECAPEN = 1.</p> <p>DECAP bit is cleared automatically by hardware if dual edge capture one-shot mode is selected and when the capture of channel (n+1) event is made.</p> <p>0 The dual edge captures are inactive. 1 The dual edge captures are active.</p>
2 DECAPEN	<p>Dual Edge Capture Mode Enable</p> <p>Enables the dual edge capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA, and ELS(n+1)B:ELSn+1)A bits in dual edge capture mode according to the table Mode, Edge, and Level Selection in the description of the CnSC register.</p> <p>This field applies only when MODE[FTMEN] = 1.</p> <p>DECAPEN is write protected, this bit can be written only if MODE[WPDIS] = 1.</p> <p>0 The dual edge capture mode in this pair of channels is disabled. 1 The dual edge capture mode in this pair of channels is enabled.</p>
1 COMP	<p>Complement of Channel (n)</p> <p>Enables complementary mode for the combined channels. In complementary mode the channel (n+1) output is the inverse of the channel (n) output.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.</p>
0 COMBINE	<p>Combine Channels</p> <p>Enables the combine feature for channels (n) and (n+1).</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.</p>

37.3.19 Deadtime Insertion Control (FTMx_DEADTIME)

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 2Bh offset

Bit	7	6	5	4	3	2	1	0
Read	DTPS				DTVAL			
Write								
Reset	0	0	0	0	0	0	0	0

FTMx_DEADTIME field descriptions

Field	Description
7–6 DTPS	<p>Deadtime Prescaler Value</p> <p>Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter.</p> <p>DTPS is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0x Divide the system clock by 1. 10 Divide the system clock by 4. 11 Divide the system clock by 16.</p>
5–0 DTVVAL	<p>Deadtime Value</p> <p>Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS.</p> <p>Deadtime insert value = (DTPS × DTVVAL).</p> <p>DTVVAL selects the number of deadtime counts inserted as follows:</p> <ul style="list-style-type: none"> • When DTVVAL is 0, no counts are inserted. • When DTVVAL is 1, 1 count is inserted. • When DTVVAL is 2, 2 counts are inserted. <p>This pattern continues up to a possible 63 counts.</p> <p>DTVVAL is write protected. It can be written only when MODE[WPDIS] = 1.</p>

37.3.20 External Trigger (FTMx_EXTTRIG)

This register indicates when a channel trigger was generated, enables the generation of a trigger when the FTM counter is equal to its initial value, and selects which channels are used in the generation of the channel triggers. Several FTM channels can be selected to generate multiple triggers in one PWM period.

Channels 6 and 7 are not used to generate channel triggers.

Field	Description
7 TRIGF	<p>Channel Trigger Flag</p> <p>Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect.</p> <p>If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF.</p>

Table continues on the next page...

FTMx_EXTTRIG field descriptions (continued)

Field	Description
	0 No channel trigger was generated. 1 A channel trigger was generated.
6 INITTRIGEN	Initialization Trigger Enable Enables the generation of the trigger when the FTM counter is equal to its initial value. 0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.
5 CH1TRIG	Channel 1 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
4 CH0TRIG	Channel 0 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
3 CH5TRIG	Channel 5 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
2 CH4TRIG	Channel 4 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
1 CH3TRIG	Channel 3 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
0 CH2TRIG	Channel 2 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.

37.3.21 Channels Polarity (FTMx_POL)

This register defines the output polarity of the FTM channels.

NOTE

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

Address: Base address + 2Dh offset

37.3.23 Input Capture Filter Control (FTMx_FILTERn)

This register selects the filter value for the inputs of channels.

- FILTER0 supports Channels 0 and 1.
- FILTER1 supports Channels 2 and 3.
- Channels 4 and 5 do not have an input filter.

NOTE

Writing to this register has immediate effect and must be done only when the input capture modes of the affected channels are disabled. Failure to do this could result in a missing valid signal.

Address: Base address + 2Fh offset + (1d × i), where i=0d to 1d

0 QUADEN	<p>Quadrature Decoder Mode Enable</p> <p>Enables the quadrature decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The quadrature decoder mode has precedence over the other modes. (See the table Mode, Edge, and Level Selection in the description of the CnSC register.)</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Quadrature decoder mode is disabled. 1 Quadrature decoder mode is enabled.</p>

37.4 Functional Description

The following sections describe the FTM features.

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

Channel (n) - high-true EPWM

PS[2:0] = 001

CNTINH:L = 0x0000

MODH:L = 0x0004

CnVH:L = 0x0002

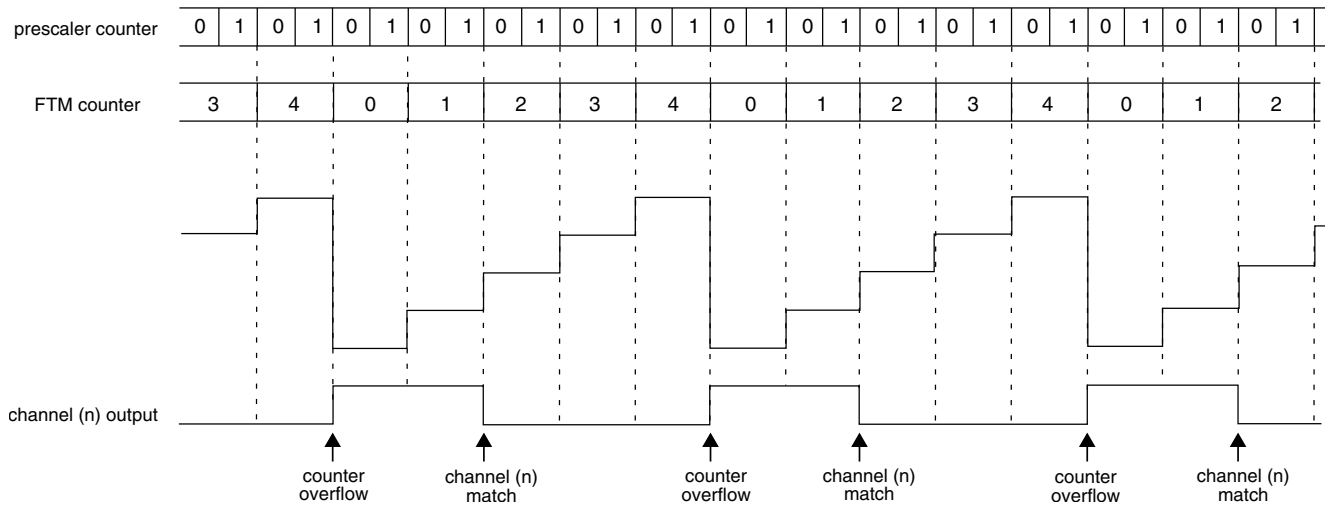

Figure 37-143. Notation used

37.4.1 Clock Source

FTM module has only one clock domain that is the system clock.

37.4.1.1 Counter Clock Source

The CLKS[1:0] bits in the SC register select one of three possible clock sources for the FTM counter or disable the FTM counter. After any MCU reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration. Refer to chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to ensure that counter transitions are properly aligned to system clock transitions. Therefore, to meet the Nyquist criteria and account for jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

37.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

Figure 37-144. Example of the prescaler counter

37.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler (see [Prescaler](#)).

The FTM counter has these modes of operation:

- up counting (see [Up counting](#))
- up-down counting (see [Up-down counting](#))
- quadrature mode, if it is supported (see [Quadrature Decoder Mode](#))

37.4.3.1 Up counting

Up counting is selected when (CPWMS = 0) and, if the quadrature decoder feature is supported, when (QUADEN = 0).

CNTINH:L defines the starting value of the count and MODH:L defines the final value of the count; see the following figure. The value of CNTINH:L is loaded into the FTM counter, and the counter increments until the value of MODH:L is reached, at which point the counter is reloaded with CNTINH:L.

The FTM period when using up counting is $(\text{MODH:L} - \text{CNTINH:L} + 0x0001) \times \text{period}$ of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MODH:L to CNTINH:L.

Figure 37-145. Example of FTM up and signed counting

If (CNTINH:L = 0x0000), the FTM counting is equivalent to TPM up counting; that is, up and unsigned counting. See the following figure. If (CNTINH[7] = 1), then the initial value of the FTM counter is a negative number in two's complement format, so the FTM counting is up and signed. Conversely, if (CNTINH[7] = 0 and CNTINH:L \neq 0x0000), then the initial value of the FTM counter is a positive number, therefore the FTM counting is up and unsigned.

Functional Description

FTM counting is up

CNTINH:L = 0x0000

MODH:L = 0x0004

Figure 37-146. Example of FTM up counting with CNTIN = 0x0000

Note

- FTM operation is valid only when the value of the CNTINH:L registers is less than the value of the MODH:L registers, either in the unsigned counting or signed counting.. Software must ensure that the values in the CNTINH:L and MODH:L registers meet this requirement. Any values of CNTINH:L and MODH:L that do not satisfy this criteria can result in unpredictable behavior.
- MODH:L = CNTINH:L is a redundant condition. In this case, the FTM counter is always equal to MODH:L and the TOF bit is set in each rising edge of the FTM counter clock.
- When MODH:L = 0x0000, CNTINH:L = 0x0000 (for example after reset), and FTMMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MODH:L or CNTINH:L registers.
- Setting CNTINH:L to be greater than the value of MODH:L is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

FTM counting is up
 MODH:L = 0x0005
 CNTINH:L = 0x0015

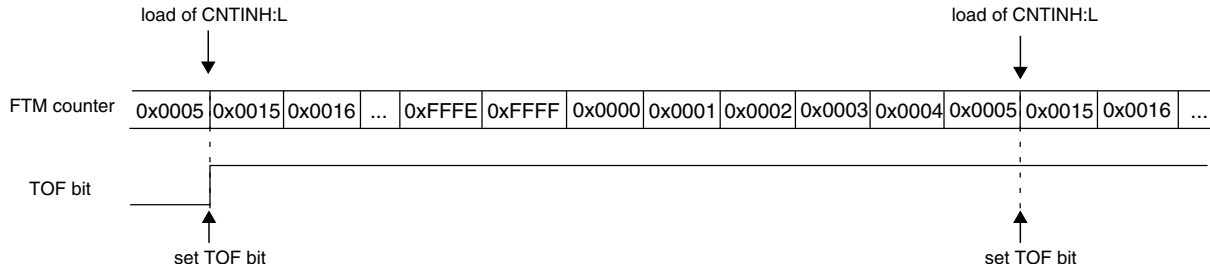

Figure 37-147. Example of up counting when the value of CNTIN registers is greater than the value of MOD registers

37.4.3.2 Up-down counting

Up-down counting is selected when (CPWMS = 1) and, if the quadrature decoder feature is supported, when (QUADEN = 0).

CNTINH:L defines the starting value of the count and MODH:L defines the final value of the count. The value of CNTINH:L is loaded into the FTM counter, and the counter increments until the value of MODH:L is reached, at which point the counter is decremented until it returns to the value of CNTINH:L and the up-down counting restarts.

The FTM period when using up-down counting is $2 \times (\text{MODH:L} - \text{CNTINH:L}) \times \text{period of the FTM counter clock}$.

The TOF bit is set when the FTM counter changes from MODH:L to (MODH:L – 1).

If (CNTINH:L = 0x0000), the FTM counting is equivalent to TPM up-down counting; that is, up-down and unsigned counting. See the following figure.

Functional Description

FTM counting is up-down

CNTINH:L = 0x0000
MODH:L = 0x0004

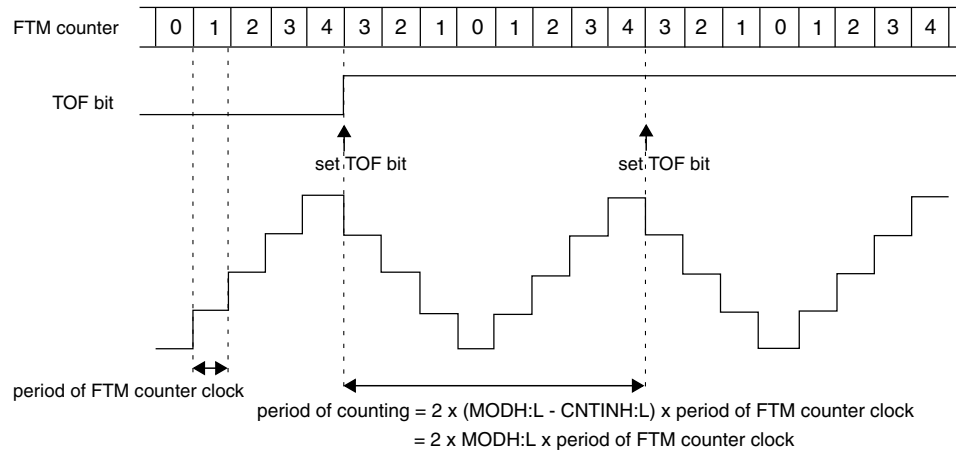

Figure 37-148. Example of up-down counting when CNTIN = 0x0000

Note

- The up-down counting is available only when (CNTINH:L = 0x0000).
- The configuration with (CNTINH:L ≠ 0x0000) when (CPWMS = 1) is not recommended and its results are not guaranteed.

37.4.3.3 Free running counter

If (FTMEN = 0) and (MODH:L = 0x0000 or MODH:L = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

FTMEN = 0
MODH:L = 0x0000

Figure 37-149. Example when the FTM counter is a free running

The FTM counter is also a free running counter when all of the following apply:

- (FTMEN = 1)

- (CPWMS = 0)
- (CNTINH:L = 0x0000)
- (MODH:L = 0xFFFF)
- (QUADEN = 0) if the quadrature decoder feature is supported

In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000.

37.4.3.4 Counter reset

Any write to CNTH or CNTL register resets the FTM counter to the value of CNTINH:L and the channels output to its initial value, except for channels in output compare mode.

The [FTM counter synchronization](#) can also be used to force the value of CNTINH:L into the FTM counter and the channels output to its initial value, except for channels in output compare mode.

37.4.4 Input capture mode

The input capture mode is selected when (DECAPEN = 0), (COMBINE = 0), (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA ≠ 0:0).

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnVH:L registers. At the same time, the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by four, which is required to meet Nyquist criteria for signal sampling.

When either half of the 16-bit capture register (CnVH:L) is read, the other half is latched into a buffer to support coherent 16-bit access in big-endian or little-endian order. This read coherency mechanism can be manually reset by writing to CnSC register.

Writes to the CnVH:L registers are ignored in input capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnVH:L registers and the CHnF bit is set.

Functional Description

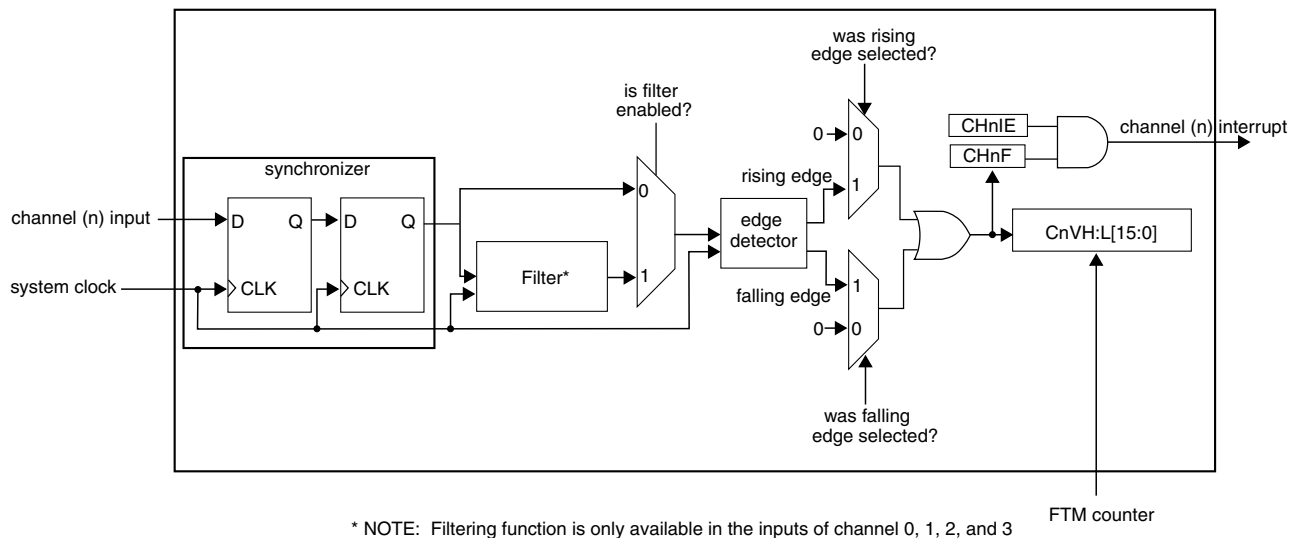

Figure 37-150. Input capture mode

If the channel input does not have a filter enabled, then the input signal is always delayed three rising edges of the system clock; that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

Note

- Input capture mode is available only with (CNTINH:L = 0x0000).
- Input capture mode with (CNTINH:L ≠ 0x0000) is not recommended and its results are not guaranteed.

37.4.4.1 Filter for input capture mode

The filter function is available only on channels 0, 1, 2, and 3.

Firstly, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block; see the following figure. When there is a state change in the input signal, the 5-bit counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. If the 5-bit counter overflows (the counter exceeds the value of the CHnFVAL[3:0] bits), the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

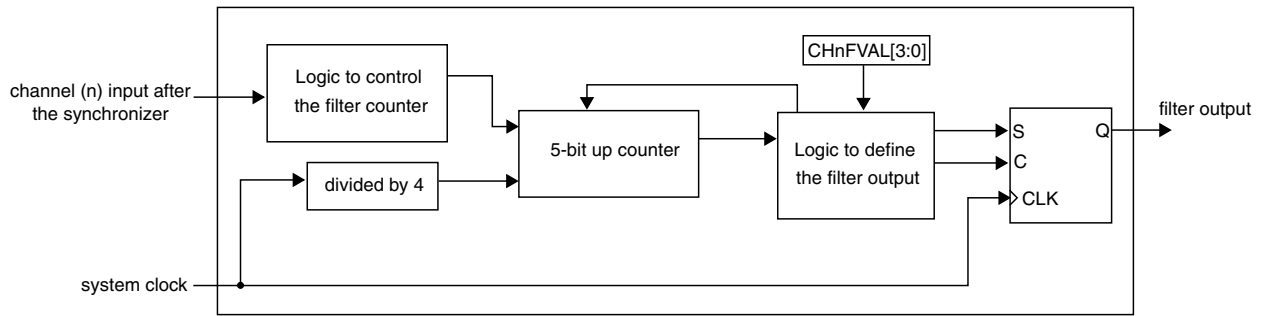

Figure 37-151. Channel input filter

If the opposite edge appears on the input signal before validation, the counter is reset. At the next input transition, the counter starts counting again. Any pulse shorter than the minimum valid width ($\text{CHnFVAL}[3:0] \text{ bits} \times 4 \text{ system clocks}$) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when $\text{CHnFVAL}[3:0]$ bits are zero. In this case, the input signal is delayed three rising edges of the system clock. If ($\text{CHnFVAL}[3:0] \neq 0000$), then the input signal is delayed by the minimum pulse width ($\text{CHnFVAL}[3:0] \times 4 \text{ system clocks}$) plus a further four rising edges of the system clock (two rising edges to the synchronizer, one rising edge to the filter output plus one more to the edge detector). In other words, CHnF is set ($4 + 4 \times \text{CHnFVAL}[3:0]$) system clock periods after a valid edge occurs on the channel input.

The clock for the 5-bit counter in the channel input filter is the system clock divided by 4.

Figure 37-152. Channel input filter example

37.4.5 Output compare mode

The output compare mode is selected when ($\text{DECAPEN} = 0$), ($\text{COMBINE} = 0$), ($\text{CPWMS} = 0$) and ($\text{MSnB:MSnA} = 0:1$).

Functional Description

In output compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnVH:CnVL registers of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnVH:CnVL).

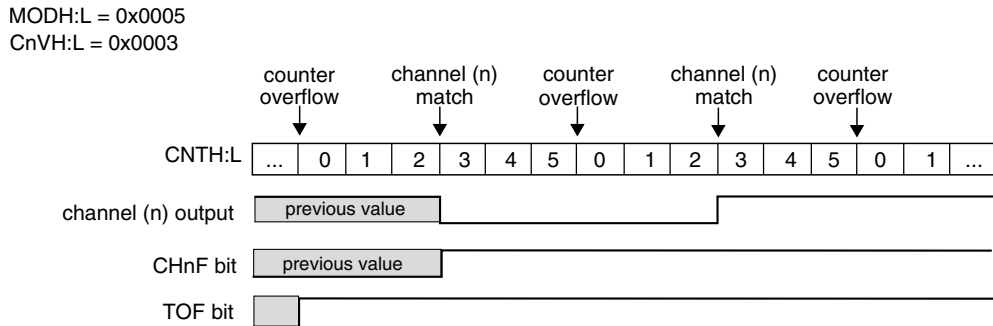

Figure 37-153. Example of the output compare mode when the match toggles the channel output

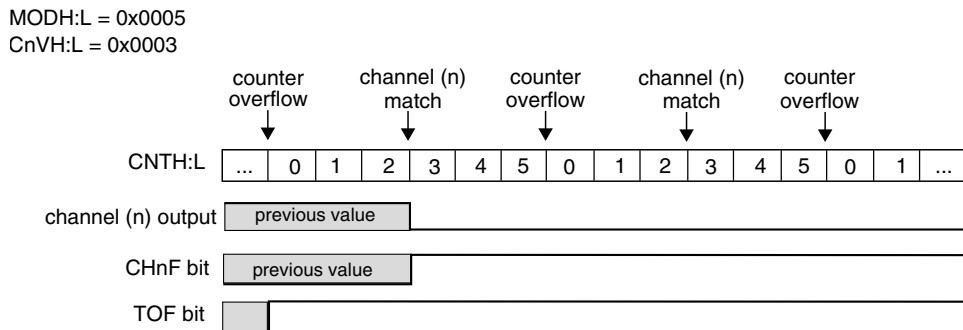

Figure 37-154. Example of the output compare mode when the match clears the channel output

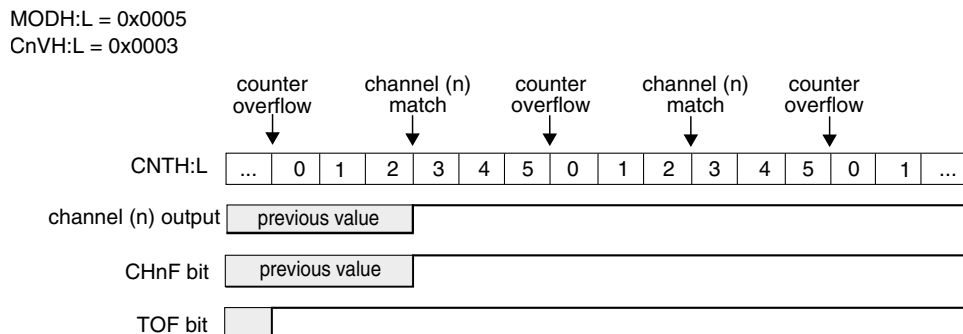

Figure 37-155. Example of the output compare mode when the match sets the channel output

It is possible to use the output compare mode with ($ELSnB:ELSnA = 0:0$). In this case, when the counter reaches the value in the $CnVH:CnVL$ registers, the $CHnF$ bit is set and the channel (n) interrupt is generated, if $CHnIE = 1$. However, the channel (n) output is not modified and controlled by FTM.

Note

- Output compare mode is available only with ($CNTINH:CNTINL = 0x0000$).
- Output compare mode with ($CNTINH:CNTINL \neq 0x0000$) is not recommended and its results are not guaranteed.

37.4.6 Edge-aligned PWM (EPWM) mode

The edge-aligned mode is selected when all of the following apply:

- ($DECAPEN = 0$)
- ($COMBINE = 0$)
- ($CPWMS = 0$)
- ($MSnB = 1$)
- ($QUADEN = 0$) if the quadrature decoder feature is supported

The EPWM period is determined by ($MODH:L - CNTINH:L + 0x0001$) and the pulse width (duty cycle) is determined by ($CnVH:L - CNTINH:L$).

The $CHnF$ bit is set and the channel (n) interrupt is generated (if $CHnIE = 1$) at the channel (n) match (FTM counter = $CnVH:L$), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

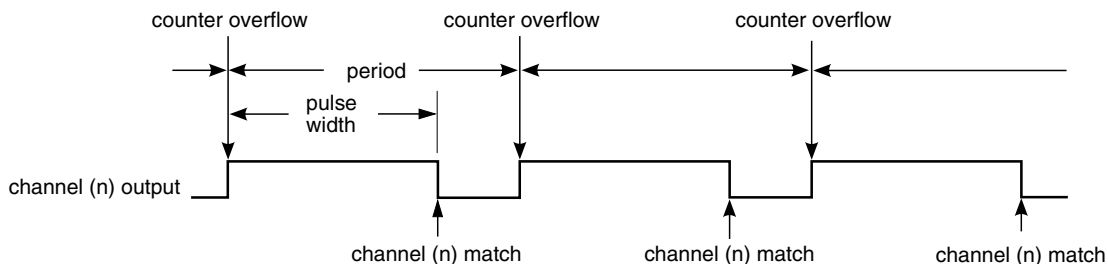

Figure 37-156. EPWM period and pulse width with $ELSnB:ELSnA = 1:0$

If ($ELSnB:ELSnA = 0:0$) when the counter reaches the value in the $CnVH:L$ registers, the $CHnF$ bit is set and the channel (n) interrupt is generated (if $CHnIE = 1$), however, the channel (n) output is not controlled by FTM.

Functional Description

If $(ELSnB:ELSnA = 1:0)$, then the channel (n) output is forced high at the counter overflow, when the value of $CNTINH:L$ is loaded into the FTM counter. Additionally, it is forced low at the channel (n) match, when the FTM counter = $CnVH:L$. See the following figure.

Figure 37-157. EPWM signal with $ELSnB:ELSnA = 1:0$

If $(ELSnB:ELSnA = X:1)$, then the channel (n) output is forced low at the counter overflow, when the value of $CNTINH:L$ is loaded into the FTM counter. Additionally, it is forced high at the channel (n) match, when the FTM counter = $CnVH:L$. See the following figure.

Figure 37-158. EPWM signal with $ELSnB:ELSnA = X:1$

If $(CnVH:L = 0x0000)$, then the channel (n) output is a 0% duty cycle EPWM signal and $CHnF$ bit is not set, even when there is the channel (n) match. If $(CnVH:L > MODH:L)$, then the channel (n) output is a 100% duty cycle EPWM signal and $CHnF$ bit is not set, even when there is the channel (n) match. Therefore, $MODH:MODL$ must be less than $0xFFFF$ in order to get a 100% duty cycle EPWM signal.

Note

- EPWM mode is available only with $(CNTINH:L = 0x0000)$.
- EPWM mode with $(CNTINH:L \neq 0x0000)$ is not recommended and its results are not guaranteed.

37.4.7 Center-aligned PWM (CPWM) mode

The center-aligned mode is selected when all of the following apply:

- (QUADEN = 0) if the quadrature decoder feature is supported
- (DECAPEN = 0)
- (COMBINE = 0)
- (CPWMS = 1)

The CPWM pulse width (duty cycle) is determined by $2 \times (\text{CnVH:L} - \text{CNTINH:L})$. The period is determined by $2 \times (\text{MODH:L} - \text{CNTINH:L})$. See the following figure. MODH:L must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MODH:L and then counts down until it reaches the value of CNTINH:L.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnVH:L) when the FTM counting is down, at the begin of the pulse width, and when the FTM counting is up, at the end of the pulse width.

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTINH:L.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

Figure 37-159. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnVH:L registers, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

Functional Description

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnVH:L) when counting down, and it is forced low at the channel (n) match when counting up; see the following figure.

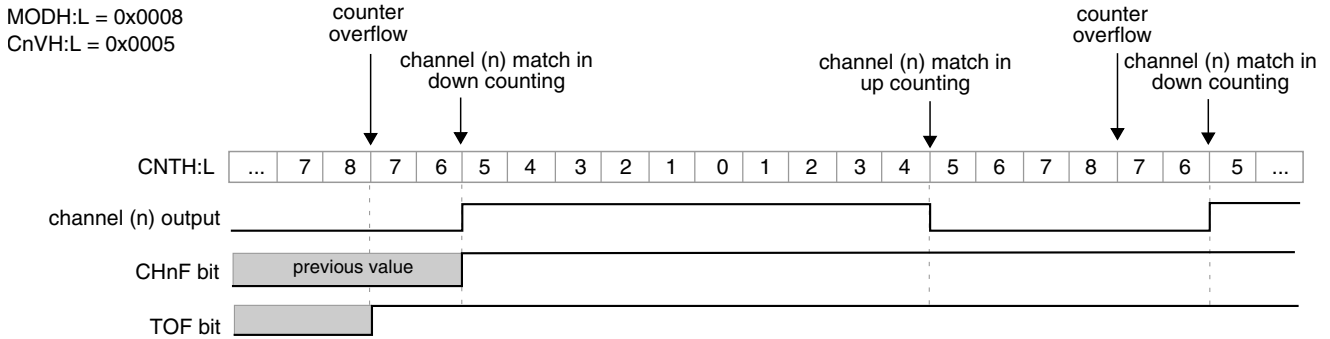

Figure 37-160. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnVH:L) when counting down, and it is forced high at the channel (n) match when counting up; see the following figure.

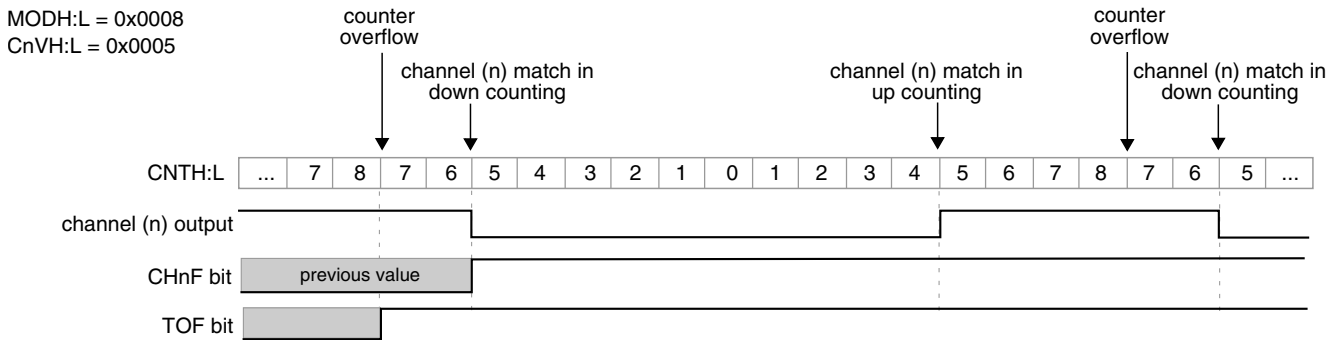

Figure 37-161. CPWM signal with ELSnB:ELSnA = X:1

If (CnVH:L = 0x0000) or (CnVH:L is a negative value, that is, CnVH[7] = 1) then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnVH:L is a positive value, that is, CnVH[7] = 0), (CnVH:L ≥ MODH:L), and (MODH:L ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MODH:L is 0x0001 through 0x7FFE, or 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

Note

- CPWM mode is available only with (CNTINH:L = 0x0000).
- CPWM mode with (CNTINH:L \neq 0x0000) is not recommended and its results are not guaranteed.

37.4.8 Combine mode

The combine mode is selected when all of the following apply:

- (FTMEN = 1)
- (QUADEN = 0) if the quadrature decoder feature is supported
- (DECAPEN = 0)
- (COMBINE = 1)
- (CPWMS = 0)

In combine mode, the even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the combine mode, the PWM period is determined by (MODH:L – CNTINH:L + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)VH:L – C(n)VH:L|).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)VH:L). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1) at the channel (n+1) match (FTM counter = C(n+1)VH:C(n+1)VL).

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTINH:L) and at the channel (n+1) match (FTM counter = C(n+1)VH:L). It is forced high at the channel (n) match (FTM counter = C(n)VH:L). See the following figure.

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTINH:L) and at the channel (n+1) match (FTM counter = C(n+1)VH:L). It is forced low at the channel (n) match (FTM counter = C(n)VH:L). See the following figure.

In combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output.

Functional Description

Figure 37-162. Combine mode

The following figures illustrate the generation of PWM signals using combine mode.

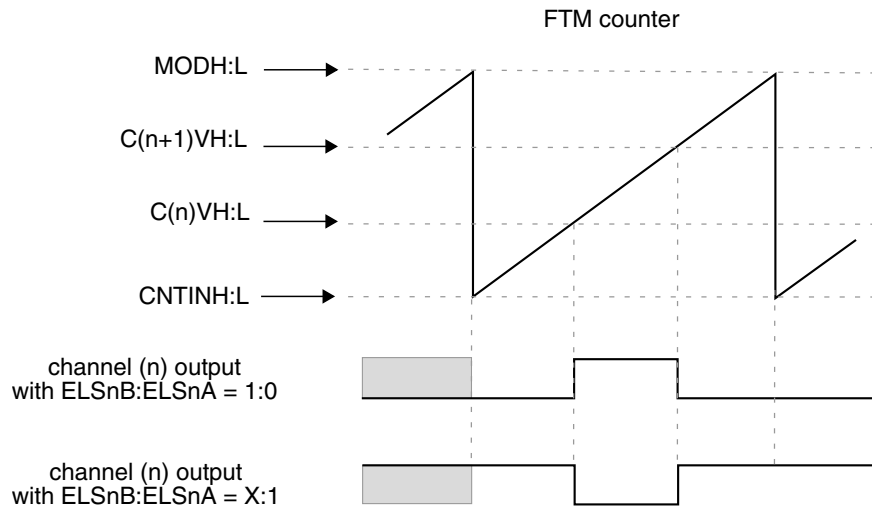

Figure 37-163. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(CNTIN < C(n+1)V < MOD)$ and $(C(n)V < C(n+1)V)$

Figure 37-164. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(C(n+1)V = MOD)$

Figure 37-165. Channel (n) output if $(C(n)V = CNTIN)$ and $(CNTIN < C(n+1)V < MOD)$

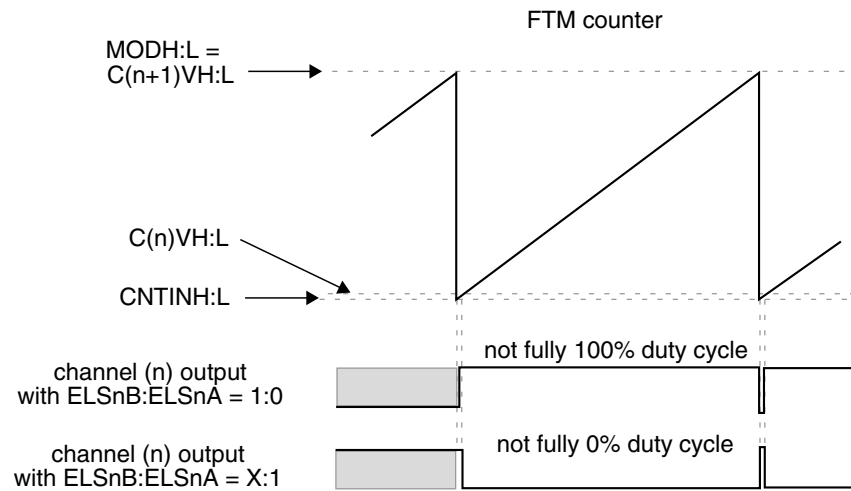

Figure 37-166. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(C(n)V$ is almost equal to $CNTIN)$ and $(C(n+1)V = MOD)$

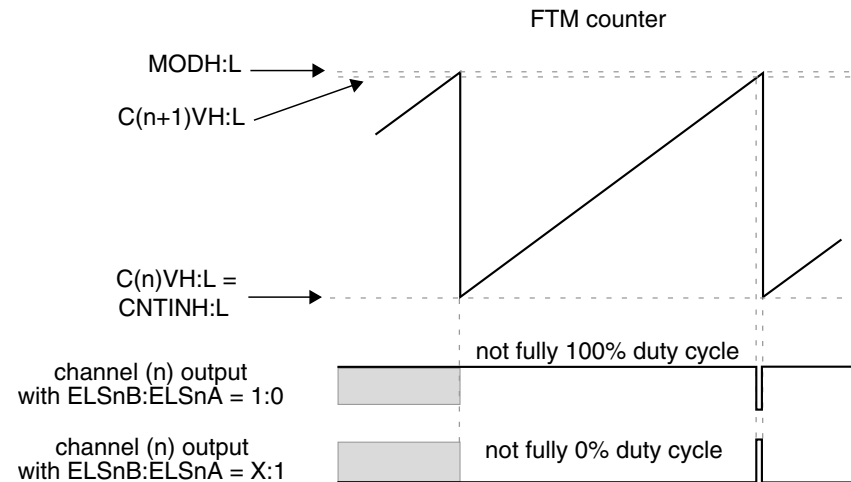

Figure 37-167. Channel (n) output if $(C(n)V = CNTIN)$ and $(CNTIN < C(n+1)V < MOD)$ and $(C(n+1)V$ is almost equal to $MOD)$

Functional Description

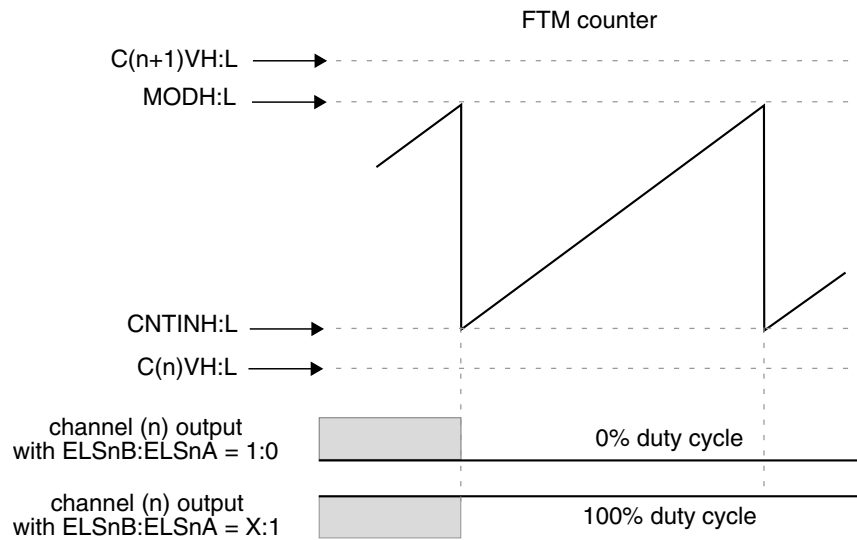

Figure 37-168. Channel (n) output if $C(n)V$ and $C(n+1)V$ are not between $CNTIN$ and MOD

Figure 37-169. Channel (n) output if $(CNTIN < C(n)V < MOD)$ and $(CNTIN < C(n+1)V < MOD)$ and $(CnV = C(n+1)V)$

Figure 37-174. Channel (n) output if $(C(n+1)V < CNTIN)$ and $(CNTIN < C(n)V < MOD)$

Figure 37-175. Channel (n) output if $(C(n)V > MOD)$ and $(CNTIN < C(n+1)V < MOD)$

Figure 37-176. Channel (n) output if $(C(n+1)V > MOD)$ and $(CNTIN < C(n)V < MOD)$

Figure 37-177. Channel (n) output if $(C(n+1)V > MOD)$ and $(CNTIN < C(n)V = MOD)$

37.4.8.1 Asymmetrical PWM

In the combine mode, the control of the PWM signal first edge (when the channel (n) match occurs, that is, FTM counter = $C(n)VH:L$) is independent of the control of the PWM signal second edge (when the channel (n+1) match occurs, that is, FTM counter = $C(n+1)VH:L$). So, the combine mode allows to generate asymmetrical PWM signals.

37.4.9 Complementary mode

The complementary mode is selected when all of the following apply:

- (FTMEN = 1)
- (QUADEN = 0) if the quadrature decoder feature is supported
- (DECAPEN = 0)
- (COMBINE = 1)
- (CPWMS = 0)
- (COMP = 1)

In complementary mode the channel (n+1) output is the inverse of the channel (n) output.

The channel (n+1) output is the same as the channel (n) output if all of the following apply:

- (FTMEN = 1)
- (QUADEN = 0) if the quadrature decoder feature is supported
- (DECAPEN = 0)
- (COMBINE = 1)

- (CPWMS = 0)
- (COMP = 0)

Figure 37-178. Channel (n+1) output in complementary mode with (ELSnB:ELSnA = 1:0)

Figure 37-179. Channel (n+1) output in complementary mode with (ELSnB:ELSnA = X:1)

37.4.10 Update of the registers with write buffers

This section describes the updating of registers that have write buffers.

37.4.10.1 CNTINH:L registers

CNTINH:L registers are always updated with their write buffer after both bytes have been written.

37.4.10.2 MODH:L registers

If (CLKS[1:0] = 0:0), then MODH:L registers are updated when their second byte is written, independent of FTMEN bit.

If (CLKS[1:0] ≠ 0:0 and FTMEN = 0), then MODH:L registers are updated according to the CPWMS bit:

- If the selected mode is not CPWM mode, then MODH:L registers are updated after both bytes have been written and the FTM counter changes from (MODH:L) to (CNTINH:L). If the FTM counter is a free-running counter, then this update is made when the FTM counter changes from 0xFFFF to 0x0000.
- If the selected mode is CPWM mode, then MODH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to (MODH:L – 0x0001).

If (CLKS[1:0] ≠ 0:0 and FTMEN = 1), then MODH:L registers are updated by PWM synchronization. See [MODH:L registers synchronization](#).

37.4.10.3 CnVH:L registers

If (CLKS[1:0] = 0:0), then CnVH:L registers are updated when their second byte is written, independent of FTMEN bit.

If (CLKS[1:0] ≠ 0:0 and FTMEN = 0), then CnVH:L registers are updated according to the selected mode:

- If the selected mode is output compare mode, then CnVH:L registers are updated after their second byte is written and on the next change of the FTM counter.
- If the selected mode is EPWM mode, the CnVH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to CNTINH:L. If the FTM counter is a free running counter, then this update is made when the FTM counter changes from 0xFFFF to 0x0000.
- If the selected mode is CPWM mode, then CnVH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to (MODH:L – 0x0001).

If (CLKS[1:0] ≠ 0:0 and FTMEN = 1), then CnVH:L registers are updated according to the selected mode:

- If the selected mode is output compare mode, then CnVH:L registers are updated according to the SYNCEN bit. If (SYNCEN = 0), then CnVH:L registers are updated after their second byte is written and on the next change of the FTM counter. If (SYNCEN = 1), then CnVH:L registers are updated by PWM synchronization. See [CnVH:L registers synchronization](#).
- If the selected mode is not output compare mode and (SYNCEN = 1), then CnVH:L registers are updated by PWM synchronization. See [CnVH:L registers synchronization](#).

37.4.11 PWM synchronization

PWM synchronization provides an opportunity to update registers with the contents of their write buffers. It can also be used to synchronize two or more FlexTimer modules on the same MCU.

PWM synchronization updates the MODH:L and CnVH:L registers with their write buffers. It is also possible to force the FTM counter to its initial value and update the CHnOM bits in OUTMASK using PWM synchronization.

Note

PWM synchronization is available only in combine mode.

37.4.11.1 Hardware trigger

Each hardware trigger is synchronized by the system clock. The input signals are: trigger_0, trigger_1, and trigger_2.

A rising edge on the selected hardware trigger input (trigger n event) initiates PWM synchronization. A hardware trigger is selected when its enable bit is set (TRIGN = 1 where n = 0, 1, or 2). The TRIGN bit is cleared when 0 is written to it or when the trigger n event is detected.

For example, if TRIG0 and TRIG1 are enabled and only the trigger 1 event occurs, only the TRIG1 bit is cleared.

If a trigger n event occurs together with a write to set the TRIGN bit, then the synchronization is made, but the TRIGN bit remains set because of the last write.

Notes
 - All hardware trigger (input signals: trigger_0, trigger_1, and trigger_2) have this same behavior

Figure 37-180. Hardware trigger event

37.4.11.2 Software trigger

A software trigger event occurs when 1 is written to the SWSYNC bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, which is initiated by the software event, is completed.

If the software trigger event occurs together with the event that clears the SWSYNC bit, then the synchronization is made using this trigger event and the SWSYNC bit remains set because of the last write.

For example, if $PWMSYNC = 0$ and $REINIT = 0$ and there is a software trigger event, then the load of MODH:L and CnVH:L registers is made only at the boundary cycle (CNTMIN and CNTMAX). In this case, the SWSYNC bit is cleared only at the boundary cycle, so you do not know when this bit is cleared. Therefore, it is possible a new write to set SWSYNC happens when FTM is clearing the SWSYNC because it is the selected boundary cycle of PWM synchronization that was started previously by the software trigger event.

Figure 37-181. Software Trigger event

37.4.11.3 Boundary cycle

The CNTMAX and CNTMIN bits select the boundary cycle when the MODH:L and CnVH:L registers are updated with the value of their write buffer by PWM synchronization, except if (PWMSYNC = 0 and REINIT = 1).

If CNTMIN = 1, then the boundary cycle is the CNTINH:L value. MODH:L and CnVH:L registers are updated when the FTM counter reaches the CNTINH:L value. If CPWMS = 0, then CNTINH:L is reached when the FTM counter changes from MODH:L to CNTINH:L. If CPWMS = 1, then CNTINH:L is reached when the FTM counter changes from (CNTINH:L + 0x0001) to CNTINH:L.

If CNTMAX = 1, then the boundary cycle is the MODH:L value. MODH:L and CnVH:L registers are updated when the FTM counter reaches the MODH:L value. MODH:L is reached when the FTM counter changes from (MODH:L - 0x0001) to MODH:L, regardless of the CPWMS configuration.

If no boundary cycle was selected (CNTMAX = 0 and CNTMIN = 0), then the update of the MODH:L and CnVH:L registers is not made, unless (PWMSYNC = 0 and REINIT = 1).

If both boundary cycles were selected (CNTMAX = 1 and CNTMIN = 1), then the update of the MODH:L and CnVH:L registers is made in the first boundary cycle that occurs with valid conditions for MODH:L or CnVH:L synchronization, except if (PWMSYNC = 0 and REINIT = 1).

The CNTMAX and CNTMIN bits are cleared only by software.

Note

- PWM synchronization boundary cycle is available only when (CNTMIN = 1).
- PWM synchronization with (CNTMAX = 1) is not recommended and its results are not guaranteed.

37.4.11.4 MODH:L registers synchronization

The MODH:L synchronization occurs when the MODH:L registers are updated with the value of their write buffer.

The synchronization requires both bytes of MODH:L to have been written in one of the following situations.

- If PWMSYNC = 0 and REINIT = 0, then the synchronization is made on the next selected boundary cycle after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected boundary cycle. See the following figure.

Figure 37-182. MODH:L synchronization when (PWMSYNC = 0), (REINIT = 0), and software trigger was used

If the trigger event was a hardware trigger, then the trigger enable bit (TRIGN) is cleared when the trigger n event is detected. See the following figure.

Figure 37-183. MODH:L synchronization when (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used

- If PWMSYNC = 0 and REINIT = 1, then the synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared. See the following figure.

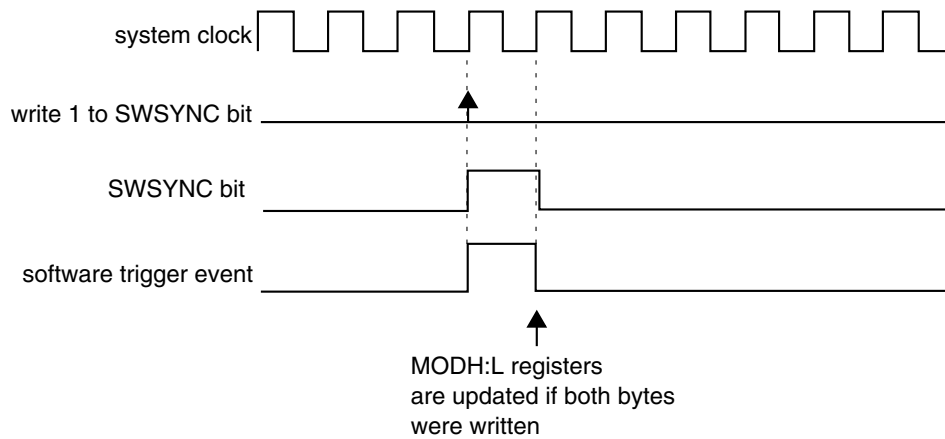

Figure 37-184. MODH:L synchronization when (PWMSYNC = 0), (REINIT = 1), and software trigger was used

If the trigger event was a hardware trigger, then the TRIGn bit is cleared. See the following figure.

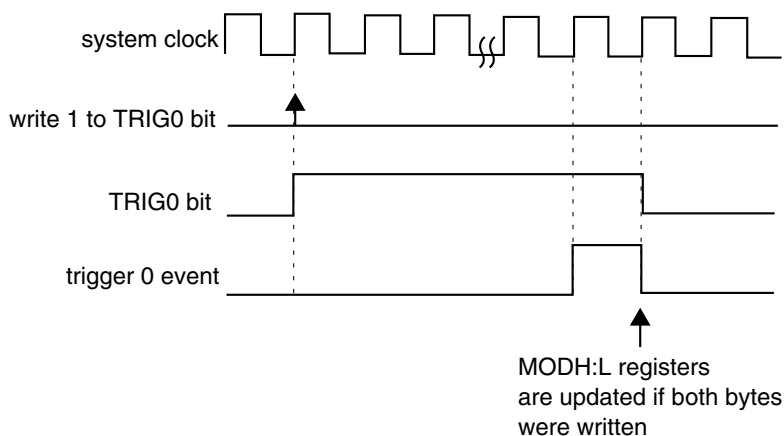

Figure 37-185. MODH:L synchronization when (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used

- If PWMSYNC = 1, then the synchronization is made on the next selected boundary cycle after the enabled software trigger event takes place. The SWSYNC bit is cleared on the next selected boundary cycle. See the following figure.

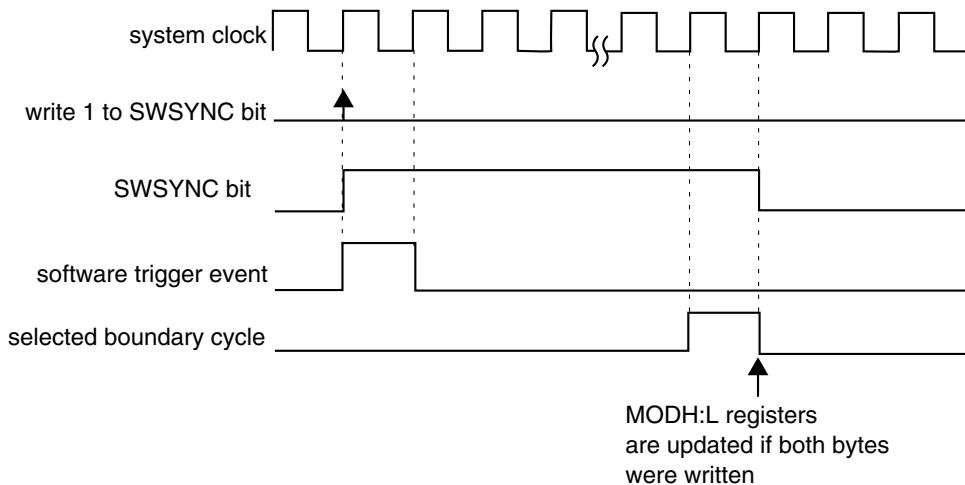

Figure 37-186. MODH:L synchronization when (PWMSYNC = 1)

37.4.11.5 CnVH:L registers synchronization

The CnVH:L synchronization occurs when the CnVH:L registers are updated with the value of their write buffer.

The synchronization requires both bytes of CnVH:L to have been written, SYNCEN = 1 and either a hardware or software trigger event as per [MODH:L registers synchronization](#).

37.4.11.6 OUTMASK register synchronization

Any write to a CHnOM bit updates the OUTMASK write buffer. The CHnOM bit is updated with the value of its corresponding bit in the OUTMASK write buffer according to SYNCHOM and PWMSYNC bits.

- If SYNCHOM = 0, then the CHnOM bit is updated with the value of its write buffer equivalent in all rising edges of the system clock.

Figure 37-187. CHnOM synchronization when (SYNCHOM = 0)

- If SYNCHOM = 1 and PWMSYNC = 0, then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected boundary cycle. See the following figure.

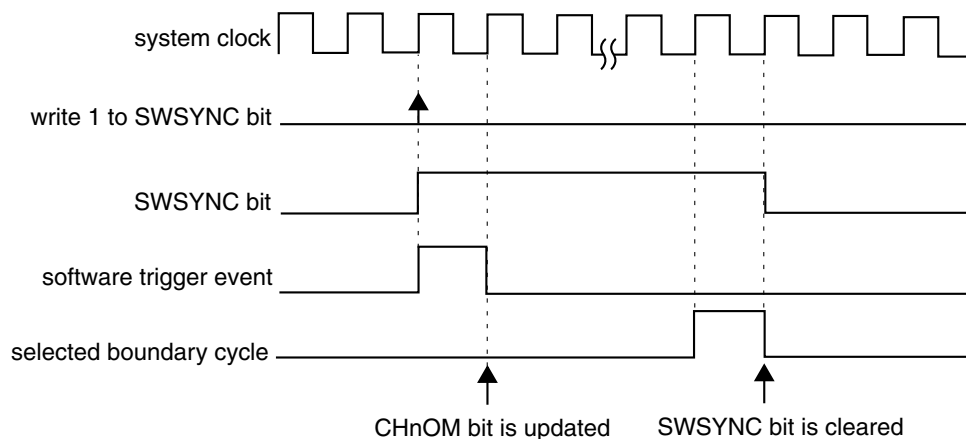

Figure 37-188. CHnOM synchronization when (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used

If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared when the trigger n event is detected. See the following figure.

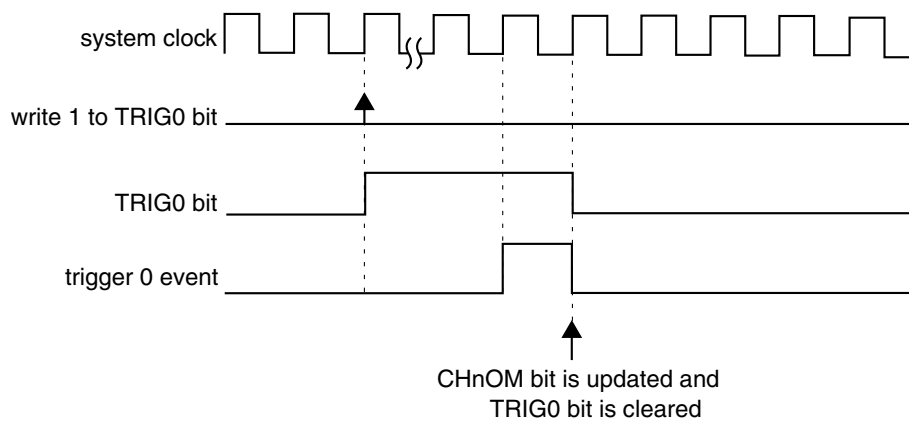

Figure 37-189. CHnOM synchronization when (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used

- If SYNCHOM = 1 and PWMSYNC = 1, then this synchronization is made on the next enabled hardware trigger event. The trigger enable bit (TRIGn) is cleared when the enabled hardware trigger n event is detected. See the following figure.

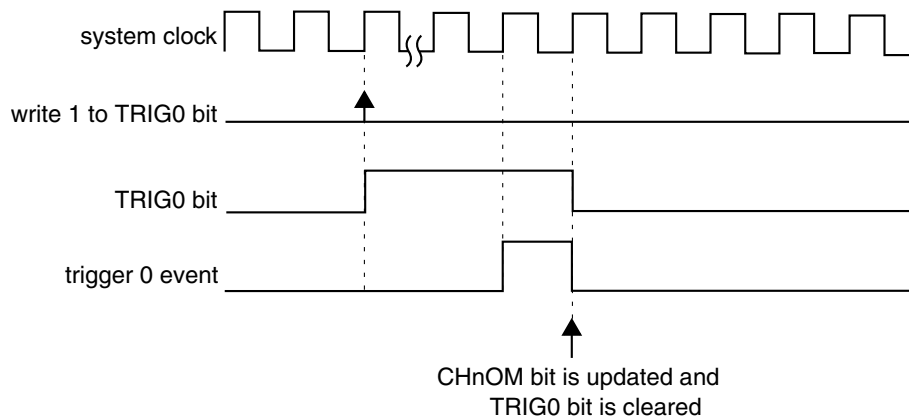

Figure 37-190. CHnOM Synchronization when (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used

37.4.11.7 FTM counter synchronization

The FTM counter synchronization occurs when the FTM counter is updated with the value of the CNTINH:L registers and the channel outputs are forced to their initial value as defined by the channel configuration.

- If REINIT = 0, then this synchronization is made when the FTM counter changes from MODH:L to CNTINH:L.
- If REINIT = 1 and PWMSYNC = 0, then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared. See the following figure.

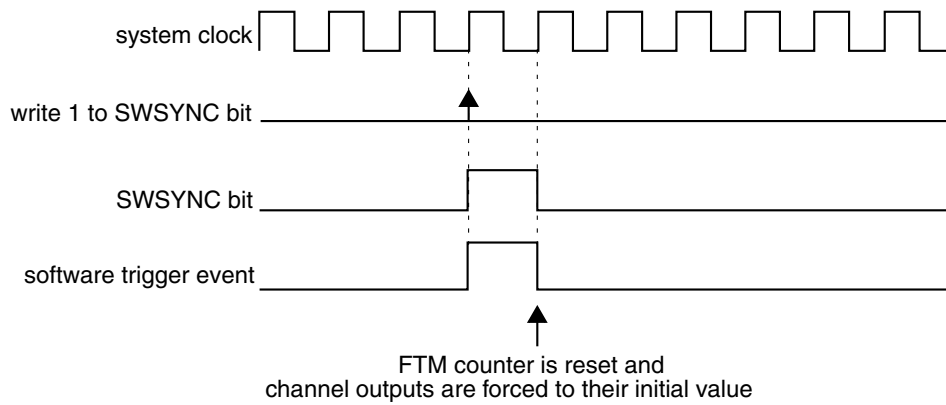

Figure 37-191. FTM counter synchronization when (REINIT = 1), (PWMSYNC = 0), and software trigger was used

If the trigger event was a hardware trigger, then the TRIGN bit is cleared. See the following figure.

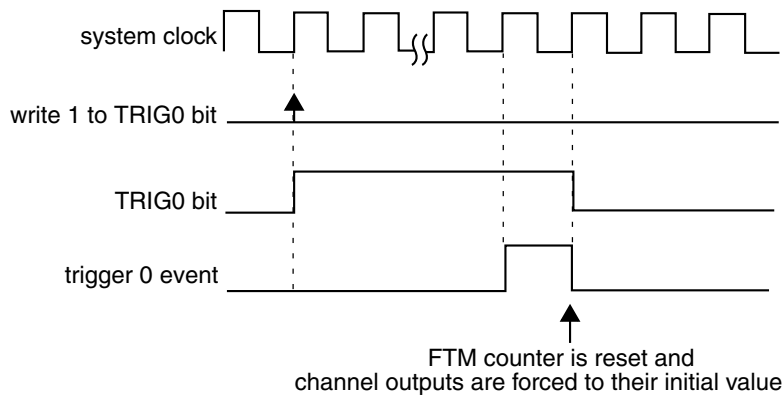

Figure 37-192. FTM counter synchronization when (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used

- If REINIT = 1 and PWMSYNC = 1, then this synchronization is made on the next enabled hardware trigger event. The trigger enable bit (TRIGN) is cleared when the enabled hardware trigger n event is detected. See the following figure.

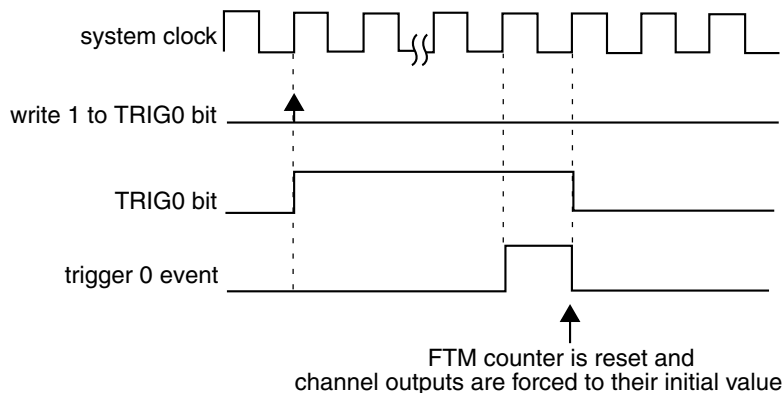

Figure 37-193. FTM counter synchronization when (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used

37.4.11.8 Summary of PWM synchronization

The following table shows the summary of PWM synchronization.

Table 37-188. Summary of PWM synchronization

Register or bit	PWMSYN C	REINIT	SYNCH OM	CNTMA X	CNTMI N	SYNCE N	Description
CNTINH:L	X	X	X	X	X	X	Changes take effect after the second byte is written. Effect is seen after the next TOF or PWM synchronization.
MODH:L	0	0	X	1	0	X	MODH:L are updated with their write buffer contents when the counter reaches its maximum value after the enabled hardware or software trigger has occurred.
	0	0	X	0	1	X	MODH:L are updated with their write buffer contents when the counter reaches its minimum value after the enabled hardware or software trigger has occurred.
	0	1	X	X	X	X	MODH:L are updated with their write buffer contents when the enabled hardware or software trigger occurs.
	1	X	X	1	0	X	MODH:L are updated with their write buffer contents when the counter reaches its maximum value after the enabled software trigger has occurred.
	1	X	X	0	1	X	MODH:L are updated with their write buffer contents when the counter reaches its minimum value after the enabled software trigger has occurred.

Table continues on the next page...

Table 37-188. Summary of PWM synchronization (continued)

Register or bit	PWMSYN C	REINIT	SYNCH OM	CNTMA X	CNTMI N	SYNCE N	Description
CnVH:L	0	0	X	1	0	1	CnVH:L are updated with their write buffer contents when the counter reaches its maximum value after the enabled hardware or software trigger has occurred.
	0	0	X	0	1	1	CnVH:L are updated with their write buffer contents when the counter reaches its minimum value after the enabled hardware or software trigger has occurred.
	0	1	X	X	X	1	CnVH:L are updated with their write buffer contents when the enabled hardware or software trigger occurs.
	1	X	X	1	0	1	CnVH:L are updated with their write buffer contents when the counter reaches its maximum value after the enabled software trigger has occurred.
	1	X	X	0	1	1	CnVH:L are updated with their write buffer contents when the counter reaches its minimum value after the enabled software trigger has occurred.
CNTN:L	0	1	X	X	X	X	CNTN:L are forced to the FTM counter initial value when the enabled hardware or software trigger occurs.
	1	1	X	X	X	X	CNTN:L are forced to the FTM counter initial value when the enabled hardware trigger occurs.
OUTMASK	X	X	0	X	X	X	Changes to OUTMASK take effect on the next rising edge of the system clock.
	0	X	1	X	X	X	OUTMASK is updated with its write buffer contents when the enabled hardware or software trigger occurs.
	1	X	1	X	X	X	OUTMASK is updated with its write buffer contents when the enabled hardware trigger occurs.

Table continues on the next page...

Table 37-188. Summary of PWM synchronization (continued)

Register or bit	PWMSYN C	REINIT	SYNCH OM	CNTMA X	CNTMI N	SYNCE N	Description
SWSYNC bit	0	0	X	1	0	X	SWSYNC bit is cleared when the counter reaches its maximum value after the enabled software trigger has occurred.
	0	0	X	0	1	X	SWSYNC bit is cleared when the counter reaches its minimum value after the enabled software trigger has occurred.
	0	1	X	X	X	X	SWSYNC bit is cleared when the enabled software trigger occurs.
	1	X	X	1	0	X	SWSYNC bit is cleared when the counter reaches its maximum value after the enabled software trigger has occurred.
	1	X	X	0	1	X	SWSYNC bit is cleared when the counter reaches its minimum value after the enabled software trigger has occurred.
TRIGn bit	X	X	X	X	X	X	TRIGn bit is cleared when the enabled hardware trigger has occurred.

37.4.12 Deadtime insertion

The deadtime insertion is enabled when ($DTEN = 1$) and ($DTVAL[5:0]$ is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The $DTPS[1:0]$ bits define the prescaler for the system clock and the $DTVAL[5:0]$ bits define the deadtime modulo; that is, the number of deadtime prescaler clocks).

The deadtime delay insertion ensures that no two complementary signals (channel (n) and (n+1)) drive the active state at the same time.

For $POL(n) = 0$, $POL(n+1) = 0$, and deadtime enabled, a rising edge on the output of channel (n) remains low for the duration of the deadtime delay, after which the rising edge appears on the output. Similarly, when a falling edge is due on the output of channel (n), the channel (n+1) output remains low for the duration of the deadtime delay, after which the channel (n+1) output will have a rising edge.

For $POL(n) = 1$, $POL(n+1) = 1$, and deadtime enabled, a falling edge on the output of channel (n) remains high for the duration of the deadtime delay, after which the falling edge appears on the output. Similarly, when a rising edge is due on the output of channel (n), the channel (n+1) output remains high for the duration of the deadtime delay, after which the channel (n+1) output will have a falling edge.

Figure 37-194. Deadtime insertion with $ELSnB:ELSnA = 1:0$, $POL(n) = 0$, and $POL(n+1) = 0$

Figure 37-195. Deadtime insertion with $ELSnB:ELSnA = X:1$, $POL(n) = 0$, and $POL(n+1) = 0$

NOTE

Deadtime feature is available only in combine and complementary modes.

37.4.12.1 Deadtime insertion corner cases

If (PS[2:0] bits are cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ($(C(n+1)VH:L - C(n)VH:L) \times \text{system clock}$), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ($(MODH:L - CNTINH:L + 1 - (C(n+1)VH:L - C(n)VH:L)) \times \text{system clock}$), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

Figure 37-196. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle

Figure 37-197. Example of the deadtime insertion ($ELSnB:ELSnA = 1:0$, $POL(n) = 0$, and $POL(n+1) = 0$) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle

37.4.13 Output mask

The output mask register OUTMASK can be used to force channel outputs to their inactive state through software; for example, to control a BLDC motor.

Any write to a CHnOM bit updates the OUTMASK write buffer. The CHnOM bit is updated with the value of its corresponding bit in the OUTMASK write buffer according to [OUTMASK register synchronization](#).

If CHnOM = 1, then the channel (n) output is forced to its inactive state, defined by the POLn bit in register POL. If CHnOM = 0, then the channel (n) output is unaffected by the output mask function.

When a CHnOM bit is cleared, the channel (n) output is enabled. See the following figure.

Figure 37-198. Output mask

The following table shows the output mask result before the polarity control.

Table 37-189. Output mask result for channel (n) before the polarity control

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	

Note

Output mask is available only in combine mode.

37.4.14 Fault control

The fault control is enabled if (FTMEN = 1) and (FAULTM[1:0] ≠ 0:0).

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter

is reset and starts counting up. As long as the new state is stable on the fault input n, the counter continues to increment. If the 5-bit counter overflows and exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits (\times system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case the fault input n signal is delayed two rising edges of the system clock and the FAULTFn bit is set on the third rising edge of the system clock after a rising edge occurs on the fault input n.

If FFVAL[3:0] \neq 0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock; that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

* where n = 3, 2, 1, 0

Figure 37-199. Fault input n control block diagram

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, then the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

Figure 37-200. FAULTF and FAULTIN bits and fault interrupt

Functional Description

If the fault control is enabled ($FAULTM[1:0] \neq 0:0$), a fault condition has occurred (rising edge at the logic OR of the enabled fault input) and ($FAULTEN = 1$), then channel (n) and (n+1) outputs are forced to their safe value (that is, the channel (n) output is forced to the value of $POL(n)$ and the channel (n+1) is forced to the value of $POL(n+1)$).

The fault interrupt is generated when ($FAULTF = 1$) and ($FAULTIE = 1$). This interrupt request remains set until:

- Software clears the $FAULTF$ bit (by reading $FAULTF$ bit as 1 and writing 0 to it)
- Software clears the $FAULTIE$ bit
- A reset occurs

Note

Fault control is available only in combine mode.

37.4.14.1 Automatic fault clearing

If the automatic fault clearing is selected ($FAULTM[1:0] = 1:1$), then the disabled channel outputs are enabled when the fault input signal ($FAULTIN$) returns to zero and a new PWM cycle begins. See the following figure.

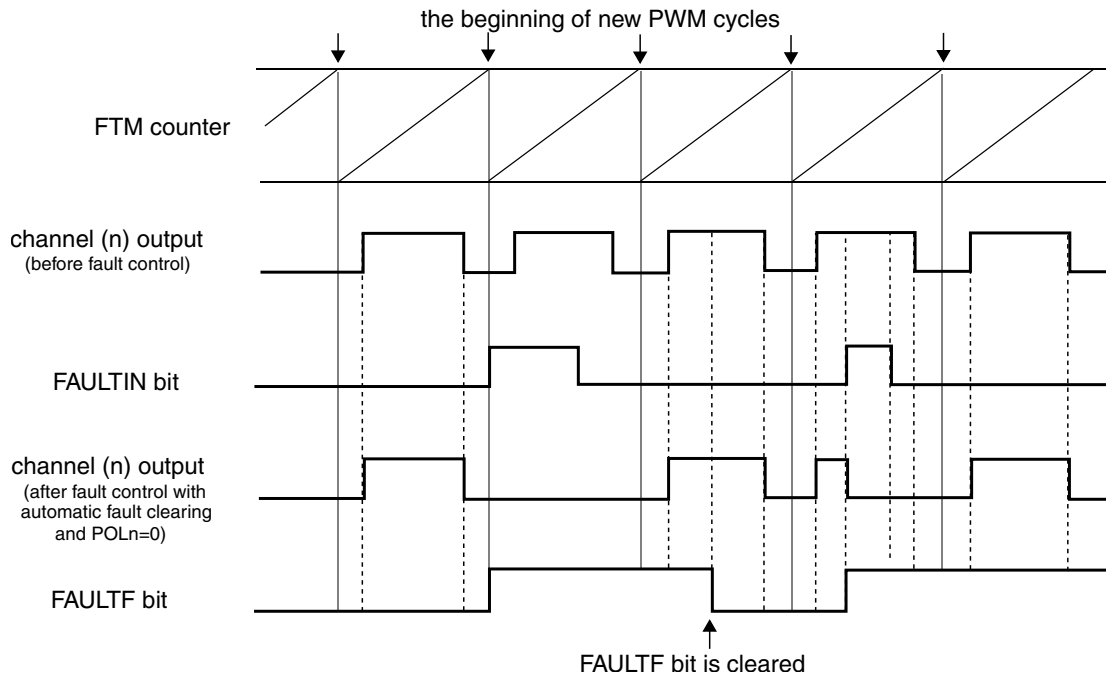

Figure 37-201. Fault control with automatic fault clearing

37.4.14.2 Manual fault clearing

If the manual fault clearing is selected ($\text{FAULTM}[1:0] = 0:1$ or $1:0$), then disabled channel outputs are enabled when the FAULTF bit is cleared and a new PWM cycle begins. See the following figure.

It is possible to manually clear a fault by clearing the FAULTF bit, and enable disabled channels regardless of the fault input signal (FAULTIN) (the filter output if the filter is enabled or the synchronizer output if the filter is disabled). However, it is recommended to verify the value of the fault input signal (value of the FAULTIN bit) before clearing the FAULTF bit to avoid unpredictable results.

Figure 37-202. Fault control with manual fault clearing

37.4.15 Polarity control

The POLn bit selects the channel (n) output polarity:

- If ($\text{POLn} = 0$), the channel (n) output polarity is active-high: one is the active state; zero is the inactive state.
- If ($\text{POLn} = 1$), the channel (n) output polarity is active-low: zero is the active state; one is the inactive state.

Note

Polarity control is available only in combine mode.

37.4.16 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

Note

- It is recommended to use the initialization only when the FTM counter is disabled (CLKS[1:0] = 0:0).
- Initialization is available only in combine mode.

37.4.17 Features priority

The following figure shows the priority of the features that can be combined to generate channel (n) and (n+1) outputs.

Figure 37-203. FTM features priority

37.4.18 Channel trigger output

The channel trigger output is generated if (FTMEN = 1) and one or more channels were selected by the CHjTRIG bit, where j = 0, 1, 2, 3, 4, or 5. The CHjTRIG bit defines if the channel (j) match (that is, FTM counter = C(j)VH:L) generates the trigger.

The channel trigger output provides a trigger signal that is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

Figure 37-204. Match triggers

Note

Match trigger is available only in combine mode.

37.4.19 Initialization trigger

If INITTRIGEN = 1, the FTM generates a trigger when the FTM counter is updated with the CNTINH:L registers value in the following cases:

- The FTM counter is automatically updated with the CNTINH:L registers value by selected counting mode.

CNTINH:L = 0x0000
 MODH:L = 0x000F
 CPWMS = 0

Figure 37-205. Initialization trigger is generated when the FTM counter achieves the value of CNTINH:L

Functional Description

- When there is a write to CNTH or CNTL register

CNTINH:L = 0x0000
 MODH:L = 0x000F
 CPWMS = 0

Figure 37-206. Initialization trigger is generated when there is a write to CNTH or CNTL

- When there is the **FTM counter synchronization**

CNTINH:L = 0x0000
 MODH:L = 0x000F
 CPWMS = 0
 REINIT = 1

Figure 37-207. Initialization trigger is generated when there is the FTM counter synchronization

- If (CNTH:L = CNTINH:L), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits

CNTINH:L = 0x0000
 MODH:L = 0x000F
 CPWMS = 0

Figure 37-208. Initialization trigger is generated if (CNTH:L = CNTINH:L) and (CLKS[1:0] = 0:0) and a value different from zero is written to CLKS[1:0] bits

The initialization trigger output provides a trigger signal that is used for on-chip modules.

Note

Initialization trigger is available only in combine mode.

37.4.20 Capture test mode

The capture test mode allows the testing of the CnVH:L registers, the FTM counter, and the interconnection logic between the FTM counter and CnVH:L registers.

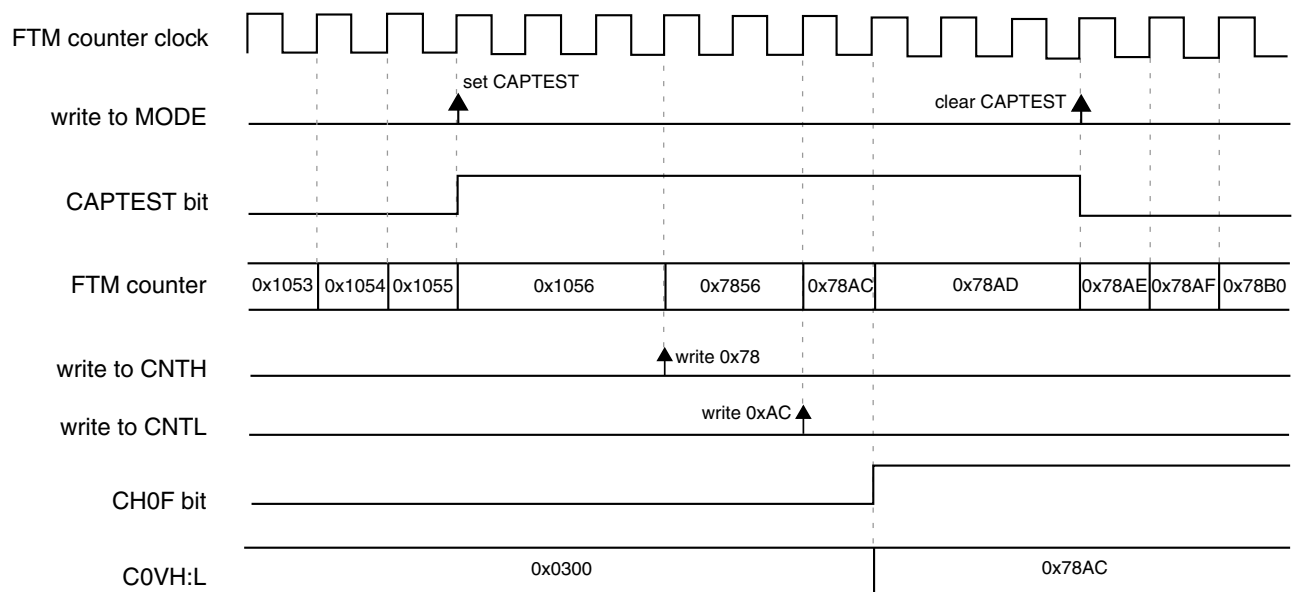

In this test mode, all channels must be configured for input capture mode (see [Input capture mode](#)) and FTM counter must be configured for up-counting (see [Up counting](#)).

When the capture test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNTH and CNTL updates directly the FTM counter; see the following figure. After both bytes were written, independent of the order, all CnVH:L registers are updated with the value that was written to CNTH:L registers and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTINH:L, MODH:L, and the value that was written to FTM counter.

The next reads of CnVH:L registers return the value that was written to FTM counter and the next reads of CNTH:L register return the next value of the FTM counter.

The read coherency mechanism of CNTH:L and CnVH:L registers remains enabled.

Functional Description

Notes

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0) if the quadrature decoder feature is supported, (CAPTEST = 1), (CPWMS = 0), (CNTINH:L = 0x0000), and (MODH:L = 0xFFFF)
- FTM channel n configuration: input capture mode – (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 37-209. Capture test mode

37.4.21 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits (see the following table).

Table 37-190. Channel DMA Transfer Request

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a logic 0 to CHnF bit according to CHnIE bit (see the following table).

Table 37-191. Clear CHnF Bit when DMA = 1

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either by the channel DMA transfer done or reading CnSC while CHnF is set and then writing a logic 0 to CHnF bit.
1	CHnF bit is cleared by the channel DMA transfer done.

37.4.22 Dual edge capture mode

The dual edge capture mode is selected if $FTMEN = 1$ and $DECAPEN = 1$. This mode allows software to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is the channels 0 or 2.

* Filtering function for dual edge capture mode is only available in the channels 0 and 2

Figure 37-210. Dual edge capture mode block diagram

The $MS(n)A$ bit defines if the dual edge capture mode is one-shot or continuous according to table "Mode, Edge, and Level Selection".

The $ELS(n)B:ELS(n)A$ bits select the edge that is captured by channel (n), and $ELS(n+1)B:ELS(n+1)A$ bits select the edge that is captured by channel (n+1) as described in table "Dual Edge Capture Mode — Edge Polarity Selection". If both $ELS(n)B:ELS(n)A$ and $ELS(n+1)B:ELS(n+1)A$ bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the dual edge capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)VH:L registers store the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)VH:L registers store the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, the coherency mechanism of the pair of channels ensures that data is coherent when the C(n)VH:L and C(n+1)VH:L registers are read. Note that the C(n)VH:L registers must be read first before reading the C(n+1)VH:L registers. C(n)VH:L registers must be read first than C(n+1)VH:L registers.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- It is expected that the dual edge capture mode be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in free running counter mode. See [Free running counter](#).

37.4.22.1 One-shot capture mode

The one-shot capture mode is selected when (FTMEN = 1), (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in one-shot capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)VH:L and C(n+1)VH:L registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)VH:L and C(n+1)VH:L registers.

37.4.22.2 Continuous capture mode

The continuous capture mode is selected when (FTMEN = 1), (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges are captured and the captured values are ready for reading in the C(n)VH:L and C(n+1)VH:L registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)VH:L and C(n+1)VH:L registers.

For a new sequence of the measurements in the dual edge capture – continuous mode, it is recommended to clear the CH(n)F and CH(n+1)F bits to start new measurements.

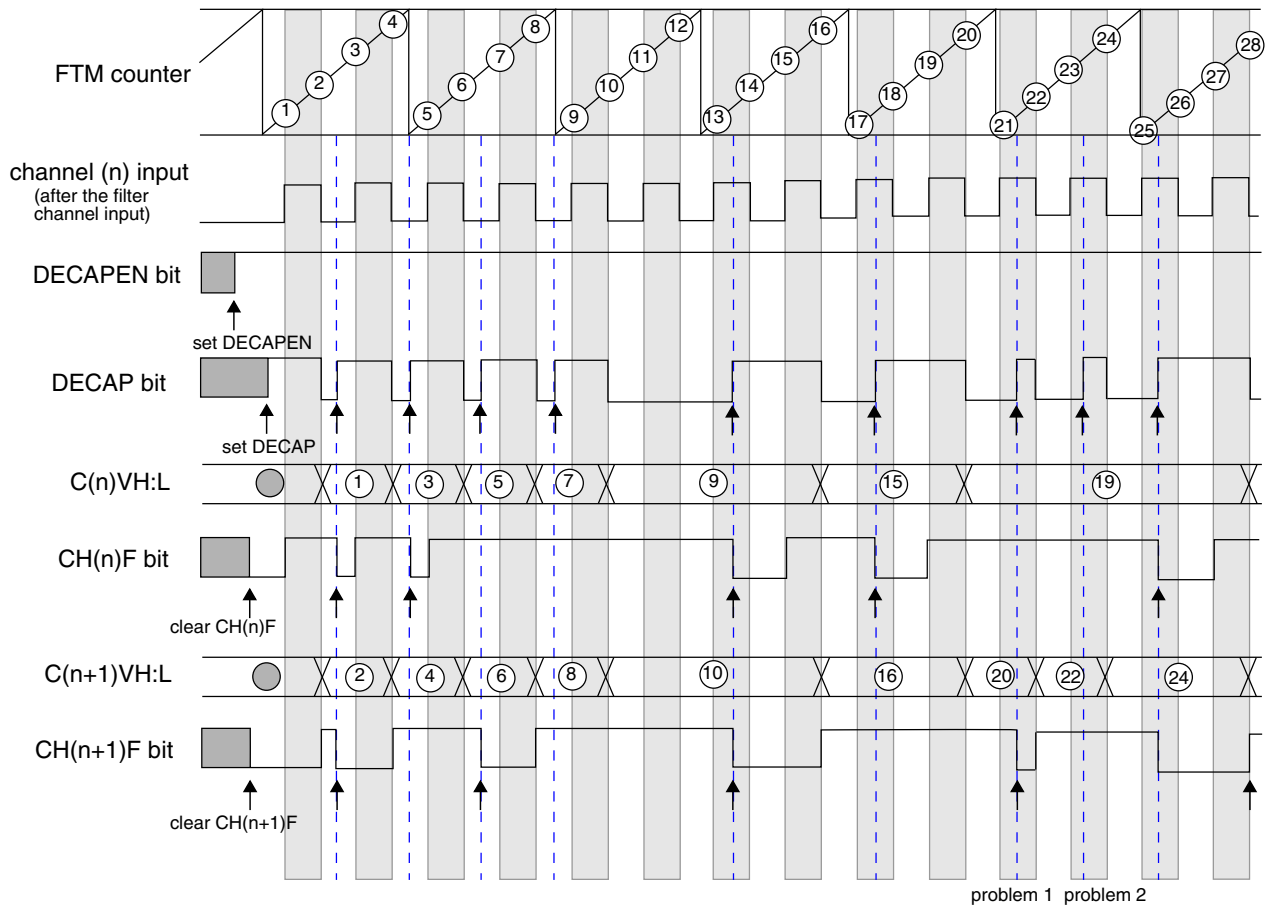

37.4.22.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n+1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in one-shot capture mode ([One-shot capture mode](#)) or continuous capture mode ([Continuous capture mode](#)).

The following figure shows an example of the dual edge capture – one-shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the dual edge capture mode. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)VH:L and C(n+1)VH:L registers are ready for reading.

Functional Description

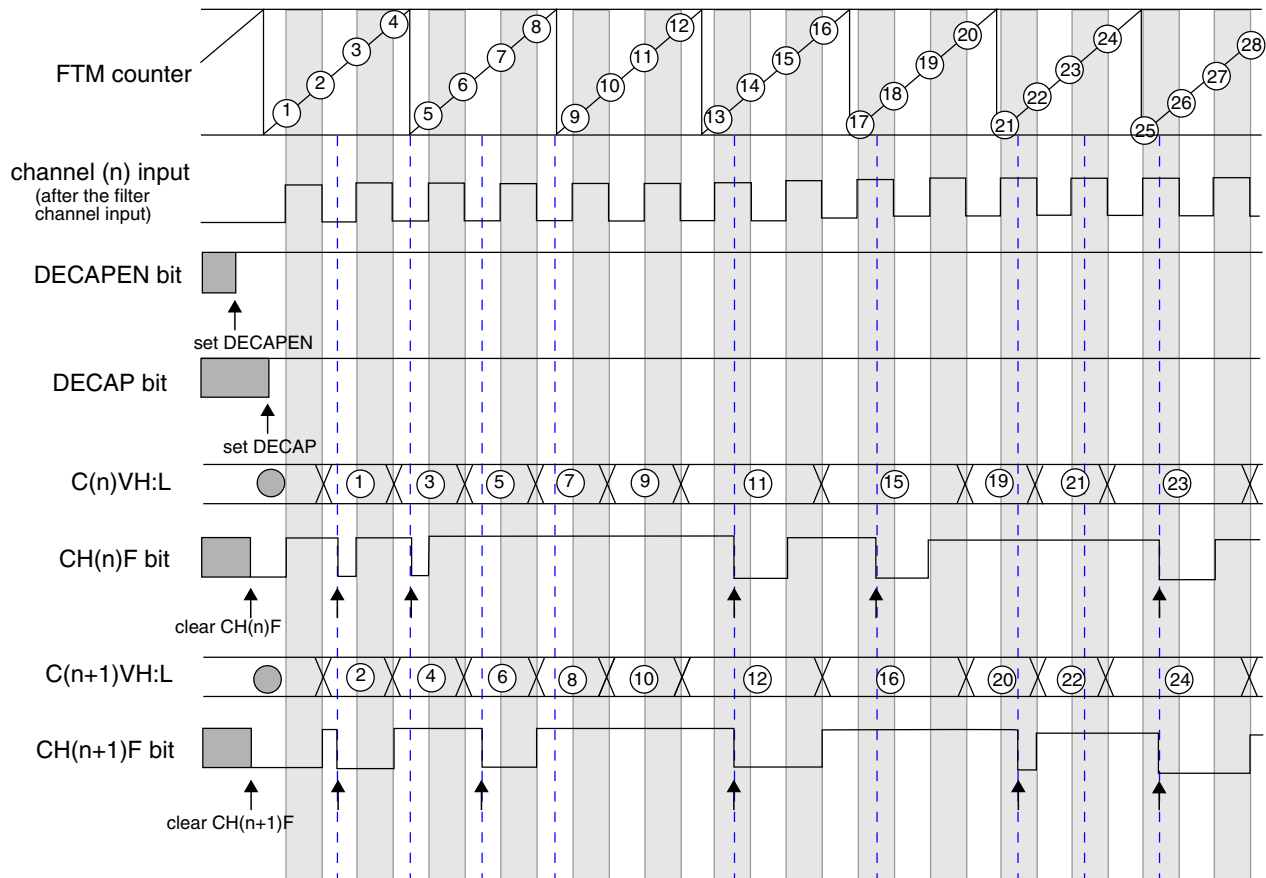

Note:

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 37-211. Dual edge capture – one-shot mode for positive polarity pulse width measurement

The following figure shows an example of the dual edge capture – continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the dual edge capture mode, so it keeps set in all operation mode. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)VH:L and C(n+1)VH:L registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 37-212. Dual edge capture – continuous mode for positive polarity pulse width measurement

37.4.22.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ($ELS(n)B:ELS(n)A = 0:1$ and $ELS(n+1)B:ELS(n+1)A = 0:1$), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ($ELS(n)B:ELS(n)A = 1:0$ and $ELS(n+1)B:ELS(n+1)A = 1:0$), then the period between two consecutive falling edges is measured.

The period measurement can be made in one-shot capture mode ([One-shot capture mode](#)) or continuous capture mode ([Continuous capture mode](#)).

The following figure shows an example of the dual edge capture – one-shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the dual edge capture mode, so it keeps set in all operation mode. The DECAP bit is set

enable the measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)VH:L and C(n+1)VH:L registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 37-213. Dual edge capture – one-shot mode to measure of the period between two consecutive rising edges

The following figure shows an example of the dual edge capture – continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the dual edge capture mode, so it keeps set in all operation mode. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit

is set when the second rising edge is detected, that is, the edge selected by $ELS(n+1)B:ELS(n+1)A$ bits. The $CH(n+1)F$ bit indicates when two edges of the period were captured and the $C(n)VH:L$ and $C(n+1)VH:L$ registers are ready for reading.

Note:

- The commands set DECAPEN, set DECAP, clear $CH(n)F$, and clear $CH(n+1)F$ are made by the user.

Figure 37-214. Dual edge capture – continuous mode to measure of the period between two consecutive rising edges

37.4.22.5 Read coherency mechanism

The dual edge capture mode implements a read coherency mechanism between the FTM counter value captured in $C(n)VH:L$ and $C(n+1)VH:L$ registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in dual edge capture – continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)VH:L registers when a falling edge occurs in the channel (n) input signal. C(n)VH:L registers have the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a negative edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)VH:L registers when the first byte of C(n)VH:L registers is read.

In the following figure, the read of C(n)VH returns the FTM counter high byte value when the event 1 occurred, and the read of C(n+1)VL returns the FTM counter low byte value when the event 1 occurred. The read of C(n+1)VL returns the FTM counter low byte value when the event 2 occurred, and the read of C(n+1)VH returns the FTM counter high byte value when the event 2 occurred.

Figure 37-215. Dual edge capture mode read coherency mechanism

C(n)VH:L registers must be read prior to C(n+1)VH:L registers in dual edge capture oneshot and continuous modes for the read coherency mechanism works properly. Either the high or low bytes of C(n)VH:L and C(n+1)VH:L registers can be accessed first; however, the C(n)VH:L registers must be read prior to the C(n+1)VH:L registers in dual edge capture oneshot and continuous modes for the read coherency mechanism to work properly.

37.4.23 Quadrature Decoder Mode

The quadrature decoder mode is selected if $FTMEN = 1$ and $QUADEN = 1$ (when the quadrature decoder feature is supported). The quadrature decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure is the quadrature decoder block diagram.

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input ([Filter for input capture mode](#)). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits of FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits of FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in quadrature decoder mode.

Figure 37-216. Quadrature Decoder Block Diagram

Note

It is important to notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the quadrature decoder be used only with the FTM channels in input capture or output compare modes.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

Functional Description

The QUADMODE selects the encoding mode used in the quadrature decoder mode. If QUADMODE = 1, then the count and direction encoding mode (refer to the following figure) is enabled. In this mode, the phase B input value indicates the counting direction (FTM counter increment or decrement), and the phase A input defines the counting rate (FTM counter is updated when there is a rising edge at phase A input signal).

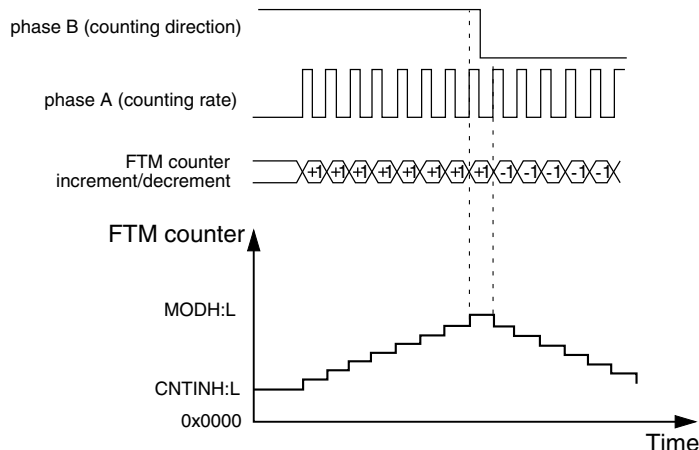

Figure 37-217. Quadrature Decoder – Count and Direction Encoding Mode

If QUADMODE = 0, then the phase A and phase B encoding mode (refer to the following figure) is enabled. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate (FTM counter is updated when there is an edge either at the phase A or phase B signals).

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

Figure 37-218. Quadrature Decoder – Phase A and Phase B Encoding Mode

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MODH:L to CNTINH:L, the TOF and TOFDIR bits are set. The TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

Figure 37-219. FTM Counter Overflow in Up Counting for Quadrature Decoder Mode

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTINH:L to MODH:L, the TOF bit is set and the TOFDIR bit is cleared. The TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

Functional Description

Figure 37-220. FTM Counter Overflow in Down Counting for Quadrature Decoder Mode

37.4.23.1 Quadrature Decoder Boundary Conditions

The following two figures illustrate examples of motor jittering that cause FTM counter transitions. Motor position control applications are expected to observe these behaviors.

Figure 37-221. Motor Position Jittering in a Mid Count Value

The following figure shows motor jittering produced by the phase B and A pulses, respectively. The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MODH:L). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values, which are defined by the MODH:L and CNTINH:L registers.

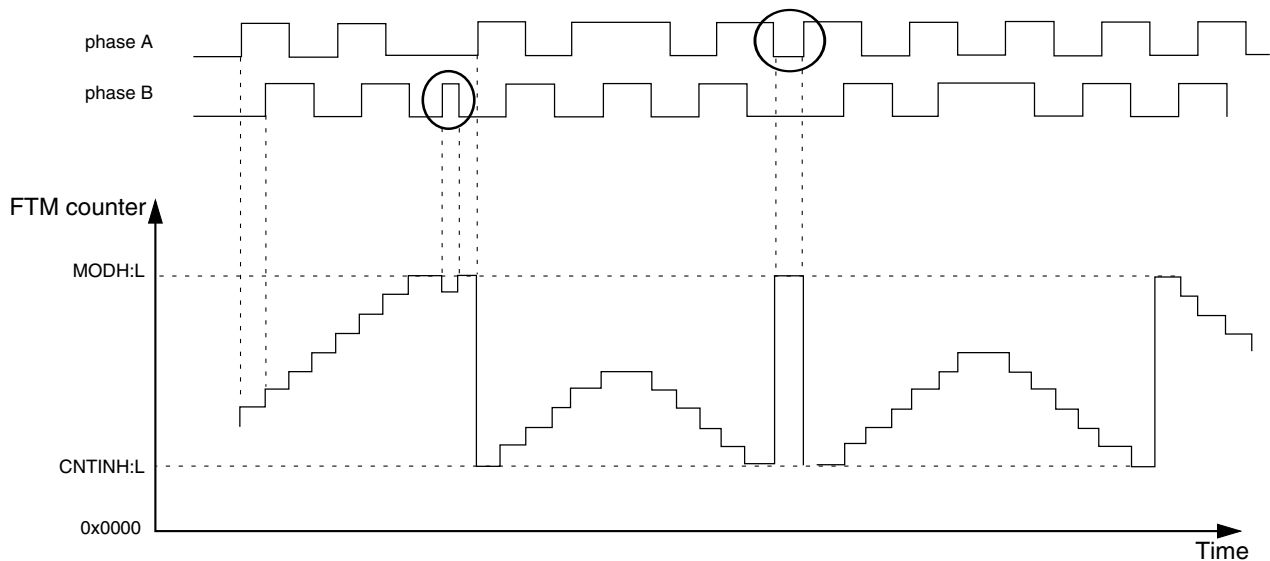

Figure 37-222. Motor Position Jittering Near Maximum and Minimum Count Value

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The two preceding figures show examples of oscillations that can be caused by poor input filter setup. To avoid these oscillations, guarantee a minimum pulse width.

37.4.24 TPM emulation

This section describe the FTM features that are selected according to the FTMEN bit.

37.4.24.1 MODH:L and CnVH:L synchronization

If (FTMEN = 0), then the MODH:L and CnVH:L registers are updated according to the [Update of the registers with write buffers](#) and they are not updated by PWM synchronization.

If (FTMEN = 1), then the MODH:L and CnVH:L registers are updated only by PWM synchronization ([PWM synchronization](#)).

37.4.24.2 Free running counter

If (FTMEN = 0), then the FTM counter is a free running counter when (MODH:L = 0x0000) or (MODH:L = 0xFFFF).

If (FTMEN = 1), then the FTM counter is a free running counter when (CPWMS = 0), (CNTINH:L = 0x0000), and (MODH:L = 0xFFFF).

37.4.24.3 Write to SC

If (FTMEN = 0), then a write to the SC register resets the write coherency mechanism of MODH:L registers.

If (FTMEN = 1), then a write to the SC register does not reset the write coherency mechanism of MODH:L registers.

37.4.24.4 Write to CnSC

If (FTMEN = 0), then a write to the CnSC register resets the write coherency mechanism of CnVH:L registers.

If (FTMEN = 1), then a write to the CnSC register does not reset the write coherency mechanism of CnVH:L registers.

37.4.25 BDM mode

When BDM mode is active, the FlexTimer counter and the channels output are frozen.

However, the value of FlexTimer counter or the channels output are modified in BDM mode when:

- A write of any value to the CNTH or CNTL registers ([Counter reset](#)) resets the FTM counter to the value of CNTINH:L and the channels output to their initial value, except for channels in output compare mode.
- The PWM synchronization with REINIT = 1 (see [FTM counter synchronization](#)) resets the FTM counter to the value of CNTINH:L registers and the channels output to their initial value, except for channels in output compare mode.
- The initialization ([Initialization](#)) forces the value of the CHnOI bit to the channel (n) output.

Note

Do not use the above cases together with fault control ([Fault control](#)). If fault control is enabled and the fault condition is at the enabled fault input, these cases reset the FTM counter to the CNTINH:L value and the channels output to their initial value.

37.5 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

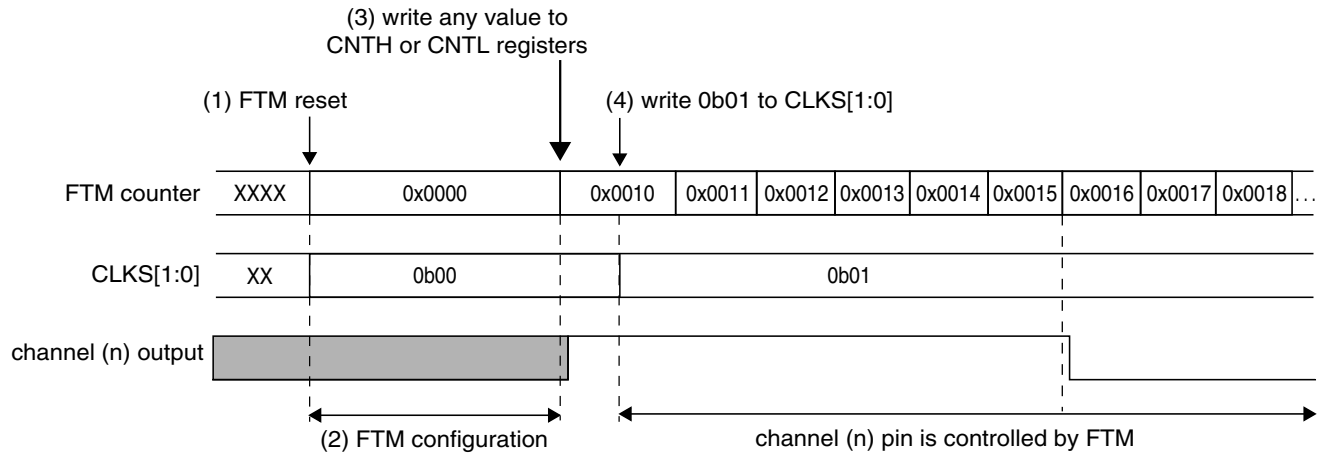

- The FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 0b00)
- The timer overflow interrupt is zero ([Timer overflow interrupt](#))
- The channels interrupts are zero ([Channel \(n\) interrupt](#))
- The fault interrupt is zero ([Fault interrupt](#))
- The channels are in input capture mode ([Input capture mode](#))
- The channels outputs are zero
- The channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0b00). See table "Mode, Edge, and Level Selection"

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see table "FTM Clock Source Selection"), its value is updated to zero and the pins are not controlled by FTM (table "Mode, Edge, and Level Selection").

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MODH:L and CNTINH:L registers value), the channels mode and CnVH:L registers value according to the channels mode.

Because of this, you should write any value to CNTH or CNTL registers (item 3). This write updates the FTM counter with the value of CNTINH:L and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are controlled only by FTM when CLKS[1:0] bits are different from zero (table "Mode, Edge, and Level Selection").

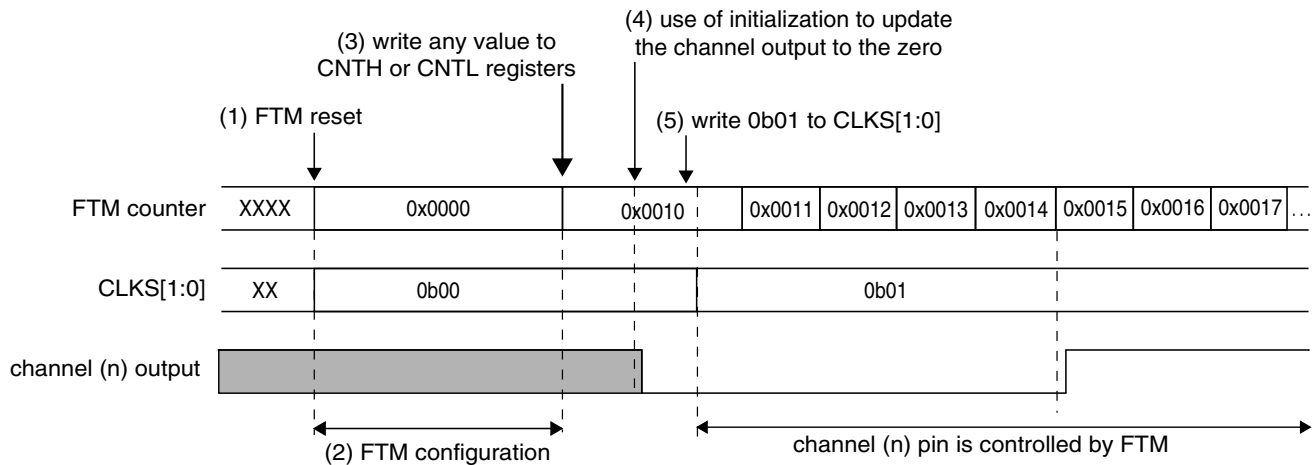

Note

- CNTINH:L = 0x0010
- Channel (n) is in low-true combine mode with CNTINH:L < C(n)VH:L < C(n+1)VH:L < MODH:L
- C(n)VH:L = 0x0015

Figure 37-223. FTM behavior after the reset when the channel (n) is in combine mode

The following figure shows an example when the channel (n) is in output compare mode and the channel (n) output is toggled when there is a match. In the output compare mode, the channel output is not updated to its initial value when there is a write to CNTH or CNTL registers (item 3). In this case, it is recommended to use the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

Note

- CNTINH:L = 0x0010
- Channel (n) is in output compare and the channel (n) output is toggled when there is a match
- C(n)VH:L = 0x0014

Figure 37-224. FTM behavior after the reset when the channel (n) is in output compare mode

37.6 FTM Interrupts

37.6.1 Timer overflow interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

37.6.2 Channel (n) interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

37.6.3 Fault interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

Chapter 38

Serial Peripheral Interface (SPI)

38.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The serial peripheral interface (SPI) module provides for full-duplex, synchronous, serial communication between the MCU and peripheral devices. These peripheral devices can include other microcontrollers, analog-to-digital converters, shift registers, sensors, and memories, among others.

The SPI runs at a baud rate up to the bus clock divided by two in master mode and up to the bus clock divided by four in slave mode. Software can poll the status flags, or SPI operation can be interrupt driven.

NOTE

For the actual maximum SPI baud rate, refer to the Chip Configuration details and to the device's Data Sheet.

The SPI also supports a data length of 8 or 16 bits and includes a hardware match feature for the receive data buffer.

The SPI includes an internal DMA interface to support continuous SPI transmission through an on-chip DMA controller instead of through the CPU. This feature decreases CPU loading, allowing CPU time to be used for other work.

38.1.1 Features

The SPI includes these distinctive features:

- Master mode or slave mode operation

- Full-duplex or single-wire bidirectional mode
- Programmable transmit bit rate
- Double-buffered transmit and receive data register
- Serial clock phase and polarity options
- Slave select output
- Mode fault error flag with CPU interrupt capability
- Control of SPI operation during wait mode
- Selectable MSB-first or LSB-first shifting
- Programmable 8- or 16-bit data transmission length
- Receive data buffer hardware match feature
- 64-bit FIFO mode for high speed/large amounts of data transfers
- Support transmission of both Transmit and Receive by DMA

38.1.2 Modes of Operation

The SPI functions in three modes, run, wait, and stop.

- Run Mode

This is the basic mode of operation.

- Wait Mode

SPI operation in wait mode is a configurable low power mode, controlled by the SPISWAI bit located in the SPIx_C2 register. In wait mode, if the SPISWAI bit is clear, the SPI operates like in Run Mode. If the SPISWAI bit is set, the SPI goes into a power conservative state, with the SPI clock generation turned off. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU enters run mode. If the SPI is configured as a slave, reception and transmission of a byte continues, so that the slave stays synchronized to the master.

- Stop Mode

To reduce power consumption, the SPI is inactive in stop modes where the peripheral bus clock is stopped but internal logic states are retained. If the SPI is configured as a master, any transmission in progress stops, but is resumed after the CPU enters run mode. If the SPI is configured as a slave, reception and transmission of a data continues, so that the slave stays synchronized to the master.

The SPI is completely disabled in stop modes where the peripheral bus clock is stopped and internal logic states are not retained. When the CPU wakes from these stop modes, all SPI register content is reset.

Detailed descriptions of operating modes appear in [Low Power Mode Options](#).

38.1.3 Block Diagrams

This section includes block diagrams showing SPI system connections, the internal organization of the SPI module, and the SPI clock dividers that control the master mode bit rate.

38.1.3.1 SPI System Block Diagram

The following figure shows the SPI modules of two MCUs connected in a master-slave arrangement. The master device initiates all SPI data transfers. During a transfer, the master shifts data out (on the MOSI pin) to the slave while simultaneously shifting data in (on the MISO pin) from the slave. The transfer effectively exchanges the data that was in the SPI shift registers of the two SPI systems. The SPSCK signal is a clock output from the master and an input to the slave. The slave device must be selected by a low level on the slave select input (SS pin). In this system, the master device has configured its SS pin as an optional slave select output.

Figure 38-1. SPI System Connections

38.1.3.2 SPI Module Block Diagram

The following is a block diagram of the SPI module. The central element of the SPI is the SPI shift register. Data is written to the double-buffered transmitter (write to SPIx_DH:SPIx_DL) and gets transferred to the SPI shift register at the start of a data transfer. After shifting in 8 bits or 16 bits (as determined by the SPIMODE bit) of data, the data is transferred into the double-buffered receiver where it can be read from SPIx_DH:SPIx_DL. Pin multiplexing logic controls connections between MCU pins and the SPI module.

When the FIFO feature is supported: Additionally there is an 8-byte receive FIFO and an 8-byte transmit FIFO that (once enabled) provide features to allow fewer CPU interrupts to occur when transmitting/receiving high volume/high speed data. When FIFO mode is enabled, the SPI can still function in either 8-bit or 16-bit mode (as per SPIMODE bit) and three additional flags help monitor the FIFO status. Two of these flags can provide CPU interrupts.

When the SPI is configured as a master, the clock output is routed to the SPSCK pin, the shifter output is routed to MOSI, and the shifter input is routed from the MISO pin.

When the SPI is configured as a slave, the SPSCK pin is routed to the clock input of the SPI, the shifter output is routed to MISO, and the shifter input is routed from the MOSI pin.

In the external SPI system, simply connect all SPSCK pins to each other, all MISO pins together, and all MOSI pins together. Peripheral devices often use slightly different names for these pins.

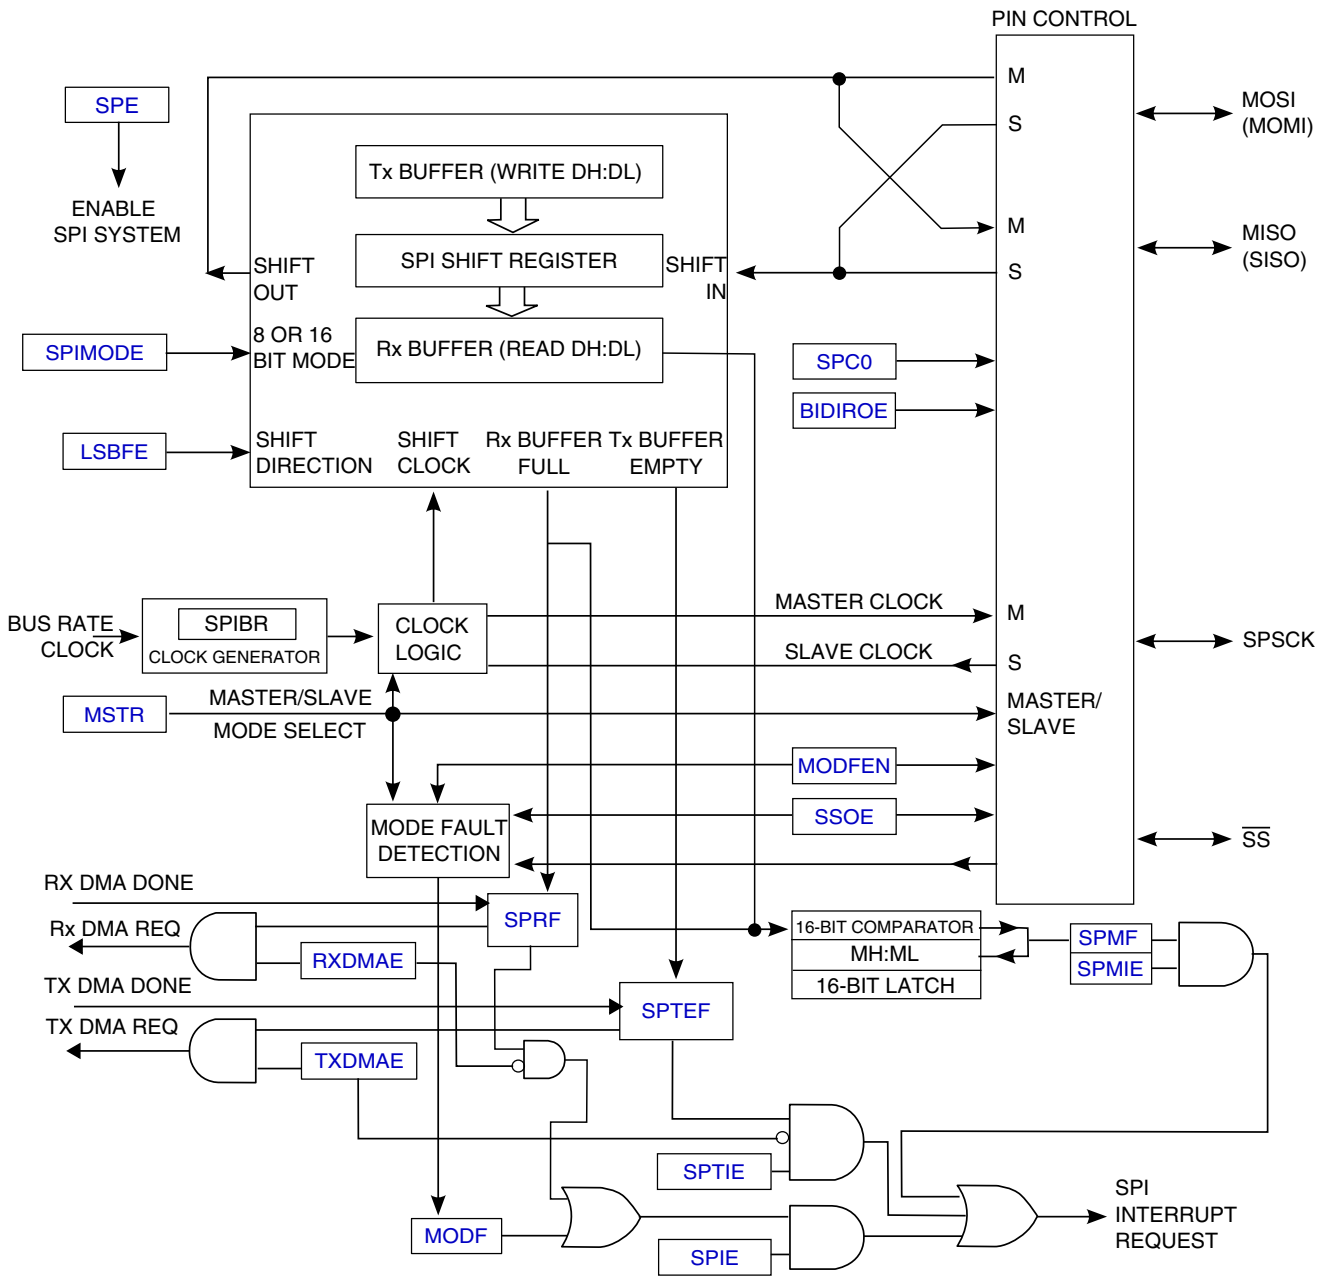

Figure 38-2. SPI Module Block Diagram without FIFO

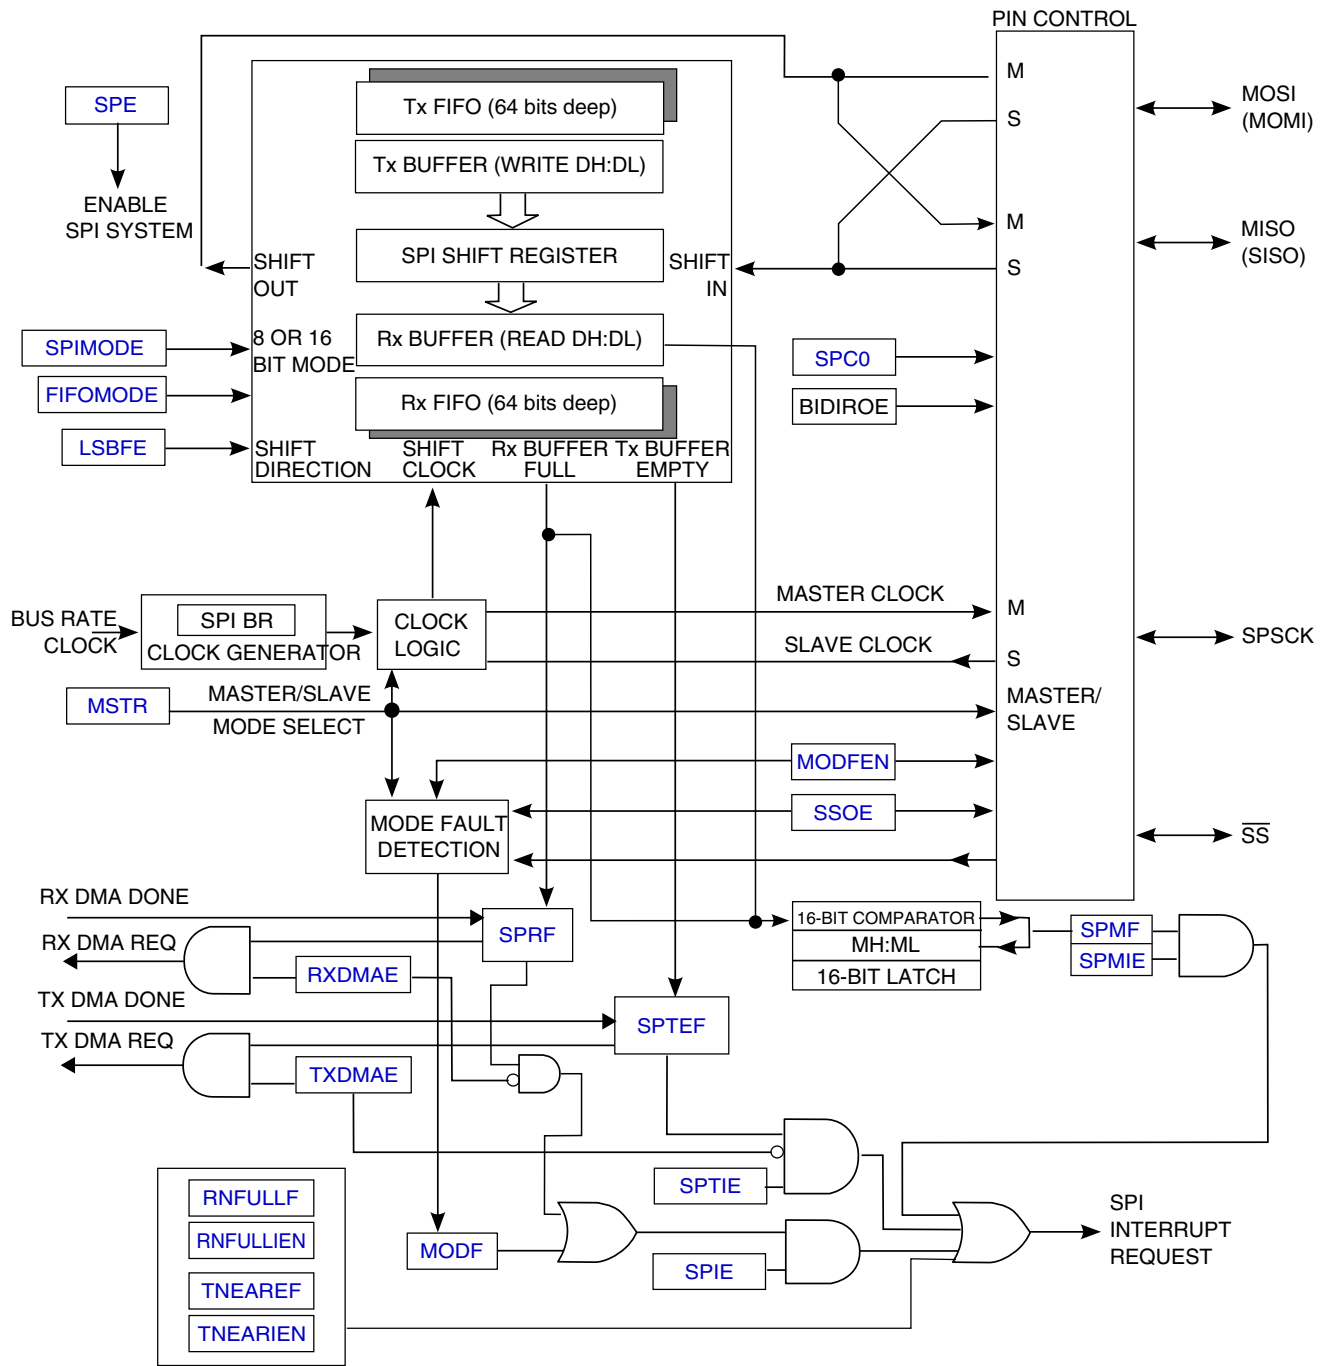

Figure 38-3. SPI Module Block Diagram with FIFO

38.2 External Signal Description

The SPI optionally shares four port pins. The function of these pins depends on the settings of SPI control bits. When the SPI is disabled ($SPE = 0$), these four pins revert to other functions that are not controlled by the SPI (based on chip configuration).

38.2.1 SPCK — SPI Serial Clock

When the SPI is enabled as a slave, this pin is the serial clock input. When the SPI is enabled as a master, this pin is the serial clock output.

38.2.2 MOSI — Master Data Out, Slave Data In

When the SPI is enabled as a master and SPI pin control zero (SPC0) is 0 (not bidirectional mode), this pin is the serial data output. When the SPI is enabled as a slave and SPC0 is 0, this pin is the serial data input. If SPC0 is 1 to select single-wire bidirectional mode, and master mode is selected, this pin becomes the bidirectional data I/O pin (MOMI). Also, the bidirectional mode output enable bit determines whether the pin acts as an input (BIDIROE is 0) or an output (BIDIROE is 1). If SPC0 is 1 and slave mode is selected, this pin is not used by the SPI and reverts to other functions (based on chip configuration).

38.2.3 MISO — Master Data In, Slave Data Out

When the SPI is enabled as a master and SPI pin control zero (SPC0) is 0 (not bidirectional mode), this pin is the serial data input. When the SPI is enabled as a slave and SPC0 is 0, this pin is the serial data output. If SPC0 is 1 to select single-wire bidirectional mode, and slave mode is selected, this pin becomes the bidirectional data I/O pin (SISO), and the bidirectional mode output enable bit determines whether the pin acts as an input (BIDIROE is 0) or an output (BIDIROE is 1). If SPC0 is 1 and master mode is selected, this pin is not used by the SPI and reverts to other functions (based on chip configuration).

38.2.4 \overline{SS} — Slave Select

When the SPI is enabled as a slave, this pin is the low-true slave select input. When the SPI is enabled as a master and mode fault enable is off (MODFEN is 0), this pin is not used by the SPI and reverts to other functions (based on chip configuration). When the SPI is enabled as a master and MODFEN is 1, the slave select output enable bit determines whether this pin acts as the mode fault input (SSOE is 0) or as the slave select output (SSOE is 1).

38.3 Memory Map and Register Descriptions

The SPI has 8-bit registers to select SPI options, to control baud rate, to report SPI status, to hold an SPI data match value, and for transmit/receive data.

SPI memory map

Address offset (hex)	Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	FFFF_81A0	SPI control register 1 (SPI0_C1)	8	R/W	04h	38.3.1/865

1000	Baud rate divisor is 512
All others	Reserved

38.3.4 SPI status register (SPIx_S)

This register contains read-only status bits. Writes have no meaning or effect.

NOTE

When the FIFO is not supported or not enabled (FIFOMODE is not present or is 0): Bits 3 through 0 are not implemented and always read 0.

When the FIFO is supported and enabled (FIFOMODE is 1): This register has four flags that provide mechanisms to support an 8-byte FIFO mode: RNFULLF, TNEARF, TXFULLF, and RFIFOEF. When the SPI is in 8-byte FIFO mode, the function of SPRF and SPTEF differs slightly from their function in the normal buffered modes, mainly regarding how these flags are cleared by the amount available in the transmit and receive FIFOs.

- The RNFULLF and TNEAREF help improve the efficiency of FIFO operation when transferring large amounts of data. These flags provide a "watermark" feature of the FIFOs to allow continuous transmissions of data when running at high speed.
- The RNFULLF can generate an interrupt if the RNFULLIEN bit in the C3 register is set, which allows the CPU to start emptying the receive FIFO without delaying the reception of subsequent bytes. The user can also determine if all data in the receive FIFO has been read by monitoring the RFIFOEF.
- The TNEAREF can generate an interrupt if the TNEARIEN bit in the C3 register is set, which allows the CPU to start filling the transmit FIFO before it is empty and thus to prevent breaks in SPI transmission.

NOTE

At an initial POR, the values of TNEAREF and RFIFOEF are 0. However, the status (S) register and both TX and RX FIFOs are reset due to a change of SPIMODE, FIFOMODE or SPE. If

Memory Map and Register Descriptions

this type of reset occurs and FIFOMODE is 0, TNEAREF and RFIFOEF continue to reset to 0. If this type of reset occurs and FIFOMODE is 1, TNEAREF and RFIFOEF reset to 1.

SPI0_S field descriptions

Field	Description
7 SPRF	<p>SPI read buffer full flag (when FIFO is not supported or not enabled) or SPI read FIFO FULL flag (when FIFO is supported and enabled)</p> <p>When the FIFO is not supported or not enabled (FIFOMODE is not present or is 0): SPRF is set at the completion of an SPI transfer to indicate that received data may be read from the SPI data (DH:DL) register. When the receive DMA request is disabled (RXDMAE is 0), SPRF is cleared by reading SPRF while it is set and then reading the SPI data register. When the receive DMA request is enabled (RXDMAE is 1), SPRF is automatically cleared when the DMA transfer for the receive DMA request is completed (RX DMA Done is asserted).</p> <p>When FIFOMODE is 1: This bit indicates the status of the read FIFO when FIFOMODE is enabled. The SPRF is set when the read FIFO has received 64 bits (4 words or 8 bytes) of data from the shifter and there have been no CPU reads of the SPI data (DH:DL) register. When the receive DMA request is disabled (RXDMAE is 0), SPRF is cleared by reading the SPI data register, which empties the FIFO assuming another SPI message is not received. When the receive DMA request is enabled (RXDMAE is 1), SPRF is automatically cleared when the DMA transfer for the receive DMA request is completed (RX DMA Done is asserted).</p> <p>0 No data available in the receive data buffer (when FIFOMODE is not present or is 0) or Read FIFO is not full (when FIFOMODE is 1)</p> <p>1 Data available in the receive data buffer (when FIFOMODE is not present or is 0) or Read FIFO is full (when FIFOMODE is 1)</p>
6 SPMF	<p>SPI match flag</p> <p>SPMF is set after SPRF is 1 when the value in the receive data buffer matches the value in the MH:ML registers. To clear the flag, read SPMF when it is set and then write a 1 to it.</p> <p>0 Value in the receive data buffer does not match the value in the MH:ML registers</p> <p>1 Value in the receive data buffer matches the value in the MH:ML registers</p>
5 SPTEF	<p>SPI transmit buffer empty flag (when FIFO is not supported or not enabled) or SPI transmit FIFO empty flag (when FIFO is supported and enabled)</p> <p>When the FIFO is not supported or not enabled (FIFOMODE is not present or is 0): This bit is set when the transmit data buffer is empty. When the transmit DMA request is disabled (TXDMAE is 0), SPTEF is cleared by reading the S register with SPTEF set and then writing a data value to the transmit buffer at DH:DL. The S register must be read with SPTEF set to 1 before writing data to the DH:DL register; otherwise, the DH:DL write is ignored. When the transmit DMA request is enabled (TXDMAE is 1), SPTEF is automatically cleared when the DMA transfer for the transmit DMA request is completed (TX DMA Done is asserted). SPTEF is automatically set when all data from the transmit buffer transfers into the transmit shift register. For an idle SPI, data written to DH:DL is transferred to the shifter almost immediately so that SPTEF is set within two bus cycles, allowing a second set of data to be queued into the transmit buffer.</p>

Table continues on the next page...

SPI0_S field descriptions (continued)

Field	Description
	<p>After completion of the transfer of the data in the shift register, the queued data from the transmit buffer automatically moves to the shifter, and SPTEF is set to indicate that room exists for new data in the transmit buffer. If no new data is waiting in the transmit buffer, SPTEF simply remains set and no data moves from the buffer to the shifter.</p> <p>When the FIFO is not supported or not enabled (FIFOMODE is not present or is 0): If a transfer does not stop, the last data that was transmitted is sent out again.</p> <p>When the FIFO is supported and enabled (FIFOMODE is 1): This bit provides the status of the FIFO rather than of an 8-bit or a 16-bit buffer. This bit is set when the transmit FIFO is empty. When the transmit DMA request is disabled (TXDMAE is 0), SPTEF is cleared by writing a data value to the transmit FIFO at DH:DL. When the transmit DMA request is enabled (TXDMAE is 1), SPTEF is automatically cleared when the DMA transfer for the transmit DMA request is completed (TX DMA Done is asserted). SPTEF is automatically set when all data from the transmit FIFO transfers into the transmit shift register. For an idle SPI, data written to the DH:DL register is transferred to the shifter almost immediately, so that SPTEF is set within two bus cycles. A second write of data to the DH:DL register clears this SPTEF flag. After completion of the transfer of the data in the shift register, the queued data from the transmit FIFO automatically moves to the shifter, and SPTEF will be set only when all data written to the transmit FIFO has been transferred to the shifter. If no new data is waiting in the transmit FIFO, SPTEF simply remains set and no data moves from the buffer to the shifter.</p> <p>0 SPI transmit buffer not empty (when FIFOMODE is not present or is 0) or SPI FIFO not empty (when FIFOMODE is 1)</p> <p>1 SPI transmit buffer empty (when FIFOMODE is not present or is 0) or SPI FIFO empty (when FIFOMODE is 1)</p>
4 MODF	<p>Master mode fault flag</p> <p>MODF is set if the SPI is configured as a master and the slave select input goes low, indicating some other SPI device is also configured as a master. The \overline{SS} pin acts as a mode fault error input only when MSTR is 1, MODFEN is 1, and SSOE is 0; otherwise, MODF will never be set. MODF is cleared by reading MODF while it is 1 and then writing to the SPI control register 1 (C1).</p> <p>0 No mode fault error</p> <p>1 Mode fault error detected</p>
3 RNFULLF	<p>Receive FIFO nearly full flag</p> <p>This flag is set when more than three 16-bit words or six 8-bit bytes of data remain in the receive FIFO, provided C3[4] is 0, or when more than two 16-bit words or four 8-bit bytes of data remain in the receive FIFO, provided C3[4] is 1. It has no function if FIFOMODE is not present or is 0.</p> <p>0 Receive FIFO has received less than 48 bits (when C3[4] is 0) or less than 32 bits (when C3[4] is 1)</p> <p>1 Receive FIFO has received data of an amount equal to or greater than 48 bits (when C3[4] is 0) or 32 bits (when C3[4] is 1)</p>
2 TNEAREF	<p>Transmit FIFO nearly empty flag</p> <p>This flag is set when only one 16-bit word or two 8-bit bytes of data remain in the transmit FIFO, provided C3[5] is 0, or when only two 16-bit words or four 8-bit bytes of data remain in the transmit FIFO, provided C3[5] is 1. If FIFOMODE is not enabled, ignore this bit.</p> <p>NOTE: At an initial POR, the values of TNEAREF and RFIFOEF are 0. However, the status (S) register and both TX and RX FIFOs are reset due to a change of SPIMODE, FIFOMODE or SPE. If this type of reset occurs and FIFOMODE is 0, TNEAREF and RFIFOEF continue to reset to 0. If this type of reset occurs and FIFOMODE is 1, TNEAREF and RFIFOEF reset to 1.</p>

Table continues on the next page...

SPIO_S field descriptions (continued)

Field	Description
	0 Transmit FIFO has more than 16 bits (when C3[5] is 0) or more than 32 bits (when C3[5] is 1) remaining to transmit 1 Transmit FIFO has an amount of data equal to or less than 16 bits (when C3[5] is 0) or 32 bits (when C3[5] is 1) remaining to transmit
1 TXFULLF	Transmit FIFO full flag This bit indicates the status of the transmit FIFO when FIFOMODE is enabled. This flag is set when there are 8 bytes in the transmit FIFO. If FIFOMODE is not enabled, ignore this bit. 0 Transmit FIFO has less than 8 bytes 1 Transmit FIFO has 8 bytes of data
0 RFIFOEF	SPI read FIFO empty flag This bit indicates the status of the read FIFO when FIFOMODE is enabled. If FIFOMODE is not enabled, ignore this bit. NOTE: At an initial POR, the values of TNEAREF and RFIFOEF are 0. However, the status (S) register and both TX and RX FIFOs are reset due to a change of SPIMODE, FIFOMODE or SPE. If this type of reset occurs and FIFOMODE is 0, TNEAREF and RFIFOEF continue to reset to 0. If this type of reset occurs and FIFOMODE is 1, TNEAREF and RFIFOEF reset to 1. 0 Read FIFO has data. Reads of the DH:DL registers in 16-bit mode or the DL register in 8-bit mode will empty the read FIFO. 1 Read FIFO is empty.

38.3.5 SPI data register high (SPIx_DH)

Refer to the description of the DL register.

Address: FFFF_81A0h base + 4h offset = FFFF_81A4h

SPIO_DH field descriptions

Field	Description
7-0 Bits[15:8]	Data (high byte)

38.3.6 SPI data register low (SPIx_DL)

This register, together with the DH register, is both the input and output register for SPI data. A write to the registers writes to the transmit data buffer, allowing data to be queued and transmitted.

When the SPI is configured as a master, data queued in the transmit data buffer is transmitted immediately after the previous transmission has completed.

The SPTEF bit in the S register indicates when the transmit data buffer is ready to accept new data. When the transmit DMA request is disabled (TXDMAE is 0): The S register must be read when SPTEF is set before writing to the SPI data registers; otherwise, the write is ignored. When the transmit DMA request is enabled (TXDMAE is 1) when SPTEF is set, the SPI data registers can be written automatically by DMA without reading the S register first.

Data may be read from the SPI data registers any time after SPRF is set and before another transfer is finished. Failure to read the data out of the receive data buffer before a new transfer ends causes a receive overrun condition, and the data from the new transfer is lost. The new data is lost because the receive buffer still held the previous character and was not ready to accept the new data. There is no indication for a receive overrun condition, so the application system designer must ensure that previous data has been read from the receive buffer before a new transfer is initiated.

In 8-bit mode, only the DL register is available. Reads of the DH register return all zeros. Writes to the DH register are ignored.

In 16-bit mode, reading either byte (the DH or DL register) latches the contents of both bytes into a buffer where they remain latched until the other byte is read. Writing to either byte (the DH or DL register) latches the value into a buffer. When both bytes have been written, they are transferred as a coherent 16-bit value into the transmit data buffer.

Address: FFFF_81A0h base + 5h offset = FFFF_81A5h

SPI0_DL field descriptions

Field	Description
7-0 Bits[7:0]	Data (low byte)

38.3.7 SPI match register high (SPIx_MH)

Refer to the description of the ML register.

Address: FFFF_81A0h base + 6h offset = FFFF_81A6h

SPIO_MH field descriptions

Field	Description
7-0 Bits[15:8]	Hardware compare value (high byte)

38.3.8 SPI match register low (SPIx_ML)

This register, together with the MH register, contains the hardware compare value. When the value received in the SPI receive data buffer equals this hardware compare value, the SPI match flag (SPMF) sets.

In 8-bit mode, only the ML register is available. Reads of the MH register return all zeros. Writes to the MH register are ignored.

In 16-bit mode, reading either byte (the MH or ML register) latches the contents of both bytes into a buffer where they remain latched until the other byte is read. Writing to either byte (the MH or ML register) latches the value into a buffer. When both bytes have been written, they are transferred as a coherent value into the SPI match registers.

Address: FFFF_81A0h base + 7h offset = FFFF_81A7h

SPIO_ML field descriptions

Field	Description
7-0 Bits[7:0]	Hardware compare value (low byte)

38.3.9 SPI control register 3 (SPIx_C3)

This register introduces a 64-bit FIFO function on both transmit and receive buffers. It applies only for an instance of the SPI module that supports the FIFO feature.

FIFO mode is enabled by setting the FIFOMODE bit to 1. A write to this register occurs only when it sets the FIFOMODE bit to 1.

Using this FIFO feature allows the SPI to provide high speed transfers of large amounts of data without consuming large amounts of the CPU bandwidth.

Enabling this FIFO function affects the behavior of some of the read/write buffer flags in the S register as follows:

- The SPRF of the S register is 1 when the receive FIFO is filled. As a result:
 - If the RXDMAE bit in the C2 register is 1, SPRF generates a receive DMA request.
 - If the RXDMAE bit in the C2 register is 0 and the SPIE bit in the C1 register is 1, SPRF interrupts the CPU.
- The SPTEF of the S register is 1 when the transmit FIFO is empty. As a result:
 - If the TXDMAE bit in the C2 register is 1, SPTEF generates a transmit DMA request.
 - If the TXDMAE bit in the C2 register is 0 and the SPTIE bit in the C1 register is 1, SPTEF interrupts the CPU.

Two interrupt enable bits, TNEARIEN and RNFULLIEN, provide CPU interrupts based on the "watermark" feature of the TNEARF and RNFULLF flags of the S register.

Address: FFFF_81A0h base + 8h offset = FFFF_81A8h

Bit	7	6	5	4	3	2	1	0

5 TNEAREF_	Transmit FIFO nearly empty watermark This bit selects the mark after which the TNEAREF flag is asserted.
MARK	0 TNEAREF is set when the transmit FIFO has 16 bits or less 1 TNEAREF is set when the transmit FIFO has 32 bits or less

Table continues on the next page...

SPI0_C3 field descriptions (continued)

Field	Description
4 RNFULLF_ MARK	Receive FIFO nearly full watermark This bit selects the mark after which the RNFULLF flag is asserted. 0 RNFULLF is set when the receive FIFO has 48 bits or more 1 RNFULLF is set when the receive FIFO has 32 bits or more
3 INTCLR	Interrupt clearing mechanism select This bit selects the mechanism by which the SPRF, SPTEF, TNEAREF, and RNFULLF interrupts are cleared. 0 These interrupts are cleared when the corresponding flags are cleared depending on the state of the FIFOs 1 These interrupts are cleared by writing the corresponding bits in the CI register
2 TNEARIEN	Transmit FIFO nearly empty interrupt enable Writing 1 to this bit enables the SPI to interrupt the CPU when the TNEAREF flag is set. This bit is ignored and has no function if the FIFOMODE bit is 0. 0 No interrupt upon TNEAREF being set 1 Enable interrupts upon TNEAREF being set
1 RNFULLIEN	Receive FIFO nearly full interrupt enable Writing 1 to this bit enables the SPI to interrupt the CPU when the RNFULLF flag is set. This bit is ignored and has no function if the FIFOMODE bit is 0. 0 No interrupt upon RNFULLF being set 1 Enable interrupts upon RNFULLF being set
0 FIFOMODE	FIFO mode enable This bit enables the SPI to use a 64-bit FIFO (8 bytes or four 16-bit words) for both transmit and receive buffers. 0 Buffer mode disabled 1 Data available in the receive data buffer

38.3.10 SPI clear interrupt register (SPIx_CI)

This register applies only for an instance of the SPI module that supports the FIFO feature.

The register has four bits dedicated to clearing the interrupts. Writing 1 to these bits clears the corresponding interrupts if the INTCLR bit in the C3 register is 1. Reading these bits always returns 0.

This register also has two read-only bits to indicate the transmit FIFO and receive FIFO overrun conditions. When the receive FIFO is full and data is received, RXFOF is set. Similarly, when the transmit FIFO is full and a write to the data register occurs, TXFOF is set. These flags are cleared when the CI register is read while the flags are set.

The register has two more read-only bits to indicate the error flags. These flags are set when, due to some spurious reason, entries in the FIFO become greater than 8. At this point, all the flags in the status register are reset, and entries in the FIFO are flushed with the corresponding error flags set. These flags are cleared when the CI register is read while the flags are set.

Address: FFFF_81A0h base + 9h offset = FFFF_81A9h

Bit	7	6	5	4	3	2	1	0
Read	TXFERR	RXFERR	TXFOF	RXFOF	0	0	0	0
Write					TNEAREFCI	RNFULLFCI	SPTEFCI	SPRFCI
Reset	0	0	0	0	0	0	0	0

SPI0_CI field descriptions

Field	Description
7 TXFERR	Transmit FIFO error flag This flag indicates that a transmit FIFO error occurred because entries in the FIFO exceed 8. 0 No transmit FIFO error occurred 1 A transmit FIFO error occurred
6 RXFERR	Receive FIFO error flag This flag indicates that a receive FIFO error occurred because entries in the FIFO exceed 8. 0 No receive FIFO error occurred 1 A receive FIFO error occurred
5 TXFOF	Transmit FIFO overflow flag This flag indicates that a transmit FIFO overflow condition has occurred. 0 Transmit FIFO overflow condition has not occurred 1 Transmit FIFO overflow condition occurred
4 RXFOF	Receive FIFO overflow flag This flag indicates that a receive FIFO overflow condition has occurred. 0 Receive FIFO overflow condition has not occurred 1 Receive FIFO overflow condition occurred
3 TNEAREFCI	Transmit FIFO nearly empty flag clear interrupt Writing 1 to this bit clears the TNEAREF interrupt provided that C3[3] is set.
2 RNFULLFCI	Receive FIFO nearly full flag clear interrupt Writing 1 to this bit clears the RNFULLF interrupt provided that C3[3] is set.
1 SPTEFCI	Transmit FIFO empty flag clear interrupt Writing 1 to this bit clears the SPTEF interrupt provided that C3[3] is set.
0 SPRFCI	Receive FIFO full flag clear interrupt Writing 1 to this bit clears the SPRF interrupt provided that C3[3] is set.

38.4 Functional Description

This section provides the functional description of the module.

38.4.1 General

The SPI system is enabled by setting the SPI enable (SPE) bit in SPI Control Register 1. While the SPE bit is set, the four associated SPI port pins are dedicated to the SPI function as:

- Slave select (SS)
- Serial clock (SPSCK)
- Master out/slave in (MOSI)
- Master in/slave out (MISO)

An SPI transfer is initiated in the master SPI device by reading the SPI status register (SPIx_S) when SPTEF = 1 and then writing data to the transmit data buffer (write to SPIx_DH:SPIx_DL). When a transfer is complete, received data is moved into the receive data buffer. The SPIx_DH:SPIx_DL registers act as the SPI receive data buffer for reads and as the SPI transmit data buffer for writes.

The clock phase control bit (CPHA) and clock polarity control bit (CPOL) in the SPI Control Register 1 (SPIx_C1) select one of four possible clock formats to be used by the SPI system. The CPOL bit simply selects a non-inverted or inverted clock. The CPHA bit is used to accommodate two fundamentally different protocols by sampling data on odd numbered SPSCK edges or on even numbered SPSCK edges.

The SPI can be configured to operate as a master or as a slave. When the MSTR bit in SPI Control Register 1 is set, master mode is selected; when the MSTR bit is clear, slave mode is selected.

38.4.2 Master Mode

The SPI operates in master mode when the MSTR bit is set. Only a master SPI module can initiate transmissions. A transmission begins by reading the SPIx_S register while SPTEF = 1 and writing to the master SPI data registers. If the shift register is empty, the byte immediately transfers to the shift register. The data begins shifting out on the MOSI pin under the control of the serial clock.

- **SPSCK**
 - The SPR3, SPR2, SPR1, and SPR0 baud rate selection bits in conjunction with the SPPR2, SPPR1, and SPPR0 baud rate preselection bits in the SPI Baud Rate register control the baud rate generator and determine the speed of the transmission. The SPSCK pin is the SPI clock output. Through the SPSCK pin, the baud rate generator of the master controls the shift register of the slave peripheral.
- **MOSI, MISO pin**
 - In master mode, the function of the serial data output pin (MOSI) and the serial data input pin (MISO) is determined by the SPC0 and BIDIROE control bits.
- **\overline{SS} pin**
 - If MODFEN and SSOE bit are set, the SS pin is configured as slave select output. The SS output becomes low during each transmission and is high when the SPI is in idle state. If MODFEN is set and SSOE is cleared, the \overline{SS} pin is configured as input for detecting mode fault error. If the SS input becomes low this indicates a mode fault error where another master tries to drive the MOSI and SPSCK lines. In this case, the SPI immediately switches to slave mode by clearing the MSTR bit and also disables the slave output buffer MISO (or SISO in bidirectional mode). As a result, all outputs are disabled, and SPSCK, MOSI and MISO are inputs. If a transmission is in progress when the mode fault occurs, the transmission is aborted and the SPI is forced into idle state. This mode fault error also sets the mode fault (MODF) flag in the SPI Status Register (SPIx_S). If the SPI interrupt enable bit (SPIE) is set when the MODF flag gets set, then an SPI interrupt sequence is also requested. When a write to the SPI Data Register in the master occurs, there is a half SPSCK-cycle delay. After the delay, SPSCK is started within the master. The rest of the transfer operation differs slightly, depending on the clock format specified by the SPI clock phase bit, CPHA, in SPI Control Register 1 (see [SPI Clock Formats](#)).

Note

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0, BIDIROE with SPC0 set, SPIMODE, FIFOMODE, SPPR2-SPPR0 and SPR3-SPR0 in master mode abort a transmission in progress and force the SPI into idle state. The remote slave cannot detect this, therefore the master has to ensure that the remote slave is set back to idle state.

38.4.3 Slave Mode

The SPI operates in slave mode when the MSTR bit in SPI Control Register1 is clear.

- SPSCCK

In slave mode, SPSCCK is the SPI clock input from the master.

- MISO, MOSI pin

In slave mode, the function of the serial data output pin (MISO) and serial data input pin (MOSI) is determined by the SPC0 bit and BIDIROE bit in SPI Control Register 2.

- SS pin

The SS pin is the slave select input. Before a data transmission occurs, the SS pin of the slave SPI must be low. SS must remain low until the transmission is complete. If SS goes high, the SPI is forced into an idle state.

The SS input also controls the serial data output pin. If SS is high (not selected), the serial data output pin is high impedance. If SS is low, the first bit in the SPI Data Register is driven out of the serial data output pin. Also, if the slave is not selected (SS is high), then the SPSCCK input is ignored and no internal shifting of the SPI shift register occurs.

Although the SPI is capable of duplex operation, some SPI peripherals are capable of only receiving SPI data in a slave mode. For these simpler devices, there is no serial data out pin.

Note

When peripherals with duplex capability are used, take care not to simultaneously enable two receivers whose serial outputs drive the same system slave's serial data output line.

As long as no more than one slave device drives the system slave's serial data output line, it is possible for several slaves to receive the same transmission from a master, although the master would not receive return information from all of the receiving slaves.

If the CPHA bit in SPI Control Register 1 is clear, odd numbered edges on the SPSCCK input cause the data at the serial data input pin to be latched. Even numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

If the CPHA bit is set, even numbered edges on the SPSCCK input cause the data at the serial data input pin to be latched. Odd numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

When CPHA is set, the first edge is used to get the first data bit onto the serial data output pin. When CPHA is clear and the SS input is low (slave selected), the first bit of the SPI data is driven out of the serial data output pin. After the eighth (SPIMODE = 0) or sixteenth (SPIMODE = 1) shift, the transfer is considered complete and the received data is transferred into the SPI Data register. To indicate transfer is complete, the SPRF flag in the SPI Status Register is set.

Note

A change of the bits FIFOMODE, SPIMODE, BIDIROE with SPC0 set, CPOL, CPHA, SSOE, LSBFE, MODFEN, and SPC0 in slave mode will corrupt a transmission in progress and must be avoided.

38.4.4 SPI FIFO Mode

When the FIFO feature is supported: The SPI works in FIFO mode when the C3[FIFOMODE] bit is set. When the module is in FIFO mode, the SPI RX buffer and SPI TX buffer are replaced by an 8-byte-deep FIFO, as the following figures show.

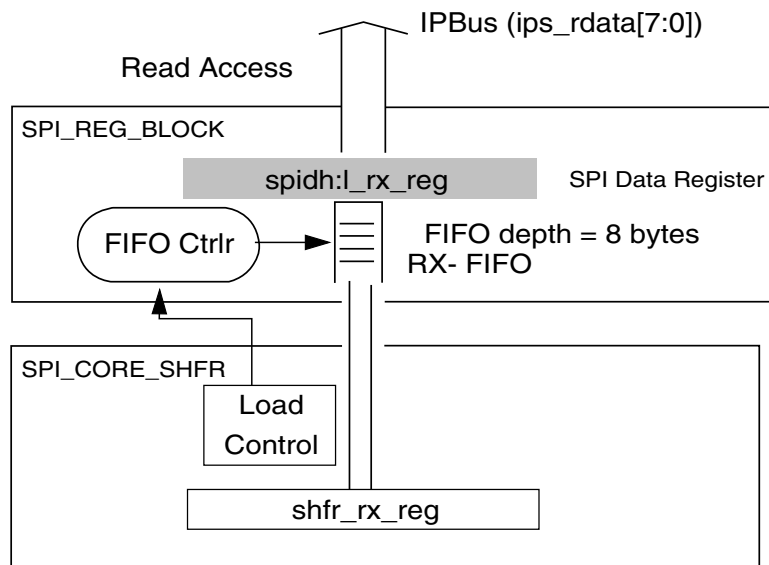

Figure 38-34. SPIH:L read side structural overview in FIFO mode

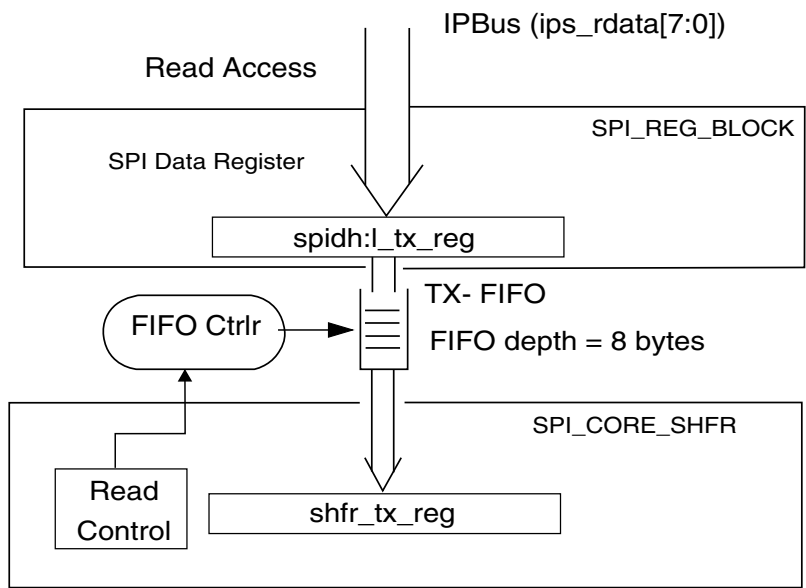

Figure 38-35. SPIH:L write side structural overview in FIFO mode

38.4.5 SPI Transmission by DMA

SPI supports both Transmit and Receive by DMA. The basic flow of SPI transmission by DMA is as below.

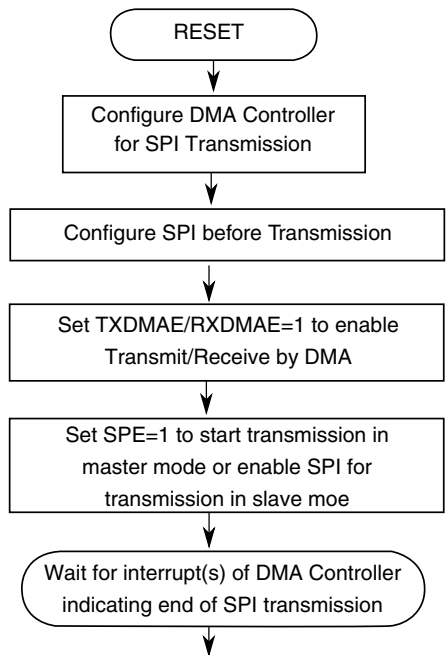

Figure 38-36. Basic Flow of SPI Transmission by DMA

38.4.5.1 Transmit by DMA

Transmit by DMA is supported only when TXDMAE is set. A transmit DMA request is asserted when both SPE and SPTEF are set. Then the on-chip DMA controller detects this request and transfers data from memory into the SPI data register. After that, TX DMA DONE is asserted to clear SPTEF automatically. This process repeats until all data for transmission (the number is decided by the configuration register[s] of the DMA controller) is sent.

When the FIFO feature is supported: In FIFO mode (FIFOMODE=1) and when a data length of 8 bits is selected (SPIMODE=0), the DMA transfer for one transmit DMA request can write more than 1 byte (up to 8 bytes) to the DL register because the TX FIFO can store 8 bytes of transmit data. In FIFO mode (FIFOMODE=1) and when a data length of 16 bits is selected (SPIMODE=1), the DMA transfer for one transmit DMA request can write more than 1 word (up to 4 words) to the DH:DL registers because the TX FIFO can store 4 words of transmit data. A larger number of bytes or words transferred from memory to the SPI data register for each transmit DMA request results in a lower total number of transmit DMA requests.

When the FIFO feature is supported and FIFOMODE is 0: After DMA transfers the first byte to the SPI data register, the SPI pushes this data into the shifter, thereby making SPTEF high again. This generates another DMA request immediately, but the CPU lacks enough time to service the first DMA interrupt service request (ISR). The subsequent DMA request is paced at the SPI transfer rate. Manage this behavior during the first byte transfer through the DMA channel. Write the first byte to the SPI data register via the CPU. The other bytes are transmitted by the DMA.

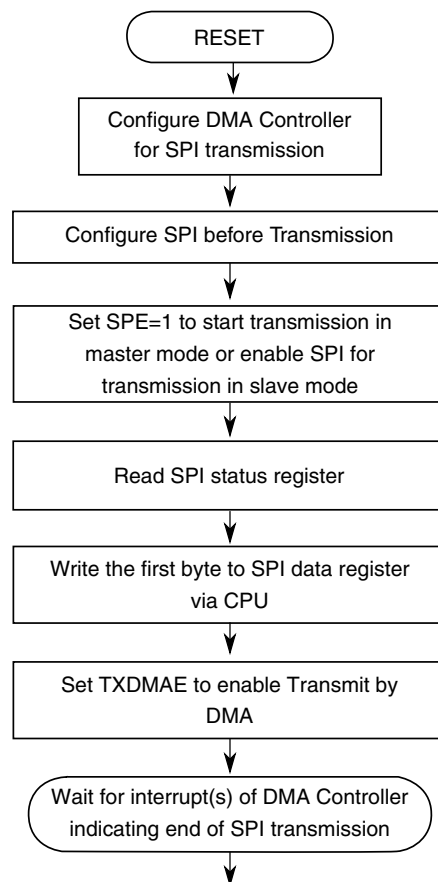

Figure 38-37. Recommended startup of SPI transmit by DMA

38.4.5.2 Receive by DMA

Receive by DMA is supported only when RXDMAE is set. A receive DMA request is asserted when both SPE and SPRF are set. Then the on-chip DMA controller detects this request and transfers data from the SPI data register into memory. After that, RX DMA DONE is asserted to clear SPRF automatically. This process repeats until all data to be received (the number is decided by configuration register[s] of the DMA controller) is received or no receive DMA request is generated again because the SPI transmission is finished.

When the FIFO feature is supported: In FIFO mode (FIFOMODE=1) and when a data length of 8 bits is selected (SPIMODE=0), the DMA transfer for one receive DMA request can read more than 1 byte (up to 8 bytes) from the SPI data register because the RX FIFO is full with 8 bytes. In FIFO mode (FIFOMODE=1) and when a data length of 16 bits is selected (SPIMODE=1), the DMA transfer for one receive DMA request can read more than 1 word (up to 4 words) from the DH:DL registers because the RX FIFO is

full with 4 words. A larger number of bytes or words transferred from the SPI data register to memory for one receive DMA request results in a lower total number of receive DMA requests.

38.4.6 Data Transmission Length

The SPI can support data lengths of 8 or 16 bits. The length can be configured with the SPIMODE bit in the SPIx_C2 register.

In 8-bit mode (SPIMODE = 0), the SPI Data Register is comprised of one byte: SPIx_DL. The SPI Match Register is also comprised of only one byte: SPIx_ML. Reads of SPIx_DH and SPIx_MH will return zero. Writes to SPIx_DH and SPIx_MH will be ignored.

In 16-bit mode (SPIMODE = 1), the SPI Data Register is comprised of two bytes: SPIx_DH and SPIx_DL. Reading either byte (SPIx_DH or SPIx_DL) latches the contents of both bytes into a buffer where they remain latched until the other byte is read. Writing to either byte (SPIx_DH or SPIx_DL) latches the value into a buffer. When both bytes have been written, they are transferred as a coherent 16-bit value into the transmit data buffer.

In 16-bit mode, the SPI Match Register is also comprised of two bytes: SPIx_MH and SPIx_ML. There is no buffer mechanism for the reading of SPIxMH and SPIxML since they can only be changed by writing at CPU side. Writing to either byte (SPIx_MH or SPIx_ML) latches the value into a buffer. When both bytes have been written, they are transferred as a coherent 16-bit value into the SPI Match Register.

Any switching between 8- and 16-bit data transmission length (controlled by SPIMODE bit) in master mode will abort a transmission in progress, force the SPI system into idle state, and reset all status bits in the SPIx_S register. To initiate a transfer after writing to SPIMODE, the SPIx_S register must be read with SPTEF = 1, and data must be written to SPIx_DH:SPIx_DL in 16-bit mode (SPIMODE = 1) or SPIx_DL in 8-bit mode (SPIMODE = 0).

In slave mode, user software should write to SPIMODE only once to prevent corrupting a transmission in progress.

Note

Data can be lost if the data length is not the same for both master and slave devices.

38.4.7 SPI Clock Formats

To accommodate a wide variety of synchronous serial peripherals from different manufacturers, the SPI system has a clock polarity (CPOL) bit and a clock phase (CPHA) control bit to select one of four clock formats for data transfers. CPOL selectively inserts an inverter in series with the clock. CPHA chooses between two different clock phase relationships between the clock and data.

The following figure shows the clock formats when SPIMODE = 0 (8-bit mode) and CPHA = 1. At the top of the figure, the eight bit times are shown for reference with bit 1 starting at the first SPSCCK edge and bit 8 ending one-half SPSCCK cycle after the eighth SPSCCK edge. The MSB first and LSB first lines show the order of SPI data bits depending on the setting in LSBFE. Both variations of SPSCCK polarity are shown, but only one of these waveforms applies for a specific transfer, depending on the value in CPOL. The SAMPLE IN waveform applies to the MOSI input of a slave or the MISO input of a master. The MOSI waveform applies to the MOSI output pin from a master and the MISO waveform applies to the MISO output from a slave. The \overline{SS} OUT waveform applies to the slave select output from a master (provided MODFEN and SSOE = 1). The master \overline{SS} output goes to active low one-half SPSCCK cycle before the start of the transfer and goes back high at the end of the eighth bit time of the transfer. The \overline{SS} IN waveform applies to the slave select input of a slave.

Figure 38-38. SPI Clock Formats (CPHA = 1)

When $CPHA = 1$, the slave begins to drive its MISO output when \overline{SS} goes to active low, but the data is not defined until the first SPSCCK edge. The first SPSCCK edge shifts the first bit of data from the shifter onto the MOSI output of the master and the MISO output of the slave. The next SPSCCK edge causes both the master and the slave to sample the data bit values on their MISO and MOSI inputs, respectively. At the third SPSCCK edge, the SPI shifter shifts one bit position which shifts in the bit value that was just sampled, and shifts the second data bit value out the other end of the shifter to the MOSI and MISO outputs of the master and slave, respectively.

When $CPHA = 1$, the slave's \overline{SS} input is not required to go to its inactive high level between transfers. In this clock format, a back-to-back transmission can occur, as follows:

1. A transmission is in progress.
2. A new data byte is written to the transmit buffer before the in-progress transmission is complete.
3. When the in-progress transmission is complete, the new, ready data byte is transmitted immediately.

Functional Description

Between these two successive transmissions, no pause is inserted; the \overline{SS} pin remains low.

The following figure shows the clock formats when $SPIMODE = 0$ and $CPHA = 0$. At the top of the figure, the eight bit times are shown for reference with bit 1 starting as the slave is selected (\overline{SS} IN goes low), and bit 8 ends at the last SPSCCK edge. The MSB first and LSB first lines show the order of SPI data bits depending on the setting in $LSBFEE$. Both variations of SPSCCK polarity are shown, but only one of these waveforms applies for a specific transfer, depending on the value in $CPOL$. The SAMPLE IN waveform applies to the MOSI input of a slave or the MISO input of a master. The MOSI waveform applies to the MOSI output pin from a master and the MISO waveform applies to the MISO output from a slave. The \overline{SS} OUT waveform applies to the slave select output from a master (provided $MODFEN$ and $SSOE = 1$). The master \overline{SS} output goes to active low at the start of the first bit time of the transfer and goes back high one-half SPSCCK cycle after the end of the eighth bit time of the transfer. The \overline{SS} IN waveform applies to the slave select input of a slave.

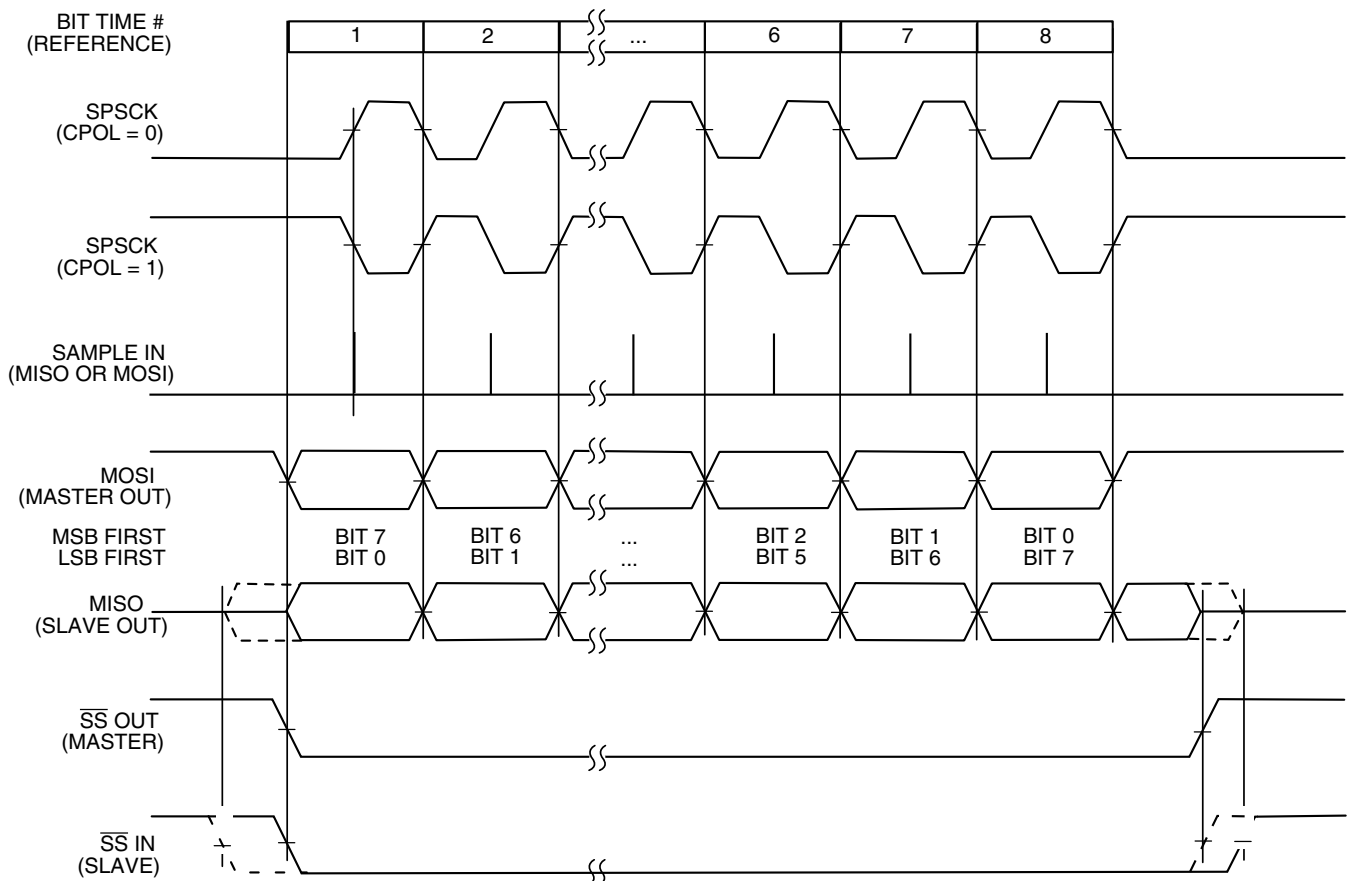

Figure 38-39. SPI Clock Formats ($CPHA = 0$)

When $CPHA = 0$, the slave begins to drive its MISO output with the first data bit value (MSB or LSB depending on LSBFE) when SS goes to active low. The first SPSCCK edge causes both the master and the slave to sample the data bit values on their MISO and MOSI inputs, respectively. At the second SPSCCK edge, the SPI shifter shifts one bit position which shifts in the bit value that was just sampled and shifts the second data bit value out the other end of the shifter to the MOSI and MISO outputs of the master and slave, respectively. When $CPHA = 0$, the slave's SS input must go to its inactive high level between transfers.

38.4.8 SPI Baud Rate Generation

As shown in the following figure, the clock source for the SPI baud rate generator is the bus clock. The three prescale bits (SPPR2:SPPR1:SPPR0) choose a prescale divisor of 1, 2, 3, 4, 5, 6, 7, or 8. The three rate select bits (SPR3:SPR2:SPR1:SPR0) divide the output of the prescaler stage by 2, 4, 8, 16, 32, 64, 128, 256, or 512 to get the internal SPI master mode bit-rate clock.

The baud rate generator is activated only when the SPI is in the master mode and a serial transfer is taking place. In the other cases, the divider is disabled to decrease I_{DD} current.

The baud rate divisor equation is as follows (except those reserved combinations in the SPI Baud Rate Divisor table).

$$\text{BaudRateDivisor} = (\text{SPPR} + 1) \times 2^{(\text{SPR} + 1)}$$

The baud rate can be calculated with the following equation:

$$\text{BaudRate} = \text{BusClock} / \text{BaudRateDivisor}$$

Figure 38-40. SPI Baud Rate Generation

38.4.9 Special Features

The following section shows the module special features.

38.4.9.1 \overline{SS} Output

The \overline{SS} output feature automatically drives the \overline{SS} pin low during transmission to select external devices and drives the \overline{SS} pin high during idle to deselect external devices. When the \overline{SS} output is selected, the \overline{SS} output pin is connected to the \overline{SS} input pin of the external device.

The \overline{SS} output is available only in master mode during normal SPI operation by asserting the SSOE and MODFEN bits as shown in the description of the C1[SSOE] bit.

The mode fault feature is disabled while \overline{SS} output is enabled.

Note

Be careful when using the \overline{SS} output feature in a multimaster system because the mode fault feature is not available for detecting system errors between masters.

38.4.9.2 Bidirectional Mode (MOMI or SISO)

The bidirectional mode is selected when the SPC0 bit is set in SPI Control Register 2 (see the following table). In this mode, the SPI uses only one serial data pin for the interface with one or more external devices. The MSTR bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the master mode, and the MISO pin becomes serial data I/O (SISO) pin for the slave mode. The MISO pin in master mode and MOSI pin in slave mode are not used by the SPI.

Table 38-34. Normal Mode and Bidirectional Mode

When SPE = 1	Master Mode MSTR = 1	Slave Mode MSTR = 0
Normal Mode SPC0 = 0		
Bidirectional Mode SPC0 = 1		

The direction of each serial I/O pin depends on the BIDIROE bit. If the pin is configured as an output, serial data from the shift register is driven out on the pin. The same pin is also the serial input to the shift register.

The SPSCCK is an output for the master mode and an input for the slave mode.

\overline{SS} is the input or output for the master mode, and it is always the input for the slave mode.

The bidirectional mode does not affect SPSCCK and \overline{SS} functions.

Note

In bidirectional master mode, with the mode fault feature enabled, both data pins MISO and MOSI can be occupied by the SPI, though MOSI is normally used for transmissions in bidirectional mode and MISO is not used by the SPI. If a mode fault occurs, the SPI is automatically switched to slave mode. In this case, MISO becomes occupied by the SPI and MOSI is not used. Consider this scenario if the MISO pin is used for another purpose.

38.4.10 Error Conditions

The SPI module has one error condition: the mode fault error.

38.4.10.1 Mode Fault Error

If the \overline{SS} input becomes low while the SPI is configured as a master, it indicates a system error where more than one master may be trying to drive the MOSI and SPSCCK lines simultaneously. This condition is not permitted in normal operation, and it sets the MODF bit in the SPI status register automatically provided that the MODFEN bit is set.

In the special case where the SPI is in master mode and the MODFEN bit is cleared, the \overline{SS} pin is not used by the SPI. In this special case, the mode fault error function is inhibited and MODF remains cleared. If the SPI system is configured as a slave, the \overline{SS} pin is a dedicated input pin. A mode fault error does not occur in slave mode.

If a mode fault error occurs, the SPI is switched to slave mode, with the exception that the slave output buffer is disabled. So the SPSCCK, MISO and MOSI pins are forced to be high impedance inputs to avoid any possibility of conflict with another output driver. A transmission in progress is aborted and the SPI is forced into idle state.

If the mode fault error occurs in the bidirectional mode for an SPI system configured in master mode, the output enable of MOMI (MOSI in bidirectional mode) is cleared if it was set. No mode fault error occurs in the bidirectional mode for the SPI system configured in slave mode.

The mode fault flag is cleared automatically by a read of the SPI Status Register (with MODF set) followed by a write to SPI Control Register 1. If the mode fault flag is cleared, the SPI becomes a normal master or slave again.

38.4.11 Low Power Mode Options

This section describes the low power mode options.

38.4.11.1 SPI in Run Mode

In run mode, with the SPI system enable (SPE) bit in the SPI control register clear, the SPI system is in a low-power, disabled state. SPI registers can still be accessed, but clocks to the core of this module are disabled.

38.4.11.2 SPI in Wait Mode

SPI operation in wait mode depends upon the state of the SPISWAI bit in SPI Control Register 2.

- If SPISWAI is clear, the SPI operates normally when the CPU is in wait mode.
- If SPISWAI is set, SPI clock generation ceases and the SPI module enters a power conservation state when the CPU is in wait mode.
 - If SPISWAI is set and the SPI is configured for master, any transmission and reception in progress stops at wait mode entry. The transmission and reception resumes when the SPI exits wait mode.
 - If SPISWAI is set and the SPI is configured as a slave, any transmission and reception in progress continues if the SPSCCK continues to be driven from the master. This keeps the slave synchronized to the master and the SPSCCK.

If the master transmits data while the slave is in wait mode, the slave continues to send data consistent with the operation mode at the start of wait mode (that is, if the slave is currently sending its SPIx_DH:SPIx_DL to the master, it continues to send the same byte. Otherwise, if the slave is currently sending the last data received byte from the master, it continues to send each previously received data from the master byte).

Note

Care must be taken when expecting data from a master while the slave is in a wait mode or a stop mode where the peripheral bus clock is stopped but internal logic states are retained. Even though the shift register continues to operate, the rest of the SPI is shut down (that is, an SPRF interrupt is not generated until an exit from stop or wait mode). Also, the data from the shift register is not copied into the SPIx_DH:SPIx_DL registers until after the slave SPI has exited wait or stop mode. An SPRF flag and SPIx_DH:SPIx_DL copy is only generated if wait mode is entered or exited during a transmission. If the slave enters wait mode in idle mode and exits wait mode in idle mode, neither an SPRF nor a SPIx_DH:SPIx_DL copy occurs.

38.4.11.3 SPI in Stop Mode

Operation in a stop mode where the peripheral bus clock is stopped but internal logic states are retained depends on the SPI system. The stop mode does not depend on the SPISWAI bit. Upon entry to this type of stop mode, the SPI module clock is disabled (held high or low).

- If the SPI is in master mode and exchanging data when the CPU enters the stop mode, the transmission is frozen until the CPU exits stop mode. After the exit from stop mode, data to and from the external SPI is exchanged correctly.
- In slave mode, the SPI remains synchronized with the master.

The SPI is completely disabled in a stop mode where the peripheral bus clock is stopped and internal logic states are not retained. After an exit from this type of stop mode, all registers are reset to their default values, and the SPI module must be re-initialized.

38.4.12 Reset

The reset values of registers and signals are described in the Memory Map and Register Descriptions content, which details the registers and their bitfields.

- If a data transmission occurs in slave mode after a reset without a write to SPIx_DH:SPIx_DL, the transmission consists of "garbage" or the data last received from the master before the reset.
- Reading from SPIx_DH:SPIx_DL after reset always returns zeros.

38.4.13 Interrupts

The SPI originates interrupt requests only when the SPI is enabled (the SPE bit in the SPIx_C1 register is set). The following is a description of how the SPI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt priority are chip dependent.

Four flag bits, three interrupt mask bits, and one interrupt vector are associated with the SPI system. The SPI interrupt enable mask (SPIE) enables interrupts from the SPI receiver full flag (SPRF) and mode fault flag (MODF). The SPI transmit interrupt enable mask (SPTIE) enables interrupts from the SPI transmit buffer empty flag (SPTEF). The SPI match interrupt enable mask bit (SPIMIE) enables interrupts from the SPI match flag (SPMF). When one of the flag bits is set, and the associated interrupt mask bit is set, a hardware interrupt request is sent to the CPU. If the interrupt mask bits are cleared, software can poll the associated flag bits instead of using interrupts. The SPI interrupt service routine (ISR) should check the flag bits to determine which event caused the interrupt. The service routine should also clear the flag bit(s) before returning from the ISR (usually near the beginning of the ISR).

38.4.13.1 MODF

MODF occurs when the master detects an error on the \overline{SS} pin. The master SPI must be configured for the MODF feature (see the description of the C1[SSOE] bit). Once MODF is set, the current transfer is aborted and the master (MSTR) bit in the SPIx_C1 register resets to 0.

The MODF interrupt is reflected in the status register's MODF flag. Clearing the flag also clears the interrupt. This interrupt stays active while the MODF flag is set. MODF has an automatic clearing process that is described in the SPI Status Register.

38.4.13.2 SPRF

SPRF occurs when new data has been received and copied to the SPI receive data buffer. In 8-bit mode, SPRF is set only after all 8 bits have been shifted out of the shift register and into SPIx_DL. In 16-bit mode, SPRF is set only after all 16 bits have been shifted out of the shift register and into SPIx_DH:SPIx_DL.

After SPRF is set, it does not clear until it is serviced. SPRF has an automatic clearing process that is described in the SPI Status Register details. If the SPRF is not serviced before the end of the next transfer (that is, SPRF remains active throughout another transfer), the subsequent transfers are ignored and no new data is copied into the Data register.

38.4.13.3 SPTEF

SPTEF occurs when the SPI transmit buffer is ready to accept new data. In 8-bit mode, SPTEF is set only after all 8 bits have been moved from SPIx_DL into the shifter. In 16-bit mode, SPTEF is set only after all 16 bits have been moved from SPIx_DH:SPIx_DL into the shifter.

After SPTEF is set, it does not clear until it is serviced. SPTEF has an automatic clearing process that is described in the SPI Status Register details.

38.4.13.4 SPMF

SPMF occurs when the data in the receive data buffer is equal to the data in the SPI match register. In 8-bit mode, SPMF is set only after bits 7–0 in the receive data buffer are determined to be equivalent to the value in SPIx_ML. In 16-bit mode, SPMF is set after bits 15–0 in the receive data buffer are determined to be equivalent to the value in SPIx_MH:SPIx_ML.

38.4.13.5 TNEAREF

The TNEAREF bit applies when the FIFO feature is supported.

The TNEAREF flag is set when only one 16-bit word or two 8-bit bytes of data remain in the transmit FIFO provided C3[5] = 0 or when only two 16-bit words or four 8-bit bytes of data remain in the transmit FIFO provided C3[5] = 1. If FIFOMODE is not enabled, ignore this bit.

Clearing this interrupt depends on the state of C3[3] and the status of TNEAREF. Refer to the description of the SPI status (S) register.

38.4.13.6 RNFULLF

The RNFULLF bit applies when the FIFO feature is supported.

RNFULLF is set when more than three 16-bit words or six 8-bit bytes of data remain in the receive FIFO provided C3[4] = 0 or when more than two 16-bit words or four 8-bit bytes of data remain in the receive FIFO provided C3[4] = 1.

Clearing this interrupt depends on the state of C3[3] and the status of RNFULLF. Refer to the description of the SPI status (S) register.

38.5 Initialization/Application Information

This section discusses an example of how to initialize and use the SPI.

38.5.1 Initialization Sequence

Before the SPI module can be used for communication, an initialization procedure must be carried out, as follows:

1. Update control register 1 (SPIx_C1) to enable the SPI and to control interrupt enables. This register also sets the SPI as master or slave, determines clock phase and polarity, and configures the main SPI options.
2. Update control register 2 (SPIx_C2) to enable additional SPI functions such as the SPI match interrupt feature, the master mode-fault function, and bidirectional mode output as well as to control 8- or 16-bit mode selection and other optional features.
3. Update the baud rate register (SPIx_BR) to set the prescaler and bit rate divisor for an SPI master.
4. Update the hardware match register (SPIx_MH:SPIx_ML) with the value to be compared to the receive data register for triggering an interrupt if hardware match interrupts are enabled.
5. In the master, read SPIx_S while SPTEF = 1, and then write to the transmit data register (SPIx_DH:SPIx_DL) to begin transfer.

38.5.2 Pseudo-Code Example

In this example, the SPI module is set up for master mode with only hardware match interrupts enabled. The SPI runs in 16-bit mode at a maximum baud rate of bus clock divided by 2. Clock phase and polarity are set for an active-high SPI clock where the first edge on SPSCCK occurs at the start of the first cycle of a data transfer.

SPIx_C1=0x54(%01010100)				
Bit 7	SPIE	=	0	Disables receive and mode fault interrupts
Bit 6	SPE	=	1	Enables the SPI system
Bit 5	SPTIE	=	0	Disables SPI transmit interrupts
Bit 4	MSTR	=	1	Sets the SPI module as a master SPI device
Bit 3	CPOL	=	0	Configures SPI clock as active-high
Bit 2	CPHA	=	1	First edge on SPSCCK at start of first data transfer cycle
Bit 1	SSOE	=	0	Determines SS pin function when mode fault enabled
Bit 0	LSBFE	=	0	SPI serial data transfers start with most significant bit

SPIx_C2 = 0xC0(%11000000)				
Bit 7	SPMIE	=	1	SPI hardware match interrupt enabled
Bit 6	SPIMODE	=	1	Configures SPI for 16-bit mode
Bit 5	TXDMAE	=	0	DMA request disabled
Bit 4	MODFEN	=	0	Disables mode fault function
Bit 3	BIDIROE	=	0	SPI data I/O pin acts as input
Bit 2	RXDMAE	=	0	DMA request disabled
Bit 1	SPISWAI	=	0	SPI clocks operate in wait mode
Bit 0	SPC0	=	0	uses separate pins for data input and output

SPIx_BR = 0x00(%00000000)				
Bit 7		=	0	Reserved
Bit 6:4		=	000	Sets prescale divisor to 1
Bit 3:0		=	0000	Sets baud rate divisor to 2

SPIx_S = 0x00(%00000000)				
Bit 7	SPRF	=	0	Flag is set when receive data buffer is full
Bit 6	SPMF	=	0	Flag is set when SPIx_MH/ML = receive data buffer
Bit 5	SPTEF	=	0	Flag is set when transmit data buffer is empty
Bit 4	MODF	=	0	Mode fault flag for master mode
Bit 3:0	RNFULLF, TNEARF, TXFULLF, and RFIFOEF	=	0	Reserved (when FIFOMODE is not present or is 0) or FIFO flags (when FIFOMODE is 1)
Bit 3:0		=	0	FIFOMODE is not enabled

SPIx_MH = 0xXX	
	In 16-bit mode, this register holds bits 8–15 of the hardware match buffer. In 8-bit mode, writes to this register will be ignored.

Initialization/Application Information

SPIx_ML = 0xXX	
	Holds bits 0–7 of the hardware match buffer.

SPIx_DH = 0xxx	
	In 16-bit mode, this register holds bits 8–15 of the data to be transmitted by the transmit buffer and received by the receive buffer.

SPIx_DL = 0xxx	
	Holds bits 0–7 of the data to be transmitted by the transmit buffer and received by the receive buffer.

Figure 38-41. Initialization Flowchart Example for SPI Master Device in 16-bit Mode for FIFOMODE = 0

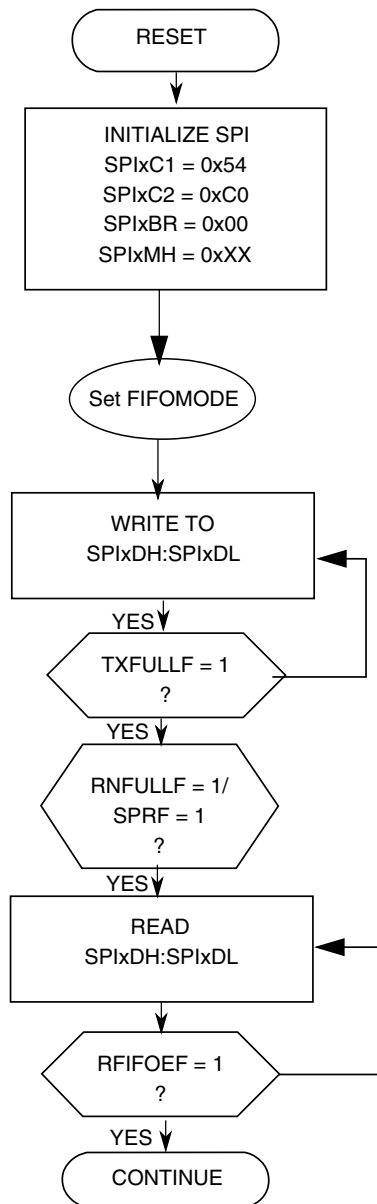

Figure 38-42. Initialization Flowchart Example for SPI Master Device in 16-bit Mode for FIFOMODE = 1

Chapter 39

Inter-Integrated Circuit (I2C)

39.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The inter-integrated circuit (I²C, I2C, or IIC) module provides a method of communication between a number of devices. The interface is designed to operate up to 100 kbit/s with maximum bus loading and timing. The I2C device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF. The I2C module also complies with the *System Management Bus (SMBus) Specification, version 2*.

39.1.1 Features

The I2C module has the following features:

- Compatible with *The I²C-Bus Specification*
- Multimaster operation
- Software programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- START and STOP signal generation and detection
- Repeated START signal generation and detection
- Acknowledge bit generation and detection
- Bus busy detection
- General call recognition

- 10-bit address extension
- Support for *System Management Bus (SMBus) Specification, version 2*
- Programmable glitch input filter
- Low power mode wakeup on slave address match
- Range slave address support
- DMA support

39.1.2 Modes of operation

The I2C module's operation in various low power modes is as follows:

- Run mode: This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode: The module continues to operate when the core is in Wait mode and can provide a wakeup interrupt.
- Stop mode: The module is inactive in Stop mode for reduced power consumption, except that address matching is enabled in Stop mode. The STOP instruction does not affect the I2C module's register states. In any VLLSx mode, the register contents are reset.

39.1.3 Block diagram

The following figure is a functional block diagram of the I2C module.

Figure 39-1. I2C Functional block diagram

39.2 I²C signal descriptions

The signal properties of I²C are shown in the following table.

Table 39-1. I²C signal descriptions

Signal	Description	I/O
SCL	Bidirectional serial clock line of the I ² C system.	I/O
SDA	Bidirectional serial data line of the I ² C system.	I/O

39.3 Memory map and register descriptions

This section describes in detail all I2C registers accessible to the end user.

I2C memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_81C0	I2C Address Register 1 (I2C0_A1)	8	R/W	00h	39.3.1/905
FFFF_81C1	I2C Frequency Divider register (I2C0_F)	8	R/W	00h	39.3.2/906
FFFF_81C2	I2C Control Register 1 (I2C0_C1)	8	R/W	00h	39.3.3/907
FFFF_81C3	I2C Status register (I2C0_S)	8	R/W	80h	39.3.4/908

39.3.1 I2C Address Register 1 (I2Cx_A1)

This register contains the slave address to be used by the I2C module.

Address: Base address + 0h offset

I2Cx_A1 field descriptions

Field	Description
7–1 AD[7:1]	Address Contains the primary slave address used by the I2C module when it is addressed as a slave. This field is used in the 7-bit address scheme and the lower seven bits in the 10-bit address scheme.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

39.3.2 I2C Frequency Divider register (I2Cx_F)

Address: Base address + 1h offset

I2Cx_F field descriptions

Field	Description																																	
7–6 MULT	<p>The MULT bits define the multiplier factor mul. This factor is used along with the SCL divider to generate the I2C baud rate.</p> <p>00 mul = 1 01 mul = 2 10 mul = 4 11 Reserved</p>																																	
5–0 ICR	<p>ClockRate</p> <p>Prescales the bus clock for bit rate selection. This field and the MULT field determine the I2C baud rate, the SDA hold time, the SCL start hold time, and the SCL stop hold time. For a list of values corresponding to each ICR setting, see I2C divider and hold values.</p> <p>The SCL divider multiplied by multiplier factor (mul) determines the I2C baud rate.</p> <p>$I2C \text{ baud rate} = \text{bus speed (Hz)} / (\text{mul} \times \text{SCL divider})$</p> <p>The SDA hold time is the delay from the falling edge of SCL (I2C clock) to the changing of SDA (I2C data).</p> <p>$SDA \text{ hold time} = \text{bus period (s)} \times \text{mul} \times \text{SDA hold value}$</p> <p>The SCL start hold time is the delay from the falling edge of SDA (I2C data) while SCL is high (start condition) to the falling edge of SCL (I2C clock).</p> <p>$SCL \text{ start hold time} = \text{bus period (s)} \times \text{mul} \times \text{SCL start hold value}$</p> <p>The SCL stop hold time is the delay from the rising edge of SCL (I2C clock) to the rising edge of SDA (I2C data) while SCL is high (stop condition).</p> <p>$SCL \text{ stop hold time} = \text{bus period (s)} \times \text{mul} \times \text{SCL stop hold value}$</p> <p>For example, if the bus speed is 8 MHz, the following table shows the possible hold time values with different ICR and MULT selections to achieve an I²C baud rate of 100 kbps.</p> <table border="1"> <thead> <tr> <th rowspan="2">MULT</th> <th rowspan="2">ICR</th> <th colspan="3">Hold times (μs)</th> </tr> <tr> <th>SDA</th> <th>SCL Start</th> <th>SCL Stop</th> </tr> </thead> <tbody> <tr> <td>2h</td> <td>00h</td> <td>3.500</td> <td>3.000</td> <td>5.500</td> </tr> <tr> <td>1h</td> <td>07h</td> <td>2.500</td> <td>4.000</td> <td>5.250</td> </tr> <tr> <td>1h</td> <td>0Bh</td> <td>2.250</td> <td>4.000</td> <td>5.250</td> </tr> <tr> <td>0h</td> <td>14h</td> <td>2.125</td> <td>4.250</td> <td>5.125</td> </tr> <tr> <td>0h</td> <td>18h</td> <td>1.125</td> <td>4.750</td> <td>5.125</td> </tr> </tbody> </table>	MULT	ICR	Hold times (μs)			SDA	SCL Start	SCL Stop	2h	00h	3.500	3.000	5.500	1h	07h	2.500	4.000	5.250	1h	0Bh	2.250	4.000	5.250	0h	14h	2.125	4.250	5.125	0h	18h	1.125	4.750	5.125

39.3.3 I2C Control Register 1 (I2Cx_C1)

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	IICEN	IICIE	MST	TX	TXAK	0	WUEN	DMAEN
Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_C1 field descriptions

Field	Description
7 IICEN	<p>I2C Enable</p> <p>Enables I2C module operation.</p> <p>0 Disabled 1 Enabled</p>
6 IICIE	<p>I2C Interrupt Enable</p> <p>Enables I2C interrupt requests.</p> <p>0 Disabled 1 Enabled</p>
5 MST	<p>Master Mode Select</p> <p>When the MST bit is changed from a 0 to a 1, a START signal is generated on the bus and master mode is selected. When this bit changes from a 1 to a 0, a STOP signal is generated and the mode of operation changes from master to slave.</p> <p>0 Slave mode 1 Master mode</p>
4 TX	<p>Transmit Mode Select</p> <p>Selects the direction of master and slave transfers. In master mode this bit must be set according to the type of transfer required. Therefore, for address cycles, this bit is always set. When addressed as a slave this bit must be set by software according to the SRW bit in the status register.</p> <p>0 Receive 1 Transmit</p>
3 TXAK	<p>Transmit Acknowledge Enable</p> <p>Specifies the value driven onto the SDA during data acknowledge cycles for both master and slave receivers. The value of the FACK bit affects NACK/ACK generation.</p> <p>NOTE: SCL is held low until TXAK is written.</p> <p>0 An acknowledge signal is sent to the bus on the following receiving byte (if FACK is cleared) or the current receiving byte (if FACK is set). 1 No acknowledge signal is sent to the bus on the following receiving data byte (if FACK is cleared) or the current receiving data byte (if FACK is set).</p>
2 RSTA	Repeat START

Table continues on the next page...

I2Cx_C1 field descriptions (continued)

Field	Description
	Writing a one to this bit generates a repeated START condition provided it is the current master. This bit will always be read as zero. Attempting a repeat at the wrong time results in loss of arbitration.
1 WUEN	<p>Wakeup Enable</p> <p>The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs.</p> <p>0 Normal operation. No interrupt generated when address matching in low power mode. 1 Enables the wakeup function in low power mode.</p>
0 DMAEN	<p>DMA Enable</p> <p>The DMAEN bit enables or disables the DMA function.</p> <p>0 All DMA signalling disabled. 1 DMA transfer is enabled and the following conditions trigger the DMA request:</p> <ul style="list-style-type: none"> While FACK = 0, a data byte is received, either address or data is transmitted. (ACK/NACK automatic) While FACK = 0, the first byte received matches the A1 register or is general call address. <p>If any address matching occurs, IAAS and TCF are set. If the direction of transfer is known from master to slave, then it is not required to check the SRW. With this assumption, DMA can also be used in this case. In other cases, if the master reads data from the slave, then it is required to rewrite the C1 register operation. With this assumption, DMA cannot be used.</p> <p>When FACK = 1, an address or a data byte is transmitted.</p>

39.3.4 I2C Status register (I2Cx_S)

Address: Base address + 3h offset

0 RXAK	<p>Receive Acknowledge</p> <p>0 Acknowledge signal was received after the completion of one byte of data transmission on the bus 1 No acknowledge signal detected</p>

39.3.5 I2C Data I/O register (I2Cx_D)

Address: Base address + 4h offset

I2Cx_D field descriptions

Field	Description
7-0 DATA	<p>Data</p> <p>In master transmit mode, when data is written to this register, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data.</p> <p>NOTE: When making the transition out of master receive mode, switch the I2C mode before reading the Data register to prevent an inadvertent initiation of a master receive data transfer.</p> <p>In slave mode, the same functions are available after an address match occurs.</p> <p>The C1[TX] bit must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For example, if the I2C module is configured for master transmit but a master receive is desired, reading the Data register does not initiate the receive.</p> <p>Reading the Data register returns the last byte received while the I2C module is configured in master receive or slave receive mode. The Data register does not reflect every byte that is transmitted on the I2C bus, and neither can software verify that a byte has been written to the Data register correctly by reading it back.</p> <p>In master transmit mode, the first byte of data written to the Data register following assertion of MST (start bit) or assertion of RSTA (repeated start bit) is used for the address transfer and must consist of the calling address (in bits 7-1) concatenated with the required R/W bit (in position bit 0).</p>

39.3.6 I2C Control Register 2 (I2Cx_C2)

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	GCAEN	ADEXT	HDRS	SBRC	RMEN	AD[10:8]		
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_C2 field descriptions

Field	Description
7 GCAEN	<p>General Call Address Enable</p> <p>Enables general call address.</p> <p>0 Disabled 1 Enabled</p>
6 ADEXT	<p>Address Extension</p> <p>Controls the number of bits used for the slave address.</p> <p>0 7-bit address scheme 1 10-bit address scheme</p>
5 HDRS	<p>High Drive Select</p> <p>Controls the drive capability of the I2C pads.</p> <p>0 Normal drive mode 1 High drive mode</p>
4 SBRC	<p>Slave Baud Rate Control</p> <p>Enables independent slave mode baud rate at maximum frequency, which forces clock stretching on SCL in very fast I2C modes. To a slave, an example of a "very fast" mode is when the master transfers at 40 kbps but the slave can capture the master's data at only 10 kbps.</p> <p>0 The slave baud rate follows the master baud rate and clock stretching may occur 1 Slave baud rate is independent of the master baud rate</p>
3 RMEN	<p>Range Address Matching Enable</p> <p>This bit controls slave address matching for addresses between the values of the A1 and RA registers. When this bit is set, a slave address match occurs for any address greater than the value of the A1 register and less than or equal to the value of the RA register.</p> <p>0 Range mode disabled. No address match occurs for an address within the range of values of the A1 and RA registers. 1 Range mode enabled. Address matching occurs when a slave receives an address within the range of values of the A1 and RA registers.</p>
2-0 AD[10:8]	<p>Slave Address</p> <p>Contains the upper three bits of the slave address in the 10-bit address scheme. This field is valid only while the ADEXT bit is set.</p>

39.3.7 I2C Programmable Input Glitch Filter register (I2Cx_FLT)

Address: Base address + 6h offset

I2Cx_FLT field descriptions

Field	Description
7 Reserved	This field is reserved. Writing this bit has no effect.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 FLT	I2C Programmable Filter Factor Controls the width of the glitch, in terms of bus clock cycles, that the filter must absorb. For any glitch whose size is less than or equal to this width setting, the filter does not allow the glitch to pass. 0h No filter/bypass 1-Fh Filter glitches up to width of <i>n</i> bus clock cycles, where <i>n</i> =1-15d

39.3.8 I2C Range Address register (I2Cx_RA)

Address: Base address + 7h offset

I2Cx_RA field descriptions

Field	Description
7–1 RAD	Range Slave Address This field contains the slave address to be used by the I2C module. The field is used in the 7-bit address scheme. Any nonzero write enables this register. This register's use is similar to that of the A1 register, but in addition this register can be considered a maximum boundary in range matching mode.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

39.3.9 I2C SMBus Control and Status register (I2Cx_SMB)

NOTE

When the SCL and SDA signals are held high for a length of time greater than the high timeout period, the SHTF1 flag sets. Before reaching this threshold, while the system is detecting how long these signals are being held high, a master assumes that the bus is free. However, the SHTF1 bit rises in the bus transmission process with the idle bus state.

NOTE

When the TCKSEL bit is set, there is no need to monitor the SHTF1 bit because the bus speed is too high to match the protocol of SMBus.

Address: Base address + 8h offset

Field	Description
7-0 SSLT[15:8]	Most significant byte of SCL low timeout value that determines the timeout period of SCL low.

39.3.12 I2C SCL Low Timeout Register Low (I2Cx_SLTL)

Address: Base address + Bh offset

Bit	7	6	5	4	3	2	1	0
Read	SSLT[7:0]							
Write	SSLT[7:0]							
Reset	0	0	0	0	0	0	0	0

I2Cx_SLTL field descriptions

Field	Description
7-0 SSLT[7:0]	Least significant byte of SCL low timeout value that determines the timeout period of SCL low.

39.4 Functional description

This section provides a comprehensive functional description of the I2C module.

39.4.1 I2C protocol

The I2C bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfers. All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors depends on the system.

Normally, a standard instance of communication is composed of four parts:

1. START signal
2. Slave address transmission
3. Data transfer
4. STOP signal

The STOP signal should not be confused with the CPU STOP instruction. The following figure illustrates I2C bus system communication.

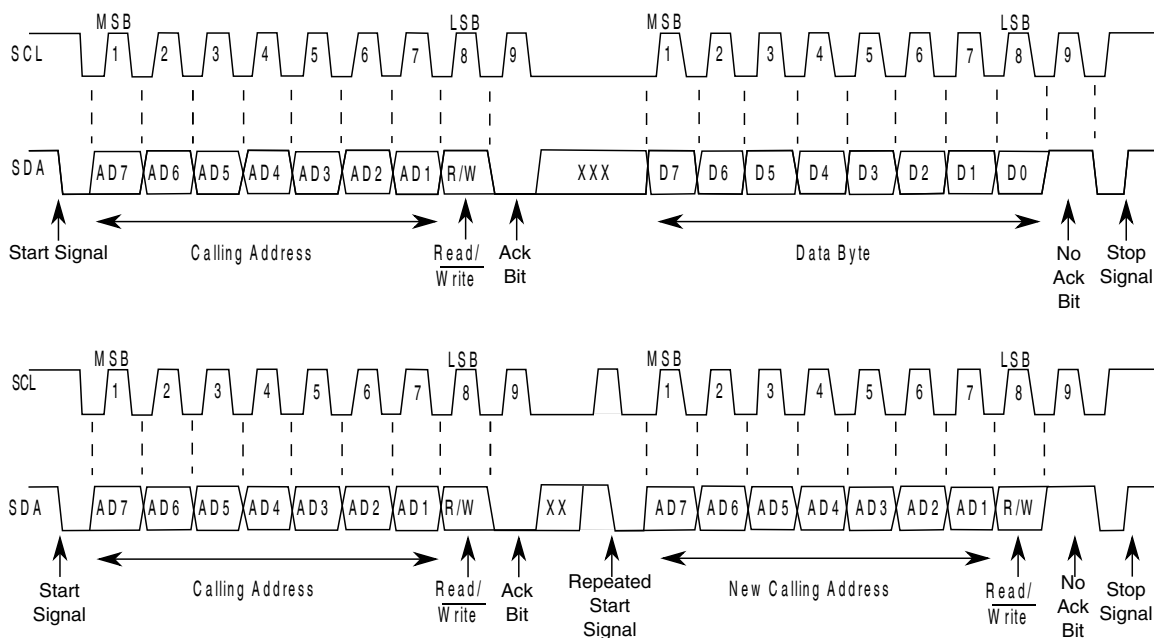

Figure 39-62. I2C bus transmission signals

39.4.1.1 START signal

The bus is free when no master device is engaging the bus (both SCL and SDA are high). When the bus is free, a master may initiate communication by sending a START signal. A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer—each data transfer might contain several bytes of data—and brings all slaves out of their idle states.

39.4.1.2 Slave address transmission

Immediately after the START signal, the first byte of a data transfer is the slave address transmitted by the master. This address is a 7-bit calling address followed by an R/\overline{W} bit. The R/\overline{W} bit tells the slave the desired direction of data transfer.

- 1 = Read transfer: The slave transmits data to the master
- 0 = Write transfer: The master transmits data to the slave

Only the slave with a calling address that matches the one transmitted by the master responds by sending an acknowledge bit. The slave sends the acknowledge bit by pulling SDA low at the ninth clock.

No two slaves in the system can have the same address. If the I2C module is the master, it must not transmit an address that is equal to its own slave address. The I2C module cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the I2C module reverts to slave mode and operates correctly even if it is being addressed by another master.

39.4.1.3 Data transfers

When successful slave addressing is achieved, data transfer can proceed on a byte-by-byte basis in the direction specified by the R/\overline{W} bit sent by the calling master.

All transfers that follow an address cycle are referred to as data transfers, even if they carry subaddress information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low. Data must be held stable while SCL is high. There is one clock pulse on SCL for each data bit, and the MSB is transferred first. Each data byte is followed by a ninth (acknowledge) bit, which is signaled from the receiving device by pulling SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master in the ninth bit, the slave must leave SDA high. The master interprets the failed acknowledgement as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets it as an end to data transfer and releases the SDA line.

In the case of a failed acknowledgement by either the slave or master, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a STOP signal.
- Commences a new call by generating a repeated START signal.

39.4.1.4 STOP signal

The master can terminate the communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is asserted.

The master can generate a STOP signal even if the slave has generated an acknowledgement, at which point the slave must release the bus.

39.4.1.5 Repeated START signal

The master may generate a START signal followed by a calling command without generating a STOP signal first. This action is called a repeated START. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

39.4.1.6 Arbitration procedure

The I2C bus is a true multimaster bus that allows more than one master to be connected on it.

If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. The bus clock's low period is equal to the longest clock low period, and the high period is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic level 1 while another master transmits logic level 0. The losing masters immediately switch to slave receive mode and stop driving SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets a status bit to indicate the loss of arbitration.

39.4.1.7 Clock synchronization

Because wire AND logic is performed on SCL, a high-to-low transition on SCL affects all devices connected on the bus. The devices start counting their low period and, after a device's clock has gone low, that device holds SCL low until the clock reaches its high state. However, the change of low to high in this device clock might not change the state of SCL if another device clock is still within its low period. Therefore, the synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time; see the following diagram. When all applicable devices have counted off their low period, the synchronized clock SCL is released and pulled high. Afterward there is no difference between the device clocks and the state of SCL, and all devices start counting their high periods. The first device to complete its high period pulls SCL low again.

Figure 39-63. I2C clock synchronization

39.4.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. A slave device may hold SCL low after completing a single byte transfer (9 bits). In this case, it halts the bus clock and forces the master clock into wait states until the slave releases SCL.

39.4.1.9 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master drives SCL low, a slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL

low period, the resulting SCL bus signal's low period is stretched. In other words, the SCL bus signal's low period is increased to be the same length as the slave's SCL low period.

39.4.1.10 I2C divider and hold values

NOTE

For some cases on some devices, the SCL divider value may vary by +/-2 or +/-4 when ICR's value ranges from 00h to 0Fh. These potentially varying SCL divider values are highlighted in the following table. For the actual SCL divider values for your device, see the chip-specific details about the I2C module.

Table 39-67. I2C divider and hold values

ICR (hex)	SCL divider	SDA hold value	SCL hold (start) value	SCL hold (stop) value	ICR (hex)	SCL divider (clocks)	SDA hold (clocks)	SCL hold (start) value	SCL hold (stop) value
00	20	7	6	11	20	160	17	78	81

39.4.2 10-bit address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

39.4.2.1 Master-transmitter addresses a slave-receiver

The transfer direction is not changed. When a 10-bit address follows a START condition, each slave compares the first 7 bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit (R/\overline{W} direction bit) is 0. It is possible that more than one device finds a match and generates an acknowledge (A1). Each slave that finds a match compares the 8 bits of the second byte of the slave address with its own address, but only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

Table 39-68. Master-transmitter addresses slave-receiver with a 10-bit address

S	Slave address first 7 bits 11110 + AD10 + AD9	R/ \overline{W} 0	A1	Slave address second byte AD[8:1]	A2	Data	A	...	Data	A/A	P
---	---	---------------------	----	-----------------------------------	----	------	---	-----	------	-----	---

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

39.4.2.2 Master-receiver addresses a slave-transmitter

The transfer direction is changed after the second R/\overline{W} bit. Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and it tests whether the eighth (R/\overline{W}) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

After a repeated START condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth (R/\overline{W}) bit. However, none of them are addressed because $R/\overline{W} = 1$ (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

Table 39-69. Master-receiver addresses a slave-transmitter with a 10-bit address

S	Slave address first 7 bits 11110 + AD10 + AD9	R/ \overline{W} 0	A1	Slave address second byte AD[8:1]	A2	Sr	Slave address first 7 bits 11110 + AD10 + AD9	R/ \overline{W} 1	A3	Data	A	...	Data	A	P
---	--	---------------------	----	--------------------------------------	----	----	--	---------------------	----	------	---	-----	------	---	---

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

39.4.3 Address matching

All received addresses can be requested in 7-bit or 10-bit address format.

- AD[7:1] in Address Register 1, which contains the I2C primary slave address, always participates in the address matching process. It provides a 7-bit address.
- If the ADEXT bit is set, AD[10:8] in Control Register 2 participates in the address matching process. It extends the I2C primary slave address to a 10-bit address.

Additional conditions that affect address matching include:

- If the GCAEN bit is set, general call participates the address matching process.
- If the ALERTEN bit is set, alert response participates the address matching process.
- If the SIICAEN bit is set, Address Register 2 participates in the address matching process.
- If the Range Address register is programmed to a nonzero value, the range address itself participates in the address matching process.
- If the RMEN bit is set, any address within the range of values of Address Register 1 and the Range Address register participates in the address matching process. The Range Address register must be programmed to a value greater than the value of Address Register 1.

When the I2C module responds to one of these addresses, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the Data register after the first byte transfer to determine that the address is matched.

39.4.4 System management bus specification

SMBus provides a control bus for system and power management related tasks. A system can use SMBus to pass messages to and from devices instead of tripping individual control lines. Removing the individual control lines reduces pin count. Accepting messages ensures future expandability. With the system management bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status.

39.4.4.1 Timeouts

The $T_{\text{TIMEOUT,MIN}}$ parameter allows a master or slave to conclude that a defective device is holding the clock low indefinitely or a master is intentionally trying to drive devices off the bus. The slave device must release the bus (stop driving the bus and let SCL and SDA float high) when it detects any single clock held low longer than $T_{\text{TIMEOUT,MIN}}$. Devices that have detected this condition must reset their communication and be able to receive a new START condition within the timeframe of $T_{\text{TIMEOUT,MAX}}$.

SMBus defines a clock low timeout, T_{TIMEOUT} , of 35 ms, specifies $T_{\text{LOW:SEXT}}$ as the cumulative clock low extend time for a slave device, and specifies $T_{\text{LOW:MEXT}}$ as the cumulative clock low extend time for a master device.

39.4.4.1.1 SCL low timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than a timeout value condition. Devices that have detected the timeout condition must reset the communication. When the I2C module is an active master, if it detects that SMBCLK low has exceeded the value of $T_{\text{TIMEOUT,MIN}}$, it must generate a stop condition within or after the current data byte in the transfer process. When the I2C module is a slave, if it detects the $T_{\text{TIMEOUT,MIN}}$ condition, it resets its communication and is then able to receive a new START condition.

39.4.4.1.2 SCL high timeout

When the I2C module has determined that the SMBCLK and SMBDAT signals have been high for at least $T_{\text{HIGH:MAX}}$, it assumes that the bus is idle.

A HIGH timeout occurs after a START condition appears on the bus but before a STOP condition appears on the bus. Any master detecting this scenario can assume the bus is free when either of the following occurs:

- SHTF1 rises.
- The BUSY bit is high and SHTF1 is high.

When the SMBDAT signal is low and the SMBCLK signal is high for a period of time, another kind of timeout occurs. The time period must be defined in software. SHTF2 is used as the flag when the time limit is reached. This flag is also an interrupt resource, so it triggers IICIF.

39.4.4.1.3 CSMBCLK TIMEOUT MEXT and CSMBCLK TIMEOUT SEXT

The following figure illustrates the definition of the timeout intervals $T_{\text{LOW:SEXT}}$ and $T_{\text{LOW:MEXT}}$. When in master mode, the I2C module must not cumulatively extend its clock cycles for a period greater than $T_{\text{LOW:MEXT}}$ within a byte, where each byte is defined as START-to-ACK, ACK-to-ACK, or ACK-to-STOP. When CSMBCLK TIMEOUT MEXT occurs, SMBus MEXT rises and also triggers the SLTF.

Figure 39-64. Timeout measurement intervals

A master is allowed to abort the transaction in progress to any slave that violates the $T_{LOW:SEXT}$ or $T_{TIMEOUT,MIN}$ specifications. To abort the transaction, the master issues a STOP condition at the conclusion of the byte transfer in progress. When a slave, the I2C module must not cumulatively extend its clock cycles for a period greater than $T_{LOW:SEXT}$ during any message from the initial START to the STOP. When CSMBCLK TIMEOUT SEXT occurs, SEXT rises and also triggers SLTF.

NOTE

CSMBCLK TIMEOUT SEXT and CSMBCLK TIMEOUT MEXT are optional functions that are implemented in the second step.

39.4.4.2 FAST ACK and NACK

To improve reliability and communication robustness, implementation of packet error checking (PEC) by SMBus devices is optional for SMBus devices but required for devices participating in and only during the address resolution protocol (ARP) process. The PEC is a CRC-8 error checking byte, calculated on all the message bytes. The PEC is appended to the message by the device that supplied the last data byte. If the PEC is present but not correct, a NACK is issued by the receiver. Otherwise an ACK is issued. To calculate the CRC-8 by software, this module can hold the SCL line low after receiving the eighth SCL (8th bit) if this byte is a data byte. So software can determine whether an ACK or NACK should be sent to the bus by setting or clearing the TXAK bit if the FACK (fast ACK/NACK enable) bit is enabled.

SMBus requires a device always to acknowledge its own address, as a mechanism to detect the presence of a removable device (such as a battery or docking station) on the bus. In addition to indicating a slave device busy condition, SMBus uses the NACK mechanism to indicate the reception of an invalid command or invalid data. Because such a condition may occur on the last byte of the transfer, SMBus devices are required to

have the ability to generate the not acknowledge after the transfer of each byte and before the completion of the transaction. This requirement is important because SMBus does not provide any other resend signaling. This difference in the use of the NACK signaling has implications on the specific implementation of the SMBus port, especially in devices that handle critical system data such as the SMBus host and the SBS components.

NOTE

In the last byte of master receive slave transmit mode, the master must send a NACK to the bus, so FACK must be switched off before the last byte transmits.

39.4.5 Resets

The I2C module is disabled after a reset. The I2C module cannot cause a core reset.

39.4.6 Interrupts

The I2C module generates an interrupt when any of the events in the following table occur, provided that the IICIE bit is set. The interrupt is driven by the IICIF bit (of the I2C Status Register) and masked with the IICIE bit (of the I2C Control Register 1). The IICIF bit must be cleared (by software) by writing 1 to it in the interrupt routine. The SMBus timeouts interrupt is driven by SLTF and masked with the IICIE bit. The SLTF bit must be cleared by software by writing 1 to it in the interrupt routine. You can determine the interrupt type by reading the Status Register.

NOTE

In master receive mode, the FACK bit must be set to zero before the last byte transfer.

Table 39-70. Interrupt summary

Interrupt source	Status	Flag	Local enable
Complete 1-byte transfer	TCF	IICIF	IICIE
Match of received calling address	IAAS	IICIF	IICIE
Arbitration lost	ARBL	IICIF	IICIE
SMBus SCL low timeout	SLTF	IICIF	IICIE
SMBus SCL high SDA low timeout	SHTF2	IICIF	IICIE & SHTF2IE
Wakeup from stop or wait mode	IAAS	IICIF	IICIE & WUEN

39.4.6.1 Byte transfer interrupt

The Transfer Complete Flag (TCF) bit is set at the falling edge of the ninth clock to indicate the completion of a byte and acknowledgement transfer. When FACK is enabled, TCF is then set at the falling edge of eighth clock to indicate the completion of byte.

39.4.6.2 Address detect interrupt

When the calling address matches the programmed slave address (I2C Address Register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the Status Register is set. The CPU is interrupted, provided the IICIE bit is set. The CPU must check the SRW bit and set its Tx mode accordingly.

39.4.6.3 Exit from low-power/stop modes

The slave receive input detect circuit and address matching feature are still active on low power modes (wait and stop). An asynchronous input matching slave address or general call address brings the CPU out of low power/stop mode if the interrupt is not masked. Therefore, TCF and IAAS both can trigger this interrupt.

39.4.6.4 Arbitration lost interrupt

The I2C is a true multimaster bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The I2C module asserts the arbitration-lost interrupt when it loses the data arbitration process and the ARBL bit in the Status Register is set.

Arbitration is lost in the following circumstances:

1. SDA is sampled as low when the master drives high during an address or data transmit cycle.
2. SDA is sampled as low when the master drives high during the acknowledge bit of a data receive cycle.
3. A START cycle is attempted when the bus is busy.
4. A repeated START cycle is requested in slave mode.
5. A STOP condition is detected when the master did not request it.

The ARBL bit must be cleared (by software) by writing 1 to it.

39.4.6.5 Timeout interrupt in SMBus

When the IICIE bit is set, the I2C module asserts a timeout interrupt (outputs SLTF and SHTF2) upon detection of any of the mentioned timeout conditions, with one exception. The SCL high and SDA high TIMEOUT mechanism must not be used to influence the timeout interrupt output, because this timeout indicates an idle condition on the bus. SHTF1 rises when it matches the SCL high and SDA high TIMEOUT and falls automatically just to indicate the bus status. The SHTF2's timeout period is the same as that of SHTF1, which is short compared to that of SLTF, so another control bit, SHTF2IE, is added to enable or disable it.

39.4.7 Programmable input glitch filter

An I2C glitch filter has been added outside legacy I2C modules but within the I2C package. This filter can absorb glitches on the I2C clock and data lines for the I2C module. The width of the glitch to absorb can be specified in terms of the number of (half) bus clock cycles. A single Programmable Input Glitch Filter control register is provided. Effectively, any down-up-down or up-down-up transition on the data line that occurs within the number of clock cycles programmed in this register is ignored by the I2C module. The programmer must specify the size of the glitch (in terms of bus clock cycles) for the filter to absorb and not pass.

Figure 39-65. Programmable input glitch filter diagram

39.4.8 Address matching wakeup

When a primary, range, or general call address match occurs when the I2C module is in slave receive mode, the MCU wakes from a low power mode with no peripheral bus running. Data sent on the bus that is the same as a target device address might also wake the target MCU.

After the address matching IAAS bit is set, an interrupt is sent at the end of address matching to wake the core. The IAAS bit must be cleared after the clock recovery.

NOTE

After the system recovers and is in Run mode, restart the I2C module if it is needed to transfer packets. The SCL line is not held low until the I2C module resets after address matching. The main purpose of this feature is to wake the MCU from a low power mode where no peripheral bus is running. When the MCU is in such a mode: addressing as a slave, slave read/write, and sending an acknowledge bit are not fully supported. To avoid I2C transfer problems resulting from this situation, firmware should prevent the MCU execution of a STOP instruction when the I2C module is in the middle of a transfer.

39.4.9 DMA support

If the DMAEN bit is cleared and the IICIE bit is set, an interrupt condition generates an interrupt request. If the DMAEN bit is set and the IICIE bit is set, an interrupt condition generates a DMA request instead. DMA requests are generated by the transfer complete flag (TCF).

If the DMAEN bit is set, the only arbitration lost is to another I2C module (error), and SCL low timeouts (error) generate CPU interrupts. All other events initiate a DMA transfer.

NOTE

Before the last byte of master receive mode, TXAK must be set to send a NACK after the last byte's transfer. Therefore, the DMA must be disabled before the last byte's transfer.

NOTE

In 10-bit address mode transmission, the addresses to send occupy 2-3 bytes. During this transfer period, the DMA must be disabled because the C1 register is written to send a repeat start or to change the transfer direction.

39.5 Initialization/application information

Module Initialization (Slave)

Initialization/application information

1. Write: Control Register 2
 - to enable or disable general call
 - to select 10-bit or 7-bit addressing mode
2. Write: Address Register 1 to set the slave address
3. Write: Control Register 1 to enable the I2C module and interrupts
4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
5. Initialize RAM variables used to achieve the routine shown in the following figure

Module Initialization (Master)

1. Write: Frequency Divider register to set the I2C baud rate (see example in description of [ICR](#))
2. Write: Control Register 1 to enable the I2C module and interrupts
3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
4. Initialize RAM variables used to achieve the routine shown in the following figure
5. Write: Control Register 1 to enable TX
6. Write: Control Register 1 to enable MST (master mode)
7. Write: Data register with the address of the target slave (the LSB of this byte determines whether the communication is master receive or transmit)

The routine shown in the following figure encompasses both master and slave I2C operations. For slave operation, an incoming I2C message that contains the proper address begins I2C communication. For master operation, communication must be initiated by writing the Data register.

- Notes:**
1. If general call is enabled, check to determine if the received address is a general call address (0x00). If the received address is a general call address, the general call must be handled by user software.
 2. When 10-bit addressing addresses a slave, the slave sees an interrupt following the first byte of the extended address. Ensure that for this interrupt, the contents of the Data register are ignored and not treated as a valid data transfer.

Figure 39-66. Typical I2C interrupt routine

Notes:

1. If general call or SIICAEN is enabled, check to determine if the received address is a general call address (0x00) or an SMBus device default address. In either case, they must be handled by user software.
2. In receive mode, one bit time delay may be needed before the first and second data reading.

Figure 39-67. Typical I2C SMBus interrupt routine

Chapter 40

Universal Asynchronous Receiver/Transmitter (UART)

40.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The UART allows asynchronous serial communication with peripheral devices and CPUs.

40.1.1 Features

The UART includes the following features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 13-bit baud rate selection with /32 fractional divide, based on the module clock frequency
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable transmitter output polarity
- Programmable receive input polarity
- 13-bit break character option
- 11-bit break character detection option

- Independent FIFO structure for transmit and receive
- Two receiver wakeup methods:
 - Idle line wakeup
 - Address mark wakeup
- Address match feature in the receiver to reduce address mark wakeup ISR overhead
- Ability to select MSB or LSB to be first bit on wire
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Support for ISO 7816 protocol to interface with SIM cards and smart cards
 - Support for T=0 and T=1 protocols
 - Automatic retransmission of NACK'd packets with programmable retry threshold
 - Support for 11 and 12 ETU transfers
 - Detection of initial packet and automated transfer parameter programming
 - Interrupt-driven operation with seven ISO-7816 specific interrupts:
 - Wait time violated
 - Character wait time violated
 - Block wait time violated
 - Initial frame detected
 - Transmit error threshold exceeded
 - Receive error threshold exceeded
 - Guard time violated
- Interrupt-driven operation with 12 flags, not specific to ISO-7816 support
 - Transmitter data buffer at or below watermark
 - Transmission complete
 - Receiver data buffer at or above watermark
 - Idle receiver input
 - Receiver data buffer overrun

- Receiver data buffer underflow
- Transmit data buffer overflow
- Noise error
- Framing error
- Parity error
- Active edge on receive pin
- LIN break detect
- Receiver framing error detection
- Hardware parity generation and checking
- 1/16 bit-time noise detection
- DMA interface

40.1.2 Modes of operation

The UART functions in the same way in all the normal modes.

It has the following two low power modes:

- Wait mode
- Stop mode

40.1.2.1 Run mode

This is the normal mode of operation.

40.1.2.2 Wait mode

UART operation in the Wait mode depends on the state of the C1[UARTSWAI] field.

- If C1[UARTSWAI] is cleared, and the CPU is in Wait mode, the UART operates normally.
- If C1[UARTSWAI] is set, and the CPU is in Wait mode, the UART clock generation ceases and the UART module enters a power conservation state.

C1[UARTSWAI] does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

Setting C1[UARTSWAI] does not affect the state of the C2[RE] or C2[TE].

If C1[UARTSWAI] is set, any ongoing transmission or reception stops at the Wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of Wait mode. Bringing the CPU out of Wait mode by reset aborts any ongoing transmission or reception and resets the UART.

40.1.2.3 Stop mode

The UART is inactive during Stop mode for reduced power consumption. The STOP instruction does not affect the UART register states, but the UART module clock is disabled. The UART operation resumes after an external interrupt brings the CPU out of Stop mode. Bringing the CPU out of Stop mode by reset aborts any ongoing transmission or reception and resets the UART. Entering or leaving Stop mode does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

40.2 UART signal descriptions

The UART signals are shown in the following table.

Table 40-1. UART signal descriptions

Signal	Description	I/O
CTS	Clear to send	I
RTS	Request to send	O
RXD	Receive data	I
TXD	Transmit data	O

40.2.1 Detailed signal descriptions

The detailed signal descriptions of the UART are shown in the following table.

Table 40-2. UART—Detailed signal descriptions

Signal	I/O	Description
CTS	I	Clear to send. Indicates whether the UART can start transmitting data when flow control is enabled.
		State meaning Asserted—Data transmission can start. Negated—Data transmission cannot start.
		Timing Assertion—When transmitting device's RTS asserts. Negation—When transmitting device's RTS deasserts.
RTS	O	Request to send. When driven by the receiver, indicates whether the UART is ready to receive data. When driven by the transmitter, can enable an external transceiver during transmission.
		State meaning Asserted—When driven by the receiver, ready to receive data. When driven by the transmitter, enable the external transmitter. Negated—When driven by the receiver, not ready to receive data. When driven by the transmitter, disable the external transmitter.
		Timing Assertion—Can occur at any time; can assert asynchronously to the other input signals. Negation—Can occur at any time; can deassert asynchronously to the other input signals.
RXD	I	Receive data. Serial data input to receiver.
		State meaning Whether RXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		Timing Sampled at a frequency determined by the module clock divided by the baud rate.
TXD	O	Transmit data. Serial data output from transmitter.
		State meaning Whether TXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		Timing Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing.

40.3 Memory map and registers

This section provides a detailed description of all memory and registers.

Accessing reserved addresses within the memory map results in a transfer error. None of the contents of the implemented addresses are modified as a result of that access.

Only byte accesses are supported.

UART memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
FFFF_8140	UART Baud Rate Registers: High (UART0_BDH)	8	R/W	00h	40.3.1/940
FFFF_8141	UART Baud Rate Registers: Low (UART0_BDL)	8	R/W	04h	40.3.2/941

40.3.1 UART Baud Rate Registers: High (UARTx_BDH)

This register, along with the BDL register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting (SBR[12:0]), first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written.

BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 0h offset

UARTx_BDH field descriptions

Field	Description
7 LBKDIE	LIN Break Detect Interrupt Enable Enables the LIN break detect flag, LBKDIF, to generate interrupt requests based on the state of LBKDDMAS.

Table continues on the next page...

UARTx_BDH field descriptions (continued)

Field	Description
	0 LBKDIF interrupt requests disabled. 1 LBKDIF interrupt requests enabled.
6 RXEDGIE	RxD Input Active Edge Interrupt Enable Enables the receive input active edge, RXEDGIF, to generate interrupt requests. 0 Hardware interrupts from RXEDGIF disabled using polling. 1 RXEDGIF interrupt request enabled.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 SBR	UART Baud Rate Bits The baud rate for the UART is determined by the 13 SBR fields. See Baud rate generation for details. NOTE: <ul style="list-style-type: none"> The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0. Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.

40.3.2 UART Baud Rate Registers: Low (UARTx_BDL)

This register, along with the BDH register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting, SBR[12:0], first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written. BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 1h offset

Write								
Reset	0	0	0	0	0	1	0	0

UARTx_BDL field descriptions

Field	Description
7–0 SBR	UART Baud Rate Bits The baud rate for the UART is determined by the 13 SBR fields. See Baud rate generation for details. NOTE: <ul style="list-style-type: none"> The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0. Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.

40.3.3 UART Control Register 1 (UARTx_C1)

This read/write register controls various optional features of the UART system.

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	LOOPS	UARTSWAI	RSRC	M	WAKE	ILT	PE	PT
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C1 field descriptions

Field	Description
7 LOOPS	<p>Loop Mode Select</p> <p>When LOOPS is set, the RxD pin is disconnected from the UART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.</p> <p>0 Normal operation. 1 Loop mode where transmitter output is internally connected to receiver input. The receiver input is determined by RSRC.</p>
6 UARTSWAI	<p>UART Stops in Wait Mode</p> <p>0 UART clock continues to run in Wait mode. 1 UART clock freezes while CPU is in Wait mode.</p>
5 RSRC	<p>Receiver Source Select</p> <p>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.</p> <p>0 Selects internal loop back mode. The receiver input is internally connected to transmitter output. 1 Single wire UART mode where the receiver input is connected to the transmit pin input signal.</p>
4 M	<p>9-bit or 8-bit Mode Select</p> <p>This field must be set when C7816[ISO_7816E] is set/enabled.</p> <p>0 Normal—start + 8 data bits (MSB/LSB first as determined by MSBF) + stop. 1 Use—start + 9 data bits (MSB/LSB first as determined by MSBF) + stop.</p>
3 WAKE	<p>Receiver Wakeup Method Select</p> <p>Determines which condition wakes the UART:</p> <ul style="list-style-type: none"> • Address mark in the most significant bit position of a received data character, or • An idle condition on the receive pin input signal. <p>0 Idle line wakeup. 1 Address mark wakeup.</p>
2 ILT	<p>Idle Line Type Select</p> <p>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.</p>

Table continues on the next page...

UARTx_C1 field descriptions (continued)

Field	Description
	<p>NOTE:</p> <ul style="list-style-type: none"> In case the UART is programmed with ILT = 1, a logic of 1'b0 is automatically shifted after a received stop bit, therefore resetting the idle count. In case the UART is programmed for IDLE line wakeup (RWU = 1 and WAKE = 0), ILT has no effect on when the receiver starts counting logic 1s as idle character bits. In idle line wakeup, an idle character is recognized at anytime the receiver sees 10, 11, or 12 1s depending on the M, PE, and C4[M10] fields. <p>0 Idle character bit count starts after start bit. 1 Idle character bit count starts after stop bit.</p>
1 PE	<p>Parity Enable</p> <p>Enables the parity function. When parity is enabled, parity function inserts a parity bit in the bit position immediately preceding the stop bit. This field must be set when C7816[ISO_7816E] is set/enabled.</p> <p>0 Parity function disabled. 1 Parity function enabled.</p>
0 PT	<p>Parity Type</p> <p>Determines whether the UART generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. This field must be cleared when C7816[ISO_7816E] is set/enabled.</p> <p>0 Even parity. 1 Odd parity.</p>

40.3.4 UART Control Register 2 (UARTx_C2)

This register can be read or written at any time.

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C2 field descriptions

Field	Description
7 TIE	<p>Transmitter Interrupt or DMA Transfer Enable.</p> <p>Enables S1[TDRE] to generate interrupt requests or DMA transfer requests, based on the state of C5[TDMAS].</p> <p>NOTE: If C2[TIE] and C5[TDMAS] are both set, then TCIE must be cleared, and D[D] must not be written unless servicing a DMA request.</p> <p>0 TDRE interrupt and DMA transfer requests disabled. 1 TDRE interrupt or DMA transfer requests enabled.</p>

Table continues on the next page...

UARTx_C2 field descriptions (continued)

Field	Description
6 TCIE	<p>Transmission Complete Interrupt Enable</p> <p>Enables the transmission complete flag, S1[TC], to generate interrupt requests .</p> <p>0 TC interrupt requests disabled. 1 TC interrupt requests enabled.</p>
5 RIE	<p>Receiver Full Interrupt or DMA Transfer Enable</p> <p>Enables S1[RDRF] to generate interrupt requests or DMA transfer requests, based on the state of C5[RDMAS].</p> <p>0 RDRF interrupt and DMA transfer requests disabled. 1 RDRF interrupt or DMA transfer requests enabled.</p>
4 ILIE	<p>Idle Line Interrupt Enable</p> <p>Enables the idle line flag, S1[IDLE], to generate interrupt requests , based on the state of C5[ILDMAS].</p> <p>0 IDLE interrupt requests disabled. 1 IDLE interrupt requests enabled.</p>
3 TE	<p>Transmitter Enable</p> <p>Enables the UART transmitter. TE can be used to queue an idle preamble by clearing and then setting TE. When C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block has been transmitted. This condition is detected when TL7816[TLEN] = 0 and four additional characters are transmitted.</p> <p>0 Transmitter off. 1 Transmitter on.</p>
2 RE	<p>Receiver Enable</p> <p>Enables the UART receiver.</p> <p>0 Receiver off. 1 Receiver on.</p>
1 RWU	<p>Receiver Wakeup Control</p> <p>This field can be set to place the UART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when C1[WAKE] is clear or an address match when C1[WAKE] is set. This field must be cleared when C7816[ISO_7816E] is set.</p> <p>NOTE: RWU must be set only with C1[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by S2[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the UART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to reasserted.</p> <p>0 Normal operation. 1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.</p>
0 SBK	<p>Send Break</p> <p>Toggling SBK sends one break character from the following: See for the number of logic 0s for the different configurations. Toggling implies clearing the SBK field before the break character has finished</p>

Table continues on the next page...

UARTx_C2 field descriptions (continued)

Field	Description
	<p>transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10, 11, or 12 bits, or 13 or 14 bits).</p> <ul style="list-style-type: none"> • 10, 11, or 12 logic 0s if S2[BRK13] is cleared • 13 or 14 logic 0s if S2[BRK13] is set. <p>Transmitting break characters This field must be cleared when C7816[ISO_7816E] is set.</p> <p>0 Normal transmitter operation.</p> <p>1 Queue break characters to be sent.</p>

40.3.5 UART Status Register 1 (UARTx_S1)

The S1 register provides inputs to the MCU for generation of UART interrupts or DMA requests. This register can also be polled by the MCU to check the status of its fields. To clear a flag, the status register should be read followed by a read or write to D register, depending on the interrupt flag type. Other instructions can be executed between the two steps as long as the handling of I/O is not compromised, but the order of operations is important for flag clearing. When a flag is configured to trigger a DMA request, assertion of the associated DMA done signal from the DMA controller clears the flag.

NOTE

- If the condition that results in the assertion of the flag, interrupt, or DMA request is not resolved prior to clearing the flag, the flag, and interrupt/DMA request, reasserts. For example, if the DMA or interrupt service routine fails to write sufficient data to the transmit buffer to raise it above the watermark level, the flag reasserts and generates another interrupt or DMA request.
- Reading an empty data register to clear one of the flags of the S1 register causes the FIFO pointers to become misaligned. A receive FIFO flush reinitializes the pointers.

Address: Base address + 4h offset

Bit	7	6	5	4	3	2	1	0
Read	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
Write								
Reset	1	1	0	0	0	0	0	0

UARTx_S1 field descriptions

Field	Description
7 TDRE	<p>Transmit Data Register Empty Flag</p> <p>TDRE will set when the number of datawords in the transmit buffer (D and C3[T8]) is equal to or less than the number indicated by TWFIFO[TXWATER]. A character that is in the process of being transmitted is not included in the count. To clear TDRE, read S1 when TDRE is set and then write to the UART data register (D). For more efficient interrupt servicing, all data except the final value to be written to the buffer must be written to D/C3[T8]. Then S1 can be read before writing the final data value, resulting in the clearing of the TDRE flag. This is more efficient because the TDRE reasserts until the watermark has been exceeded. So, attempting to clear the TDRE with every write will be ineffective until sufficient data has been written.</p> <p>0 The amount of data in the transmit buffer is greater than the value indicated by TWFIFO[TXWATER]. 1 The amount of data in the transmit buffer is less than or equal to the value indicated by TWFIFO[TXWATER] at some point in time since the flag has been cleared.</p>
6 TC	<p>Transmit Complete Flag</p> <p>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by reading S1 with TC set and then doing one of the following: When C7816[ISO_7816E] is set/enabled, this field is set after any NACK signal has been received, but prior to any corresponding guard times expiring.</p> <ul style="list-style-type: none"> • Writing to D to transmit new data. • Queuing a preamble by clearing and then setting C2[TE]. • Queuing a break character by writing 1 to SBK in C2. <p>0 Transmitter active (sending data, a preamble, or a break). 1 Transmitter idle (transmission activity complete).</p>
5 RDRF	<p>Receive Data Register Full Flag</p> <p>RDRF is set when the number of datawords in the receive buffer is equal to or more than the number indicated by RWFIFO[RXWATER]. A dataword that is in the process of being received is not included in the count. RDRF is prevented from setting while S2[LBKDE] is set. Additionally, when S2[LBKDE] is set, the received datawords are stored in the receive buffer but over-write each other. To clear RDRF, read S1 when RDRF is set and then read D. For more efficient interrupt and DMA operation, read all data except the final value from the buffer, using D/C3[T8]/ED. Then read S1 and the final data value, resulting in the clearing of the RDRF flag. Even if RDRF is set, data will continue to be received until an overrun condition occurs.</p> <p>0 The number of datawords in the receive buffer is less than the number indicated by RXWATER. 1 The number of datawords in the receive buffer is equal to or greater than the number indicated by RXWATER at some point in time since this flag was last cleared.</p>
4 IDLE	<p>Idle Line Flag</p> <p>After the IDLE flag is cleared, a frame must be received (although not necessarily stored in the data buffer, for example if C2[RWU] is set), or a LIN break character must set the S2[LBKDIF] flag before an idle condition can set the IDLE flag. To clear IDLE, read UART status S1 with IDLE set and then read D. IDLE is set when either of the following appear on the receiver input:</p> <ul style="list-style-type: none"> • 10 consecutive logic 1s if C1[M] = 0 • 11 consecutive logic 1s if C1[M] = 1 and C4[M10] = 0 • 12 consecutive logic 1s if C1[M] = 1, C4[M10] = 1, and C1[PE] = 1 <p>Idle detection is not supported when 7816E is set/enabled and hence this flag is ignored.</p> <p>NOTE: When RWU is set and WAKE is cleared, an idle line condition sets the IDLE flag if RWUID is set, else the IDLE flag does not become set.</p>

Table continues on the next page...

UARTx_S1 field descriptions (continued)

Field	Description
	<p>0 Receiver input is either active now or has never become active since the IDLE flag was last cleared.</p> <p>1 Receiver input has become idle or the flag has not been cleared since it last asserted.</p>
3 OR	<p>Receiver Overrun Flag</p> <p>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the UART data registers is not affected. If the OR flag is set, no data is stored in the data buffer even if sufficient room exists. Additionally, while the OR flag is set, the RDRF and IDLE flags are blocked from asserting, that is, transition from an inactive to an active state. To clear OR, read S1 when OR is set and then read D. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if S2[LBKDIF] is not cleared before the next data character is received. See for more details regarding the operation of the OR bit. Overrun (OR) flag implicationsIn 7816 mode, it is possible to configure a NACK to be returned by programing C7816[ONACK].</p> <p>0 No overrun has occurred since the last time the flag was cleared.</p> <p>1 Overrun has occurred or the overrun flag has not been cleared since the last overrun occurred.</p>
2 NF	<p>Noise Flag</p> <p>NF is set when the UART detects noise on the receiver input. NF does not become set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). When NF is set, it indicates only that a dataword has been received with noise since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has noise or that there is only one dataword in the buffer that was received with noise unless the receive buffer has a depth of one. To clear NF, read S1 and then read D.</p> <p>0 No noise detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1 then there may be data in the receiver buffer that was received with noise.</p> <p>1 At least one dataword was received with noise detected since the last time the flag was cleared.</p>
1 FE	<p>Framing Error Flag</p> <p>FE is set when a logic 0 is accepted as the stop bit. FE does not set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). FE inhibits further data reception until it is cleared. To clear FE, read S1 with FE set and then read D. The last data in the receive buffer represents the data that was received with the frame error enabled. Framing errors are not supported when 7816E is set/enabled. However, if this flag is set, data is still not received in 7816 mode.</p> <p>0 No framing error detected.</p> <p>1 Framing error.</p>
0 PF	<p>Parity Error Flag</p> <p>PF is set when PE is set, S2[LBKDE] is disabled, and the parity of the received data does not match its parity bit. The PF is not set in the case of an overrun condition. When PF is set, it indicates only that a dataword was received with parity error since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has a parity error or that there is only one dataword in the buffer that was received with a parity error, unless the receive buffer has a depth of one. To clear PF, read S1 and then read D. Within the receive buffer structure the received dataword is tagged if it is received with a parity error. This information is available by reading the ED register prior to reading the D register.</p> <p>0 No parity error detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1, then there may be data in the receive buffer what was received with a parity error.</p> <p>1 At least one dataword was received with a parity error since the last time this flag was cleared.</p>

40.3.6 UART Status Register 2 (UARTx_S2)

The S2 register provides inputs to the MCU for generation of UART interrupts or DMA requests. Also, this register can be polled by the MCU to check the status of these bits. This register can be read or written at any time, with the exception of the MSBF and RXINV bits, which should be changed by the user only between transmit and receive packets.

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	LBKDIF	RXEDGIF	MSBF	RXINV	RWUID	BRK13	LBKDE	RAF
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_S2 field descriptions

Field	Description
7 LBKDIF	<p>LIN Break Detect Interrupt Flag</p> <p>LBKDIF is set when LBKDE is set and a LIN break character is detected on the receiver input. The LIN break characters are 11 consecutive logic 0s if C1[M] = 0 or 12 consecutive logic 0s if C1[M] = 1. LBKDIF is set after receiving the last LIN break character. LBKDIF is cleared by writing a 1 to it.</p> <p>0 No LIN break character detected. 1 LIN break character detected.</p>
6 RXEDGIF	<p>RxD Pin Active Edge Interrupt Flag</p> <p>RXEDGIF is set when an active edge occurs on the RxD pin. The active edge is falling if RXINV = 0, and rising if RXINV=1. RXEDGIF is cleared by writing a 1 to it. See for additional details. RXEDGIF description</p> <p>NOTE: The active edge is detected only in two wire mode and on receiving data coming from the RxD pin.</p> <p>0 No active edge on the receive pin has occurred. 1 An active edge on the receive pin has occurred.</p>
5 MSBF	<p>Most Significant Bit First</p> <p>Setting this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p>0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1 MSB (bit8, bit7 or bit6) is the first bit that is transmitted following the start bit, depending on the setting of C1[M] and C1[PE]. Further, the first bit received after the start bit is identified as bit8, bit7, or bit6, depending on the setting of C1[M] and C1[PE].</p>
4 RXINV	<p>Receive Data Inversion</p>

Table continues on the next page...

UARTx_S2 field descriptions (continued)

Field	Description
	<p>Setting this field reverses the polarity of the received data input. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p>NOTE: Setting RXINV inverts the RxD input for data bits, start and stop bits, break, and idle. When C7816[ISO7816E] is set/enabled, only the data bits and the parity bit are inverted.</p> <p>0 Receive data is not inverted. 1 Receive data is inverted.</p>
3 RWUID	<p>Receive Wakeup Idle Detect</p> <p>When RWU is set and WAKE is cleared, this field controls whether the idle character that wakes the receiver sets S1[IDLE]. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>0 S1[IDLE] is not set upon detection of an idle character. 1 S1[IDLE] is set upon detection of an idle character.</p>
2 BRK13	<p>Break Transmit Character Length</p> <p>Determines whether the transmit break character is 10, 11, or 12 bits long, or 13 or 14 bits long. See for the length of the break character for the different configurations. The detection of a framing error is not affected by this field. Transmitting break characters</p> <p>0 Break character is 10, 11, or 12 bits long. 1 Break character is 13 or 14 bits long.</p>
1 LBKDE	<p>LIN Break Detection Enable</p> <p>Selects a longer break character detection length. While LBKDE is set, S1[RDRF], S1[NF], S1[FE], and S1[PF] are prevented from setting. When LBKDE is set, see . Overrun operationLBKDE must be cleared when C7816[ISO7816E] is set.</p> <p>0 Break character is detected at one of the following lengths: <ul style="list-style-type: none"> • 10 bit times if C1[M] = 0 • 11 bit times if C1[M] = 1 and C4[M10] = 0 • 12 bit times if C1[M] = 1, C4[M10] = 1, and S1[PE] = 1 </p> <p>1 Break character is detected at length of 11 bit times if C1[M] = 0 or 12 bits time if C1[M] = 1.</p>
0 RAF	<p>Receiver Active Flag</p> <p>RAF is set when the UART receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character when C7816[ISO7816E] is cleared/disabled. When C7816[ISO7816E] is enabled, the RAF is cleared if the C7816[TTYPE] = 0 expires or the C7816[TTYPE] = 1 expires.</p> <p>NOTE: In case C7816[ISO7816E] is set and C7816[TTYPE] = 0, it is possible to configure the guard time to 12. However, if a NACK is required to be transmitted, the data transfer actually takes 13 ETU with the 13th ETU slot being an inactive buffer. Therefore, in this situation, the RAF may deassert one ETU prior to actually being inactive.</p> <p>0 UART receiver idle/inactive waiting for a start bit. 1 UART receiver active, RxD input not idle.</p>

40.3.7 UART Control Register 3 (UARTx_C3)

Writing R8 does not have any effect. TXDIR and TXINV can be changed only between transmit and receive packets.

Address: Base address + 6h offset

Bit	7	6	5	4	3	2	1	0
Read	R8	T8	TXDIR	TXINV	ORIE	NEIE	FEIE	PEIE
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C3 field descriptions

Field	Description
7 R8	Received Bit 8 R8 is the ninth data bit received when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1.
6 T8	Transmit Bit 8 T8 is the ninth data bit transmitted when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. NOTE: If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.
5 TXDIR	Transmitter Pin Data Direction in Single-Wire mode Determines whether the TXD pin is used as an input or output in the single-wire mode of operation. This field is relevant only to the single wire mode. When C7816[ISO7816E] is set/enabled and C7816[TTYPE] = 1, this field is automatically cleared after the requested block is transmitted. This condition is detected when TL7816[TLEN] = 0 and 4 additional characters are transmitted. Additionally, if C7816[ISO7816E] is set/enabled and C7816[TTYPE] = 0 and a NACK is being transmitted, the hardware automatically overrides this field as needed. In this situation, TXDIR does not reflect the temporary state associated with the NACK. 0 TXD pin is an input in single wire mode. 1 TXD pin is an output in single wire mode.
4 TXINV	Transmit Data Inversion. Setting this field reverses the polarity of the transmitted data output. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode. NOTE: Setting TXINV inverts all transmitted values, including idle, break, start, and stop bits. In loop mode, if TXINV is set, the receiver gets the transmit inversion bit when RXINV is disabled. When C7816[ISO7816E] is set/enabled then only the transmitted data bits and parity bit are inverted. 0 Transmit data is not inverted. 1 Transmit data is inverted.
3 ORIE	Overrun Error Interrupt Enable

Table continues on the next page...

UARTx_C3 field descriptions (continued)

Field	Description
	Enables the overrun error flag, S1[OR], to generate interrupt requests. 0 OR interrupts are disabled. 1 OR interrupt requests are enabled.
2 NEIE	Noise Error Interrupt Enable Enables the noise flag, S1[NF], to generate interrupt requests. 0 NF interrupt requests are disabled. 1 NF interrupt requests are enabled.
1 FEIE	Framing Error Interrupt Enable Enables the framing error flag, S1[FE], to generate interrupt requests. 0 FE interrupt requests are disabled. 1 FE interrupt requests are enabled.
0 PEIE	Parity Error Interrupt Enable Enables the parity error flag, S1[PF], to generate interrupt requests. 0 PF interrupt requests are disabled. 1 PF interrupt requests are enabled.

40.3.8 UART Data Register (UARTx_D)

This register is actually two separate registers. Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

NOTE

- In 8-bit or 9-bit data format, only UART data register (D) needs to be accessed to clear the S1[RDRF] bit (assuming receiver buffer level is less than RWFIFO[RXWATER]). The C3 register needs to be read, prior to the D register, only if the ninth bit of data needs to be captured. Similarly, the ED register needs to be read, prior to the D register, only if the additional flag data for the dataword needs to be captured.
- In the normal 8-bit mode (M bit cleared) if the parity is enabled, you get seven data bits and one parity bit. That one parity bit is loaded into the D register. So, for the data bits, mask off the parity bit from the value you read out of this register.
- When transmitting in 9-bit data format and using 8-bit write instructions, write first to transmit bit 8 in UART

control register 3 (C3[T8]), then D. A write to C3[T8] stores the data in a temporary register. If D register is written first, and then the new data on data bus is stored in D, the temporary value written by the last write to C3[T8] gets stored in the C3[T8] register.

Address: Base address + 7h offset

UARTx_D field descriptions

Field	Description
7-0 RT	Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

40.3.9 UART Match Address Registers 1 (UARTx_MA1)

The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. These registers can be read and written at anytime.

Address: Base address + 8h offset

UARTx_MA1 field descriptions

Field	Description
7-0 MA	Match Address

40.3.10 UART Match Address Registers 2 (UARTx_MA2)

These registers can be read and written at anytime. The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded.

Address: Base address + 9h offset

Bit	7	6	5	4	3	2	1	0
Read	MA							
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_MA2 field descriptions

Field	Description
7–0 MA	Match Address

40.3.11 UART Control Register 4 (UARTx_C4)

Address: Base address + Ah offset

Bit	7	6	5	4	3	2	1	0
Read	MAEN1	MAEN2	M10	BRFA				
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C4 field descriptions

Field	Description
7 MAEN1	<p>Match Address Mode Enable 1</p> <p>See Match address operation for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN2 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA1 register. If no match occurs, the data is discarded. If match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p>
6 MAEN2	<p>Match Address Mode Enable 2</p> <p>See Match address operation for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN1 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA2 register. If no match occurs, the data is discarded. If a match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p>

Table continues on the next page...

UARTx_C4 field descriptions (continued)

Field	Description
5 M10	<p>10-bit Mode select</p> <p>Causes a tenth, non-memory mapped bit to be part of the serial transmission. This tenth bit is generated and interpreted as a parity bit. The M10 field does not affect the LIN send or detect break behavior. If M10 is set, then both C1[M] and C1[PE] must also be set. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>See Data format (non ISO-7816) for more information.</p> <p>0 The parity bit is the ninth bit in the serial transmission. 1 The parity bit is the tenth bit in the serial transmission.</p>
4–0 BRFA	<p>Baud Rate Fine Adjust</p> <p>This bit field is used to add more timing resolution to the average baud frequency, in increments of 1/32. See Baud rate generation for more information.</p>

40.3.12 UART Control Register 5 (UARTx_C5)

Address: Base address + Bh offset

UARTx_C5 field descriptions

Field	Description
7 TDMAS	<p>Transmitter DMA Select</p> <p>Configures the transmit data register empty flag, S1[TDRE], to generate interrupt or DMA requests if C2[TIE] is set.</p> <p>NOTE:</p> <ul style="list-style-type: none"> • If C2[TIE] is cleared, TDRE DMA and TDRE interrupt request signals are not asserted when the TDRE flag is set, regardless of the state of TDMAS. • If C2[TIE] and TDMAS are both set, then C2[TCIE] must be cleared, and D must not be written unless a DMA request is being serviced. <p>0 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE interrupt request signal is asserted to request interrupt service. 1 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE DMA request signal is asserted to request a DMA transfer.</p>
6 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
5 RDMAS	<p>Receiver Full DMA Select</p> <p>Configures the receiver data register full flag, S1[RDRF], to generate interrupt or DMA requests if C2[RIE] is set.</p> <p>NOTE: If C2[RIE] is cleared, and S1[RDRF] is set, the RDRF DMA and RDRF interrupt request signals are not asserted, regardless of the state of RDMAS.</p>

Table continues on the next page...

UARTx_C5 field descriptions (continued)

Field	Description
	0 If C2[RIE] and S1[RDRF] are set, the RDRF interrupt request signal is asserted to request an interrupt service. 1 If C2[RIE] and S1[RDRF] are set, the RDRF DMA request signal is asserted to request a DMA transfer.
4–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.3.13 UART Extended Data Register (UARTx_ED)

This register contains additional information flags that are stored with a received dataword. This register may be read at any time but contains valid data only if there is a dataword in the receive FIFO.

NOTE

- The data contained in this register represents additional information regarding the conditions on which a dataword was received. The importance of this data varies with the application, and in some cases maybe completely optional. These fields automatically update to reflect the conditions of the next dataword whenever D is read.
- If S1[NF] and S1[PF] have not been set since the last time the receive buffer was empty, the NOISY and PARITYE fields will be zero.

Address: Base address + Ch offset

Bit	7	6	5	4	3	2	1	0
Read	NOISY	PARITYE	0					
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_ED field descriptions

Field	Description
7 NOISY	The current received dataword contained in D and C3[R8] was received with noise. 0 The dataword was received without noise. 1 The data was received with noise.
6 PARITYE	The current received dataword contained in D and C3[R8] was received with a parity error. 0 The dataword was received without a parity error. 1 The dataword was received with a parity error.
5–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.3.14 UART Modem Register (UARTx_MODEM)

The MODEM register controls options for setting the modem configuration.

NOTE

RXRTSE, TXRTSPOL, TXRTSE, and TXCTSE must all be cleared when C7816[ISO7816EN] is enabled. This will cause the RTS to deassert during ISO-7816 wait times. The ISO-7816 protocol does not use the RTS and CTS signals.

Address: Base address + Dh offset

Bit	7	6	5	4	3	2	1	0
Read	0				RXRTSE	TXRTSPOL	TXRTSE	TXCTSE
Write	0							
Reset	0	0	0	0	0	0	0	0

UARTx_MODEM field descriptions

Field	Description
7-4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. NOTE: Do not set both RXRTSE and TXRTSE. 0 The receiver has no effect on RTS. 1 RTS is deasserted if the number of characters in the receiver data register (FIFO) is equal to or greater than RWFIFO[RXWATER]. RTS is asserted when the number of characters in the receiver data register (FIFO) is less than RWFIFO[RXWATER].
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. 0 Transmitter RTS is active low. 1 Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. 0 The transmitter has no effect on RTS. 1 When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. (FIFO)(FIFO)
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.

Table continues on the next page...

UARTx_MODEM field descriptions (continued)

Field	Description
0	CTS has no effect on the transmitter.
1	Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

40.3.15 UART FIFO Parameters (UARTx_PFIFO)

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when C2[RE] and C2[TE] are cleared/not set and when the data buffer/FIFO is empty.

Address: Base address + 10h offset

* Notes:

- TXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.
- RXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.

UARTx_PFIFO field descriptions

Field	Description
7 TXFE	<p>Transmit FIFO Enable</p> <p>When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field.</p> <p>0 Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support). 1 Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.</p>
6-4 TXFIFOSIZE	<p>Transmit FIFO. Buffer Depth</p> <p>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.</p> <p>000 Transmit FIFO/Buffer depth = 1 dataword.</p>

Table continues on the next page...

UARTx_PFIFO field descriptions (continued)

Field	Description
	001 Transmit FIFO/Buffer depth = 4 datawords. 010 Transmit FIFO/Buffer depth = 8 datawords. 011 Transmit FIFO/Buffer depth = 16 datawords. 100 Transmit FIFO/Buffer depth = 32 datawords. 101 Transmit FIFO/Buffer depth = 64 datawords. 110 Transmit FIFO/Buffer depth = 128 datawords. 111 Reserved.
3 RXFE	Receive FIFO Enable When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field. 0 Receive FIFO is not enabled. Buffer is depth 1. (Legacy support) 1 Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO. Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only. 000 Receive FIFO/Buffer depth = 1 dataword. 001 Receive FIFO/Buffer depth = 4 datawords. 010 Receive FIFO/Buffer depth = 8 datawords. 011 Receive FIFO/Buffer depth = 16 datawords. 100 Receive FIFO/Buffer depth = 32 datawords. 101 Receive FIFO/Buffer depth = 64 datawords. 110 Receive FIFO/Buffer depth = 128 datawords. 111 Reserved.

40.3.16 UART FIFO Control Register (UARTx_CFIFO)

This register provides the ability to program various control fields for FIFO operation. This register may be read or written at any time. Note that writing to TXFLUSH and RXFLUSH may result in data loss and requires careful action to prevent unintended/unpredictable behavior. Therefore, it is recommended that TE and RE be cleared prior to flushing the corresponding FIFO.

Address: Base address + 11h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0	0			RXOFE	TXOFE	RXUFE
Write	TXFLUSH	RXFLUSH						
Reset	0	0	0	0	0	0	0	0

UARTx_CFIFO field descriptions

Field	Description
7 TXFLUSH	Transmit FIFO/Buffer Flush Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register. 0 No flush operation occurs. 1 All data in the transmit FIFO/Buffer is cleared out.
6 RXFLUSH	Receive FIFO/Buffer Flush Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register. 0 No flush operation occurs. 1 All data in the receive FIFO/buffer is cleared out.
5-3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RXOFE	Receive FIFO Overflow Interrupt Enable When this field is set, the RXOF flag generates an interrupt to the host. 0 RXOF flag does not generate an interrupt to the host. 1 RXOF flag generates an interrupt to the host.
1 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0 TXOF flag does not generate an interrupt to the host. 1 TXOF flag generates an interrupt to the host.
0 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0 RXUF flag does not generate an interrupt to the host. 1 RXUF flag generates an interrupt to the host.

40.3.17 UART FIFO Status Register (UARTx_SFIFO)

This register provides status information regarding the transmit and receiver buffers/FIFOs, including interrupt information. This register may be written to or read at any time.

Address: Base address + 12h offset

Bit	7	6	5	4	3	2	1	0
Read	TXEMPT	RXEMPT	0			RXOF	TXOF	RXUF
Write								
Reset	1	1	0	0	0	0	0	0

UARTx_SFIFO field descriptions

Field	Description
7 TXEMPT	<p>Transmit Buffer/FIFO Empty</p> <p>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.</p> <p>0 Transmit buffer is not empty. 1 Transmit buffer is empty.</p>
6 RXEMPT	<p>Receive Buffer/FIFO Empty</p> <p>Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.</p> <p>0 Receive buffer is not empty. 1 Receive buffer is empty.</p>
5–3 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
2 RXOF	<p>Receiver Buffer Overflow Flag</p> <p>Indicates that more data has been written to the receive buffer than it can hold. This field will assert regardless of the value of CFIFO[RXOFE]. However, an interrupt will be issued to the host only if CFIFO[RXOFE] is set. This flag is cleared by writing a 1.</p> <p>0 No receive buffer overflow has occurred since the last time the flag was cleared. 1 At least one receive buffer overflow has occurred since the last time the flag was cleared.</p>
1 TXOF	<p>Transmitter Buffer Overflow Flag</p> <p>Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of CFIFO[TXOFE]. However, an interrupt will be issued to the host only if CFIFO[TXOFE] is set. This flag is cleared by writing a 1.</p> <p>0 No transmit buffer overflow has occurred since the last time the flag was cleared. 1 At least one transmit buffer overflow has occurred since the last time the flag was cleared.</p>
0 RXUF	<p>Receiver Buffer Underflow Flag</p> <p>Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of CFIFO[RXUFE]. However, an interrupt will be issued to the host only if CFIFO[RXUFE] is set. This flag is cleared by writing a 1.</p> <p>0 No receive buffer underflow has occurred since the last time the flag was cleared. 1 At least one receive buffer underflow has occurred since the last time the flag was cleared.</p>

40.3.18 UART FIFO Transmit Watermark (UARTx_TWFIFO)

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when C2[TE] is not set. Changing the value of the watermark will not clear the S1[TDRE] flag.

Address: Base address + 13h offset

UARTx_TWFIFO field descriptions

Field	Description
7–0 TXWATER	<p>Transmit Watermark</p> <p>When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt via S1[TDRE] or a DMA request via C5[TDMAS] is generated as determined by C5[TDMAS] and C2[TIE]. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by PFIFO[TXFIFOSIZE] and PFIFO[TXFE].</p>

40.3.19 UART FIFO Transmit Count (UARTx_TCFIFO)

This is a read only register that indicates how many datawords are currently in the transmit buffer/FIFO. It may be read at any time.

Address: Base address + 14h offset

UARTx_TCFIFO field descriptions

Field	Description
7–0 TXCOUNT	<p>Transmit Counter</p> <p>The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with PFIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.</p>

40.3.20 UART FIFO Receive Watermark (UARTx_RWFIFO)

This register provides the ability to set a programmable threshold for notification of the need to remove data from the receiver FIFO/buffer. This register may be read at any time but must be written only when C2[RE] is not asserted. Changing the value in this register will not clear S1[RDRF].

Address: Base address + 15h offset

UARTx_RWFIFO field descriptions

Field	Description
7-0 RXWATER	<p>Receive Watermark</p> <p>When the number of datawords in the receive FIFO/buffer is equal to or greater than the value in this register field, an interrupt via S1[RDRF] or a DMA request via C5[RDMA5] is generated as determined by C5[RDMA5] and C2[RIE]. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by PFIFO[RXFIFOSIZE] and PFIFO[RXFE] and must be greater than 0.</p>

40.3.21 UART FIFO Receive Count (UARTx_RCFIFO)

This is a read only register that indicates how many datawords are currently in the receive FIFO/buffer. It may be read at any time.

Address: Base address + 16h offset

UARTx_RCFIFO field descriptions

Field	Description
7-0 RXCOUNT	<p>Receive Counter</p> <p>The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with PFIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.</p>

40.3.22 UART 7816 Control Register (UARTx_C7816)

The C7816 register is the primary control register for ISO-7816 specific functionality. This register is specific to 7816 functionality and the values in this register have no effect on UART operation and should be ignored if ISO_7816E is not set/enabled. This register may be read at any time but values must be changed only when ISO_7816E is not set.

Address: Base address + 18h offset

Bit	7	6	5	4	3	2	1	0
Read	0			ONACK	ANACK	INIT	TTYTYPE	ISO_7816E
Write	0							
Reset	0	0	0	0	0	0	0	0

UARTx_C7816 field descriptions

Field	Description
7-5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 ONACK	<p>Generate NACK on Overflow</p> <p>When this field is set, the receiver automatically generates a NACK response if a receive buffer overrun occurs, as indicated by S1[OR]. In many systems, this results in the transmitter resending the packet that overflowed until the retransmit threshold for that transmitter is reached. A NACK is generated only if TTYTYPE=0. This field operates independently of ANACK. See . Overrun NACK considerations</p> <p>0 The received data does not generate a NACK when the receipt of the data results in an overflow event.</p> <p>1 If the receiver buffer overflows, a NACK is automatically sent on a received character.</p>
3 ANACK	<p>Generate NACK on Error</p> <p>When this field is set, the receiver automatically generates a NACK response if a parity error occurs or if INIT is set and an invalid initial character is detected. A NACK is generated only if TTYTYPE = 0. If ANACK is set, the UART attempts to retransmit the data indefinitely. To stop retransmission attempts, clear C2[TE] or ISO_7816E and do not set until S1[TC] sets C2[TE] again.</p> <p>0 No NACK is automatically generated.</p> <p>1 A NACK is automatically generated if a parity error is detected or if an invalid initial character is detected.</p>
2 INIT	<p>Detect Initial Character</p> <p>When this field is set, all received characters are searched for a valid initial character. If an invalid initial character is identified, and ANACK is set, a NACK is sent. All received data is discarded and error flags blocked (S1[NF], S1[OR], S1[FE], S1[PF], IS7816[WT], IS7816[CWT], IS7816[BWT], IS7816[GTV]) until a valid initial character is detected. Upon detecting a valid initial character, the configuration values S2[MBSF], C3[TXINV], and S2[RXINV] are automatically updated to reflect the initial character that was received. The actual INIT data value is not stored in the receive buffer. Additionally, upon detection of a valid initial character, IS7816[INITD] is set and an interrupt issued as programmed by IE7816[INITDE]. When a valid initial character is detected, INIT is automatically cleared. This Initial Character Detect feature is supported only in T = 0 protocol mode.</p> <p>0 Normal operating mode. Receiver does not seek to identify initial character.</p> <p>1 Receiver searches for initial character.</p>

UARTx_C7816 field descriptions (continued)

Field	Description
1 TTYPE	Transfer Type Indicates the transfer protocol being used. See ISO-7816 / smartcard support for more details. 0 T = 0 per the ISO-7816 specification. 1 T = 1 per the ISO-7816 specification.
0 ISO_7816E	ISO-7816 Functionality Enabled Indicates that the UART is operating according to the ISO-7816 protocol. NOTE: This field must be modified only when no transmit or receive is occurring. If this field is changed during a data transfer, the data being transmitted or received may be transferred incorrectly. 0 ISO-7816 functionality is turned off/not enabled. 1 ISO-7816 functionality is turned on/enabled.

40.3.23 UART 7816 Interrupt Enable Register (UARTx_IE7816)

The IE7816 register controls which flags result in an interrupt being issued. This register is specific to 7816 functionality, the corresponding flags that drive the interrupts are not asserted when 7816E is not set/enabled. However, these flags may remain set if they are asserted while 7816E was set and not subsequently cleared. This register may be read or written to at any time.

40.3.24 UART 7816 Interrupt Status Register (UARTx_IS7816)

The IS7816 register provides a mechanism to read and clear the interrupt flags. All flags/interrupts are cleared by writing a 1 to the field location. Writing a 0 has no effect. All bits are "sticky", meaning they indicate that only the flag condition that occurred since the last time the bit was cleared, not that the condition currently exists. The status flags are set regardless of whether the corresponding field in the IC7816 is set or cleared. The IC7816 controls only if an interrupt is issued to the host processor. This register is specific to 7816 functionality and the values in this register have no affect on UART operation and should be ignored if 7816E is not set/enabled. This register may be read or written at anytime.

UARTx_IS7816 field descriptions

Field	Description
7 WT	Wait Timer Interrupt Indicates that the wait time, the time between the leading edge of a character being transmitted and the leading edge of the next response character, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 0. This interrupt is cleared by writing 1.

Table continues on the next page...

UARTx_IS7816 field descriptions (continued)

Field	Description
	0 Wait time (WT) has not been violated. 1 Wait time (WT) has been violated.
6 CWT	Character Wait Timer Interrupt Indicates that the character wait time, the time between the leading edges of two consecutive characters in a block, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 1. This interrupt is cleared by writing 1. 0 Character wait time (CWT) has not been violated. 1 Character wait time (CWT) has been violated.
5 BWT	Block Wait Timer Interrupt Indicates that the block wait time, the time between the leading edge of first received character of a block and the leading edge of the last character the previously transmitted block, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 1. This interrupt is cleared by writing 1. 0 Block wait time (BWT) has not been violated. 1 Block wait time (BWT) has been violated.
4 INITD	Initial Character Detected Interrupt Indicates that a valid initial character is received. This interrupt is cleared by writing 1. 0 A valid initial character has not been received. 1 A valid initial character has been received.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 GTV	Guard Timer Violated Interrupt Indicates that one or more of the character guard time, block guard time, or guard time are violated. This interrupt is cleared by writing 1. 0 A guard time (GT, CGT, or BGT) has not been violated. 1 A guard time (GT, CGT, or BGT) has been violated.
1 TXT	Transmit Threshold Exceeded Interrupt Indicates that the transmit NACK threshold has been exceeded as indicated by ET7816[TXTHRESHOLD]. Regardless of whether this flag is set, the UART continues to retransmit indefinitely. This flag asserts only when C7816[TTYTYPE] = 0. If 7816E is cleared/disabled, ANACK is cleared/disabled, C2[TE] is cleared/disabled, C7816[TTYTYPE] = 1, or packet is transferred without receiving a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next received NACK. This interrupt is cleared by writing 1. 0 The number of retries and corresponding NACKS does not exceed the value in ET7816[TXTHRESHOLD]. 1 The number of retries and corresponding NACKS exceeds the value in ET7816[TXTHRESHOLD].
0 RXT	Receive Threshold Exceeded Interrupt Indicates that there are more than ET7816[RXTHRESHOLD] consecutive NACKS generated in response to parity errors on received data. This flag requires ANACK to be set. Additionally, this flag asserts only when C7816[TTYTYPE] = 0. Clearing this field also resets the counter keeping track of consecutive NACKS. The UART will continue to attempt to receive data regardless of whether this flag is set. If 7816E is cleared/disabled, RE is cleared/disabled, C7816[TTYTYPE] = 1, or packet is received without needing to

UARTx_WN7816 field descriptions

Field	Description
7–0 GTN	Guard Band N Defines a parameter used in the calculation of GT, CGT, and BGT counters. The value represents an integer number between 0 and 255. See Wait time and guard time parameters .

40.3.28 UART 7816 Wait FD Register (UARTx_WF7816)

The WF7816 contains parameters that are used in the generation of various counters including GT, CGT, BGT, WT, and BWT. This register may be read at any time. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Dh offset

Bit	7	6	5	4	3	2	1	0
Read	GTFD							
Write	GTFD							
Reset	0	0	0	0	0	0	0	1

UARTx_WF7816 field descriptions

Field	Description
7–0 GTFD	FD Multiplier Used as another multiplier in the calculation of WT and BWT. This value represents a number between 1 and 255. The value of 0 is invalid. This value is not used in baud rate generation. See Wait time and guard time parameters and Baud rate generation .

40.3.29 UART 7816 Error Threshold Register (UARTx_ET7816)

The ET7816 register contains fields that determine the number of NACKs that must be received or transmitted before the host processor is notified. This register may be read at anytime. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Eh offset

Bit	7	6	5	4	3	2	1	0
Read	TXTHRESHOLD				RXTHRESHOLD			
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_ET7816 field descriptions

Field	Description
7–4 TXTHRESHOLD	<p>Transmit NACK Threshold</p> <p>The value written to this field indicates the maximum number of failed attempts (NACKs) a transmitted character can have before the host processor is notified. This field is meaningful only when C7816[TTYPE] = 0 and C7816[ANACK] = 1. The value read from this field represents the number of consecutive NACKs that have been received since the last successful transmission. This counter saturates at 4'hF and does not wrap around. Regardless of how many NACKs that are received, the UART continues to retransmit indefinitely. This flag only asserts when C7816[TTYPE] = 0. For additional information see the IS7816[TXT] field description.</p> <p>0 TXT asserts on the first NACK that is received. 1 TXT asserts on the second NACK that is received.</p>
3–0 RXTHRESHOLD	<p>Receive NACK Threshold</p> <p>The value written to this field indicates the maximum number of consecutive NACKs generated as a result of a parity error or receiver buffer overruns before the host processor is notified. After the counter exceeds that value in the field, the IS7816[RXT] is asserted. This field is meaningful only when C7816[TTYPE] = 0. The value read from this field represents the number of consecutive NACKs that have been transmitted since the last successful reception. This counter saturates at 4'hF and does not wrap around. Regardless of the number of NACKs sent, the UART continues to receive valid packets indefinitely. For additional information, see IS7816[RXT] field description.</p>

40.3.30 UART 7816 Transmit Length Register (UARTx_TL7816)

The TL7816 register is used to indicate the number of characters contained in the block being transmitted. This register is used only when C7816[TTYPE] = 1. This register may be read at anytime. This register must be written only when C2[TE] is not enabled.

Address: Base address + 1Fh offset

UARTx_TL7816 field descriptions

Field	Description
7-0 TLEN	<p>Transmit Length</p> <p>This value plus four indicates the number of characters contained in the block being transmitted. This register is automatically decremented by 1 for each character in the information field portion of the block. Additionally, this register is automatically decremented by 1 for the first character of a CRC in the epilogue field. Therefore, this register must be programmed with the number of bytes in the data packet if an LRC is being transmitted, and the number of bytes + 1 if a CRC is being transmitted. This register is not decremented for characters that are assumed to be part of the Prologue field, that is, the first three characters transmitted in a block, or the LRC or last CRC character in the Epilogue field, that is, the last character transmitted. This field must be programmed or adjusted only when C2[TE] is cleared.</p>

40.4 Functional description

This section provides a complete functional description of the UART block.

The UART allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The UART transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the UART, writes the data to be transmitted, and processes received data.

40.4.1 Transmitter

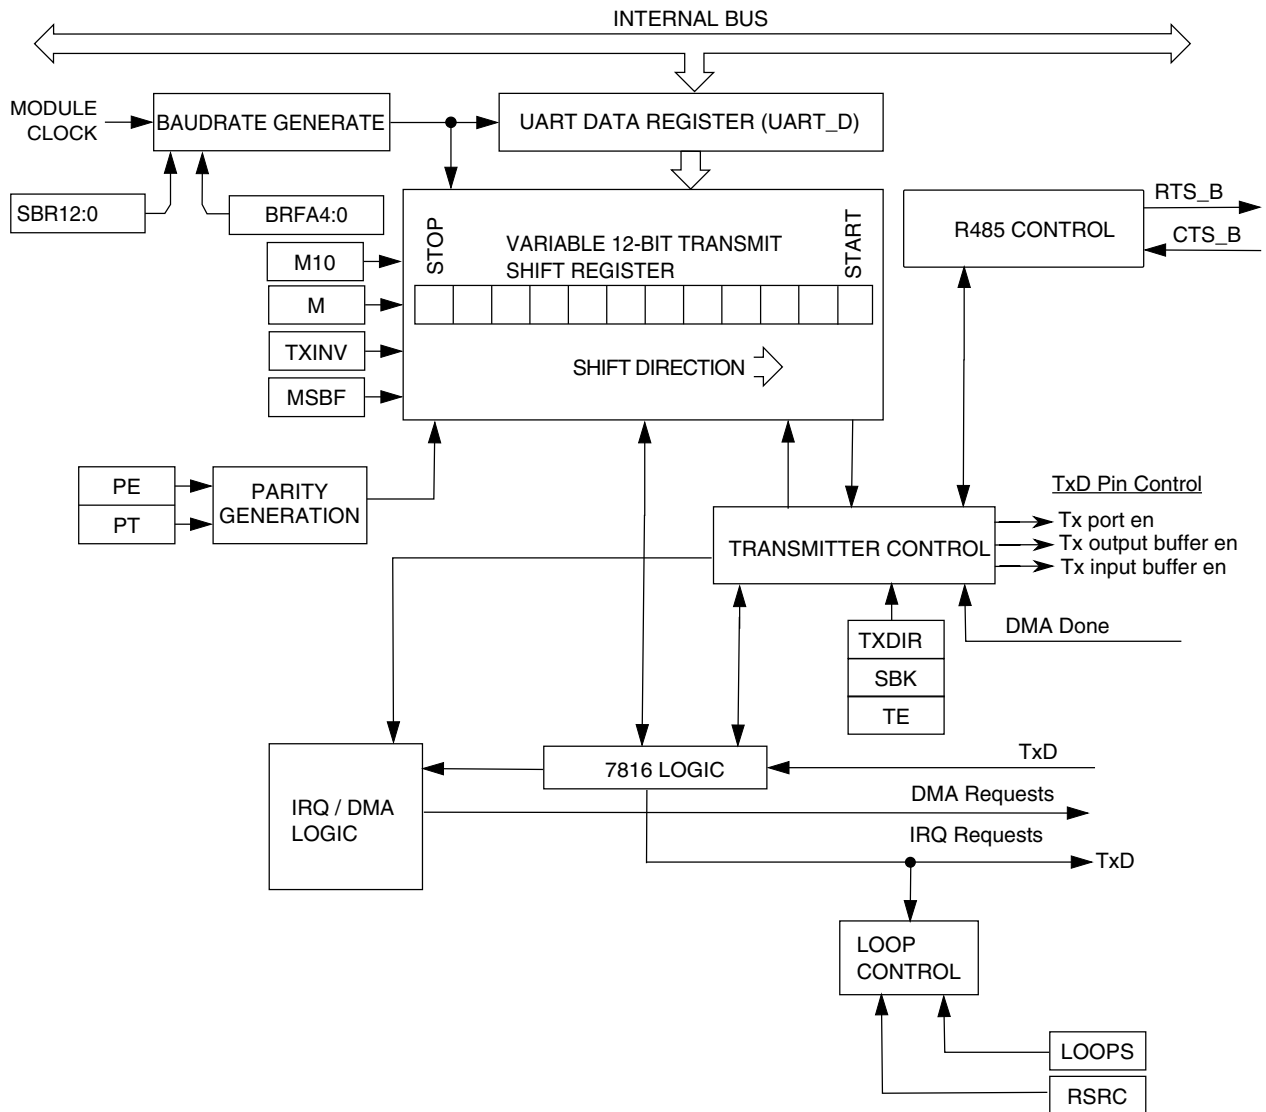

Figure 40-91. Transmitter Block Diagram

40.4.1.1 Transmitter character length

The UART transmitter can accommodate either 8, 9, or 10-bit data characters. The state of the C1[M] and C1[PE] bits and the C4[M10] bit determine the length of data characters. When transmitting 9-bit data, bit C3[T8] is the ninth bit (bit 8).

40.4.1.2 Transmission bit order

When S2[MSBF] is set, the UART automatically transmits the MSB of the data word as the first bit after the start bit. Similarly, the LSB of the data word is transmitted immediately preceding the parity bit, or the stop bit if parity is not enabled. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data written to D for transmission is completely independent of the S2[MSBF] setting.

40.4.1.3 Character transmission

To transmit data, the MCU writes the data bits to the UART transmit buffer using UART data registers C3[T8] and D. Data in the transmit buffer is then transferred to the transmitter shift register as needed. The transmit shift register then shifts a frame out through the transmit data output signal after it has prefaced it with any required start and stop bits. The UART data registers, C3[T8] and D, provide access to the transmit buffer structure.

The UART also sets a flag, the transmit data register empty flag S1[TDRE], and generates an interrupt or DMA request (C5[TDMAS]) whenever the number of datawords in the transmit buffer is equal to or less than the value indicated by TWFIFO[TXWATER]. The transmit driver routine may respond to this flag by writing additional datawords to the transmit buffer using C3[T8]/D as space permits.

See [Application information](#) for specific programming sequences.

Setting C2[TE] automatically loads the transmit shift register with the following preamble:

- 10 logic 1s if C1[M] = 0
- 11 logic 1s if C1[M] = 1 and C4[M10] = 0
- 12 logic 1s if C1[M] = 1, C4[M10] = 1, C1[PE] = 1

After the preamble shifts out, control logic transfers the data from the D register into the transmit shift register. The transmitter automatically transmits the correct start bit and stop bit before and after the dataword.

When C7816[ISO_7816E] = 1, setting C2[TE] does not result in a preamble being generated. The transmitter starts transmitting as soon as the corresponding guard time expires. When C7816[TTYPE] = 0, the value in GT is used. When C7816[TTYPE] = 1, the value in BGT is used, because C2[TE] will remain asserted until the end of the block transfer. C2[TE] is automatically cleared when C7816[TTYPE] = 1 and the block being transmitted has completed. When C7816[TTYPE] = 0, the transmitter listens for a NACK indication. If no NACK is received, it is assumed that the character was correctly

received. If a NACK is received, the transmitter resends the data, assuming that the number of retries for that character, that is, the number of NACKs received, is less than or equal to the value in ET7816[TXTHRESHOLD].

Hardware supports odd or even parity. When parity is enabled, the bit immediately preceding the stop bit is the parity bit.

When the transmit shift register is not transmitting a frame, the transmit data output signal goes to the idle condition, logic 1. If at any time software clears C2[TE], the transmitter enable signal goes low and the transmit signal goes idle.

If the software clears C2[TE] while a transmission is in progress, the character in the transmit shift register continues to shift out, provided S1[TC] was cleared during the data write sequence. To clear S1[TC], the S1 register must be read followed by a write to D register.

If S1[TC] is cleared during character transmission and C2[TE] is cleared, the transmission enable signal is deasserted at the completion of the current frame. Following this, the transmit data out signal enters the idle state even if there is data pending in the UART transmit data buffer. To ensure that all the data written in the FIFO is transmitted on the link before clearing C2[TE], wait for S1[TC] to set. Alternatively, the same can be achieved by setting TWFIFO[TXWATER] to 0x0 and waiting for S1[TDRE] to set.

40.4.1.4 Transmitting break characters

Setting C2[SBK] loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on C1[M] and C1[PE], S2[BRK13], and C4[M10]. See the following table.

Table 40-96. Transmit break character length

S2[BRK13]	C1[M]	C4[M10]	C1[PE]	Bits transmitted
0	0	—	—	10
0	1	0	—	11
0	1	1	0	11
0	1	1	1	12
1	0	—	—	13
1	1	—	—	14

As long as C2[SBK] is set, the transmitter logic continuously loads break characters into the transmit shift register. After the software clears C2[SBK], the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character. Break bits are not supported when C7816[ISO_7816E] is set/enabled.

NOTE

When queuing a break character, it will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that, if data is queued in the data buffer to be transmitted, the break character preempts that queued data. The queued data is then transmitted after the break character is complete.

40.4.1.5 Idle characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on C1[M], C1[PE], and C4[M10]. The preamble is a synchronizing idle character that begins the first transmission initiated after setting C2[TE]. When C7816[ISO_7816E] is set/enabled, idle characters are not sent or detected. When data is not being transmitted, the data I/O line is in an inactive state.

If C2[TE] is cleared during a transmission, the transmit data output signal becomes idle after completion of the transmission in progress. Clearing and then setting C2[TE] during a transmission queues an idle character to be sent after the dataword currently being transmitted.

Note

When queuing an idle character, the idle character will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that if data is queued in the data buffer to be transmitted, the idle character preempts that queued data. The queued data is then transmitted after the idle character is complete.

If C2[TE] is cleared and the transmission is completed, the UART is not the master of the TXD pin.

40.4.1.6 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS. If the clear-to-send operation is enabled, the character is transmitted when CTS is asserted. If CTS is deasserted in the middle of a transmission with characters remaining in the receiver data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS is reasserted.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS. Also, if the transmitter is forced to send a continuous low condition because it is sending a break character, the transmitter ignores the state of CTS regardless of whether the clear-to-send operation is enabled.

The transmitter's CTS signal can also be enabled even if the same UART receiver's RTS signal is disabled.

40.4.1.7 Transceiver driver enable

The transmitter can use RTS as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using RTS](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS asserts one bit time before the start bit is transmitted. RTS remains asserted for the whole time that the transmitter data buffer has any characters. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS signal asserts only when the transmitter is enabled. However, the transmitter's RTS signal is unaffected by its CTS signal. RTS will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

The following figure shows the functional timing information for the transmitter. Along with the actual character itself, TXD shows the start bit. The stop bit is also indicated, with a dashed line if necessary.

Functional description

1. Cn = transmit characters

Figure 40-92. Transmitter RTS and CTS timing diagram

40.4.2 Receiver

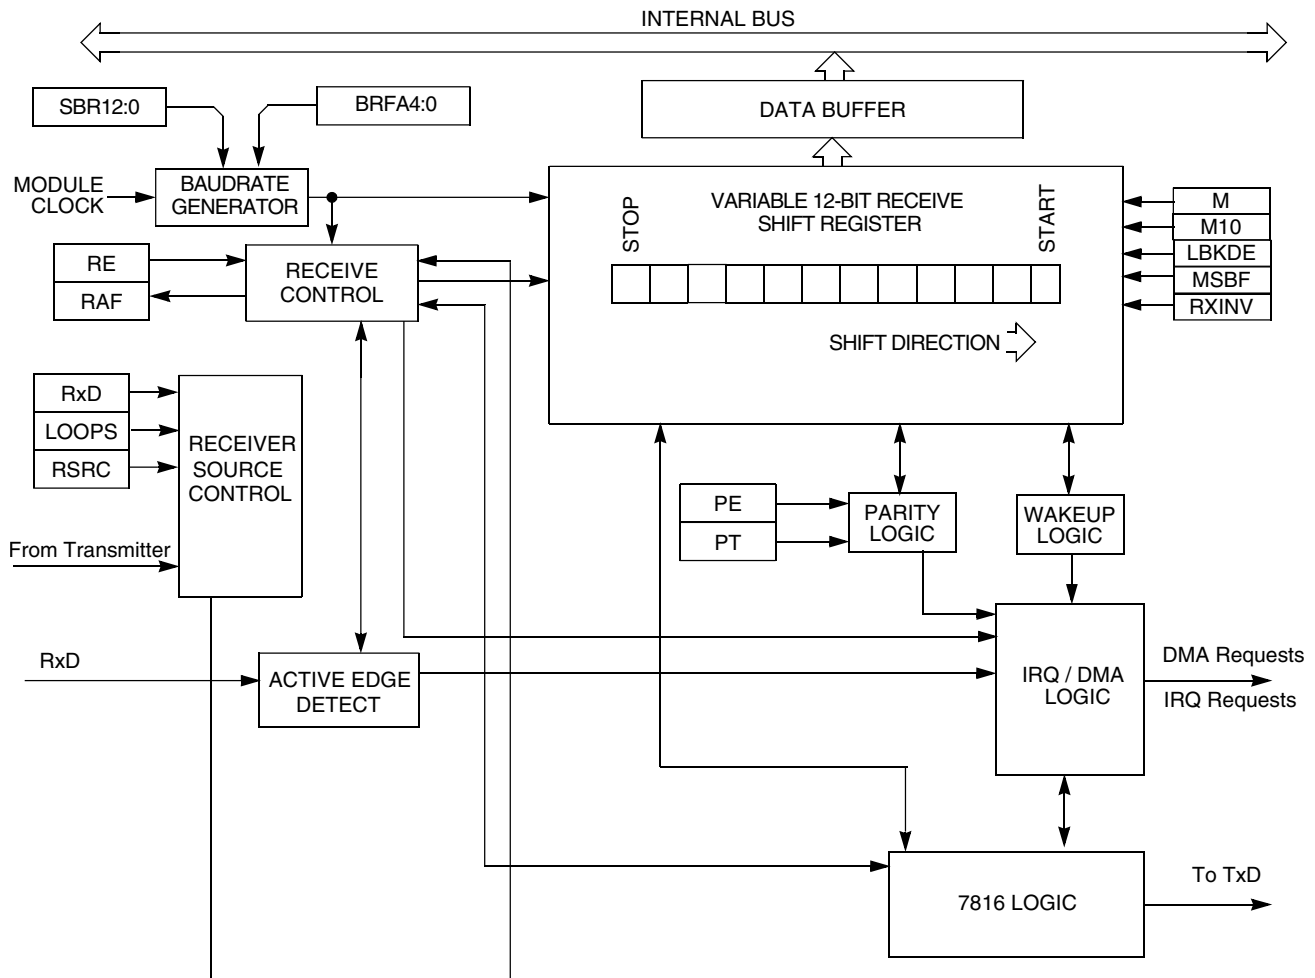

Figure 40-93. UART receiver block diagram

40.4.2.1 Receiver character length

The UART receiver can accommodate 8-, 9-, or 10-bit data characters. The states of C1[M], C1[PE], and C4[M10] determine the length of data characters. When receiving 9 or 10-bit data, C3[R8] is the ninth bit (bit 8).

40.4.2.2 Receiver bit ordering

When S2[MSBF] is set, the receiver operates such that the first bit received after the start bit is the MSB of the dataword. Similarly, the bit received immediately preceding the parity bit, or the stop bit if parity is not enabled, is treated as the LSB for the dataword. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data read from receive data buffer is completely independent of S2[MSBF].

40.4.2.3 Character reception

During UART reception, the receive shift register shifts a frame in from the unsynchronized receiver input signal. After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the UART receive buffer. Additionally, the noise and parity error flags that are calculated during the receive process are also captured in the UART receive buffer. The receive data buffer is accessible via the D and C3[T8] registers. Additional received information flags regarding the receive dataword can be read in ED register. S1[RDRF] is set if the number of resulting datawords in the receive buffer is equal to or greater than the number indicated by RWFIFO[RXWATER]. If the C2[RIE] is also set, RDRF generates an RDRF interrupt request. Alternatively, by programming C5[RDMAS], a DMA request can be generated.

When C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 0, character reception operates slightly differently. Upon receipt of the parity bit, the validity of the parity bit is checked. If C7816[ANACK] is set and the parity check fails, or if INIT and the received character is not a valid initial character, then a NACK is sent by the receiver. If the number of consecutive receive errors exceeds the threshold set by ET7816[RXTHRESHOLD], then IS7816[RXT] is set and an interrupt generated if IE7816[RXTE] is set. If an error is detected due to parity or an invalid initial character, the data is not transferred from the receive shift register to the receive buffer. Instead, the data is overwritten by the next incoming data.

When the C7816[ISO_7816E] is set/enabled, C7816[ONACK] is set/enabled, and the received character results in the receive buffer overflowing, a NACK is issued by the receiver. Additionally, S1[OR] is set and an interrupt is issued if required, and the data in the shift register is discarded.

40.4.2.4 Data sampling

The receiver samples the unsynchronized receiver input signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see the following figure) is re-synchronized:

- After every start bit.
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0).

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

Figure 40-94. Receiver data sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7 when C7816[ISO_7816E] is cleared/disabled and RT8, RT9 and RT10 when C7816[ISO_7816E] is set/enabled. The following table summarizes the results of the start bit verification samples.

Table 40-97. Start bit verification

RT3, RT5, and RT7 samples RT8, RT9, RT10 samples when 7816E	Start bit verification	Noise flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

Functional description

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the data bit samples.

Table 40-98. Data bit recovery

RT8, RT9, and RT10 samples	Data bit determination	Noise flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

Note

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (S1[NF]) is set and the receiver assumes that the bit is a start bit (logic 0). With the exception of when C7816[ISO_7816E] is set/enabled, where the values of RT8, RT9 and RT10 exclusively determine if a start bit exists.

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the stop bit samples. In the event that C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 0, verification of a stop bit does not take place. Rather, starting with RT8 the receiver transmits a NACK as programmed until time RT9 of the following time period. Framing Error detection is not supported when C7816[ISO_7816E] is set/enabled.

Table 40-99. Stop bit recovery

RT8, RT9, and RT10 samples	Framing error flag	Noise flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In the following figure, the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. In this example $C7816[ISO_7816E] = 0$. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

Figure 40-95. Start bit search example 1 ($C7816[ISO_7816E] = 0$)

In the following figure, verification sample at RT3 is high. In this example $C7816[ISO_7816E] = 0$. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

Figure 40-96. Start bit search example 2 ($C7816[ISO_7816E] = 0$)

In the following figure, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. In this example $C7816[ISO_7816E] = 0$. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

Functional description

Figure 40-97. Start bit search example 3 (C7816[ISO_7816E] = 0)

The following figure shows the effect of noise early in the start bit time. In this example C7816[ISO_7816E] = 0. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

Figure 40-98. Start bit search example 4 (C7816[ISO_7816E] = 0)

The following figure shows a burst of noise near the beginning of the start bit that resets the RT clock. In this example C7816[ISO_7816E] = 0. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

Figure 40-99. Start bit search example 5 (C7816[ISO_7816E] = 0)

In the following figure, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. In this example C7816[ISO_7816E] = 0. This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored. In this example, if C7816[ISO_7816E] = 1 then a start bit would not have been detected at all since at least two of the three samples (RT8, RT9, RT10) were high.

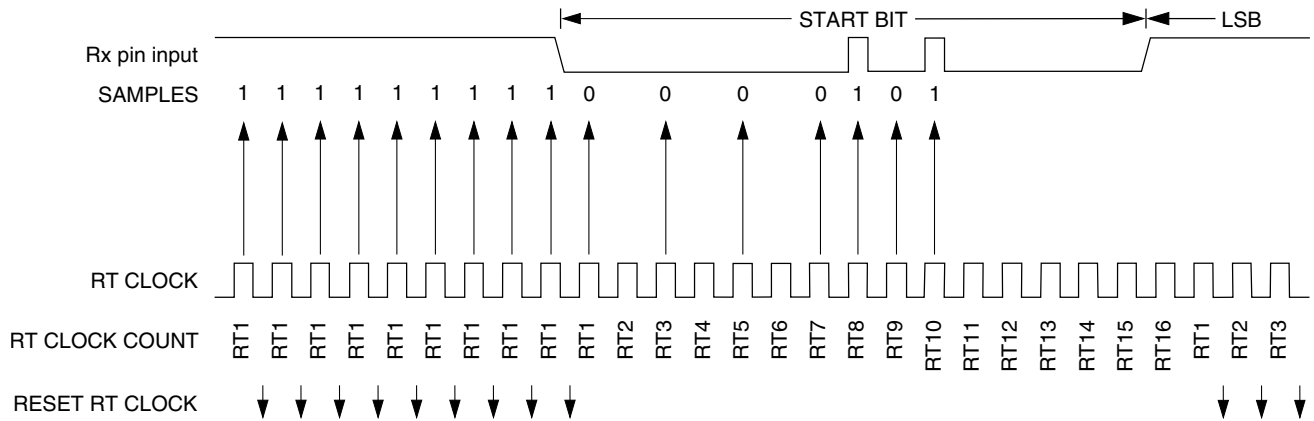

Figure 40-100. Start bit search example 6

40.4.2.5 Framing errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, S1[FE], if S2[LBKDE] is disabled. When S2[LBKDE] is disabled, a break character also sets the S1[FE] because a break character has no stop bit. S1[FE] is set at the same time that received data is placed in the receive data buffer. Framing errors are not supported when C7816[ISO7816E] is set/enabled. However, if S1[FE] is set, data will not be received when C7816[ISO7816E] is set.

40.4.2.6 Receiving break characters

The UART recognizes a break character when a start bit is followed by eight, nine, or ten logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on UART registers:

- Sets the framing error flag, S1[FE].
- Writes an all 0 dataword to the data buffer, which may cause S1[RDRF] to set, depending on the watermark and number of values in the data buffer.
- May set the overrun flag, S1[OR], noise flag, S1[NF], parity error flag, S1[PE], or the receiver active flag, S2[RAF].

The detection threshold for a break character can be adjusted when using an internal oscillator in a LIN system by setting S2[LBKDE]. The UART break character detection threshold depends on C1[M], C1[PE], C4[LBKDE], and C4[M10]. See the following table.

Table 40-100. Receive break character detection threshold

LBKDE	M	M10	PE	Threshold (bits)
0	0	—	—	10
0	1	0	—	11
0	1	1	0	11
0	1	1	1	12
1	0	—	—	11
1	1	—	—	12

While C4[LBKDE] is set, it will have these effects on the UART registers:

- Prevents S1[RDRF], S1[FE], S1[NF], and S1[PF] from being set. However, if they are already set, they will remain set.
- Sets the LIN break detect interrupt flag, S2[LBKDIF], if a LIN break character is received.

Break characters are not detected or supported when C7816[ISO_7816E] is set/enabled.

40.4.2.7 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS.

- RTS remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using RTS](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS if the number of characters in the receiver data register is equal to or greater than receiver data buffer's watermark, RWFIFO[RXWATER].
- The receiver asserts RTS when the number of characters in the receiver data register is less than the watermark. It is not affected if RDRF is asserted.
- Even if RTS is deasserted, the receiver continues to receive characters until the receiver data buffer is full or is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS remains deasserted.

The following figure shows receiver hardware flow control functional timing. Along with the actual character itself, RXD shows the start bit. The stop bit can also be indicated, with a dashed line, if necessary. The watermark is set to 2.

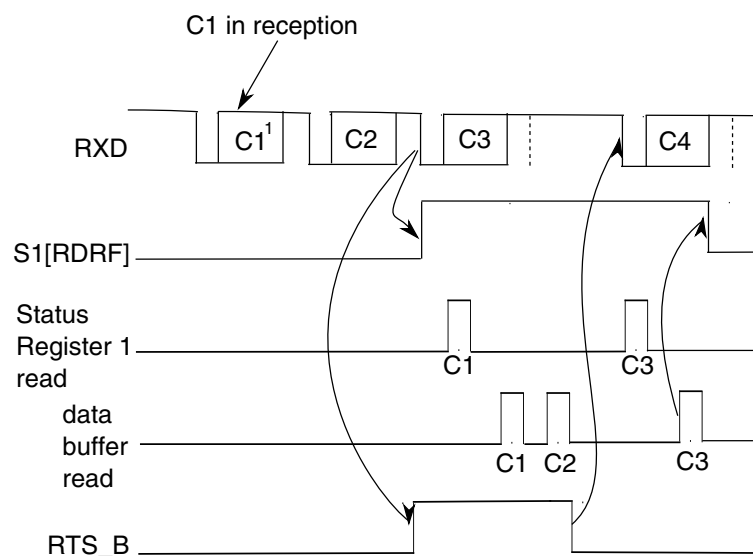

Figure 40-101. Receiver hardware flow control timing diagram

40.4.2.8 Baud rate tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic 0.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

40.4.2.8.1 Slow data tolerance

The following figure shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

Figure 40-102. Slow data

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 40-102](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 147 RT cycles (9 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) \div 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 40-102](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 163 RT cycles (10 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) \div 170) \times 100 = 4.12\%$$

40.4.2.8.2 Fast data tolerance

The following figure shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

Figure 40-103. Fast data

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times \times 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 40-103](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 160 RT cycles (10 bit times \times 16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) \div 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times \times 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 40-103](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 176 RT cycles (11 bit times \times 16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) \div 170) \times 100 = 3.53\%$$

40.4.2.9 Receiver wakeup

C1[WAKE] determines how the UART is brought out of the standby state to process an incoming message. C1[WAKE] enables either idle line wakeup or address mark wakeup.

Receiver wakeup is not supported when C7816[ISO_7816E] is set/enabled because multi-receiver systems are not allowed.

40.4.2.9.1 Idle input line wakeup (C1[WAKE] = 0)

In this wakeup method, an idle condition on the unsynchronized receiver input signal clears C2[RWU] and wakes the UART. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another idle character appears on the unsynchronized receiver input signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

When C2[RWU] is 1 and S2[RWUID] is 0, the idle character that wakes the receiver does not set S1[IDLE] or the receive data register full flag, S1[RDRF]. The receiver wakes and waits for the first data character of the next message which is stored in the receive data buffer. When S2[RWUID] and C2[RWU] are set and C1[WAKE] is cleared, any idle condition sets S1[IDLE] and generates an interrupt if enabled.

Idle input line wakeup is not supported when C7816[ISO_7816E] is set/enabled.

40.4.2.9.2 Address mark wakeup (C1[WAKE] = 1)

In this wakeup method, a logic 1 in the bit position immediately preceding the stop bit of a frame clears C2[RWU] and wakes the UART. A logic 1 in the bit position immediately preceding the stop bit marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another address frame appears on the unsynchronized receiver input signal.

A logic 1 in the bit position immediately preceding the stop bit clears the receiver's C2[RWU] before the stop bit is received and places the received data into the receiver data buffer.

Address mark wakeup allows messages to contain idle characters but requires that the bit position immediately preceding the stop bit be reserved for use in address frames.

If module is in standby mode and nothing triggers to wake the UART, no error flag is set even if an invalid error condition is detected on the receiving data line.

Address mark wakeup is not supported when C7816[ISO_7816E] is set/enabled.

40.4.2.9.3 Match address operation

Match address operation is enabled when C4[MAEN1] or C4[MAEN2] is set. In this function, a frame received by the RX pin with a logic 1 in the bit position immediately preceding the stop bit is considered an address and is compared with the associated MA1 or MA2 register. The frame is transferred to the receive buffer, and S1[RDRF] is set, only if the comparison matches. All subsequent frames received with a logic 0 in the bit position immediately preceding the stop bit are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs, then no transfer is made to the receive data buffer, and all following frames with logic 0 in the bit position immediately preceding the stop bit are also discarded. If both C4[MAEN1] and C4[MAEN2] are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Match address operation functions in the same way for both MA1 and MA2 registers.

- If only one of C4[MAEN1] and C4[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If C4[MAEN1] and C4[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

Address match operation is not supported when C7816[ISO_7816E] is set/enabled.

40.4.3 Baud rate generation

A 13-bit modulus counter and a 5-bit fractional fine-adjust counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the module clock divisor. The SBR bits are in the UART baud rate registers, BDH and BDL. The baud rate clock is synchronized with the module clock and drives the receiver. The fractional fine-adjust counter adds fractional delays to the baud rate clock to allow fine trimming of the baud rate to match the system baud rate. The transmitter is driven by the baud rate clock divided by 16. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to two sources of error:

- Integer division of the module clock may not give the exact target frequency. This error can be reduced with the fine-adjust counter.
- Synchronization with the module clock can cause phase shift.

The [Table 40-101](#) lists the available baud divisor fine adjust values.

Functional description

UART baud rate = UART module clock / (16 × (SBR[12:0] + BRFD))

The following table lists some examples of achieving target baud rates with a module clock frequency of 10.2 MHz, with and without fractional fine adjustment.

Table 40-101. Baud rates (example: module clock = 10.2 MHz)

Bits SBR (decimal)	Bits BRFA	BRFD value	Receiver clock (Hz)	Transmitter clock (Hz)	Target Baud rate	Error (%)
17	00000	0	600,000.0	37,500.0	38,400	2.3
16	10011	19/32=0.59375	614,689.3	38,418.08	38,400	0.047

1 1 1 0 1	29/32 = 0.90625
1 1 1 1 0	30/32 = 0.9375
1 1 1 1 1	31/32 = 0.96875

40.4.4 Data format (non ISO-7816)

Each data character is contained in a frame that includes a start bit and a stop bit. The rest of the data format depends upon C1[M], C1[PE], S2[MSBF], and C4[M10].

40.4.4.1 Eight-bit configuration

Clearing C1[M] configures the UART for 8-bit data characters, that is, eight bits are memory mapped in D. A frame with eight data bits has a total of 10 bits. The most significant bit of the eight data bits can be used as an address mark to wake the receiver. If the most significant bit is used in this way, then it serves as an address or data indication, leaving the remaining seven bits as actual data. When C1[PE] is set, the eighth data bit is automatically calculated as the parity bit. See the following table.

Table 40-103. Configuration of 8-bit data format

UART_C1[PE]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	1	8	0	0	1
0	1	7	1 ¹	0	1
1	1	7	0	1	1

1. The address bit identifies the frame as an address character. See [Receiver wakeup](#).

40.4.4.2 Nine-bit configuration

When C1[M] is set and C4[M10] is cleared, the UART is configured for 9-bit data characters. If C1[PE] is enabled, the ninth bit is either C3[T8/R8] or the internally generated parity bit. This results in a frame consisting of a total of 11 bits. In the event that the ninth data bit is selected to be C3[T8], it will remain unchanged after transmission and can be used repeatedly without rewriting it, unless the value needs to be changed. This feature may be useful when the ninth data bit is being used as an address mark.

When C1[M] and C4[M10] are set, the UART is configured for 9-bit data characters, but the frame consists of a total of 12 bits. The 12 bits include the start and stop bits, the 9 data character bits, and a tenth internal data bit. Note that if C4[M10] is set, C1[PE] must also be set. In this case, the tenth bit is the internally generated parity bit. The ninth bit can either be used as an address mark or a ninth data bit.

See the following table.

Table 40-104. Configuration of 9-bit data formats

C1[PE]	UC1[M]	C1[M10]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	0	0	See Eight-bit configuration				
0	0	1	Invalid configuration				
0	1	0	1	9	0	0	1
0	1	0	1	8	1 ¹	0	1
0	1	1	Invalid Configuration				
1	0	0	See Eight-bit configuration				
1	0	1	Invalid Configuration				
1	1	0	1	8	0	1	1
1	1	1	1	9	0	1	1
1	1	1	1	8	1 ²	1	1

1. The address bit identifies the frame as an address character.
2. The address bit identifies the frame as an address character.

Note

Unless in 9-bit mode with M10 set, do not use address mark wakeup with parity enabled.

40.4.4.3 Timing examples

Timing examples of these configurations in the NRZ mark/space data format are illustrated in the following figures. The timing examples show all of the configurations in the following sub-sections along with the LSB and MSB first variations.

40.4.4.3.1 Eight-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

Figure 40-104. Eight bits of data with LSB first

Figure 40-105. Eight bits of data with MSB first

40.4.4.3.2 Eight-bit format with parity enabled

Figure 40-106. Seven bits of data with LSB first and parity

Figure 40-107. Seven bits of data with MSB first and parity

40.4.4.3.3 Nine-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

Figure 40-108. Nine bits of data with LSB first

40.4.5 Single-wire operation

Normally, the UART uses two pins for transmitting and receiving. In single wire operation, the RXD pin is disconnected from the UART and the UART implements a half-duplex serial connection. The UART uses the TXD pin for both receiving and transmitting.

Figure 40-114. Single-wire operation (C1[LOOPS] = 1, C1[RSRC] = 1)

Enable single wire operation by setting C1[LOOPS] and the receiver source field, C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Setting C1[RSRC] connects the receiver input to the output of the

TXD pin driver. Both the transmitter and receiver must be enabled ($C2[TE] = 1$ and $C2[RE] = 1$). When $C7816[ISO_7816EN]$ is set, it is not required that both $C2[TE]$ and $C2[RE]$ are set.

40.4.6 Loop operation

In loop operation, the transmitter output goes to the receiver input. The unsynchronized receiver input signal is disconnected from the UART.

Figure 40-115. Loop operation ($C1[LOOPS] = 1$, $C1[RSRC] = 0$)

Enable loop operation by setting $C1[LOOPS]$ and clearing $C1[RSRC]$. Setting $C1[LOOPS]$ disables the path from the unsynchronized receiver input signal to the receiver. Clearing $C1[RSRC]$ connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled ($C2[TE] = 1$ and $C2[RE] = 1$). When $C7816[ISO_7816EN]$ is set, it is not required that both $C2[TE]$ and $C2[RE]$ are set.

40.4.7 ISO-7816/smartcard support

The UART provides mechanisms to support the ISO-7816 protocol that is commonly used to interface with smartcards. The ISO-7816 protocol is an NRZ, single wire, half-duplex interface. The TxD pin is used in open-drain mode because the data signal is used for both transmitting and receiving. There are multiple subprotocols within the ISO-7816 standard. The UART supports both $T = 0$ and $T = 1$ protocols. The module also provides for automated initial character detection and configuration, which allows for support of both direct convention and inverse convention data formats. A variety of interrupts specific to 7816 are provided in addition to the general interrupts to assist software. Additionally, the module is able to provide automated NACK responses and has programmed automated retransmission of failed packets. An assortment of programmable timeouts and guard band times are also supported.

The term elemental time unit (ETU) is frequently used in the context of ISO-7816. This concept is used to relate the frequency that the system (UART) is running at and the frequency that data is being transmitted and received. One ETU represents the time it

takes to transmit or receive a single bit. For example, a standard 7816 packet, excluding any guard time or NACK elements is 10 ETUs (start bit, 8 data bits, and a parity bit). Guard times and wait times are also measured in ETUs.,

NOTE

The ISO-7816 specification may have certain configuration options that are reserved. To maintain maximum flexibility to support future 7816 enhancements or devices that may not strictly conform to the specification, the UART does not prevent those options being used. Further, the UART may provide configuration options that exceed the flexibility of options explicitly allowed by the 7816 specification. Failure to correctly configure the UART may result in unexpected behavior or incompatibility with the ISO-7816 specification.

40.4.7.1 Initial characters

In ISO-7816 with T = 0 mode, the UART can be configured to use C7816[INIT] to detect the next valid initial character, referred to by the ISO-7816 specifically as a TS character. When the initial character is detected, the UART provides the host processor with an interrupt if IE7816[INITDE] is set. Additionally, the UART will alter S2[MSBF], C3[TXINV], and S2[RXINV] automatically, based on the initial character. The corresponding initial character and resulting register settings are listed in the following table.

Table 40-105. Initial character automated settings

Initial character (bit 1-10)	Initial character (hex)	MSBF	TXINV	RXINV
LHHL LLL LLH inverse convention	3F	1	1	1
LHHL HHH LLH direct convention	3B	0	0	0

S2[MSBF], C3[TXINV], and S2[RXINV] must be reset to their default values before C7816[INIT] is set. Once C7816[INIT] is set, the receiver searches all received data for the first valid initial character. Detecting a Direct Convention Initial Character will cause no change to S2[MSBF], C3[TXINV], and S2[RXINV], while detecting an Inverse Convention Initial Character will cause these fields to set automatically. All data received, which is not a valid initial character, is ignored and all flags resulting from the invalid data are blocked from asserting. If C7816[ANACK] is set, a NACK is returned for invalid received initial characters and an RXT interrupt is generated as programmed.

40.4.7.2 Protocol T = 0

When T = 0 protocol is selected, a relatively complex error detection scheme is used. Data characters are formatted as illustrated in the following figure. This scheme is also used for answer to reset and Peripheral Pin Select (PPS) formats.

Figure 40-116. ISO-7816 T = 0 data format

As with other protocols supported by the UART, the data character includes a start bit. However, in this case, there are two stop bits rather than the typical single stop bit. In addition to a standard even parity check, the receiver has the ability to generate and return a NACK during the second half of the first stop bit period. The NACK must be at least one time period (ETU) in length and no more than two time periods (ETU) in length. The transmitter must wait for at least two time units (ETU) after detection of the error signal before attempting to retransmit the character.

It is assumed that the UART and the device (smartcard) know in advance which device is receiving and which is transmitting. No special mechanism is supplied by the UART to control receive and transmit in the mode other than C2[TE] and C2[RE]. Initial Character Detect feature is also supported in this mode.

40.4.7.3 Protocol T = 1

When T = 1 protocol is selected, the NACK error detection scheme is not used. Rather, the parity bit is used on a character basis and a CRC or LRC is used on the block basis, that is, for each group of characters. In this mode, the data format allows for a single stop bit although additional inactive bit periods may be present between the stop bit and the next start bit. Data characters are formatted as illustrated in the following figure.

Figure 40-117. ISO 7816 T=1 data format

The smallest data unit that is transferred is a block. A block is made up of several data characters and may vary in size depending on the block type. The UART does not provide a mechanism to decode the block type. As part of the block, an LRC or CRC is included. The UART does not calculate the CRC or LRC for transmitted blocks, nor does it verify the validity of the CRC or LRC for received blocks. The 7816 protocol requires that the initiator and the smartcard (device) takes alternate turns in transmitting and receiving blocks. When the UART detects that the last character in a block has been transmitted it will automatically clear C2[TE] and enter receive mode. Therefore, the software must program the transmit buffer with the next data to be transmitted, and then enable C2[TE], once the software has determined that the last character of the received block has been received. The UART detects that the last character of the transmit block has been sent when TL7816[TLEN] = 0 and four additional characters have been sent. The four additional characters are made up of three prior to TL7816[TLEN] decrementing (prologue) and one after TL7816[TLEN] = 0, the final character of the epilogue.

40.4.7.4 Wait time and guard time parameters

The ISO-7816 specification defines several wait time and guard time parameters. The UART allows for flexible configuration and violation detection of these settings. On reset, the wait time (IS7816[WT]) defaults to 9600 ETUs and guard time (GT) to 12 ETUs. These values are controlled by parameters in the WP7816, WN7816, and WF7816 registers. Additionally, the value of C7816[TTYPE] also factors into the calculation. The formulae used to calculate the number ETUs for each wait time and guard time value are shown in [Table 40-106](#).

Wait time (WT) is defined as the maximum allowable time between the leading edge of a character transmitted by the smartcard device and the leading edge of the previous character that was transmitted by the UART or the device. Similarly, character wait time (CWT) is defined as the maximum allowable time between the leading edge of two characters within the same block. Block wait time (BWT) is defined as the maximum time between the leading edge character of the last block received by the smartcard device and the leading edge of the first character transmitted by the smartcard device.

Guard time (GT) is defined as the minimum allowable time between the leading edge of two consecutive characters. Character guard time (CGT) is the minimum allowable time between the leading edges of two consecutive characters in the same direction, that is, transmission or reception. Block guard time (BGT) is the minimum allowable time between the leading edges of two consecutive characters in opposite directions, that is, transmission then reception or reception then transmission.

The GT and WT counters reset whenever $C7816[TTYPE] = 1$ or $C7816[ISO_7816E] = 0$ or a new dataword start bit has been received or transmitted as specified by the counter descriptions. The CWT, CGT, BWT, BGT counters reset whenever $C7816[TTYPE] = 0$ or $C7816[ISO_7816E] = 0$ or a new dataword start bit is received or transmitted as specified by the counter descriptions. When $C7816[TTYPE] = 1$, some of the counter values require an assumption regarding the first data transferred when the UART first starts. This assumption is required when the 7816E is disabled, when transition from $C7816[TTYPE] = 0$ to $C7816[TTYPE] = 1$ or when coming out of reset. In this case, it is assumed that the previous non-existent transfer was a received transfer.

The UART will automatically handle GT, CGT, and BGT such that the UART will not send a packet before the corresponding guard time expiring.

Table 40-106. Wait and guard time calculations

Parameter	Reset value [ETU]	$C7816[TTYPE] = 0$ [ETU]	$C7816[TTYPE] = 1$ [ETU]
Wait time (WT)	9600	$WI \times 960 \times GTFD$	Not used
Character wait time (CWT)	Not used	Not used	$11 + 2^{CWI}$
Block wait time (BWT)	Not used	Not used	$11 + 2^{BWI} \times 960 \times GTFD$
Guard time (GT)	12	GTN not wqual to 255 $12 + GTN$ GTN wqual to 255 12	Not used
Character guard time (CGT)	Not used	Not used	GTN not equal to 255 $12 + GTN$ GTN equal to 255 11
Block guard time (BGT)	Not used	Not used	22

40.4.7.5 Baud rate generation

The value in $WF7816[GTFD]$ does not impact the clock frequency. SBR and BRFD are used to generate the clock frequency. This clock frequency is used by the UART only and is not seen by the smartcard device. The transmitter clocks operates at 1/16 the frequency of the receive clock so that the receiver is able to sample the received value 16 times during the ETU.

40.4.7.6 UART restrictions in ISO-7816 operation

Due to the flexibility of the UART module, there are several features and interrupts that are not supported while running in ISO-7816 mode. These restrictions are documented within the register field definitions.

40.5 Reset

All registers reset to a particular value are indicated in [Memory map and registers](#).

40.6 System level interrupt sources

There are several interrupt signals that are sent from the UART. The following table lists the interrupt sources generated by the UART. The local enables for the UART interrupt sources are described in this table. Details regarding the individual operation of each interrupt are contained under various sub-sections of [Memory map and registers](#).

However, [RXEDGIF description](#) also outlines additional details regarding the RXEDGIF interrupt because of its complexity of operation. Any of the UART interrupt requests listed in the table can be used to bring the CPU out of Wait mode.

Table 40-107. UART interrupt sources

Interrupt Source	Flag	Local enable	DMA select
Transmitter	TDRE	TIE	TDMAS = 0
Transmitter	TC	TCIE	-
Receiver	IDLE	ILIE	
Receiver	RDRF	RIE	RDMAS = 0
Receiver	LBKDIF	LBKDIE	-
Receiver	RXEDGIF	RXEDGIE	-
Receiver	OR	ORIE	-
Receiver	NF	NEIE	-
Receiver	FE	FEIE	-
Receiver	PF	PEIE	-
Receiver	RXUF	RXUFE	-
Transmitter	TXOF	TXOFE	-
Receiver	WT	WTWE	-
Receiver	CWT	CWTE	-
Receiver	BWT	BWTE	-
Receiver	INITD	INITDE	-
Receiver	TXT	TXTE	-

Table continues on the next page...

Table 40-107. UART interrupt sources (continued)

Interrupt Source	Flag	Local enable	DMA select
Receiver	RXT	RXTE	-
Receiver	GTV	GTVE	-

40.6.1 RXEDGIF description

S2[RXEDGIF] is set when an active edge is detected on the RxD pin. Therefore, the active edge can be detected only when in two wire mode. A RXEDGIF interrupt is generated only when S2[RXEDGIF] is set. If RXEDGIE is not enabled before S2[RXEDGIF] is set, an interrupt is not generated until S2[RXEDGIF] is set.

40.6.1.1 RxD edge detect sensitivity

Edge sensitivity can be software programmed to be either falling or rising. The polarity of the edge sensitivity is selected using S2[RXINV]. To detect the falling edge, S2[RXINV] is programmed to 0. To detect the rising edge, S2[RXINV] is programmed to 1.

Synchronizing logic is used prior to detect edges. Prior to detecting an edge, the receive data on RxD input must be at the deasserted logic level. A falling edge is detected when the RxD input signal is seen as a logic 1 (the deasserted level) during one module clock cycle, and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input is seen as a logic 0 during one module clock cycle and then a logic 1 during the next cycle.

40.6.1.2 Clearing RXEDGIF interrupt request

Writing a logic 1 to S2[RXEDGIF] immediately clears the RXEDGIF interrupt request even if the RxD input remains asserted. S2[RXEDGIF] remains set if another active edge is detected on RxD while attempting to clear S2[RXEDGIF] by writing a 1 to it.

40.6.1.3 Exit from low-power modes

The receive input active edge detect circuit is still active on low power modes (Wait and Stop). An active edge on the receive input brings the CPU out of low power mode if the interrupt is not masked (S2[RXEDGIF] = 1).

40.7 DMA operation

In the transmitter, S1[TDRE] can be configured to assert a DMA transfer request. In the receiver, S1[RDRF] can be configured to assert a DMA transfer request. The following table shows the configuration field settings required to configure each flag for DMA operation.

Table 40-108. DMA configuration

Flag	Request enable bit	DMA select bit
TDRE	TIE = 1	TDMAS = 1
RDRF	RIE = 1	RDMAS = 1

When a flag is configured for a DMA request, its associated DMA request is asserted when the flag is set. When S1[RDRF] is configured as a DMA request, the clearing mechanism of reading S1, followed by reading D, does not clear the associated flag. The DMA request remains asserted until an indication is received that the DMA transactions are done. When this indication is received, the flag bit and the associated DMA request is cleared. If the DMA operation failed to remove the situation that caused the DMA request, another request is issued.

40.8 Application information

This section describes the UART application information.

40.8.1 Transmit/receive data buffer operation

The UART has independent receive and transmit buffers. The size of these buffers may vary depending on the implementation of the module. The implemented size of the buffers is a fixed constant via PFIFO[TXFIFOSIZE] and PFIFO[RXFIFOSIZE]. Additionally, legacy support is provided that allows for the FIFO structure to operate as a depth of one. This is the default/reset behavior of the module and can be adjusted using the PFIFO[RXFE] and PFIFO[TXFE] bits. Individual watermark levels are also provided for transmit and receive.

There are multiple ways to ensure that a data block, which is a set of characters, has completed transmission. These methods include:

1. Set TXFIFO[TXWATER] to 0. TDRE asserts when there is no further data in the transmit buffer. Alternatively the S1[TC] flag can be used to indicate when the transmit shift register is also empty.
2. Poll TCFIFO[TXCOUNT]. Assuming that only data for a data block has been put into the data buffer, when TCFIFO[TXCOUNT] = 0, all data has been transmitted or is in the process of transmission.
3. S1[TC] can be monitored. When S1[TC] asserts, it indicates that all data has been transmitted and there is no data currently being transmitted in the shift register.

40.8.2 ISO-7816 initialization sequence

This section outlines how to program the UART for ISO-7816 operation. Elements such as procedures to power up or power down the smartcard, and when to take those actions, are beyond the scope of this description. To set up the UART for ISO-7816 operation:

1. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL. According to the 7816 specification the initial (default) baud rating setting should be $F_i = 372$ and $D_i = 1$ and a maximum frequency of 5 MHz. In other words, the BDH, BDL, and C4 registers should be programmed such that the transmission frequency provided to the smartcard device must be $1/372$ th of the clock and must not exceed 5 MHz.
2. Write to set BDH[LBKDIE] = 0.
3. Write to C1 to configure word length, parity, and other configuration fields (LOOPS, RSRC) and set C1[M] = 1, C1[PE] = 1, and C1[PT] = 0.
4. Write to set S2[RWUID] = 0 and S2[LBKDE] = 0.
5. Write to set MODEM[RXRTSE] = 0, MODEM[TXRTSPOL] = 0, MODEM[TXRTSE] = 0, and MODEM[TXCTSE] = 0.
6. Write to set up interrupt enable fields desired (C3[ORIE], C3[NEIE], C3[PEIE], and C3[FEIE])
7. Write to set C4[MAEN1] = 0 and C4[MAEN2] = 0.
8. Write to C5 register and configure DMA control register fields as desired for application.

9. Write to set C7816[INIT] = 1, C7816[TTYPE] = 0, and C7816[ISO_7816E] = 1. Program C7816[ONACK] and C7816[ANACK] as desired.
10. Write to IE7816 to set interrupt enable parameters as desired.
11. Write to ET7816 and set as desired.
12. Write to set C2[ILIE] = 0, C2[RE] = 1, C2[TE] = 1, C2[RWU] = 0, and C2[SBK] = 0. Set up interrupt enables C2[TIE], C2[TCIE], and C2[RIE] as desired.

At this time, the UART will start listening for an initial character. After being identified, it will automatically adjust S2[MSBF], C3[TXINV], and S2[RXINV]. The software must then receive and process an answer to reset. Upon processing the answer to reset, the software must write to set C2[RE] = 0 and C2[TE] = 0. The software should then adjust 7816 specific and UART generic parameters to match and configure data that was received during the answer on reset period. After the new settings have been programmed, including the new baud rate and C7816[TTYPE], C2[RE] and C2[TE] can be reenabled as required.

40.8.2.1 Transmission procedure for (C7816[TTYPE] = 0)

When the protocol selected is C7816[TTYPE] = 0, it is assumed that the software has a prior knowledge of who should be transmitting and receiving. Therefore, no mechanism is provided for automated transmission/receipt control. The software must monitor S1[TDRE], or configure for an interrupt, and provide additional data for transmission, as appropriate. Additionally, software should set C2[TE] = 1 and control TXDIR whenever it is the UART's turn to transmit information. For ease of monitoring, it is suggested that only data be transmitted until the next receiver/transmit switchover is loaded into the transmit FIFO/buffer.

40.8.2.2 Transmission procedure for (C7816[TTYPE] = 1)

When the protocol selected is C7816[TTYPE] = 1, data is transferred in blocks. Before starting a transmission, the software must write the size, in number of bytes, for the Information Field portion of the block into TLEN. If a CRC is being transmitted for the block, the value in TLEN must be one more than the size of the information field. The software must then set C2[TE] = 1 and C2[RE] = 1. The software must then monitor S1[TDRE]/interrupt and write the prologue, information, and epilogue field to the transmit buffer. TLEN automatically decrements, except for prologue bytes and the final epilogue byte. When the final epilogue byte has been transmitted, the UART automatically clears C2[TE] to 0, and the UART automatically starts capturing the

response to the block that was transmitted. After the software has detected the receipt of the response, the transmission process must be repeated as needed with sufficient urgency to ensure that the block wait time and character wait times are not violated.

40.8.3 Initialization sequence (non ISO-7816)

To initiate a UART transmission:

1. Configure the UART.
 - a. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL.
 - b. Write to C1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, and PT). Write to C4, MA1, and MA2 to configure.
 - c. Enable the transmitter, interrupts, receiver, and wakeup as required, by writing to C2 (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK), S2 (MSBF and BRK13), and C3 (ORIE, NEIE, PEIE, and FEIE). A preamble or idle character is then shifted out of the transmitter shift register.
2. Transmit procedure for each byte.
 - a. Monitor S1[TDRE] by reading S1 or responding to the TDRE interrupt. The amount of free space in the transmit buffer directly using TCFIFO[TXCOUNT] can also be monitored.
 - b. If the TDRE flag is set, or there is space in the transmit buffer, write the data to be transmitted to (C3[T8]/D). A new transmission will not result until data exists in the transmit buffer.
3. Repeat step 2 for each subsequent transmission.

Note

During normal operation, S1[TDRE] is set when the shift register is loaded with the next data to be transmitted from the transmit buffer and the number of datawords contained in the transmit buffer is less than or equal to the value in TWFIFO[TXWATER]. This occurs 9/16ths of a bit time after the start of the stop bit of the previous frame.

To separate messages with preambles with minimum idle line time, use this sequence between messages.

1. Write the last dataword of the first message to C3[T8]/D.
2. Wait for S1[TDRE] to go high with TWFIFO[TXWATER] = 0, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting C2[TE].
4. Write the first and subsequent datawords of the second message to C3[T8]/D.

40.8.4 Overrun (OR) flag implications

To be flexible, the overrun flag (OR) operates slightly differently depending on the mode of operation. There may be implications that need to be carefully considered. This section clarifies the behavior and the resulting implications. Regardless of mode, if a dataword is received while S1[OR] is set, S1[RDRF] and S1[IDLE] are blocked from asserting. If S1[RDRF] or S1[IDLE] were previously asserted, they will remain asserted until cleared.

40.8.4.1 Overrun operation

The assertion of S1[OR] indicates that a significant event has occurred. The assertion indicates that received data has been lost because there was a lack of room to store it in the data buffer. Therefore, while S1[OR] is set, no further data is stored in the data buffer until S1[OR] is cleared. This ensures that the application will be able to handle the overrun condition.

In most applications, because the total amount of lost data is known, the application will attempt to return the system to a known state. Before S1[OR] is cleared, all received data will be dropped. For this, the software does the following.

1. Remove data from the receive data buffer. This could be done by reading data from the data buffer and processing it if the data in the FIFO was still valuable when the overrun event occurred, or using CFIFO[RXFLUSH] to clear the buffer.
2. Clear S1[OR]. Note that if data was cleared using CFIFO[RXFLUSH], then clearing S1[OR] will result in SFIFO[RXUF] asserting. This is because the only way to clear S1[OR] requires reading additional information from the FIFO. Care should be taken to disable the SFIFO[RXUF] interrupt prior to clearing the OR flag and then clearing SFIFO[RXUF] after the OR flag has been cleared.

Note that, in some applications, if an overrun event is responded to fast enough, the lost data can be recovered. For example, when C7816[ISO_7816E] is asserted, C7816[TTYTYPE]=1 and C7816[ONACK] = 1, the application may reasonably be able to determine whether the lost data will be resent by the device. In this scenario, flushing the receiver data buffer may not be required. Rather, if S1[OR] is cleared, the lost data may be resent and therefore may be recoverable.

When LIN break detect (LBKDE) is asserted, S1[OR] has significantly different behavior than in other modes. S1[OR] will be set, regardless of how much space is actually available in the data buffer, if a LIN break character has been detected and the corresponding flag, S2[LBKDIF], is not cleared before the first data character is received after S2[LBKDIF] asserted. This behavior is intended to allow the software sufficient time to read the LIN break character from the data buffer to ensure that a break character was actually detected. The checking of the break character was used on some older implementations and is therefore supported for legacy reasons. Applications that do not require this checking can simply clear S2[LBKDIF] without checking the stored value to ensure it is a break character.

40.8.5 Overrun NACK considerations

When C7816[ISO_7816E] is enabled and C7816[TTYTYPE] = 0, the retransmission feature of the 7816 protocol can be used to help avoid lost data when the data buffer overflows. Using C7816[ONACK], the module can be programmed to issue a NACK on an overflow event. Assuming that the smartcard device has implemented retransmission, the lost data will be retransmitted. While useful, there is a programming implication that may require special consideration. The need to transmit a NACK must be determined and committed to prior to the dataword being fully received. While the NACK is being received, it is possible that the application code will read the data buffer such that sufficient room will be made to store the dataword that is being NACK'ed. Even if room has been made in the data buffer after the transmission of a NACK is completed, the received data will always be discarded as a result of an overflow and the ET7816[RXTHRESHOLD] value will be incremented by one. However, if sufficient space now exists to write the received data which was NACK'ed, S1[OR] will be blocked and kept from asserting.

40.8.6 Match address registers

The two match address registers allow a second match address function for a broadcast or general call address to the serial bus, as an example.

40.8.7 Modem feature

This section describes the modem features.

40.8.7.1 Ready-to-receive using RTS

To help to stop overrun of the receiver data buffer, the RTS signal can be used by the receiver to indicate to another UART that it is ready to receive data. The other UART can send the data when its CTS signal is asserted. This handshaking conforms to the TIA-232-E standard. A transceiver is necessary if the required voltage levels of the communication link do not match the voltage levels of the UART's RTS and CTS signals.

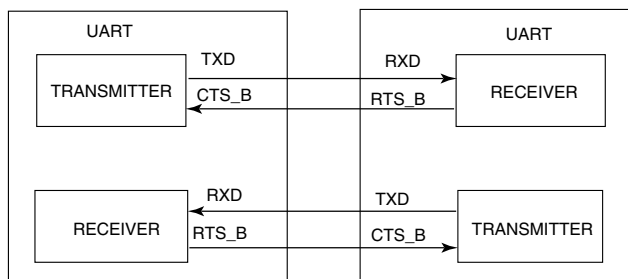

Figure 40-118. Ready-to-receive

The transmitter's CTS signal can be used for hardware flow control whether its RTS signal is used for hardware flow control, transceiver driver enable, or not at all.

40.8.7.2 Transceiver driver enable using RTS

RS-485 is a multiple drop communication protocol in which the UART transceiver's driver is 3-stated unless the UART is driving. The RTS signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS can be matched to the polarity of the transceiver's driver enable signal. See the following figure.

Figure 40-119. Transceiver driver enable using RTS

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the UART in single wire mode, freeing the RXD pin for other uses.

40.8.8 Clearing 7816 wait timer (WT, BWT, CWT) interrupts

The 7816 wait timer interrupts associated with IS7816[WT], IS7816[BWT], and IS7816[CWT] will automatically reassert if they are cleared and the wait time is still violated. This behavior is similar to most of the other interrupts on the UART. In most cases, if the condition that caused the interrupt to trigger still exists when the interrupt is cleared, then the interrupt will reassert. For example, consider the following scenario:

1. IS7816[WT] is programmed to assert after 9600 cycles of unresponsiveness.
2. The 9600 cycles pass without a response resulting in the WT interrupt asserting.
3. The IS7816[WT] is cleared at cycle 9700 by the interrupt service routine.
4. After the WT interrupt has been cleared, the smartcard remains unresponsive. At cycle 9701 the WT interrupt will be reasserted.

If the intent of clearing the interrupt is such that it does not reassert, the interrupt service routine must remove or clear the condition that originally caused the interrupt to assert prior to clearing the interrupt. There are multiple ways that this can be accomplished, including ensuring that an event that results in the wait timer resetting occurs, such as, the transmission of another packet.

40.8.9 Legacy and reverse compatibility considerations

Recent versions of the UART have added several new features. Whenever reasonably possible, reverse compatibility was maintained. However, in some cases this was either not feasible or the behavior was deemed as not intended. This section describes several differences to legacy operation that resulted from these recent enhancements. If application code from previous versions is used, it must be reviewed and modified to take the following items into account. Depending on the application code, additional items that are not listed here may also need to be considered.

1. Various reserved registers and register bits are used, such as, MSFB and M10.
2. This module now generates an error when invalid address spaces are used.
3. While documentation indicated otherwise, in some cases it was possible for S1[IDLE] to assert even if S1[OR] was set.

4. S1[OR] will be set only if the data buffer (FIFO) does not have sufficient room. Previously, the data buffer was always a fixed size of one and the S1[OR] flag would set so long as S1[RDRF] was set even if there was room in the data buffer. While the clearing mechanism has remained the same for S1[RDRF], keeping the OR flag assertion tied to the RDRF event rather than the data buffer being full would have greatly reduced the usefulness of the buffer when its size is larger than one.
5. Previously, when C2[RWU] was set (and WAKE = 0), the IDLE flag could reassert up to every bit period causing an interrupt and requiring the host processor to reassert C2[RWU]. This behavior has been modified. Now, when C2[RWU] is set (and WAKE = 0), at least one non-idle bit must be detected before an idle can be detected.

Chapter 41

Rapid GPIO (RGPIO)

41.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Rapid GPIO (RGPIO) module provides a 16-bit general-purpose I/O module directly connected to the processor's high-speed 32-bit local bus. This connection plus support for single-cycle, zero wait-state data transfers allows the RGPIO module to provide improved pin performance when compared to more traditional GPIO modules located on the internal slave peripheral bus.

Many of the pins associated with a device may be used for several different functions. Their primary functions are to provide external interfaces to access off-chip resources. When not used for their primary function, many of the pins may be used as general-purpose digital I/O (GPIO) pins. The definition of the exact pin functions and the affected signals is specific to each device. Every GPIO port, including the RGPIO module, has registers that configure, monitor, and control the port pins.

Note

Most pin functions default to GPIO and must be software configured before using RGPIO.

41.1.1 Overview

The RGPIO module provides 16-bits of high-speed GPIO functionality, mapped to the processor's bus. The key features of this module include:

- 16 bits of high-speed GPIO functionality connected to the processor's local 32-bit bus

- Memory-mapped device connected to the ColdFire core's local bus
 - Support for all access sizes: byte, word, and longword
 - All reads and writes complete in a single data phase cycle for zero wait-state response
- Data bits can be accessed directly or via alternate addresses to provide set, clear, and toggle functions
 - Alternate addresses allow set, clear, toggle functions using simple store operations without the need for read-modify-write references
- Unique data direction and pin enable control registers
- Package pin toggle rates typically 1.5–3.5x faster than comparable pin mapped onto peripheral bus

A simplified block diagram of the RGPIO module is shown in the following figure. The details of the pin muxing and pad logic are device -specific.

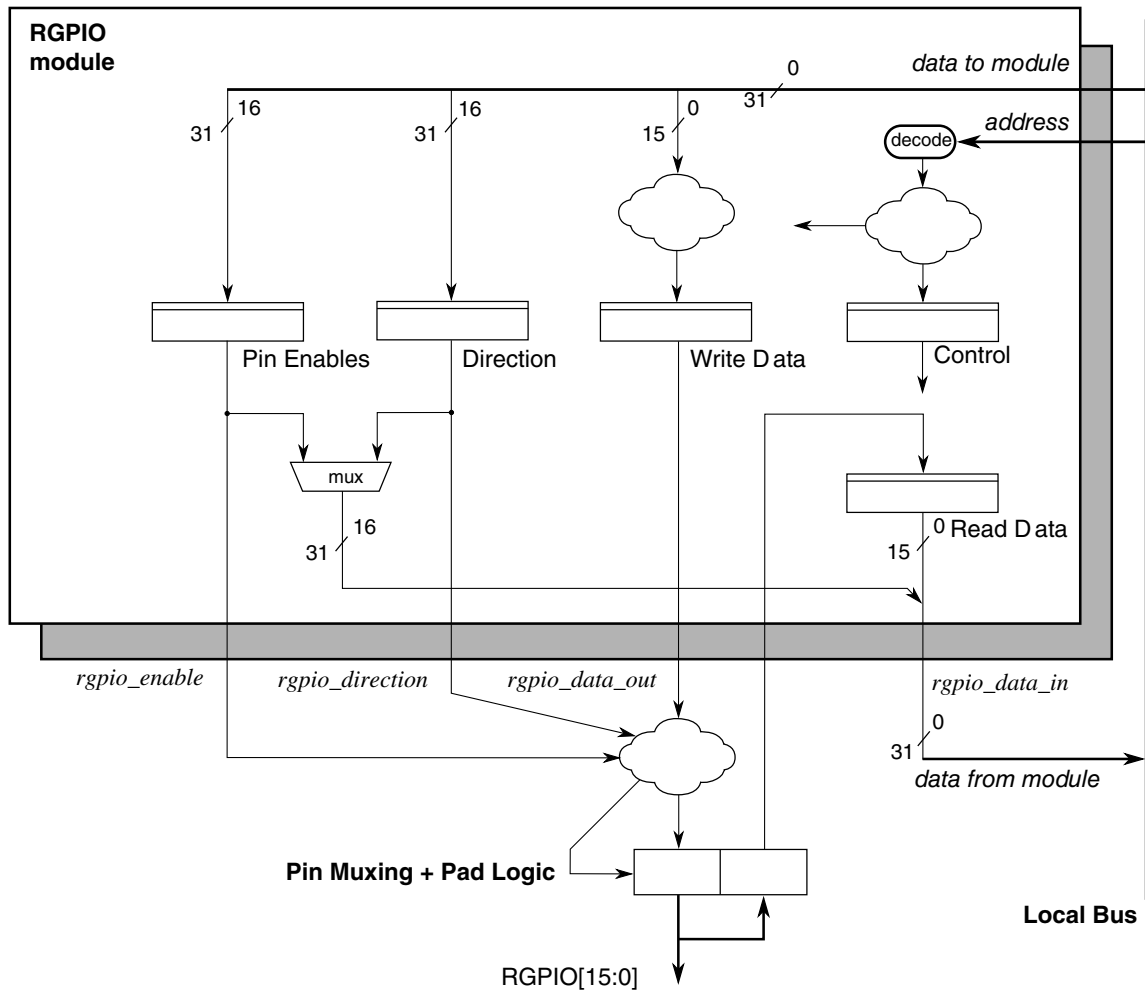

Figure 41-1. RGPIO Block Diagram

41.1.2 Features

The major features of the RGPIO module providing 16 bits of high-speed general-purpose input/output are:

- Small memory-mapped device connected to the processor's local bus
 - All memory references complete in a single cycle to provide zero wait-state responses
 - Located in processor's high-speed clock domain
- Simple programming model
 - Four 16-bit registers, mapped as three program-visible locations
 - Register for pin enables

- Register for controlling the pin data direction
- Register for storing output pin data
- Register for reading current pin state
- The two data registers (read, write) are mapped to a single program-visible location
- Alternate addresses to perform data set, clear, and toggle functions using simple writes
- Separate read and write programming model views enable simplified driver software
 - Support for any access size (byte, word, or longword)

41.1.3 Modes of Operation

The RGPIO module does not support any special modes of operation. As a memory-mapped device located on the processor's high-speed local bus, it responds based strictly on memory address and does not consider the CPU operating mode (supervisor, user) of its references.

41.2 External Signal Description

41.2.1 Overview

As shown in [Figure 41-1](#), the RGPIO module's interface to external logic is indirect via the device pin-muxing and pad logic. The following table shows a list of the associated RGPIO input/output signals.

Table 41-1. RGPIO Module External I/O Signals

Signal Name	Type	Description
RGPIO[15:0]	I/O	RGPIO Data Input/Output

41.2.2 Detailed Signal Descriptions

The following table provides descriptions of the RGPIO module's input and output signals.

Table 41-2. RGPIO Detailed Signal Descriptions

Signal	I/O	Description														
RGPIO[15:0]	I/O	Data Input/Output. When configured as an input, the state of this signal is reflected in the read data register. When configured as an output, this signal is the output of the write data register.

41.3 Memory Map and Registers

The RGPIO module provides a compact 16-byte programming model based at a system memory address of 0x(00)C0_0000 (noted as RGPIO_BASE throughout the chapter). The programming model views are different between reads and writes to enable simplified software for manipulating the RGPIO pins.

Additionally, the RGPIO programming model is defined with a 32-bit organization. The basic size of each program-visible register is 16 bits, but the programming model may be referenced using byte (8-bit), word (16-bit) or longword (32-bit) accesses. Performance is typically maximized using 32-bit accesses.

NOTE

Writes to the two-byte fields at RGPIO_BASE + 0x8 and RGPIO_BASE + 0xC are allowed, but do not affect any program-visible register within the RGPIO module.

RGPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
C0_0000	RGPIO Data Direction Register (RGPIO_DIR)	16	R/W	0000h	41.3.1/1016
C0_0002	RGPIO Data Register (RGPIO_DATA)	16	R/W	0000h	41.3.2/1017
C0_0004	RGPIO Pin Enable Register (RGPIO_ENB)	16	R/W	0000h	41.3.3/1018
C0_0006	RGPIO Clear Data Register (RGPIO_CLR)	16	W	Undefined	41.3.4/1018
C0_0008	RGPIO Data Direction Register (RGPIO_DIR)	16	R	0000h	41.3.5/1019
C0_000A	RGPIO Set Data Register (RGPIO_SET)	16	W	Undefined	41.3.6/1019
C0_000C	RGPIO Data Direction Register (RGPIO_DIR)	16	R	0000h	41.3.7/1020
C0_000E	RGPIO Toggle Data Register (RGPIO_TOG)	16	W	Undefined	41.3.8/1020

41.3.1 RGPIO Data Direction Register (RGPIO_DIR)

The read/write RGPIO_DIR register defines whether a properly-enabled RGPIO pin is configured as an input or output:

- Setting any bit in RGPIO_DIR configures a properly-enabled RGPIO port pin as an output
- Clearing any bit in RGPIO_DIR configures a properly-enabled RGPIO port pin as an input

At reset, all bits in the RGPIO_DIR are cleared.

Address: C0_0000h base + 0h offset = C0_0000h

RGPIO_DIR field descriptions

Field	Description
15–0 DIR	Data direction 0 A properly-enabled RGPIO pin is configured as an input. 1 A properly-enabled RGPIO pin is configured as an output.

41.3.2 RGPIO Data Register (RGPIO_DATA)

The read/write RGPIO_DATA register specifies the write data for a properly-enabled RGPIO output pin or the sampled read data value for a properly-enabled pin. An attempted read of the RGPIO_DATA register returns undefined data for disabled pins because the data value depends on the chip-level pin muxing and pad implementation. At reset, all bits in the RGPIO_DATA registers are cleared.

To set bits in the RGPIO_DATA register, directly set the RGPIO_DATA bits or set the corresponding bits in the RGPIO_SET register. To clear bits in the RGPIO_DATA register, directly clear the RGPIO_DATA bits or clear the corresponding bits in the RGPIO_CLR register. Setting a bit in the RGPIO_TOG register inverts (toggles) the state of the corresponding bit in the RGPIO_DATA register.

As shown in [Figure 41-1](#), the *rgpio_data_in* value is registered using the contents of the *rgpio_data* input bus. For situations where the data direction specifies driving the pins from the *rgpio_data_out* register, the *rgpio_data_in* register value is delayed by one cycle following an update of the write data register. This consecutive sequence is an inherent read-after-write data hazard that can occur with consecutive BCHG instructions and any other operand read following an operand write. Application code must be aware that operand reads of the RGPIO_DATA register immediately (on the next cycle) after an operand write to the RGPIO_DATA register may return a stale value. To prevent this consecutive cycle read-after-write sequence and the corresponding stale data value in RGPIO_DATA, insert a "TPF" instruction (opcode = 0x51FC) between the write and read operations to guarantee the updated value is read.

Address: C0_0000h base + 2h offset = C0_0002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	DATA															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RGPIO_DATA field descriptions

Field	Description
15–0 DATA	RGPIO data 0 A properly-enabled RGPIO output pin is driven with a logic 0, or a properly-enabled RGPIO pin was read as a logic 0. 1 A properly-enabled RGPIO output pin is driven with a logic 1, or a properly-enabled RGPIO pin was read as a logic 1.

41.3.3 RGPIO Pin Enable Register (RGPIO_ENB)

The read/write RGPIO_ENB register configures the corresponding package pin as an RGPIO pin instead of the normal GPIO pin mapped onto the peripheral bus.

At reset, all bits in the RGPIO_ENB register are cleared, disabling the RGPIO functionality.

Address: C0_0000h base + 4h offset = C0_0004h

RGPIO_ENB field descriptions

Field	Description
15–0 ENB	Enable pin for RGPIO 0 The corresponding package pin is configured for use as a normal GPIO pin, not an RGPIO pin. 1 The corresponding package pin is configured for use as an RGPIO pin.

41.3.4 RGPIO Clear Data Register (RGPIO_CLR)

The RGPIO_CLR register provides a mechanism to clear specific bits in the RGPIO_DATA by performing a simple write. Clearing a bit in RGPIO_CLR clears the corresponding bit in the RGPIO_DATA register. Setting it has no effect. The RGPIO_CLR register is write-only; reads of this address return the RGPIO_DATA register.

Address: C0_0000h base + 6h offset = C0_0006h

* Notes:

- x = Undefined at reset.

RGPIO_CLR field descriptions

Field	Description
15–0 CLR	Clear data 0 Clears the corresponding bit in the RGPIO_DATA register. 1 No effect.

41.3.5 RGPIO Data Direction Register (RGPIO_DIR)

Reading this read-only register returns the value of the RGPIO_DIR register at offset 0h.

Address: C0_0000h base + 8h offset = C0_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RGPIO_DIR field descriptions

Field	Description
15–0 DIR	Data direction 0 A properly-enabled RGPIO pin is configured as an input. 1 A properly-enabled RGPIO pin is configured as an output.

41.3.6 RGPIO Set Data Register (RGPIO_SET)

The RGPIO_SET register provides a mechanism to set specific bits in the RGPIO_DATA register by performing a simple write. Setting a bit in RGPIO_SET asserts the corresponding bit in the RGPIO_DATA register. Clearing it has no effect. The RGPIO_SET register is write-only; reads of this address return the RGPIO_DATA register.

Address: C0_0000h base + Ah offset = C0_000Ah

Write																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

RGPIO_DIR field descriptions

Field	Description
15–0 DIR	Data direction 0 A properly-enabled RGPIO pin is configured as an input. 1 A properly-enabled RGPIO pin is configured as an output.

41.3.8 RGPIO Toggle Data Register (RGPIO_TOG)

The RGPIO_TOG register provides a mechanism to invert (toggle) specific bits in the RGPIO_DATA register by performing a simple write. Setting a bit in RGPIO_TOG inverts the corresponding bit in the RGPIO_DATA register. Clearing it has no effect. The RGPIO_TOG register is write-only; reads of this address return the RGPIO_DATA register.

Address: C0_0000h base + Eh offset = C0_000Eh

Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0

* Notes:

- x = Undefined at reset.

RGPIO_TOG field descriptions

Field	Description
15–0 TOG	Toggle data 0 No effect 1 Inverts the corresponding bit in RGPIO_DATA

41.4 Functional Description

The RGPIO module is a relatively-simple design with its behavior controlled by the program-visible registers defined within its programming model.

The RGPIO module is connected to the processor's local two-stage pipelined bus with the stages of the ColdFire core's operand execution pipeline (OEP) mapped directly onto the bus. This structure allows the processor access to the RGPIO module for single-cycle pipelined reads and writes with a zero wait-state response (as viewed in the system bus data phase stage).

41.5 Initialization Information

The reset state of the RGPIO module disables the entire 16-bit data port. Prior to using the RGPIO port, software typically:

- Defines the contents of the data register (RGPIO_DATA) if the pin is to be an output
- Configures the pin direction in RGPIO_DIR
- Enables the appropriate pins in RGPIO_ENB

41.6 Application Information

This section examines the relative performance of the RGPIO output pins for two simple applications

- The processor executes a loop to toggle an output pin for a specific number of cycles, producing a square-wave output
- The processor transmits a 16-bit message using a three-pin SPI-like interface with a serial clock, serial chip select, and serial data bit.

In both applications, the relative speed of the GPIO output is presented as a function of the location of the output bit (RGPIO versus peripheral bus GPIO).

41.6.1 Application 1: Simple Square-Wave Generation

In this example, several different instruction loops are executed, each generating a square-wave output with a 50% duty cycle. For this analysis, the executed code is mapped into the processor's RAM. This configuration is selected to remove any jitter from the output square wave caused by the limitations defined by the two-cycle flash memory accesses and restrictions on the initiation of a flash access. The following instruction loops were studied:

- **BCHG_LOOP** — In this loop, a bit change instruction was executed using the GPIO data byte as the operand. This instruction performs a read-modify-write operation and inverts the addressed bit. A pulse counter is decremented until the appropriate number of square-wave pulses have been generated. When using back to back BCHG instructions, insert the TPF instruction between the BCHG instructions.
- **SET+CLR_LOOP** — For this construct, two store instructions are executed: one to set the GPIO data pin and another to clear it. Single-cycle NOP instructions (the TPF opcode) are included to maintain the 50% duty cycle of the generated square wave. The pulse counter is decremented until the appropriate number of square-wave pulse have been generated.

The square-wave output frequency was measured and the relative performance results are presented in the following table. The relative performance is stated as a fraction of the processor's operating frequency, defined as f MHz. The performance of the BCHG loop operating on a GPIO output is selected as the reference.

Table 41-12. Square-Wave Output Performance

Loop	Peripheral Bus-mapped GPIO			RGPIO		
	Sq-Wave Frequency	Frequency @ CPU $f = 50$ MHz	Relative Speed	Sq-Wave Frequency	Frequency @ CPU $f = 50$ MHz	Relative Speed
<i>bchg</i>	$(1/24) \times f$ MHz	2.083 MHz	1.00x	$(1/14) \times f$ MHz	3.571 MHz	1.71x
<i>set+clr (+toggle)</i>	$(1/12) \times f$ MHz	4.167 MHz	2.00x	$(1/8) \times f$ MHz	6.250 MHz	3.00x

Note

The square-wave frequency is measured from rising-edge to rising-edge, where the output wave has a 50% duty cycle.

41.6.2 Application 2: 16-bit Message Transmission using SPI Protocol

In this second example, a 16-bit message is transmitted using three programmable output pins. The output pins include a serial clock, an active-high chip select, and the serial data bit. The software is configured to sample the serial data bit at the rising-edge of the clock with the data sent in a most-significant to least-significant bit order. The resulting 3-bit output is shown in the following figure.

Figure 41-10. GPIO SPI Example Timing Diagram

For this example, the processing of the SPI message is considerably more complex than the generation of a simple square wave of the previous example. The code snippet used to extract the data bit from the message and build the required GPIO data register writes is shown in the following example.

```
# subtest: send a 16-bit message via a SPI interface using a RGPIO
# the SPI protocol uses a 3-bit value: clock, chip-select, data
# the data is centered around the rising-edge of the clock

        align    16
send_16b_spi_message_rgpio:

```

The resulting SPI performance, as measured in the effective Mbps transmission rate for the 16-bit message, is shown in the following table.

Table 41-13. Emulated SPI Performance using GPIO Outputs

Peripheral Bus-mapped GPIO		RGPIO	
SPI Speed @ CPU <i>f</i> = 50 MHz	Relative Speed	SPI Speed @ CPU <i>f</i> = 50 MHz	Relative Speed
2.063 Mbps	1.00x	3.809 Mbps	1.29x

Chapter 42

Enhanced GPIO (EGPIO)

42.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This section explains software controls related to parallel input/output (I/O) and pin control. Refer to the device's data sheet for more information about pin assignments and external hardware considerations for these pins.

In addition to standard I/O port functionality, some ports have set, clear, and toggle functions that are integrated as part of the ColdFire core itself to improve edge resolution on those pins. For additional information, see the [Functional description](#) and the description of Rapid GPIO (RGPIO). Refer to Port Mux details to identify the specific ports that have this additional RGPIO functionality.

Many port pins are shared with on-chip peripherals such as timer systems, communication systems, or keyboard interrupts as shown in [Figure 42-1](#). The peripheral modules have priority over general-purpose I/O functions. When a peripheral is enabled, the I/O functions associated with the shared pins may be disabled.

After reset, the shared peripheral functions are disabled and the pins are configured as inputs (each $PTDDn$ bit is 0). The pin control functions for each pin are configured as follows: slew rate control is disabled (each $PTSREn$ bit is 0), low drive strength is selected (each $PTDSn$ bit is 0), and internal pulls are disabled (each $PTPUEn$ bit is 0).

Note

Not all general-purpose I/O pins are available on all packages. To avoid extra current drain from floating input pins, the user's reset initialization routine in the application program must either enable on-chip pullup devices or change the direction of unconnected pins to outputs, so the pins do not float.

42.2 Overview

The second generation parallel input/output, EGPIO, is a purely digital module (synthesizable for all technologies) present at both sides of the multiplex control module, as shown in the following figure.

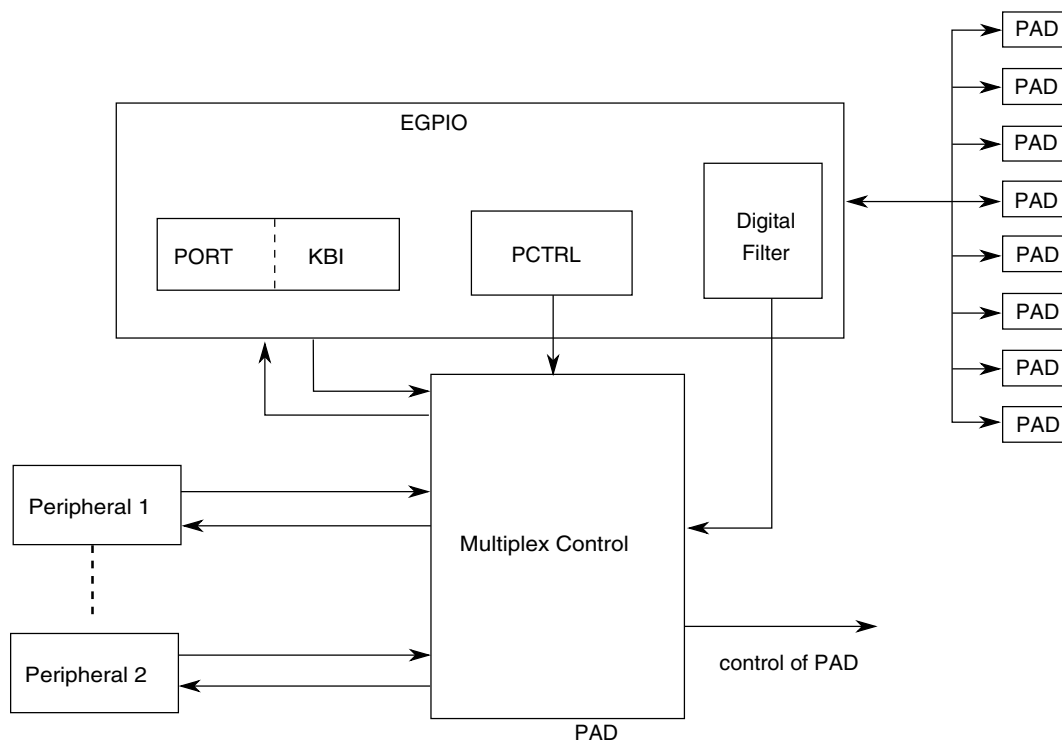

Figure 42-1. Top-level interface of EGPIO

42.2.1 Features

The EGPIO includes four main functions with these features:

- Port data logic

- Pin input data mapped to, and output data controlled through, port data (D) register
- Independent directional control per pin through data direction (DD) register
- Independent pin value (PV) register to read logic level on digital pin
- Independent port control
 - Independent internal input pulling resistor enable per pin through pulling enable (PUE) register
 - Independent internal input pullup/pulldown select per pin through pullup/pulldown select (PUS) register
 - Independent output slew rate control per pin through slew rate enable (SRE) register
 - Independent output drive strength control per pin through drive strength control (DS) register
 - Independent input passive filter per pin through PFE register
- Pin interrupt
 - Pin interrupt for each pin with individual flag and individual enable bit
 - Each pin is programmable as falling edge (or rising edge) only, or both falling edge and low level (or both rising edge and high level) interrupt sensitivity.
 - One software-enabled interrupt to CPU
 - One asynchronous interrupt to wake the CPU from low-power mode
 - DMA interface to support transfer by DMA
- Digital filters
 - Digital filter for each pin if configured as input with individual enable bit in DFE register
 - Programmable digital filtering frequency through DFC register

42.2.2 Modes of operation

The section defines the EGPIO operation in wait, stop, and background debug modes.

42.2.2.1 Operation in wait mode

All EGPIO functions continue to operate in wait mode if enabled before execution of the WAIT instruction. If a pin DMA request is not enabled (the PTDMAEN bit is 0), an enabled interrupt pin (the corresponding PTIPEn bit is 1) can be used to bring the MCU out of wait mode if the interrupt of EGPIO is enabled (the PTIE bit is 1).

42.2.2.2 Operation in stop mode

The pin interrupt function operates asynchronously in stop mode if enabled before execution of the STOP instruction. Therefore, an enabled interrupt pin (the corresponding PTIPEn bit is 1) can be used to bring the MCU out of stop mode if the interrupt of EGPIO is enabled (the PTIE bit is 1) and either the digital filter on this pin is disabled (bypass mode) or the digital filter continues to operate on the LPO clock.

The digital filter continues to operate if it is enabled and the LPO clock is selected for digital filtering before entry to stop mode.

42.2.2.3 Operation in active background mode

When the MCU is in active background mode, all EGPIO functions continue to operate normally.

42.3 Memory Map and Registers

42.3.1 Port Pulling Enable Register (PCTLx_PUE)

Address: Base address + 0h offset

PCTLx_PUE field descriptions

Field	Description
7–0 PTPUE[7:0]	<p>Port internal pulling enable bits</p> <p>Each pin has a pullup and pulldown resistor associated with it. For port pins that are not configured as inputs, these bits have no effect and the internal pull resistors are disabled.</p> <p>If there is no special note or description for the module that controls the pin whether a pulling resistor is enabled for the module, it is decided by the associated PUE bit.</p> <p>0 Pulling resistor is disabled. 1 Pulling resistor is enabled.</p>

42.3.2 Port Pullup/Pulldown Select Register (PCTLx_PUS)

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read	PTPUS[7:0]							
Write	PTPUS[7:0]							
Reset	0	0	0	0	0	0	0	0

PCTLx_PUS field descriptions

Field	Description
7–0 PTPUS[7:0]	<p>Port pullup/pulldown select bits</p> <p>Each bit selects the pullup or pulldown resistor enabled by the corresponding PUE bit. For port pins that are not configured as inputs, these bits have no effect.</p> <p>If there is no special note or description for the module that controls the pin, the selection of pullup/pulldown is decided by the associated PUS bit.</p> <p>0 Pulldown resistor is selected. 1 Pullup resistor is selected.</p>

42.3.3 Port Drive Strength Enable Register (PCTLx_DS)

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	PTDS[7:0]							
Write	PTDS[7:0]							
Reset	0	0	0	0	0	0	0	0

PCTLx_DS field descriptions

Field	Description
7–0 PTDS[7:0]	<p>Port output drive strength control bits</p> <p>Each of these control bits selects between low and high output drive for the associated port pin. For port pins that are configured as inputs, these bits have no effect.</p>

PCTLx_DS field descriptions (continued)

Field	Description
0	Low output drive strength selected.
1	High output drive strength selected.

42.3.4 Port Slew Rate Enable Register (PCTLx_SRE)

Address: Base address + 3h offset

PCTLx_SRE field descriptions

Field	Description
7-0 PTSRE[7:0]	<p>Port output slow rate enable bits</p> <p>Each of these control bits determines whether the output slew rate control is enabled for the associated port pin. For port pins that are not configured as outputs, these bits have no effect.</p> <p>0 Slew rate control disabled.</p> <p>1 Slew rate control enabled.</p>

42.3.5 Port Passive Filter Enable Register (PCTLx_PFE)

The PFE register enables control of the input low-pass filter on the pad. The filter is enabled by setting the bit corresponding to a given pin. When set high, a low pass filter (10 MHz to 30 MHz bandwidth) is enabled in the logic input path. When set low, the filter is bypassed.

The filter is enabled during and after reset by setting the associated PTPFE bit. The filter is disabled through software control by clearing the associated PTPFE bit.

Address: Base address + 4h offset

PCTLx_PFE field descriptions

Field	Description
7-0 PTPFE[7:0]	<p>Port passive input filter enable bits</p> <p>These bits enable control of input low-pass filters for port pins. For port pins not configured as inputs, these bits have no effect.</p>

PCTLx_PFE field descriptions (continued)

Field	Description
0	Input low-pass filter on pad disabled.
1	Input low-pass filter on pad enabled.

42.3.6 Port Interrupt Control Register (PCTLx_IC)

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0	
Read	PTDMAEN		0				PTIE	PTMOD	
Write	0							0	0
Reset	0	0	0	0	0	0	0	0	

PCTLx_IC field descriptions

Field	Description
7 PTDMAEN	<p>DMA enable</p> <p>Determines whether the pin DMA request is enabled. If it is enabled, the pin DMA request is asserted when an interrupt flag of any pin is set (at least one bit of the IF register is set). Meanwhile, a synchronous interrupt from the IF register is disabled if this bit is set.</p> <p>0 Pin DMA request is disabled and synchronous interrupt from IF is allowed. 1 Pin DMA request is enabled and synchronous interrupt from IF is disabled.</p>
6–2 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
1 PTIE	<p>Interrupt enable</p> <p>Determines whether a pin interrupt is requested to the CPU.</p> <p>0 Pin interrupt request not enabled. 1 Pin interrupt request enabled.</p>
0 PTMOD	<p>Direction mode for pin interrupt</p> <p>This bit (along with the EDG bits) controls the detection mode of the pin interrupt for pins.</p> <p>0 Pin interrupt detects edges only. 1 Pin interrupt detects both edges and levels.</p>

42.3.7 Port Interrupt Pin Enable Register (PCTLx_IPE)

This register's bits enable control of pin interrupts.

Address: Base address + 6h offset

Bit	7	6	5	4	3	2	1	0
Read	PTIPE[7:0]							
Write	0							
Reset	0	0	0	0	0	0	0	0

PCTLx_IPE field descriptions

Field	Description
7-0 PTIPE[7:0]	<p>Interrupt pin enables</p> <p>Each PTIPE bit enables the corresponding pin for a pin interrupt.</p> <p>0 Pin not enabled for pin interrupt. 1 Pin enabled for pin interrupt.</p>

42.3.8 Port Interrupt Flag Register (PCTLx_IF)

This register contains the interrupt flag bits for pin interrupts.

Address: Base address + 7h offset

PCTLx_IF field descriptions

Field	Description
7-0 PTIF[7:0]	<p>Interrupt flags</p> <p>Indicate whether a pin interrupt condition is detected on each input pin if the interrupt is enabled by the associated PTIPE bit. Writing 1 to one bit clears the associated PTIF bit if it is set.</p> <p>0 No condition of pin interrupt detected. 1 Condition of pin interrupt detected.</p>

42.3.9 Interrupt Edge Select Register (PCTLx_IES)

This register contains the edge select control bits.

Address: Base address + 8h offset

PCTLx_IES field descriptions

Field	Description
7-0 PTEDG[7:0]	<p>Edge selects of pin interrupt</p> <p>Each EDG bit selects the falling edge/low level or rising edge/high level function of the corresponding pin.</p> <p>0 Falling edge/low level. 1 Rising edge/high level.</p>

42.3.10 Port Digital Filter Enable Register (PCTLx_DFE)

This register contains the enable control bits for digital filters.

NOTE

Only ports B and C have this register.

Address: Base address + 9h offset

Bit	7	6	5	4	3	2	1	0
Read	PTDFE[7:0]							
Write	PTDFE[7:0]							
Reset	0	0	0	0	0	0	0	0

PCTLx_DFE field descriptions

Field	Description
7–0 PTDFE[7:0]	<p>Digital filter enables</p> <p>Each PTDFE bit enables the digital filter on the pin when the pin is configured as an input. If the pin is not configured as an input, the digital filter circuit is not used. When enabled, the digital filter is included in the signal path to EGPIO and any module that gets control of the pin and configures it as an input.</p> <p>0 Digital filter disabled (bypass mode). 1 Digital filter enabled.</p>

42.3.11 Port Digital Filter Control Register (PCTLx_DFC)

This register contains the control bits to select clock and filter factors for all digital filters of the port.

NOTE

Only ports B and C have this register.

Address: Base address + Ah offset

Bit	7	6	5	4	3	2	1	0
Read	PTCLKS	0			PTFF[4:0]			
Write	PTCLKS	0			PTFF[4:0]			
Reset	0	0	0	0	0	0	0	0

PCTLx_DFC field descriptions

Field	Description
7 PTCLKS	<p>Clock select bit</p> <p>Selects the counting clock for digital filters.</p> <p>0 Digital filters count on the bus clock. 1 Digital filters count on the LPO clock.</p>

Table continues on the next page...

PCTLx_DFC field descriptions (continued)

42.4 Functional description

This section provides full descriptions for all EGPIO functions.

42.4.1 Port data logic

The following figure illustrates port data logic.

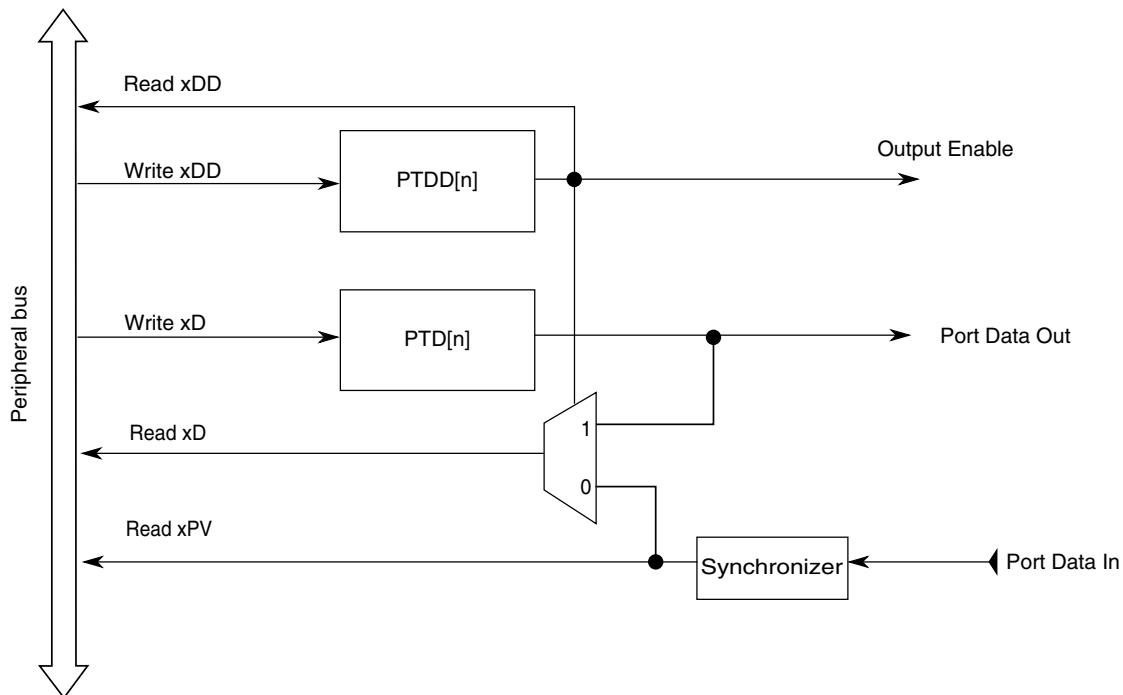

Figure 42-79. Diagram of port data logic function

Port data logic applies to the general purpose input/output function, which is the default function for a port pin when no shared on-chip module is enabled and the pin interrupt function is disabled.

Each port has a data register, a data direction register, and a pin value register. Besides the EGPIO pin interrupt function, an I/O port bit may or may not share an I/O pin with another on-chip module. Consult the Signal Multiplexing description for information about pin assignments.

42.4.1.1 Operation when EGPIO controls pin

If the pin interrupt for a pin is not enabled (the PTIPE bit is 0), the direction of the pin depends on the associated PTDD bit. When the PTDD bit is 1, data written to the port data (D) register is driven out to the corresponding pad.

If the pin interrupt for a pin is enabled (the PTIPE bit is 1), the direction of the pin is configured as an input and the associated PTDD bit has no effect. In this case, data written to the port data (D) register is not driven out to the corresponding pad. When the associated PTDD bit is cleared, a read of the port data register returns the logic level of the associated pin. When the PTDD bit is set, a read of the port data register returns the last value written to the associated bit of the port data register.

When a port pin is controlled by EGPIO, the port is configured for digital functionality, so reading the pin value (PV) register always returns the actual logic level on the pads.

42.4.1.2 Operation when another on-chip module controls pin

When a pin is controlled by another on-chip module, the PTDD bit associated with the pin does not affect the input or output direction of the pin. However, when the PTDD bit is set, reading the port data (D) register still returns the last value written to the port data register's associated bit. When the PTDD bit is cleared and the port pin is configured for digital functionality, a read of the port data register still returns the actual logic level on the pad.

42.4.1.3 Pin value register

For port pins that are configured as digital pins, no matter as input or output, pin value register read always reflects logic level on pads. For port pins that are controlled by analog functions, pin value register read returns zeros (off-value).

42.4.2 Port control

The following figure diagrams the PCTRL function.

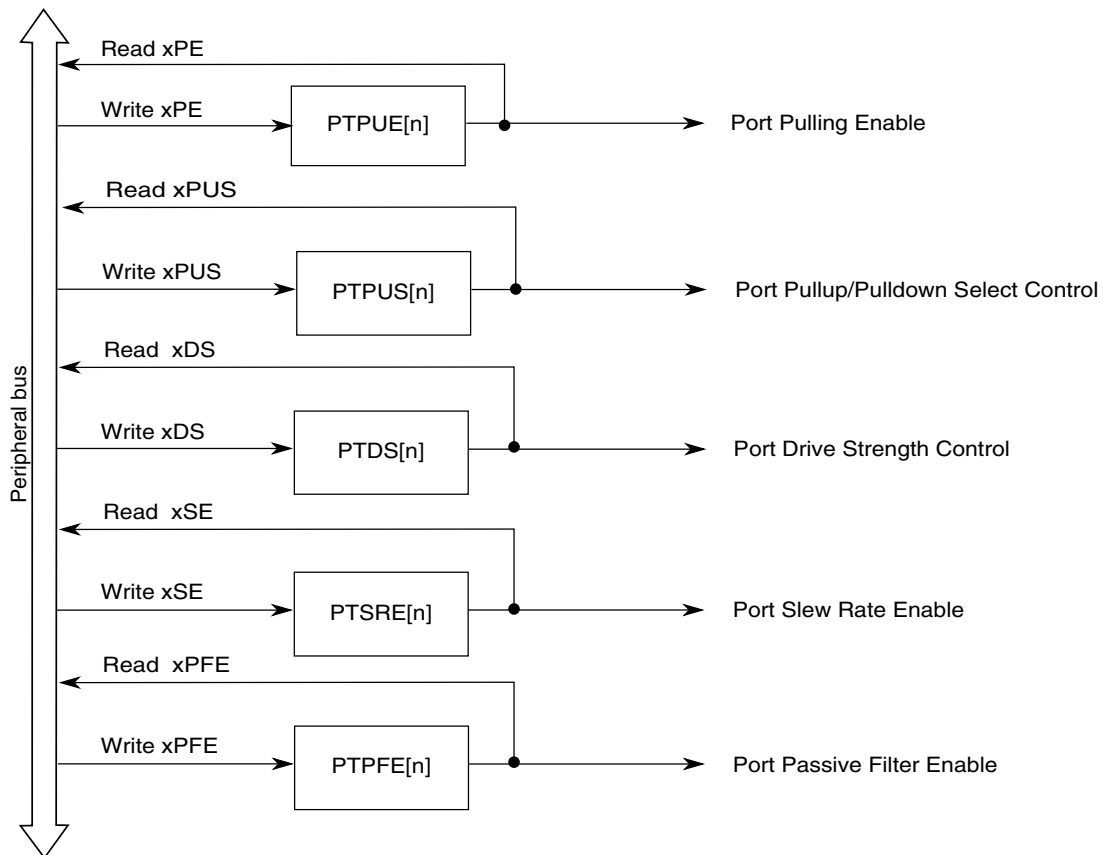

Figure 42-80. Diagram of PCTRL function

The pin control registers are CPU-accessible and operate as described in the [Memory map and registers](#).

42.4.3 Pin interrupt

The pin interrupt function provides up to eight independently enabled external interrupt sources. The following figure is the block diagram for the pin interrupt function.

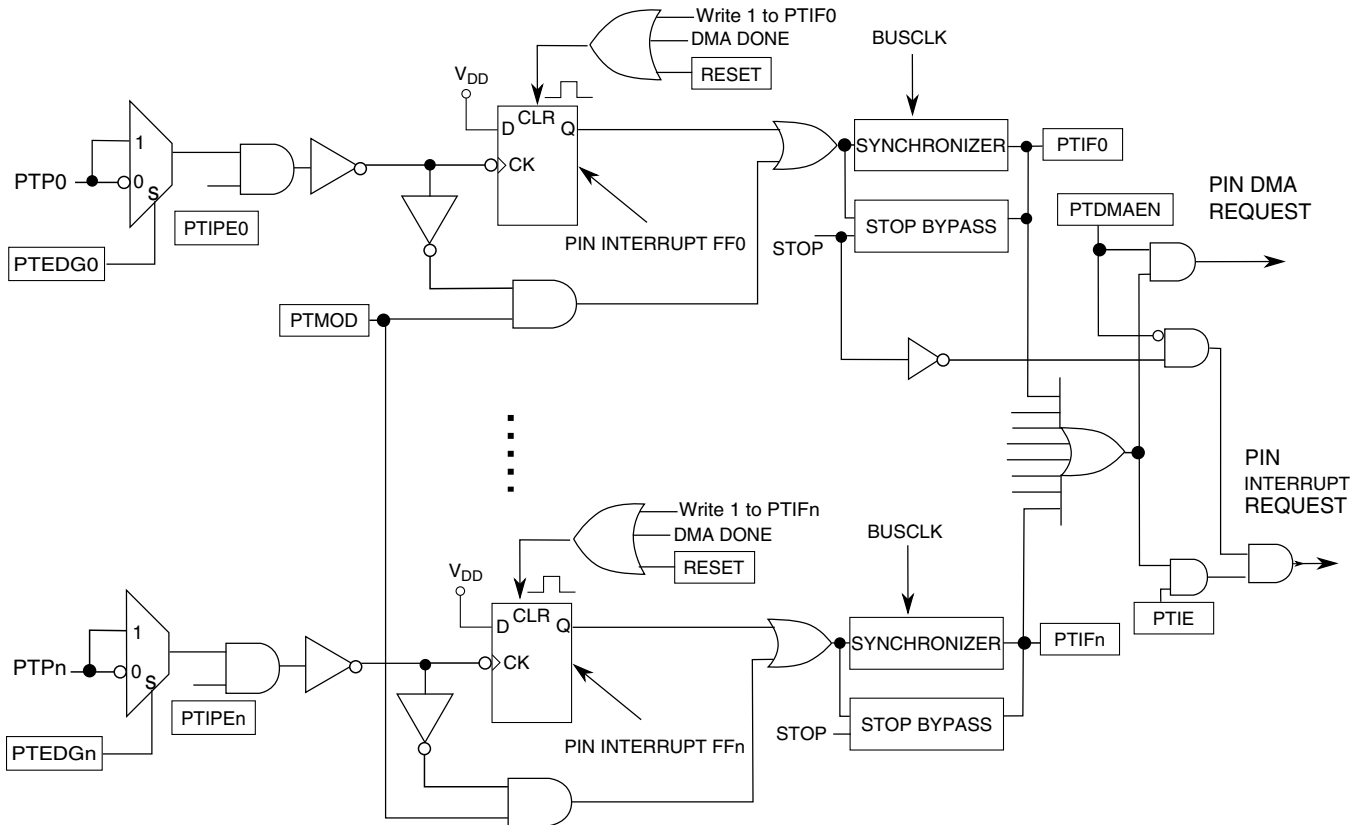

Figure 42-81. Diagram of pin interrupt function

The pin interrupt function is included in EGPIO to supersede an existing KBI module. The main difference is that the pin interrupt function is still able to operate only if a port pin is configured as a digital pin even when EGPIO does not control the pin. That means the pin interrupt, if enabled, can operate with another on-chip module at the same time.

When a port pin is controlled by EGPIO, if the pin interrupt is enabled for this pin (the port interrupt pin enable register's bit is 1), the pin is configured as an input. When a port pin is controlled by the digital function of another on-chip module, the pin interrupt, if enabled (the port interrupt pin enable register's bit is 1), still operates because the EGPIO always receives the actual logic level on external pads when the pin is configured for digital use. But special care must be taken when the pin interrupt operates at the same time with other on-chip modules, and it is strongly recommended to disable the pin interrupt function when another on-chip module controls the pin for output function. When a port pin is configured for analog function, the input for the pin interrupt function is zero and it is recommended to disable the pin interrupt function as well.

42.4.3.1 Edge only sensitivity

A valid edge on an enabled pin interrupt sets an associated PTIF bit. If the PTDMAEN bit in the IC register is set, a DMA request is asserted. If the PTDMAEN bit is not set and the PTIE bit is set, an interrupt request is presented to the CPU. Clearing a PTIF bit is accomplished by writing 1 to the same bit or when the DMA DONE signal for a pin DMA request is asserted.

42.4.3.2 Edge and level sensitivity

A valid edge or level on a pin enabled for pin interrupt sets an associated PTIF bit. If the PTDMAEN bit in the IC register is set, a DMA request is asserted. If the PTDMAEN bit is not set and the PTIE bit is set, an interrupt request is presented to the CPU. Clearing a PTIF bit is accomplished by writing 1 to the same bit or when the DMA DONE signal for a pin DMA request is asserted, provided the associated enabled input of the pin interrupt is at its negated level. During an attempt to clear a PTIF bit, if the associated pin enabled for pin interrupt is asserted, the PTIF bit remains set. Because the DMA process is automatic and negating all enabled inputs before the DMA DONE signal is done is very difficult, it is strongly recommended not to enable a pin DMA request when both edge and level are selected as valid conditions for pin interrupt (the corresponding PTMOD bit is 1).

42.4.3.3 Control of pullup/pulldown resistors

The enabled pin interrupt can be configured to use an internal pullup/pulldown resistor with the associated I/O port pulling enable register. When an internal pulling resistor is enabled (the pin is configured as an input and the PTPUE bit is 1), three situations can apply:

1. If the EGPIO gets control of the pin and the pin is enabled for pin interrupt, the associated PTEDG bit in the IES register selects whether the resistor is a pullup (the PTEDG bit is 0) or a pulldown (the PTEDG bit is 1).
2. If the EGPIO does not get control of the pin or if the pin is not enabled for pin interrupt, the PTEDG bits have no effect.
3. If the EGPIO does not get control of the pin and the pin is still enabled for pin interrupt, the PTEDG bits have no effect on selecting pullup/pulldown resistors. Nevertheless, the value of the associated PTEDG bit must match the pullup/pulldown selection on the pad as defined by the module that gets control of the pin: if the module's actual selection is an internal pullup, the PTEDG bit must be cleared, and if

the module's actual selection is an internal pulldown, the PTEDG bit must be set. Without these aligned settings, when there is no drive on the pad outside, false conditions may be detected as valid conditions for pin interrupt.

42.4.3.4 Asynchronous interrupt in stop mode

When the MCU enters stop mode, the synchronous edge-detection logic is bypassed (because clocks are stopped). In stop mode, enabled inputs of pin interrupt act as asynchronous level-sensitive inputs so they can wake the MCU from stop mode. In stop mode, the pin interrupt requests are not blocked by the PTDMAEN bit being set to 1.

42.4.3.5 Pin interrupt initialization

When an interrupt pin is first enabled or reconfigured, a false interrupt flag can result. To prevent a false interrupt request during pin interrupt initialization, you must perform the following steps:

1. Mask port interrupts by clearing the PTIE bit in the IC register.
2. Enable the polarity for pin interrupt by setting the appropriate PTEDGn bits in the IES register. If the pin interrupt function operates at the same time with another on-chip module that gets control of the pin, the associated PTEDG bit must be set according to the actual selection of internal pullup (the PTEDG bit must be cleared) or pulldown (the PTEDG bit must be set) on the pad by the module that gets control of the pin.
3. If using an internal pullup/pulldown device, configure the associated pulling enable bits in the PUE register.
4. Enable the pins for pin interrupt by setting the appropriate bits in the IPE register.
5. Execute three NOP instructions before the next step to avoid a timing conflict between setting the IPE register and clearing the flag.
6. Write FFh to the IF register to clear any false interrupt flags.
7. Enable the DMA request or interrupt request by configuring the IC register.

42.4.4 Digital filters

The passive input low-pass filter can filter only signals greater than 10 MHz . EGPIO provides programmable digital filters to filter signals much less than 10 MHz for low-speed applications.

The digital filters absorb glitches on digital pins. For the port pin configured as a digital pin, the digital filter is enabled for the pin if the associated bit is set in the port digital filter enable register. For a port pin that is not configured for analog function, the digital filter for the pin is disabled, and the associated bit in the port digital filter enable register has no effect.

The width of the glitch to absorb can be specified in terms of number of filter clock cycles. The bus clock or LPO clock can be selected as a filter clock that is configured by the PTCLKS bit in the port digital filter control register. The width of the glitch to absorb depends on the Filter Factor (FF) bits in the port digital filter control register. Effectively, any down-up-down or up-down-up transition on the digital input line that occurs within the number of clock cycles programmed by the filter factor is ignored by on-chip modules. For details, see the description of the port digital filter control register.

Because the configuration of the port digital filter control register is for all digital filters of the port, changing the port digital filter control register affects all digital filters of the port if enabled. Configuration of the port digital filter control register must occur when no digital filter is active (the port digital filter enable register is 00h).

The LPO clock can operate in stop mode; if the digital filter works in stop mode, the PTCLKS bit must be set before the entry to stop mode.

42.4.4.1 Initialization of digital filters

When a digital filter for a port pin is enabled from a disabled state or pin control is changed from one module to another module while the digital filter is active, some enabled modules may get a false input. To prevent a false input to on-chip modules and related errors during initialization of digital filters, you must do the following to enable the digital filter for input of the target module:

1. Write 0 to the PTDFE bit to disable the digital filter for the pin, if it is active.
2. Write 0 to the PTIPE bit to disable the pin interrupt function, if it is enabled.
3. Disable other on-chip modules that have higher priority for pin control than the target module.
4. Write 1 to the associated pin enable bit of the target module, if it is not enabled.

5. Follow the flow for initialization of the pin interrupt if you still want the pin interrupt function working with the target module.
6. Write 1 to the associated PTDFE bit to enable the digital filter for the pin.

The preceding flow assumes that selection of the filter clock and filter factor do not change and the target module is an on-chip module other than EGPIO.

If you enable the pin interrupt function of EGPIO on a port pin when the digital filter for the pin is active for the input of another on-chip module, you must follow the initialization of the pin interrupt.

If you enable only a digital filter for EGPIO input, you must perform the following steps:

1. Write 0 to the PTDFE bit to disable the digital filter for the pin, if it is active.
2. Disable other on-chip modules that have higher priority for pin control than EGPIO.
3. Follow initialization of the pin interrupt if you enable the pin interrupt function on this port pin.
4. Write 1 to the PTDFE bit to enable the digital filter for the pin.

42.5 Reset

The EGPIO module is reset automatically by any MCU reset.

The EGPIO module cannot cause an MCU reset.

Regarding EGPIO registers:

- The IFE register resets to FFh to disable passive low-pass filters on pads.
- The PV register is unaffected by reset. For details, refer to the register's description.
- A reset clears all other EGPIO registers.

Chapter 43

EGPIO Port Control

43.1 Introduction

Registers for EGPIO control are in two groups. Registers for general port (pin) control are described here. Refer to [Introduction](#) for more information about both sets of registers and about parallel I/O control in general.

43.2 Memory Map and Registers

43.2.1 Port Data Register (PTx_D)

Address: Base address + 0h offset

* Notes:

- PTD[7:0] field: The reset values of internal registers for D are zeros. However, a read of the D register after reset returns the actual logic level on external pins.

PTx_D field descriptions

Field	Description
7-0 PTD[7:0]	<p>Port data bits</p> <p>Writes are latched into all bits of this register. When port data direction bits for port pins are set (each DD bit is 1), reads return the last value written to this register. When a port pin is controlled by EGPIO with the pin interrupt function disabled and the associated port data direction bit is set (the DD bit is 1), the logic level is driven out to the corresponding MCU pin. When the port data direction bits for port pins are cleared (each DD bit is 0):</p> <ul style="list-style-type: none"> • For pins that are configured as digital pins, reads return the logic level on the pin. • For port pins that are controlled by analog functions, reads return zeros (off value).

43.2.2 Port Data Direction Register (PTx_DD)

Address: Base address + 1h offset

PTx_DD field descriptions

Field	Description
7-0 PTDD[7:0]	<p>Port data direction bits</p> <p>Each bit of the port data direction register controls whether an associated port pin is an input or output when pin interrupt is disabled and no other module controls the pin. If the DD bit for a port pin is equal to logic one, and Port Data Logic has control of the pin, the port pin is defined as output and the logic value of an internal register for the D register is driven out to the corresponding MCU pin.</p> <p>0 The port pin is defined only as an input. 1 The port pin is defined as an output.</p>

43.2.3 Port Pin Value Register (PTx_PV)

Address: Base address + 2h offset

* Notes:

- x = Undefined at reset.
- A read of the PV register after reset returns the actual logic level on external pins because reset configures all port pins as high-impedance inputs with pullup/pulldown disabled. x = Undefined at reset.

PTx_PV field descriptions

Field	Description
7–0 PTPV[7:0]	Port pin value bits Each bit of port pin value register is mapped to one MCU pin. For pins that are configured as digital pins, this register always reflects the digital level on the actual PAD. For pins that are controlled by analog functions, reads return zeros (off-value).

Chapter 44

Touch Sense Input (TSI)

44.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The touch sensing input (TSI) module provides capacitive touch sensing detection with high sensitivity and enhanced robustness. Each TSI pin implements the capacitive measurement of an electrode having individual programmable detection thresholds and result registers. The TSI module can be functional in several low power modes with ultra low current adder and waking up the CPU in a touch event. It provides a solid capacitive measurement module for the implementation of touch keypad, rotaries and sliders.

44.2 Features

- Support as many as 16 input capacitive touch sensing pins with individual result registers
- Automatic detection of electrode capacitance change with programmable upper and lower threshold
- Automatic periodic scan unit with different duty cycles for run and low power modes
- Full support with FSL touch sensing SW library (TSS) for the implementation of keypads, rotaries and sliders
- Operation across all low power modes: Wait, Stop, VLPR, VLPW, VLPS, LLS, VLLS{3,2,1}
- Capability to wake up MCU from low power modes
- Configurable interrupts:
 - End-of-scan or out-of-range interrupt
 - TSI error interrupts: pad short to V_{DD}/V_{SS} or conversion overrun
- Compensate temperature and supply voltage variations

Overview

- Stand alone operation not requiring any external crystal even in low power modes
- Configurable integration of each electrode capacitance measurement from 1 to 4096 times
- Programmable electrode oscillator and TSI Reference Oscillator for high sensitivity, small scan time and low power functionality
- Only uses one pin per electrode implementation with no external hardware required

44.3 Overview

This section presents an overview of the TSI module. The following figure presents the simplified TSI module block diagram.

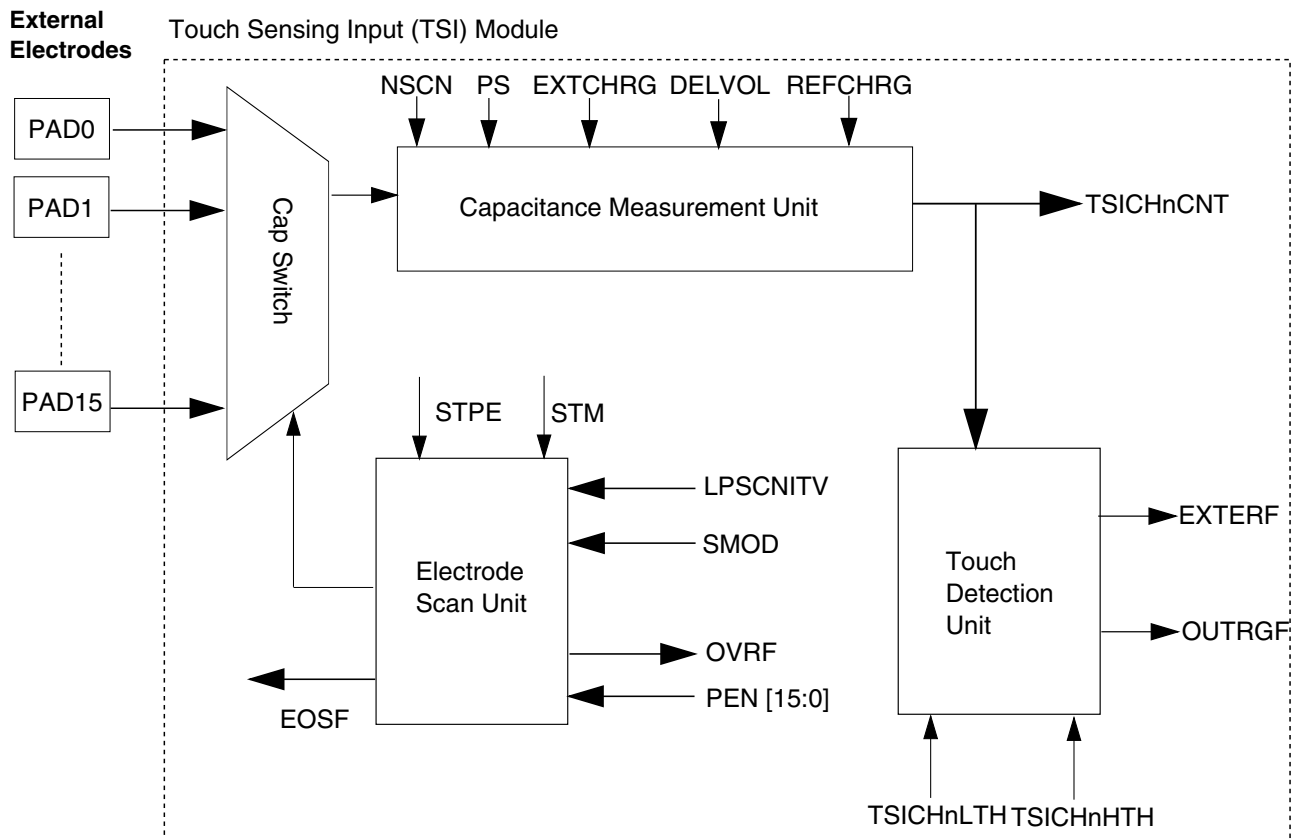

Figure 44-1. Touch sensing input block diagram

44.3.1 Electrode capacitance measurement unit

The electrode capacitance measurement unit senses the capacitance of a TSI pin and outputs a 16-bit result. This module is based in dual oscillator architecture. One oscillator is connected to the external electrode array and oscillates according to the electrode

capacitance, while the other according to an internal reference capacitor. The pin capacitance measurement is given by the counted number of periods of the reference oscillator during a configurable number of oscillations of the external electrode oscillator.

The electrode oscillator charges and discharges the pin capacitance with a programmable 5-bit binary current source in order to accommodate different sizes of electrode capacitance. The electrode oscillator frequency, before being compared to that of the reference oscillator, goes through a prescaler and modulo counter to decrease its frequency and consecutively increase the measurement resolution and noise robustness.

The following figure presents the simplified block diagram of how the electrode capacitance is measured.

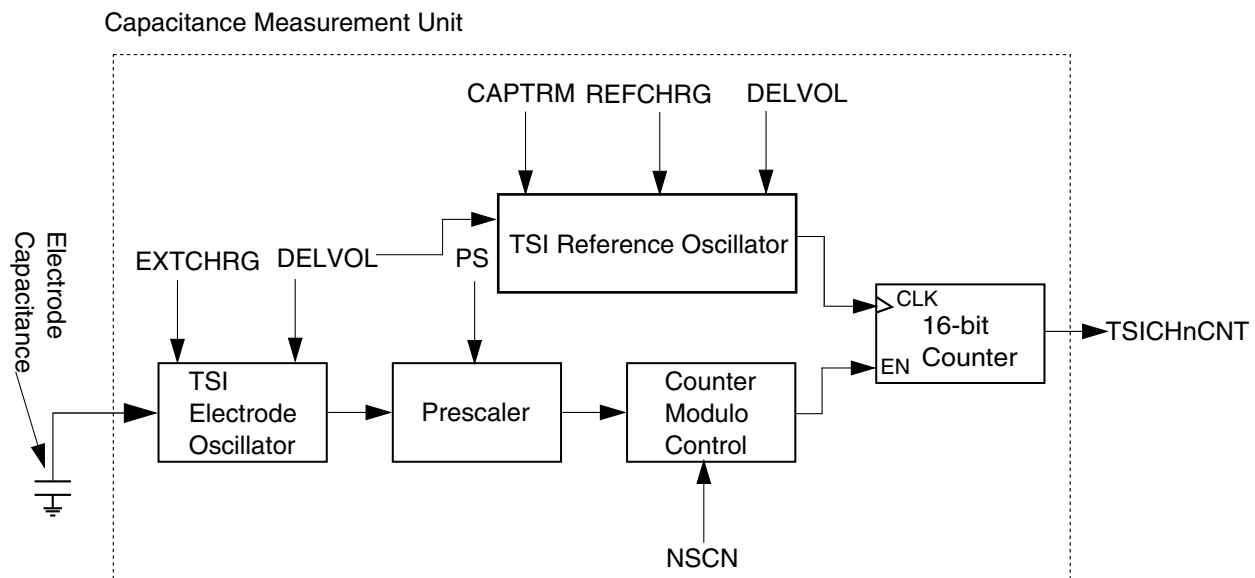

Figure 44-2. TSI capacitance measurement unit block diagram

44.3.2 Electrode scan unit

This section describes the functionality of the electrode scan unit. It is responsible for triggering the start of the active electrode scan.

The touch sense input module needs to periodically scan all active electrodes to determine if a touch event has occurred. The electrode scan unit has two independent scan periods, one for TSI active mode and the other for TSI low power mode. This independent control allows the application to configure longer scan period during low power mode, so contributing to smaller average power consumption. The TSI, in low power mode, has the capability to wake the CPU upon an electrode capacitance change. When the CPU wakes, the TSI enters active mode, and produces a shorter scan period for a faster response and more robust touch detection. Apart from the periodical mode, the

electrode scan unit also allows software triggering of the electrode scans. This feature is very useful for initialization of the touch application to detect the initial electrode capacitances. This module generates configurable end-of-scan interrupt to indicate the application that all electrodes were scanned. If a new electrode scan is started while the previous one is still in progress, an overrun error flag is generated, TSI continues the previous scan sequence and the latest trigger is ignored.

44.3.3 Touch detection unit

The touch detection unit indicates the change in the pin capacitance. This module compares the pin capacitance value in the result register with a pre-configured low and high threshold. If the capacitance result register value is outside the ranges defined by the upper and lower threshold, the touch detection unit generates an out-of-range flag to indicate a pin capacitance change.

The upper and lower threshold values are configurable allowing the application to select the magnitude of the capacitance change to trigger the out-of-range flag. With the threshold values programmed properly the application noise level does not cause frequent CPU interrupts, so minimizes the CPU touch application usage. This feature also allows the TSI to wake up the CPU from low power modes only in a capacitance change event.

44.4 Modes of operation

The TSI module has three operation modes: disabled, active mode and low power mode.

44.4.1 TSI disabled mode

When GENCS[TSIEN] is cleared, the TSI module is disabled.

44.4.2 TSI active mode

In active mode, the TSI module has its full functionality, being able to scan up to 16 electrodes. The TSI can be in active mode with the MCU in Run, Wait, VLPR, and VLPW modes, and the TSI can run in low power mode (only one electrode scanning in Stop, VLPS, LLS, and VLLSx modes).

Three clock sources can be selected for the TSI module in active mode: BUS_CLK, MCGIRCLK and OSCERCLK.

44.4.3 TSI low power mode

The TSI module enters low power mode if the GENCS[STPE] is set to one and the MCU is programmed into one of the following operational modes: LLS, VLLS1, VLLS2 or VLLS3. In low power mode, only one selectable pin is active, being able to perform capacitance measurements. The scan period is defined by GENCS[LPSCNITV]. Two low power clock sources are available in the TSI low power mode, LPOCLK and VLPOSCCLK, being selected by the GENCS[LPCLKS].

In low power mode the TSI interrupt can also be configured as end-of-scan or out-of-range and the GENCS[TSIIEN] must be set in order to generate these interrupts. The TSI interrupt causes the exit of the low power mode, entrance into the active mode, and the MCU wake up.

In low power mode the electrode scan unit is always configured to periodical low power scan.

44.4.4 Block diagram

The following figure shows the block diagram of TSI module.

Figure 44-3. TSI block diagram

44.5 TSI signal descriptions

The TSI module has up to 16 external pins for touch sensing. The table below itemizes all the TSI external pins.

Table 44-1. TSI signal descriptions

Signal	Description	I/O
TSI_IN[15:0]	TSI pins. Switchable driver that connects directly to the electrode pins TSI[15:0] can operate as GPIO pins	I/O

44.5.1 TSI_IN[15:0]

When TSI functionality is enabled by the PEN[PEN], the TSI analog portion uses corresponding TSICH_n to connect external on-board touch capacitors. The connection between the pin and the touch pad must be kept as short as possible to reduce distribution capacity on board that will add to the system base capacitance.

44.6 Memory map and register definition

This section presents the touch sensing input module memory map and registers definition.

TSI memory map

44.7 Functional descriptions

This section provides functional description of the TSI module.

44.7.1 Capacitance measurement

The electrode pin capacitance measurement uses a dual oscillator approach. The TSI electrode oscillator has its frequency dependable on the external electrode capacitance and the TSI module configuration. After going to a configurable prescaler, the TSI electrode oscillator signal goes to the input of the modulo counter. The time for the external electrode oscillations is measured using the TSI reference oscillator. The measured electrode capacitance is directly proportional to this time.

44.7.1.1 TSI electrode oscillator

The TSI electrode oscillator circuit is illustrated in the following figure. A configurable constant current source is used to charge and discharge the external electrode capacitance. A buffer hysteresis defines the oscillator delta voltage. The delta voltage defines the margin of high and low voltage which are the reference input of the comparator in different time.

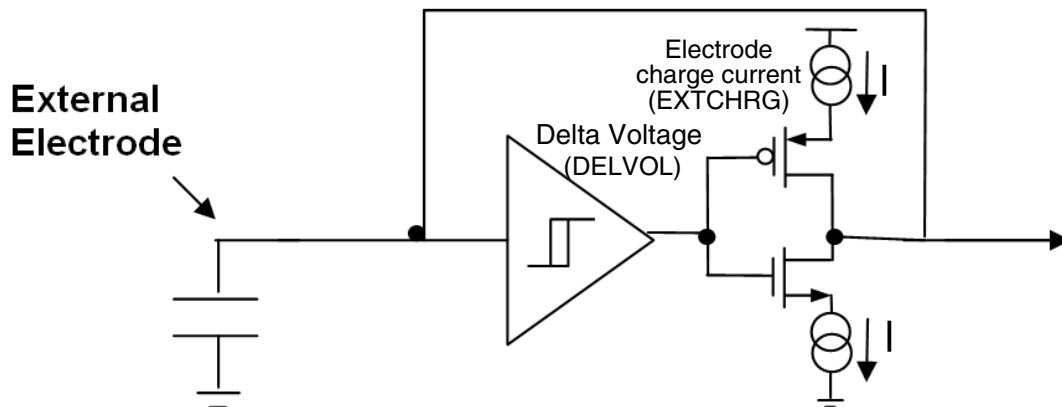

Figure 44-64. TSI electrode oscillator circuit

Functional descriptions

The current source applied to the pad capacitance is 5-bit binary controlled by the SCANC[EXTCHRG]. The hysteresis delta voltage is also configurable and is 3-bit binary controlled by the SCANC[DELVOL]. The figure below shows the voltage amplitude waveform of the electrode capacitance charging and discharging with a programmable current.

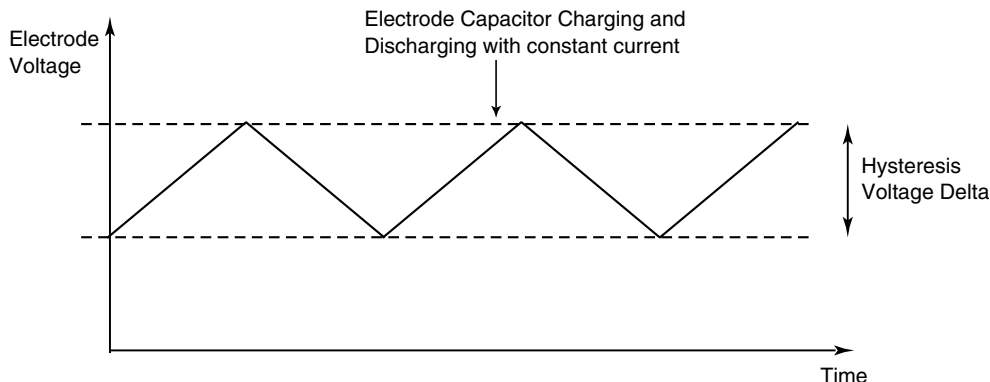

Figure 44-65. TSI electrode oscillator chart

The oscillator frequency is given by the following equation:

$$F_{elec} = \frac{I}{2 * C_{elec} * \Delta V}$$

Figure 44-66. Equation 1: TSI electrode oscillator frequency

Where:

I: constant current

C_{elec} : electrode capacitance

ΔV : Hysteresis delta voltage

So by this equation, for example, an electrode with $C_{elec} = 20$ pF, with a current source of $I = 16$ μ A and $\Delta V = 600$ mV will have the following oscillation frequency:

$$F_{elec} = \frac{16 \mu A}{2 * 20 pF * 600 mV} = 0.67 MHz$$

Figure 44-67. Equation 2: TSI electrode oscillator frequency

The current source and hysteresis delta voltage are used to accommodate the TSI electrode oscillator frequency with different electrode capacitance sizes.

44.7.1.2 Electrode oscillator and counter control

The TSI oscillator frequency signal goes through a prescaler defined by the GENCS[PS] and then enters a counter. The bit field GENCS[NSCN] defines the number of scans for each external electrode.

The pin capacitance sampling time is given by the time the module counter takes to go from zero to its maximum value, defined by NSCN. The electrode sample time is expressed by the following equation:

$$T_{cap_samp} = \frac{PS * NSCN}{F_{elec}}$$

Using Equation 1.

$$T_{cap_samp} = \frac{2 * PS * NSCN * C_{elec} * \Delta V}{I}$$

Figure 44-68. Equation 3: Electrode sampling time

Where:

PS: prescaler value

NSCN: number of scan

I: constant current

C_{elec}: electrode capacitance

ΔV: Hysteresis delta voltage

By this equation, an electrode with C = 20 pF, with a current source of I = 16 μA and ΔV = 600 mV, PS = 2 and NSCN = 16 will have the following sampling time:

$$T_{cap_samp} = \frac{2 * 2 * 16 * 20pF * 600mV}{16\mu A} = 48\mu s$$

44.7.1.3 TSI reference oscillator

The TSI reference oscillator has the same topology of the TSI electrode oscillator. The TSI reference oscillator instead of using an external capacitor for the electrode oscillator has an internal reference capacitor which can be programmable. The SCANC[CAPTRM] defines the internal reference capacitor trimming value *.

The TSI reference oscillator share the same voltage hysteresis levels defined with the SCANC[DELVOL] and has an independent programmable current source controlled by the SCANC[REFCHRG].

* The reference oscillator frequency is given by the following equation:

$$F_{ref_osc} = \frac{I_{ref}}{2 * C_{ref} * \Delta V}$$

Figure 44-69. Equation 4: TSI reference oscillator frequency

Where:

C_{ref} : Internal reference capacitor

I_{ref} : Reference oscillator current source

ΔV : Hysteresis delta voltage

Considering $C_{ref} = 1.0$ pF, $I_{ref} = 12$ μ A and $\Delta V = 600$ mV, follows

$$F_{ref_osc} = \frac{12\mu A}{2 * 1.0pF * 600mV} = 10.0MHz$$

44.7.2 TSI measurement result

The capacitance measurement result is defined by the number of TSI reference oscillator periods during the sample time and is stored in the TSICHnCNT register.

$$TSICHnCNT = T_{cap_samp} * F_{ref_osc}$$

Using Equation 2 and Equation 1 follows:

$$TSICHnCNT = \frac{I_{ref} * PS * NSCN}{C_{ref} * I_{ref}} * C_{elec}$$

Figure 44-70. Equation 5: Capacitance result value

In the example where $F_{ref_osc} = 10.0MHz$ and $T_{cap_samp} = 48$ μ s, $TSICHnCNT = 480$

44.7.3 Electrode scan unit

This section describes the functionality of the electrode scan unit. It is responsible for triggering the start of the active electrode scan.

The touch sense input module needs to periodically scan all active electrodes to determine if a touch event has occurred. The electrode scan unit has two independent scan periods, one for TSI active mode and the other for TSI low power mode. This independent control allows the application to configure longer scan period during low power mode, so contributing to smaller average power consumption. The TSI, in low power mode, has the capability to wake the CPU upon an electrode capacitance change. When the CPU wakes, the TSI enters active mode, and produces a shorter scan period for a faster response and more robust touch detection. Apart from the periodical mode, the electrode scan unit also allows software triggering of the electrode scans. This feature is very useful for initialization of the touch application to detect the initial electrode capacitances. This module generates configurable end-of-scan interrupt to indicate the application that all electrodes were scanned. If a new electrode scan is started while the previous one is still in progress, an overrun error flag is generated, TSI continues the previous scan sequence and the latest trigger is ignored.

44.7.3.1 Active electrodes

The electrode scan unit starts the capacitance measurement of all active electrodes. Each electrode pin should be activated by writing a 1 to the respective PEN[PEN] 16-bit field.

Once an electrode scan is triggered, the electrode scan unit controls the scanning of all the active electrodes sequentially. It starts the scanning of the electrode pin TSI_IN[0] and goes sequentially scanning until it reaches the electrode pin TSI_IN[15]. The electrode pin that does not have its bit (PEN[PEN]) enabled is not scanned and is skipped.

Only one electrode pin is functional in the low power mode scan and it's defined by the PEN[LPSP]. In low power scan mode, the configuration of PEN[PEN] bits is ignored.

44.7.3.2 Scan trigger

The scan trigger can be set to periodical scan or software trigger. The bit GENCS[STM] determines the TSI scan trigger mode. If STM = 1 the trigger mode is selected as continuous. If STM = 0, the software trigger mode is selected. In periodic mode the scan trigger is generated automatically by the electrode scan unit.

NOTE

It takes some time (less than 40 μ s) for TSI oscillators to be stable in software trigger mode and periodical scan mode. In the first scan process, TSI_GENCS[SCNIP] lags some time before a valid after trigger happens.

44.7.3.3 Software trigger mode

The software trigger scan is started by writing 1 to the bit GENCS[SWTS]. A single scan of all active electrodes is performed. The software trigger scan only can be initiated by the GENCS[SWTS] bit if the STM = 0. If STM = 1, any write in the GENCS[SWTS] bit is ignored.

44.7.3.4 Periodic scan control

The electrode scan unit operates both in TSI active mode and TSI low power mode. It has a separate scan period control for each one of these modes. It allows the application to controls the trade-off of the scan frequency and the average TSI module power consumption.

44.7.3.4.1 Active mode periodic scan

In active mode periodic scan the scan following clocks can be selected: BUS_CLK, MCGIRCLK and OSCERCLK. The bit field SCANC[AMCLKS] selects the TSI clock source for the active mode scan. The scan period is determined by the SCANC[SMOD] value. SMOD is the modulo of the counter that determines the scan period.

The following figure presents the scan sequence performed by the TSI module. Every active electrode is scanned sequentially, starting with the TSI_IN[0] and ending with the TSI_IN[15] pin, if they are active.

When the electrode scan unit starts a scan sequence, all the active electrodes will be scanned sequentially where each electrode has the scanned time defined by GENCS[NSCN]. The counter value is the sum of the total scan times of that electrode.

Figure 44-71. Scan sequence

44.7.3.4.2 Low power mode scan

In low power periodic scan, the scan period is defined by the 4-bit binary `GENCS[LPSCNITV]`. The TSI module is enabled in low power modes only if the bit `GENCS[STPE]` is 1.

Only one electrode pin is functional in the low power mode scan and its defined by the bit-field `PEN[LPSP]`.

44.7.3.4.3 End-of-scan interrupt

Once all the active electrodes are scanned, TSI scan unit will assert the end-of-scan flag. Upon the end-of-scan event, each electrode conversion result will be loaded to the corresponding counter register, compared with each threshold to determine if its value is out of range specified by the threshold registers, and if the counter value is stuck at extreme values (0x0000 or 0xFFFF), the corresponding error flag will also assert.

The electrode scan unit sets the EOSF flag in the `GENCS` registers once all the active electrode scan finishes. The EOSF flag generates an end-of-scan interrupt request if it is enabled. The interrupt is asserted if enabled by `GENCS[TSIIE]` and `GENCS[ESOR]` bits.

The `GENCS[EOSF]` indicates that all active electrode scans are finished and the respective capacitance results are in the `TSICHnCNT` registers. The `GENCS[EOSF]` is cleared by writing one to it.

It is worthy to note that, since all the possible flags are asserted upon the end of scan event, in TSI interrupt service routine, the end-of-scan flag will be always set until the software clears it.

44.7.3.4.4 Over-run interrupt

If an electrode scan is in progress and there is a scan trigger, the electrode scan unit generates an over-run error by asserting the GENCS[OVRF]. If the TSI error interrupt is active by setting the GENCS[ERIE] bit a interrupt request is asserted. The OVRF flag is cleared by writing 1 to it.

44.7.4 Touch detection unit

The touch detection unit is responsible to detect electrode capacitance changes. It also detects the occurrence of error with the electrode in case the capacitance result is 0x0000 or 0xFFFF. The errors can be caused by the electrode pin shorted to V_{DD} or V_{SS} or by electrode capacitances out of the configuration range of the TSI module.

44.7.4.1 Capacitance change threshold

Each TSI pin has its result register TSICHnCNT. At the end of each electrode conversion the touch detection unit compares if the TSICHnCNT result value is inside a configurable range. The comparison range is defined individually for each TSI pin by the following registers, TSICHnHTH, the upper threshold value and TSICHnLTH, the lower threshold value. If the TSICHnCNT happens to be out of the range defined by TSICHnLTH and TSICHnHTH the GENCS[OUTRGF] flag is set. Also the corresponding bit STATUS[ORNGFx] is set indicating which electrode pins happened to have their result register out-of- range.

To clear the GENCS[OUTRGF] write 1 to it.

44.7.4.1.1 Out-of-range interrupt

The GENCS[OUTRGF] flag generates a TSI interrupt request if the GENCS[TSIIE] bit is set and the GENCS[ESOR] bit is cleared. With this configuration, after the end-of-electrode scan, the TSI interrupt is only requested if there is a capacitance change. The capacitance change is detected when the result register gets outside the window defined by the TSI_THRESHLD register. If the electrodes capacitance does not vary, the TSI does not interrupt the CPU.

When GENCS[OUTRGF] flag is asserted, it is requested the software to poll which specific electrode is out of range by reading the status from STATUS register, clearing the corresponding electrodes flags will also clear the out-of-range flag in GENCS[OUTRGF].

44.7.4.2 Error interrupt

The GENCS[EXTERF] is set in the case the capacitance result registers, TSICHnCNT, of a TSI pin is either 0 or 0xFFFF, the two possible extreme values. The EXTERF flag generates a TSI Error Interrupt request if the GENCS[ERIE] bit is set.

When the GENCS[EXTERF] is set, the registers STATUS register indicates which TSI pins have the error condition by setting the correspondent STATUS[ERRORx] bit.

Before clearing the error flags, users need to check which channel is problematic and then clear the corresponding flags in STATUS register.

44.8 Application information

After enabling the TSI module for the first time, it is highly recommended to calibrate all the enabled channels by setting proper high and low threshold value for each active channel. All the channel dedicated counter values can be read from each counter value registers. The software suite can then adjust the threshold based on these values.

Follow proper PCB layout guidelines for board design on electrode shapes, sizes, routes, etc. Visit <http://www.freescale.com/touch> for application notes and reference designs.

44.8.1 TSI module sensitivity

The TSI module sensitivity is defined by the increment in the two 16-bit TSICHnCNT result registers caused by a reference capacitor value delta in the electrode pin capacitance.

It is given by the following equation:

$$TSI_{sensitivity} = \frac{I_{ref} * PS * NSCN}{C_{ref} * I}$$

For the example provided, $I_{ref} = 2 \mu A$, $PS = 2$; $NSCN = 16$, $C_{ref} = 1.0 \text{ pF}$ and $I = 1 \mu A$, the $TSI_{sensitivity} = 64 \text{ count/pF}$

Chapter 45

External Interrupt (IRQ)

45.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The IRQ (External Interrupt) module provides an interrupt input.

45.1.1 Features

The IRQ includes these distinctive features:

- IP Bus V2.0 compliant
- External interrupt pin (IRQ)
- IRQ pin can be selected as falling edge and low level or rising edge and high level
- Separate IRQ pin enable
- Software enabled interrupt
- Programmable falling edge (or rising edge) only, or both falling edge and low level (or both rising edge and high level) interrupt sensitivity
- Exit from low-power modes
- Software control of whether on-chip pullup/pulldown device is enabled on IRQ pin

45.1.2 Modes of Operation

The IRQ module is mode independent and will continue to operate in all user modes. In the low power STOP mode, the IRQ input becomes an asynchronous path.

45.1.3 Block Diagram

The following is a block diagram of the IRQ module.

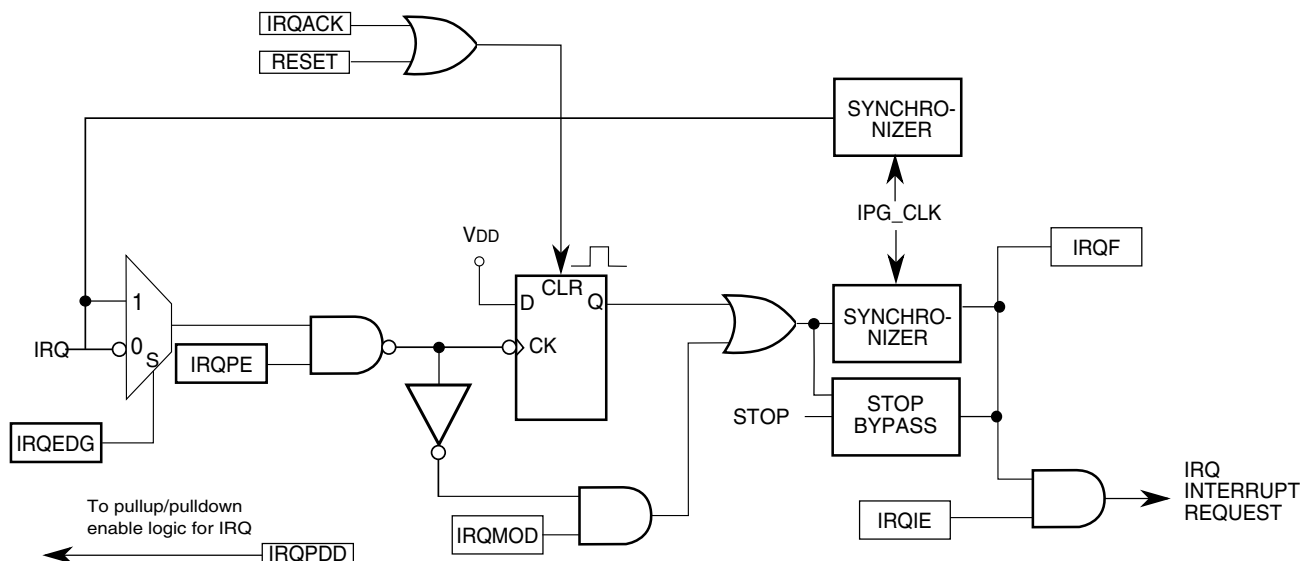

Figure 45-1. IRQ Block Diagram

45.2 Signal Description

The following table shows the user-accessible signal for the IRQ module.

Table 45-1. Signal Properties

Name	Function	Reset State
IRQ	External interrupt pin	input

45.2.1 Detailed Signal Descriptions

This section describes each user-accessible pin.

1. IRQ — External interrupt input pin

This input pin is used to detect either falling edge, or both falling edge and low level interrupt requests. This input pin can also be used to detect either rising edge, or both rising edge and high level interrupt requests.

45.3 Memory Map and Register Description

This section provides a detailed description of the IRQ register that is accessible to the end user.

IRQ memory map

Address offset (hex)	Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	FFFF_80A0	Interrupt status and control register (IRQ_SC)	8	R/W	00h	45.3.1/1081

45.3.1 Interrupt status and control register (IRQ_SC)

Address: FFFF_80A0h base + 0h offset = FFFF_80A0h

Bit	7	6	5	4	3	2	1	0
Read	0	IRQPDD	IRQEDG	IRQPE	IRQF	0	IRQIE	IRQMOD
Write						IRQACK		
Reset	0	0	0	0	0	0	0	0

IRQ_SC field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 IRQPDD	IRQ pull device disable Use this bit to disable the on-chip pullup/pulldown device on the IRQ pin. This allows users to have an external device if required for their application. 0 On-chip pullup/pulldown device is enabled 1 On-chip pullup/pulldown device is disabled
5 IRQEDG	IRQ edge select This bit selects the falling edge/low level or rising edge/high level function of the IRQ pin.

Table continues on the next page...

IRQ_SC field descriptions (continued)

Field	Description
	0 Falling edge/low level 1 Rising edge/high level
4 IRQPE	IRQ pin enable This bit determines whether the IRQ pin is enabled. 0 IRQ pin not enabled 1 IRQ pin enabled
3 IRQF	IRQ flag This bit indicates when an IRQ interrupt is detected. 0 No IRQ interrupt detected 1 IRQ interrupt detected
2 IRQACK	IRQ acknowledge Writing 1 to this bit is part of the flag clearing mechanism. For more information about flag clearing, see Clearing an IRQ Interrupt Request . This bit always reads as 0.
1 IRQIE	IRQ interrupt enable This bit determines whether an IRQ interrupt request is enabled. 0 IRQ interrupt requests not enabled 1 IRQ interrupt requests enabled
0 IRQMOD	IRQ detection mode This bit (along with the IRQEDG bit) controls the detection mode of the IRQ pin. 0 IRQ interrupt requests on falling edge only or on rising edge only 1 IRQ interrupt requests on falling edge and low level or on rising edge and high levels

45.4 Functional Description

This section provides a complete functional description of the IRQ module.

45.4.1 External Interrupt Pin

Writing to the IRQPE bit in the SC register, enables or disables the IRQ pin.

45.4.2 IRQ Edge Select

The IRQEDG bit in the SC register determines if the IRQ pin is either falling edge and low level or rising edge and high level sensitive.

45.4.3 IRQ Sensitivity

The IRQMOD bit in the SC register controls the detection mode of the IRQ module.

- If the IRQ interrupt is falling (or rising) edge sensitive only, a falling (or rising) edge on the enabled IRQ pin will set the IRQF bit.
- If the IRQ interrupt is both falling (or rising) edge and low (or high) level sensitive, a falling (or rising) edge on the enabled IRQ sets the IRQF bit. The IRQF bit remains set as long as the IRQ pin remains asserted.

45.4.4 IRQ Interrupts

The IRQ module can provide a source of interrupts. To cause an IRQ module interrupt request, the following must occur:

- The IRQIE bit in the SC register must be set.
- The IRQF bit in the SC register must become set by a triggered IRQ pin. The IRQF bit becomes set by the fifth clock cycle after the IRQ pin has become asserted.
- The IRQ pin must have been in an inactive state for at least one clock cycle before becoming active.
- Changing the IRQMOD or IRQEDG bit while the IRQPE bit is enabled may cause a spurious interrupt and the IRQF bit may be inadvertently cleared.

45.4.5 Clearing an IRQ Interrupt Request

If the IRQ module interrupt pin is either falling edge and low level sensitive or rising edge and high level sensitive, both of the following actions must occur to clear an IRQ interrupt request:

- Software provides an interrupt acknowledge by writing a logic 1 to the IRQACK bit in the SC register.
- And either of the following:
 - The IRQ pin returns to a deasserted logic state.
 - The IRQ pin is disabled using the IRQPE bit.

If the IRQ module interrupt pin is falling (or rising) edge sensitive only, writing a logic 1 to the IRQACK bit in the SC register immediately clears the IRQ interrupt request even if the enabled IRQ pin remains asserted.

45.4.6 Exit from Low-Power Modes

The IRQ interrupt, if enabled, can provide a means to exit CPU low-power modes. If the IRQ pin is enabled and asserted upon entering a low-power mode and the detection mode is set to both falling edge and low level sensitivity or both rising edge and high level sensitivity, an immediate exit from the low-power mode may occur depending on the specific chip implementation. If the detection mode is set to falling or rising edge sensitivity only, an edge must be seen on the enabled IRQ pin to exit the low-power mode.

45.4.6.1 Wait

The IRQ module remains active in WAIT mode. Setting the IRQIE bit in the SC register enables the IRQ interrupt request. Any detected IRQ interrupt will bring the CPU out of WAIT mode.

45.4.6.2 Stop modes

The IRQ module can remain active in stop modes, depending on the chip implementation. Setting the IRQIE bit in the SC register enables the IRQ interrupt request. Any detected IRQ interrupt brings the CPU out of the stop mode.

45.5 Resets

The IRQ interrupt is disabled after reset. The IRQ module cannot cause an MCU reset.

45.6 Interrupts

The IRQ module generates a single interrupt.

The IRQ interrupt is listed in the following table, which shows the interrupt name and the name of the local enable that can be used to disable a IRQ interrupt request.

Table 45-4. Interrupt Summary

Interrupt	Local Enable	Source	Description
IRQF	IRQIE	IRQ input	Software programmable for falling edge only (or rising edge only), or both falling edge and low level detection (or both rising edge and high level detection).

Chapter 46

Debug

46.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter describes the capabilities defined by the Version 1 ColdFire debug architecture. The Version 1 ColdFire core supports BDM functionality using the HCS08's single-pin interface. The traditional 3-pin full-duplex ColdFire BDM serial communication protocol based on 17-bit data packets is replaced with the HCS08 debug protocol where all communication is based on an 8-bit data packet using a single package pin (BKGD).

An on-chip trace buffer allows a stream of compressed processor execution status packets to be recorded for subsequent retrieval to provide program (and partial data) trace capabilities.

The following sections in this chapter provide details on the BKGD pin, the background debug serial interface controller (BDC), a standard 6-pin BDM connector, the BDM command set as well as real-time debug and trace capabilities. The V1 definition supports revision B+ (DEBUG_B+) of the ColdFire debug architecture.

A simplified block diagram of the V1 core including the processor and debug module is shown in the following figure.

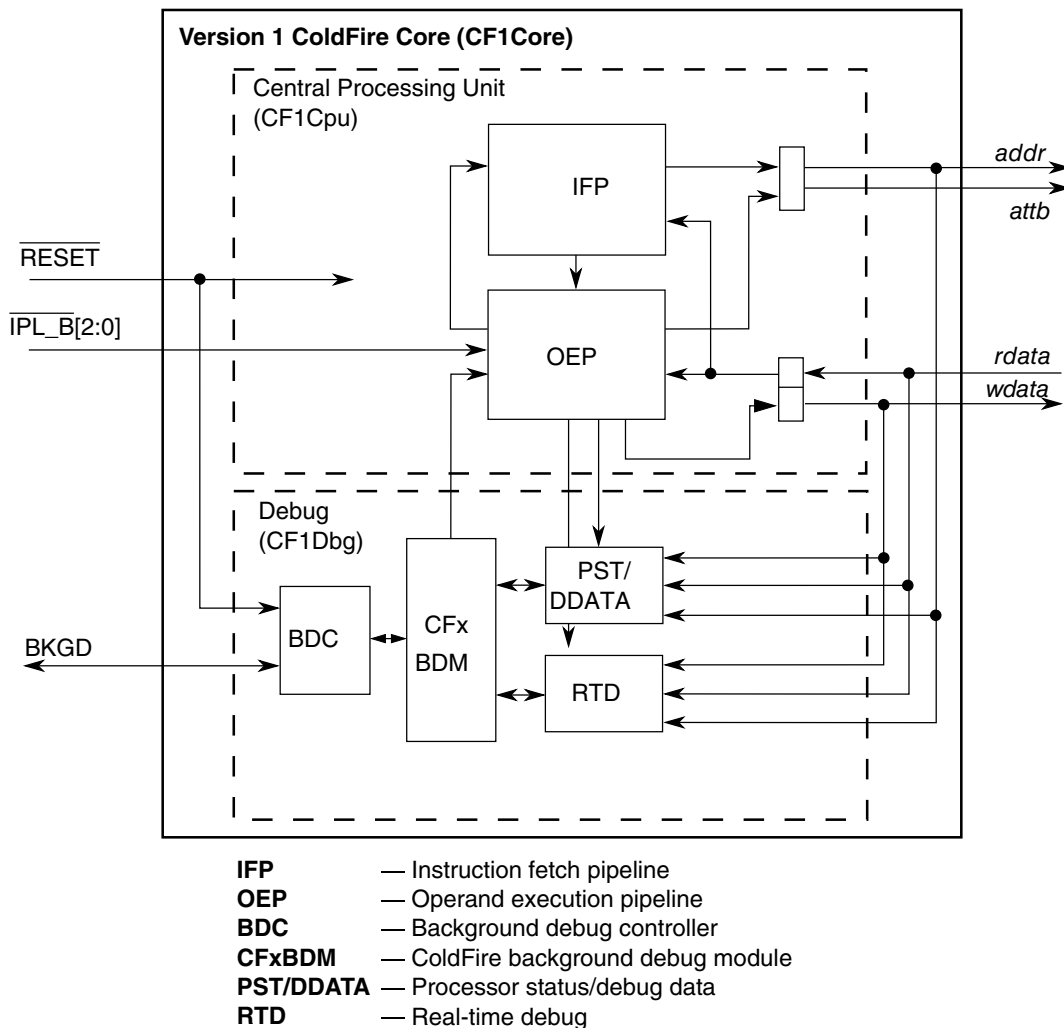

Figure 46-1. Simplified Version 1 ColdFire Core Block Diagram

46.1.1 Overview

Debug support is divided into three areas:

- **Background debug mode (BDM)**—Provides low-level debugging in the ColdFire processor core. In BDM, the processor core is halted and a variety of commands can be sent to the processor to access memory, registers, and peripherals. The external emulator uses a one-pin serial communication protocol. See [Background Debug Mode \(BDM\)](#).
- **Real-time debug support**—Use of the full BDM command set requires the processor to be halted, which many real-time embedded applications cannot support. The core includes a variety of internal breakpoint registers which can be configured to trigger and generate a special interrupt. The resulting debug interrupt lets real-time systems execute a unique service routine that can quickly save the contents of key registers

and variables and return the system to normal operation. The external development system can then access the saved data, because the hardware supports concurrent operation of the processor and BDM-initiated memory commands. In addition, the option is provided to allow interrupts to occur. See [Real-Time Debug Support](#).

- Program trace support—The ability to determine the dynamic execution path through an application is fundamental for debugging. The V1 solution implements a trace buffer that records processor execution status and data, which can be subsequently accessed by the external emulator system to provide program (and optional partial data) trace information. See [Trace Support](#).

There are two fields in debug registers which provide revision information: the hardware revision level in CSR and the 1-pin debug hardware revision level in CSR2. The following table summarizes the various debug revisions.

Table 46-1. Debug Revision Summary

Revision	CSR[HRL]	CSR2[D1HRL]	Enhancements
A	0000	N/A	Initial ColdFire debug definition
B	0001	N/A	BDM command execution does not affect hardware breakpoint logic Added BDM address attribute register (BAAR) BKPT configurable interrupt (CSR[BKD]) Level 1 and level 2 triggers on OR condition, in addition to AND SYNC_PC command to display the processor's current PC
B+	1001	N/A	Added 3 PC breakpoint registers PBR1–3
CF1_B+	1001	0001	Converted to HCS08 1-pin BDM serial interface Added PST compression and on-chip PST/DDATA buffer for program trace
CF1_B +_no_PSTB	1001	0010	Standard CF1 Debug_B+ without the PST trace buffer
CF1_B+ for 90 nm TFS	1001	0011	CF1 debug with DBGCR and DBGSR

46.1.2 Features

The Version 1 ColdFire debug definition supports the following features:

- Classic ColdFire DEBUG_B+ functionality mapped into the single-pin BDM interface
- Real time debug support, with 6 hardware breakpoints (4 PC, 1 address pair and 1 data) that can be configured into a 1- or 2-level trigger with a programmable response (processor halt or interrupt)

- Capture of compressed processor status and debug data into on-chip trace buffer provides program (and optional slave bus data) trace capabilities
- On-chip trace buffer provides programmable start/stop recording conditions plus support for obtrusive or PC-profiling modes
- Debug resources are accessible via single-pin BDM interface or the privileged WDEBUG instruction from the core

46.1.3 Modes of Operation

V1 ColdFire devices typically implement a number of modes of operation, including run, wait, and stop modes. Additionally, the operation of the core's debug module is highly dependent on a number of chip configurations that determine its operating state.

When operating in secure mode, as defined by a 2-bit field in the flash memory examined at reset, BDM access to debug resources is extremely restricted. It is possible to tell that the device has been secured and to clear security, which involves mass erasing the on-chip flash memory. No other debug access is allowed. Secure mode can be used in conjunction with each of the wait and stop low-power modes.

If the BDM interface is not enabled, access to the debug resources is limited in the same manner as a secure device.

If the device is not secure and the BDM interface is enabled (XCSR[ENBDM] is set), the device is operating in debug mode and additional resources are available via the BDM interface. In this mode, the status of the processor (running, stopped, or halted) determines which BDM commands may be used.

Debug mode functions are managed through the background debug controller (BDC) in the Version 1 ColdFire core. The BDC provides the means for analyzing MCU operation during software development.

BDM commands can be classified into three types as shown in the following table.

Table 46-2. BDM Command Types

Command Type	Flash Secure?	BDM?	Core Status	Command Set
Always-available	Secure or Unsecure	Enabled or Disabled	—	<ul style="list-style-type: none"> • Read/write access to XCSR[31–24], CSR2[31–24], CSR3[31–24]

Table continues on the next page...

Table 46-2. BDM Command Types (continued)

Command Type	Flash Secure?	BDM?	Core Status	Command Set
Non-intrusive	Unsecure	Enabled	Run, Halt	<ul style="list-style-type: none"> • Memory access • Memory access with status • Debug register access • BACKGROUND
Active background	Unsecure	Enabled	Halt	<ul style="list-style-type: none"> • Read or write CPU registers (also available in stop mode) • Single-step the application • Exit halt mode to return to the application program (GO)

For more information on these three BDM command classifications, see [BDM Command Set Summary](#).

The core's halt mode is entered in a number of ways:

- The BKGD pin is low during POR
- The BKGD pin is low immediately after a BDM-initiated force reset (see CSR2[BDFR] in [Configuration/Status Register 2 \(CSR2\)](#), for details)
- A background debug force reset occurs (CSR2[BDFR] is set) and CSR2[BFHBR] is set
- An illegal operand reset occurs and CSR2[IOPHR] is set
- An illegal address reset occurs and CSR2[IADHR] is set
- A computer operating properly reset occurs and CSR2[COPHR] is set
- A BACKGROUND command is received through the BKGD pin. If necessary, this wakes the device from STOP/WAIT modes.
- A properly-enabled (XCSR[ENBDM] is set) HALT instruction is executed
- Encountering a BDM breakpoint and the trigger response is programmed to generate a halt
- Reaching a PSTB trace buffer full condition when operating in an obtrusive recording mode (CSR2[PSTBRM] is set to 01 or 11)

While in halt mode, the core waits for serial background commands rather than executing instructions from the application program.

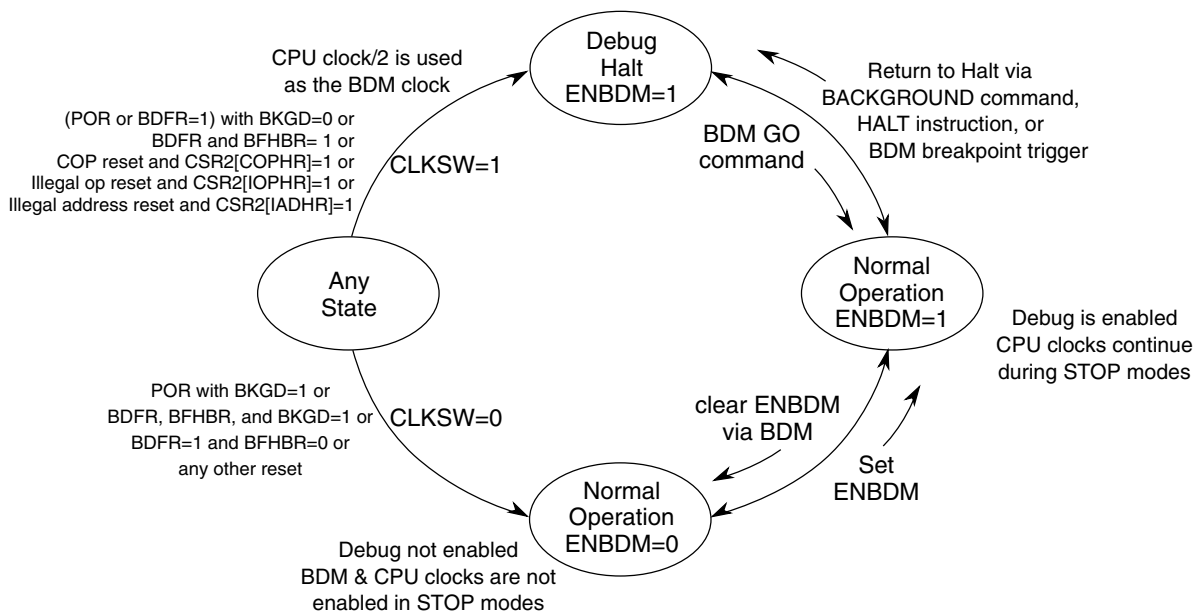

Figure 46-2. Debug Modes State Transition Diagram

The preceding figure contains a simplified view of the V1 ColdFire debug mode states. The XCSR[CLKSW] bit controls the BDC clock source. When CLKSW is set, the BDC serial clock frequency is the same as the synchronous bus clock. When CLKSW is cleared, the BDC serial clock is supplied from an alternate clock source.

The ENBDM bit determines if the device can be placed in halt mode, if the core and BDC serial clocks continue to run in STOP modes, and if the regulator can be placed into standby mode. Again, if booting to halt mode, XCSR[ENBDM, CLKSW] are automatically set.

If ENBDM is cleared, the ColdFire core treats the HALT instruction as an illegal instruction and generates a reset (if CPUCR[IRD] is cleared) or an exception (if CPUCR[IRD] is set) if execution is attempted.

If XCSR[ENBDM] is set, the device can be restarted from STOP/WAIT via the BDM interface.

46.2 External Signal Descriptions

The following table describes the debug module's 1-pin external signal (BKGD). A standard 6-pin debug connector is shown in [Freescale-Recommended BDM Pinout](#).

Table 46-3. Debug Module Signals

Signal	Description
Background Debug (BKGD)	Single-wire background debug interface pin. The primary function of this pin is for bidirectional serial communication of background debug mode commands and data. During reset, this pin selects between starting in active background (halt) mode or starting the application program. This pin also requests a timed sync response pulse to allow a host development tool to determine the correct clock frequency for background debug serial communications.

46.3 Memory Map and Register Descriptions

In addition to the BDM commands that provide access to the processor's registers and the memory subsystem, the debug module contains a number of registers. Most of these registers (all except the PST/DDATA trace buffer) are also accessible (write-only) from the processor's supervisor programming model by executing the WDEBUG instruction. Thus, the breakpoint hardware in the debug module can be read (certain registers) or written by the external development system using the serial debug interface or written by the operating system running on the processor core. Software is responsible for guaranteeing that accesses to these resources are serialized and logically consistent. The hardware provides a locking mechanism in the CSR to allow the external development system to disable any attempted writes by the processor to the breakpoint registers (setting CSR[IPW]). BDM commands must not be issued during the processor's execution of the WDEBUG instruction to configure debug module registers or the resulting behavior is undefined.

These registers are treated as 32-bit quantities regardless of the number of implemented bits. Unimplemented bits are reserved and must be cleared. These registers are also accessed through the BDM port by the commands WRITE_DREG and READ_DREG described in [BDM Command Set Summary](#). These commands contain a 5-bit field, DRc, that specifies the register, as shown in the following table.

Note

Most debug control registers can be written either by the external development system or by the CPU through the WDEBUG instruction. These control registers are write-only from the programming model and they can be written through the BDM port using the WRITE_DREG command. In addition, the four configuration/status registers (CSR, XCSR, CSR2, CSR3) can be read through the BDM port using the READ_DREG command.

The ColdFire debug architecture supports a number of hardware breakpoint registers that can be configured into single- or double-level triggers based on the PC or operand address ranges with an optional inclusion of specific data values. The triggers can be configured to halt the processor or generate a debug interrupt exception. Additionally, these same breakpoint registers can be used to specify start/stop conditions for recording in the PST trace buffer.

The core includes four PC breakpoint triggers and a set of operand address breakpoint triggers with two independent address registers (to allow specification of a range) and an optional data breakpoint with masking capabilities. Core breakpoint triggers are accessible through the serial BDM interface or written through the supervisor programming model using the WDEBUG instruction.

Table 46-4. Debug Module Memory Map

DRc[4:0]	Register	Width (bits)	Access	Reset Value
0x00	Configuration/Status Register (CSR)	32	R/W (BDM), W (CPU)	0x0090_0000
0x01	Extended Configuration/Status Register (XCSR)	32	R/W ¹ (BDM), W (CPU)	0x0000_0000

1. The most significant bytes of the XCSR, CSR2, and CSR3 registers support special control functions and are writeable via BDM using the WRITE_XCSR_BYTE, WRITE_CSR2_BYTE, and WRITE_CSR3_BYTE commands. They can be read from BDM using the READ_XCSR_BYTE, READ_CSR2_BYTE, and READ_CSR3_BYTE commands. These 3 registers, along with the CSR, can also be referenced as 32-bit quantities using the BDM READ_DREG and WRITE_DREG commands, but the WRITE_DREG command only writes bits 23–0 of these three registers.
2. Each debug register is accessed as a 32-bit value; undefined fields are reserved and must be cleared.
3. The register's reset value is undefined after POR and unaffected by any other reset type. After POR, any value written to the register is retained.
4. The contents of the PST trace buffer is only read from BDM (32 bits per access) using READ_PSTB commands.

46.3.1 Configuration/Status Register (CSR)

CSR defines the debug configuration for the processor and memory subsystem and contains status information from the breakpoint logic. CSR is accessible from the programming model using the WDEBUG instruction and through the BDM port using the READ_DREG and WRITE_DREG commands.

DRc: 0x00 (CSR)

Access: Supervisor write-only

Table 46-6. CSR Field Descriptions

Field	Description										
31–28 BSTAT	Breakpoint status Provides read-only status (from the BDM port only) information concerning hardware breakpoints. BSTAT is cleared by a TDR write, by a CSR read when a level-2 breakpoint is triggered, or a level-1 breakpoint is triggered and the level-2 breakpoint is disabled. The PSTB value that follows the PSTB entry of 0x1B is $0x20 + (2 \times \text{BSTAT})$. <table border="1"> <tr><td>0000</td><td>No breakpoints enabled</td></tr> <tr><td>0001</td><td>Waiting for level-1 breakpoint</td></tr> <tr><td>0010</td><td>Level-1 breakpoint triggered</td></tr> <tr><td>0101</td><td>Waiting for level-2 breakpointB</td></tr> <tr><td>0110</td><td>Level-2 breakpoint triggered</td></tr> </table>	0000	No breakpoints enabled	0001	Waiting for level-1 breakpoint	0010	Level-1 breakpoint triggered	0101	Waiting for level-2 breakpointB	0110	Level-2 breakpoint triggered

0001	Waiting for level-1 breakpoint										
0010	Level-1 breakpoint triggered										
0101	Waiting for level-2 breakpointB										
0110	Level-2 breakpoint triggered										
27 FOF	Fault-on-fault Indicates a catastrophic halt occurred and forced entry into BDM. FOF is cleared by reset or when CSR is read (from the BDM port only).										

Table continues on the next page...

Table 46-6. CSR Field Descriptions (continued)

Field	Description												
26 TRG	Hardware breakpoint trigger Indicates a hardware breakpoint halted the processor core and forced entry into BDM. Reset, the debug GO command, or reading CSR (from the BDM port only) clears TRG.												
25 HALT	Processor halt Indicates the processor executed a HALT and forced entry into BDM. Reset, the debug go command, or reading CSR (from the BDM port only) clears HALT.												
24 BKPT	Breakpoint assert Indicates when either: <ul style="list-style-type: none"> • The $\overline{\text{BKPT}}$ input was asserted, • BDM BACKGROUND command received, or • The PSTB halt on full condition, CSR2[PSTBH], sets. This forces the processor into a BDM halt. Reset, the debug go command, or reading CSR (from the BDM port only) clears BKPT.												
23–20 HRL	Hardware revision level Indicates, from the BDM port only, the level of debug module functionality. An emulator can use this information to identify the level of functionality supported. <table border="1"> <tr> <td>0000</td> <td>Revision A</td> </tr> <tr> <td>0001</td> <td>Revision B</td> </tr> <tr> <td>0010</td> <td>Revision C</td> </tr> <tr> <td>0011</td> <td>Revision D</td> </tr> <tr> <td>1001</td> <td>Revision B+ (The value used for this device)</td> </tr> <tr> <td>0110</td> <td>Revision D+</td> </tr> </table>	0000	Revision A	0001	Revision B	0010	Revision C	0011	Revision D	1001	Revision B+ (The value used for this device)	0110	Revision D+

While halted, any BDM command can be executed. On receipt of the GO command, the processor executes the next instruction and halts again. This process continues until SSM is cleared.				
0	Normal mode.								
1	Single-step mode. The processor halts after execution of each instruction. While halted, any BDM command can be executed. On receipt of the GO command, the processor executes the next instruction and halts again. This process continues until SSM is cleared.								
3–2	Reserved; must be cleared.								

Table continues on the next page...

Table 46-6. CSR Field Descriptions (continued)

Field	Description
1 FID	Force ipg_debug The core generates this output to the device, signaling it is in debug mode.
0	Do not force the assertion of ipg_debug.
1	Force the assertion of ipg_debug.
0 DDH	Disable ipg_debug due to a halt condition. The core generates an output to the other modules in the device, signaling it is in debug mode. By default, this output signal is asserted when the core halts.
0	Assert ipg_debug if the core is halted.
1	Negate ipg_debug due to the core being halted.

46.3.2 Extended Configuration/Status Register (XCSR)

The 32-bit XCSR is partitioned into two sections: the upper byte contains status and command bits always accessible to the BDM interface, even if debug mode is disabled. This status byte is also known as XCSR_SB. The lower 24 bits contain fields related to the generation of automatic SYNC_PC commands, which can be used to periodically capture and display the current program counter (PC) in the PST trace buffer (if properly configured).

This table summarizes the methods for accessing the XCSR.

Table 46-7. XCSR Access Summary

Reference method	Details
READ_XCSR_BYTE	Reads bits 31–24 from the BDM interface. Available in all modes.
WRITE_XCSR_BYTE	Writes bits 31–24 from the BDM interface. Available in all modes.
READ_DREG	Reads bits 31–0 from the BDM interface. Classified as a non-intrusive BDM command. Available in all modes.
WRITE_DREG	Writes bits 23–0 from the BDM interface. Classified as a non-intrusive BDM command. Available in all modes.
WDEBUG instruction	Writes bits 23–0 during execution of the core WDEBUG instruction. This instruction is a privileged supervisor-mode instruction.

DRc: 0x01 (XCSR)

Access: Supervisor write-only

24 ENBDM	<p>Enable BDM</p> <table border="1"> <tr> <td>0</td> <td>Disable BDM</td> </tr> <tr> <td>1</td> <td>Enable BDM (assuming the flash is not secure, as indicated in SEC)</td> </tr> </table>	0	Disable BDM	1	Enable BDM (assuming the flash is not secure, as indicated in SEC)				
0	Disable BDM								
1	Enable BDM (assuming the flash is not secure, as indicated in SEC)								
23–3 Reserved	Reserved for future use by the debug module. These bits must all equal 0b.								
2–1 APCSC	<p>Automatic PC Synchronization Control</p> <p>If APCENB is 1b, determines the periodic interval of PC address captures. When the selected interval is reached, a SYNC_PC command is sent to the CPU. For more information on the SYNC_PC operation, see the APCENB description.</p> <p>The chosen frequency depends on the setting of CSR2[APCDIV16], as shown in Table 46-10.</p>								
0 APCENB	<p>Automatic PC Synchronization Enable</p> <p>Enables the periodic output of the PC, which can be used for PST/DDATA trace synchronization and code profiling.</p> <p>As described in APCSC, when the enabled periodic timer expires, a SYNC_PC command is sent to the CPU that generates a forced instruction fetch of the next instruction. The PST/DDATA module captures the target address as defined by CSR[9] (two bytes if CSR[9] is 0b, three bytes if CSR[9] is 1b). This produces a PST sequence of the PST marker indicating a 2- or 3-byte address, followed by the captured instruction address.</p> <table border="1"> <tr> <td>0</td> <td>Disable automatic PC synchronization</td> </tr> <tr> <td>1</td> <td>Enable automatic PC synchronization</td> </tr> </table>	0	Disable automatic PC synchronization	1	Enable automatic PC synchronization				
0	Disable automatic PC synchronization								
1	Enable automatic PC synchronization								

This table shows the selected PC address capture period as determined by the XCSR[APCENB], CSR2[APCDIV16], and XCSR[APCSC] fields.

Table 46-10. PC address capture period (SYNC_PC interval)

XCSR[APCENB]	CSR2[APCDIV16]	XCSR[APCSC]	SYNC_PC interval (cycles)
1	1	00	128
1	1	01	256
1	1	10	512
1	1	11	1024
1	0	00	2048
1	0	01	4096
1	0	10	8092
1	0	11	16384

46.3.3 Configuration/Status Register 2 (CSR2)

The 32-bit CSR2 is partitioned into two sections. The upper byte contains status and configuration bits always accessible to the BDM interface, even if debug mode is disabled. The lower 24 bits contain fields related to the configuration of the PST trace buffer (PSTB).

This table summarizes the methods for accessing CSR2.

Table 46-11. CSR2 Access Summary

Reference method	Details
READ_CSR2_BYTE	Reads bits 31–24 from the BDM interface. Available in all modes.
WRITE_CSR2_BYTE	Writes bits 31–24 from the BDM interface. Available in all modes.
READ_DREG	Reads bits 31–0 from the BDM interface. Classified as a non-intrusive BDM command.
WRITE_DREG	Writes bits 23–0 from the BDM interface. Classified as a non-intrusive BDM command.
WDEBUG instruction	Writes bits 23–0 during execution of the core WDEBUG instruction. This instruction is a privileged supervisor-mode instruction.

111		PBR0/PBMR

46.3.4 Configuration/Status Register 3 (CSR3)

The CSR3 contains fields enabling indirect writes to the DBGCR. Writes to these CSR3 fields execute 4-bit nibble writes to the DBGCR. Thus, writing to the entire 32-bit DBGCR would require eight "write CSR3" commands be processed via the single-pin BDM interface.

When read, CSR3 enables indirect reads of the DBGSR. When a "read CSR3" command is transmitted on the single-pin BDM interface, one byte of DBGSR is read and returned. The debug logic maintains a 2-bit counter that selects the byte of the DBGSR register to be read, starting with DBGSR[7:0]. The 2-bit counter is cleared by POR and by any write to the CSR3. It is incremented by any read of the CSR3. Thus, a read of the entire 32-bit DBGSR would require four "read CSR3" commands be processed on the single-pin BDM interface, and the sequential commands would return data in the following order: DBGSR[7:0], DBGSR[15:8], DBGSR[23:16], and DBGSR[31:24].

This table summarizes the methods for accessing CSR3.

Table 46-14. CSR3 Reference Summary

Method	Reference Details
READ_CSR3_BYTE	Reads bits CSR3[31–24] from the BDM interface. Available in all modes.
WRITE_CSR3_BYTE	Writes bits CSR3[31–24] from the BDM interface. Available in all modes.
READ_DREG	Reads bits CSR3[31–0] from the BDM interface. Classified as a non-intrusive BDM command.
WRITE_DREG	Writes bits CSR3[23–0] from the BDM interface. Classified as a non-intrusive BDM command.
WDEBUG instruction	No operation while the core executes a WDEBUG instruction.

DRc: 0x03 (CSR3)

Access: Supervisor write-only

		BDM read/write															
		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 46-15. CSR3 Field Descriptions

Field	Description
31 UI	Update indicator for write to DBGCR When set to 1, this bit signals the chip that an update has been completed and the content of the DBGCR is valid.
30–28 NS	Nibble select for write to DBGCR This field selects which nibble in the DBGCR is written. 000 Write DBGCR[31:28] 001 Write DBGCR[27:24] 010 Write DBGCR[23:20] ... 111 Write DBGCR[3:0]
27–24 WD	Write data to DBGCR This field defines the data to be written into the selected nibble of the DBGCR. The selected nibble is determined by the value of CSR3[30:28].
23–0	Reserved for future use by the debug module; must be cleared.

46.3.5 Debug Control Register (DBGCR) and Debug Status Register (DBGSR)

The 32-bit DBGCR and 32-bit DBGSR are accessible only via the BDM port. They provide functionality for mass erase operations and for monitoring when the chip is or was in low power modes.

The DBGCR and DBGSR are accessed indirectly via fields in the CSR3.

The CSR3 contains fields enabling indirect writes to the DBGCR. Writes to these CSR3 fields execute 4-bit nibble writes to the DBGCR. Thus, writing to the entire 32-bit DBGCR would require eight "write CSR3" commands be processed via the single-pin BDM interface.

When read, CSR3 enables indirect reads of the DBGSR. When a "read CSR3" command is transmitted on the single-pin BDM interface, one byte of DBGSR is read and returned. The debug logic maintains a 2-bit counter that selects the byte of the DBGSR register to be read, starting with DBGSR[7:0]. The 2-bit counter is cleared by POR and by any write to the CSR3. It is incremented by any read of the CSR3. Thus, a read of the entire 32-bit DBGSR would require four "read CSR3" commands be processed on the single-pin BDM interface, and the sequential commands would return data in the following order: DBGSR[7:0], DBGSR[15:8], DBGSR[23:16], and DBGSR[31:24].

Using these registers, the flash memory mass erase procedure consists of these steps:

1. Initiate the operation: Write the CSR3 to set DBGCR[0] to 1.
2. Confirm that the operation is complete: Read the CSR3 to poll the DBGSR[0] flag, which reflects the operation's status. The operation is complete when DBGSR[0] is 1.

Table 46-16. DBGCR Definition

Bit Number	Bit Name	Description
0	Flash Mass Erase Command	Set this bit to 1 to initiate a mass erase. This bit is cleared by hardware after the launch of the mass erase operation. NOTE: When the mass erase capability is disabled (due to the values of the flash memory module's FSEC[MEEN] and FSEC[SEC] fields), the Erase Command request is still issued and acknowledged, but no erase operation occurs.
1	LLS, VLLSx Status Acknowledge	Set this bit to 1 to acknowledge that a read of the DBGSR's LLS and VLLSx Mode Exit status bits has occurred. This acknowledgement automatically clears the status bits.

Table 46-17. DBGSR Definition

Bit Number	Bit Name	Description
0	ERASE STATUS	This bit is cleared after any system reset. The bit is also cleared at the launch of a mass erase command due to a write of the DBGCR[0] bit. The bit is set at the completion of the mass erase sequence. NOTE: If the mass erase function is disabled, the mass erase sequence is completed, but no erase operation occurs. The value of DBGSR[2] reflects whether the flash memory module's FSEC[MEEN] field is set to disable the mass erase function. 0: Status cleared or mass erase not done 1: Mass erase sequence done

Table continues on the next page...

Table 46-17. DBGSR Definition (continued)

Bit Number	Bit Name	Description
1	Freescale Factory Access	This bit indicates whether or not Freescale's factory testing can access the chip's flash memory contents. 0: Freescale factory access is denied (FSEC[FSLACC] is 01 or 10) 1: Freescale factory access is granted (FSEC[FSLACC] is 00 or 11)
2	Mass Erase Enable	This bit indicates whether or not the flash memory can be mass erased. 0: Mass erase is disabled (FSEC[MEEN] is 10) 1: Mass erase is enabled (FSEC[MEEN] is 00, 01, or 11)
3	Backdoor Key Access Enable	This bit indicates whether or not the flash memory has backdoor key access enabled. 0: Backdoor key access is disabled (FSEC[KEYEN] is 00, 01, or 11) 1: Backdoor key access is enabled (FSEC[KEYEN] is 10)
4	Very Low Power Modes	This bit always indicates whether the current power mode is one of the VLPx modes. This bit is used to throttle debugger frequency up/down.
5	LLS Mode Exit	This bit indicates that an exit from LLS mode has occurred. The debugger loses communication (including access to this register) while the system is in LLS mode. When communication is re-established, this bit indicates that the system had been in LLS mode. The debug modules hold their state during LLS mode, so they do not require reconfiguration after an exit from LLS mode. The LLS Mode Exit bit is held until the debugger recognizes that LLS mode was exited. The bit is cleared by a write of 1 to the DBGCR[1] bit (LLS, VLLSx Status Acknowledge bit).
6	VLLSx Modes Exit	This bit indicates that an exit from one of the VLLSx modes has occurred. The debugger loses communication (including access to this register) while the system is in a VLLSx mode. When communication is re-established, this bit indicates that the system had been in a VLLSx mode. The debug modules lose their state during VLLSx modes, so they must be reconfigured after an exit from a VLLSx mode. The VLLSx Mode Exit bit is held until the debugger recognizes that a VLLSx mode was exited. The bit is cleared by a write of 1 to the DBGCR[1] bit (LLS, VLLSx Status Acknowledge bit).

46.3.6 BDM Address Attribute Register (BAAR)

BAAR defines the address space for memory-referencing BDM commands. BAAR[R, SZ] are loaded directly from the BDM command, while the lower five bits can be programmed from the external development system. BAAR is loaded any time AATR is

written and is initialized to a value of 0x05, setting supervisor data as the default address space. The upper 24 bits of this register are reserved for future use and any attempted write of these bits has no effect.

DRc: 0x05 (BAAR)

Access: Supervisor write-only

46.3.7 Address Attribute Trigger Register (AATR)

AATR defines address attributes and a mask to be matched in the trigger. The register value is compared with address attribute signals from the processor’s high-speed local bus, as defined by the setting of the trigger definition register (TDR). AATR is accessible in supervisor mode as debug control register 0x06 using the WDEBUG instruction and through the BDM port using the WRITE_DREG command.

DRc: 0x06 (AATR)

Access: Supervisor write-only

46.3.8 Trigger Definition Register (TDR)

TDR configures the operation of the hardware breakpoint logic that corresponds with the ABHR/ABLR/AATR, PBR/PBR1/PBR2/PBR3/PBMR, and DBR/DBMR registers within the debug module. TDR controls the actions taken under the defined conditions. Breakpoint logic may be configured as one- or two-level trigger. TDR[31–16] defines the second-level trigger, and TDR[15–0] defines the first-level trigger.

NOTE

The debug module has no hardware interlocks. To prevent spurious breakpoint triggers while the breakpoint registers are being loaded, disable TDR (write 0 to L2EBL and L1EBL) before defining triggers.

Memory Map and Register Descriptions

A write to TDR clears the CSR trigger status bits, CSR[BSTAT]. TDR is accessible in supervisor mode as debug control register 0x07 using the WDEBUG instruction and through the BDM port using the WRITE_DREG command.

DRc: 0x07 (TDR)

Access: Supervisor write-only

BDM write-only

Table 46-23. TDR Field Descriptions (continued)

Field	Description	
28–22 L2ED	Enable Level 2 Data Breakpoint Setting an L2ED bit enables the corresponding data breakpoint condition based on the size and placement on the processor's local data bus. Clearing all ED bits disables data breakpoints.	
	Bit	Description
	28	Data longword. Entire processor's local data bus
	27	Lower data word
	26	Upper data word
	25	Lower lower data byte. Low-order byte of the low-order word
	24	Lower middle data byte. High-order byte of the low-order word
	23	Upper middle data byte. Low-order byte of the high-order word
	22	Upper upper data byte. High-order byte of the high-order word
21 L2DI	Level 2 Data Breakpoint Invert Inverts the logical sense of all the data breakpoint comparators. This can develop a trigger based on the occurrence of a data value other than the DBR contents.	
	0	Do not invert
	1	Invert
20–18 L2EA	Enable Level 2 Address Breakpoint Setting an L2EA bit enables the corresponding address breakpoint. Clearing all three bits disables the breakpoint.	
	Bit	Description
	20	Address breakpoint inverted. Breakpoint is based outside the range between ABLR and ABHR.
	19	Address breakpoint range. The breakpoint is based on the inclusive range defined by ABLR and ABHR.
	18	Address breakpoint low. The breakpoint is based on the address in the ABLR.
17 L2EPC	Enable Level 2 PC Breakpoint	
	0	Disable
	1	Enable
16 L2PCI	Level 2 PC Breakpoint Invert	
	0	Do not invert
	1	Invert
15 L2T	Level 2 Trigger Determines the logic operation for the trigger between the PC_condition and the (Address_range and Data_condition) condition where the inclusion of a Data_condition is optional. The debug architecture supports the creation of single- or double-level triggers.	
	0	Trigger = PC_condition && (Address_range && Data_condition)
	1	Trigger = PC_condition (Address_range && Data_condition)

Table continues on the next page...

Table 46-23. TDR Field Descriptions (continued)

Field	Description	
14 L1T	Level 1 Trigger Determines the logic operation for the trigger between the PC_condition and the (Address_range and Data_condition) condition where the inclusion of a Data_condition is optional. The debug architecture supports the creation of single- or double-level triggers.	
	0	Trigger = PC_condition && (Address_range && Data_condition)
	1	Trigger = PC_condition (Address_range && Data_condition)
13 L1EBL	Enable Level 1 Breakpoints Global enable for the level 1 breakpoint triggers.	
	0	Disable all level 1 breakpoints
	1	Enable all level 1 breakpoints
12–6 L1ED	Enable Level 1 Data Breakpoint Setting an L1ED bit enables the corresponding data breakpoint condition based on the size and placement on the processor's local data bus. Clearing all ED bits disables data breakpoints.	
	Bit	Description
	28	Data longword. Entire processor's local data bus
	27	Lower data word
	26	Upper data word
	25	Lower lower data byte. Low-order byte of the low-order word
	24	Lower middle data byte. High-order byte of the low-order word
	23	Upper middle data byte. Low-order byte of the high-order word
	22	Upper upper data byte. High-order byte of the high-order word
5 L1DI	Level 1 Data Breakpoint Invert Inverts the logical sense of all the data breakpoint comparators. This can develop a trigger based on the occurrence of a data value other than the DBR contents.	
	0	Do not invert
	1	Invert
4–2 L1EA	Enable Level 1 Address Breakpoint Setting an L1EA bit enables the corresponding address breakpoint. Clearing all three bits disables the breakpoint.	
	Bit	Description
	20	Address breakpoint inverted. Breakpoint is based outside the range between ABLR and ABHR.
	19	Address breakpoint range. The breakpoint is based on the inclusive range defined by ABLR and ABHR.
	18	Address breakpoint low. The breakpoint is based on the address in the ABLR.
1 L1EPC	Enable Level 1 PC Breakpoint	
	0	Disable
	1	Enable
0 L1PCI	Level 1 PC Breakpoint Invert	
	0	Do not invert
	1	Invert

46.3.9 Program Counter Breakpoint/Mask Registers (PBR0–3, PBMR)

The PBRn registers define instruction addresses for use as part of the trigger. These registers' contents are compared with the processor's program counter register when the appropriate valid bit is set (for PBR1–3) and TDR is configured appropriately. PBR0 bits are masked by setting corresponding PBMR bits (PBMR has no effect on PBR1–3). Results are compared with the processor's program counter register, as defined in TDR. The PC breakpoint registers, PBR1–3, have no masking associated with them, but do include a valid bit. These registers' contents are compared with the processor's program counter register when TDR is configured appropriately.

The PC breakpoint registers are accessible in supervisor mode using the WDEBUG instruction and through the BDM port using the WRITE_DREG command using values shown in BDM Command Set Descriptions.

NOTE

Version 1 ColdFire core devices implement a 24-bit, 16 MB address map. When programming these registers with a 32-bit address, the upper byte must be zero-filled.

DRc: 0x08 (PBR0)

Access: Supervisor write-only

BDM write-only

Table 46-25. PBR0 Field Descriptions

Field	Description
31–0 Address	PC breakpoint address The address to be compared with the PC as a breakpoint trigger. Because all instruction sizes are multiples of 2 bytes, bit 0 of the address should always be zero.

Memory Map and Register Descriptions

Table 46-27. PBRn Field Descriptions

Field	Description
31–1 Address	PC breakpoint address The 31-bit address to be compared with the PC as a breakpoint trigger.
0 V	Valid bit This bit must be set for the PC breakpoint to occur at the address specified in the Address field.
0	PBR is disabled.
1	PBR is enabled.

The following display shows PBMR. PBMR is accessible in supervisor mode using the WDEBUG instruction and via the BDM port using the WRITE_DREG command. PBMR only masks PBR0.

Table 46-29. PBMR Field Descriptions

Field	Description
31–1	PC breakpoint mask
Mask	If using PBR0, this register must be initialized since it is undefined after reset.
	0 The corresponding PBR0 bit is compared to the appropriate PC bit.
	1 The corresponding PBR0 bit is ignored.

46.3.10 Address Breakpoint Registers (ABLR, ABHR)

The ABLR and ABHR define regions in the processor's data address space that can be used as part of the trigger. These register values are compared with the address for each transfer on the processor's high-speed local bus. The trigger definition register (TDR) identifies the trigger as one of three cases:

- Identical to the value in ABLR
- Inside the range bound by ABLR and ABHR inclusive
- Outside that same range

The address breakpoint registers are accessible in supervisor mode using the WDEBUG instruction and through the BDM port using the WRITE_DREG command using values shown in BDM Command Set Descriptions.

NOTE

Version 1 ColdFire core devices implement a 24-bit, 16 MB address map. When programming these registers with a 32-bit address, the upper byte should be zero-filled when referencing

the flash, RAM, and RGPIO regions, and set to 0xFF when referencing any of the slave peripheral devices.

DRc: 0x0C (ABHR)								Access: Supervisor write-only								
0x0D (ABLR)								BDM write-only								
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	[Greyed out]															
W	Address															
ABHR Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
ABLR Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	[Greyed out]															
W	Address															
ABHR Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
ABLR Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 46-31. ABLR Field Descriptions

Field	Description
31–0 Address	Low address Holds the 32-bit address marking the lower bound of the address breakpoint range. Breakpoints for specific addresses are programmed into ABLR.

Table 46-32. ABHR Field Descriptions

Field	Description
31–0 Address	High address Holds the 32-bit address marking the upper bound of the address breakpoint range.

46.3.11 Data Breakpoint and Mask Registers (DBR, DBMR)

DBR specifies data patterns used as part of the trigger into debug mode. DBR bits are masked by setting corresponding DBMR bits, as defined in TDR.

DBR and DBMR are accessible in supervisor mode using the WDEBUG instruction and through the BDM port using the WRITE_DREG commands.

DRc: 0x0E (DBR)								Access: Supervisor write-only								
0x0F (DBMR)								BDM write-only								
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	[Greyed out]															
W	Data (DBR); Mask (DBMR)															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	[Greyed out]															
W	Data (DBR); Mask (DBMR)															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 46-34. DBR Field Descriptions

Field	Description
31–0	Data breakpoint value.
Data	Contains the value to be compared with the data value from the processor's local bus as a breakpoint trigger.

Table 46-35. DBMR Field Descriptions

Field	Description
31–0	Data breakpoint mask
Mask	The 32-bit mask for the data breakpoint trigger.
0	The corresponding DBR bit is compared to the appropriate bit of the processor's local data bus.
1	The corresponding DBR bit is ignored

The DBR supports aligned and misaligned references. This table shows the relationships between processor address, access size, and location within the 32-bit data bus.

Table 46-36. Access Size and Operand Data Location

Address[1–0]	Access Size	Operand Location
00	Byte	D[31–24]
01	Byte	D[23–16]
10	Byte	D[15–8]
11	Byte	D[7–0]
0x	Word	D[31–16]
1x	Word	D[15–0]
xx	Longword	D[31–0]

46.3.12 Resulting Set of Possible Trigger Combinations

The resulting set of possible breakpoint trigger combinations consists of the following options where || denotes logical OR, && denotes logical AND, and { } denotes an optional additional trigger term:

One-level triggers of the form:

```
if      (PC_breakpoint)
if      (PC_breakpoint || Address_breakpoint{&& Data_breakpoint})
if      (Address_breakpoint {&& Data_breakpoint})
```

Two-level triggers of the form:

```
if      (PC_breakpoint)
  then if (Address_breakpoint {&& Data_breakpoint} )

if      (Address_breakpoint {&& Data_breakpoint} )
  then if (PC_breakpoint)
```

In these examples, PC_breakpoint is the logical summation of the PBR0/PBMR, PBR1, PBR2, and PBR3 breakpoint registers; Address_breakpoint is a function of ABHR, ABLR, and AATR; Data_breakpoint is a function of DBR and DBMR. In all cases, the data breakpoints can be included with an address breakpoint to further qualify a trigger event as an option.

The breakpoint registers can also be used to define the start and stop recording conditions for the PST trace buffer.

46.3.13 PST Buffer (PSTB)

The PST trace buffer contains 64 six-bit entries, packed consecutively into 12 longword locations. The following table illustrates how the buffer entries are packed.

The write pointer for the trace buffer is available as CSR2[PSTBWA]. Using this pointer, it is possible to determine the oldest-to-newest entries in the trace buffer.

Table 46-37. PST Trace Buffer Entries and Locations

Core register number (CRN)	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

46.4 Functional Description

The following sections describe functional details of the debug module.

46.4.1 Background Debug Mode (BDM)

This section provides details on the background debug serial interface controller (BDC) and the BDM command set.

The BDC provides a single-wire debug interface to the target MCU. As shown in the Version 1 ColdFire core block diagram of [Figure 46-1](#), the BDC module interfaces between the single-pin (BKGD) interface and the remaining debug modules, including the ColdFire background debug logic, the real-time debug hardware, and the PST/DDATA trace logic. This interface provides a convenient means for programming the on-chip flash and other non-volatile memories. The BDC is the primary debug interface for development and allows non-intrusive access to memory data and traditional debug features such as run/halt control, read/write of core registers, breakpoints, and single instruction step.

Features of the background debug controller (BDC) include:

- Single dedicated pin for mode selection and background communications
- Special BDC registers not located in system memory map
- SYNC command to determine target communications rate
- Non-intrusive commands for memory access
- Active background (halt) mode commands for core register access
- GO command to resume execution
- BACKGROUND command to halt core or wake CPU from low-power modes
- Oscillator runs in stop mode, if BDM enabled

Based on these features, BDM is useful for the following reasons:

- In-circuit emulation is not needed, so physical and electrical characteristics of the system are not affected.
- BDM is always available for debugging the system and provides a communication link for upgrading firmware in existing systems.
- Provides high-speed memory downloading, especially useful for flash programming
- Provides absolute control of the processor, and thus the system. This feature allows quick hardware debugging with the same tool set used for firmware development.

46.4.1.1 CPU Halt

Although certain BDM operations can occur in parallel with CPU operations, unrestricted BDM operation requires the CPU to be halted. The sources that can cause the CPU to halt are listed below in order of priority. Recall that the default configuration of the Version 1 ColdFire core (CF1Core) defines the occurrence of certain exception types to automatically generate a system reset. Some of these fault types include illegal instructions, privilege errors, address errors, and bus error terminations, with the response under control of the processor's CPUCR[ARD, IRD] bits.

Table 46-38. CPU Halt Sources

Halt Source	Halt Timing	Description		
Fault-on-fault	Immediate	Refers to the occurrence of any fault while exception processing. For example, a bus error is signaled during exception stack frame writes or while fetching the first instruction in the exception service routine.		
		CPUCR[ARD] = 1	Immediately enters halt.	
		CPUCR[ARD] = 0	Reset event is initiated.	
Hardware breakpoint trigger	Pending	Halt is made pending in the processor. The processor samples for pending halt and interrupt conditions once per instruction. When a pending condition is asserted, the processor halts execution at the next sample point.		
HALT instruction	Immediate	BDM disabled	CPUCR[IRD] = 0	A reset is initiated since attempted execution of an illegal instruction
			CPUCR[IRD] = 1	An illegal instruction exception is generated.
		BDM enabled, supervisor mode	Processor immediately halts execution at the next instruction sample point. The processor can be restarted by a BDM GO command. Execution continues at the instruction after HALT.	
		BDM enabled, user mode	CSR[UHE] = 0 CPUCR[IRD] = 0	A reset event is initiated, because a privileged instruction was attempted in user mode.
			CSR[UHE] = 0 CPUCR[IRD] = 1	A privilege violation exception is generated.
CSR[UHE] = 1	Processor immediately halts execution at the next instruction sample point. The processor can be restarted by a BDM GO command. Execution continues at the instruction after HALT.			
BACKGROUND command	Pending	BDM disabled or flash secure	Illegal command response and BACKGROUND command is ignored.	
		BDM enabled and flash unsecure	Processor is running	Halt is made pending in the processor. The processor samples for pending halt and interrupt conditions once per instruction. When a pending condition is asserted, the processor halts execution at the next sample point.
			Processor is stopped	Processing of the BACKGROUND command is treated in a special manner. The processor exits the stopped mode and enters the halted state, at which point all BDM commands may be exercised. When restarted, the processor continues by executing the next sequential instruction (the instruction following STOP).
PSTB full condition	Pending	PSTB	PSTB obtrusive recording mode pends halt in the processor if the trace buffer reaches its full threshold (full is defined as before the buffer is overwritten). When a pending condition is asserted, the processor halts at the next sample point.	

Table continues on the next page...

Table 46-38. CPU Halt Sources (continued)

Halt Source	Halt Timing	Description	
BKGD held low for ≥ 2 bus clocks after reset negated for POR or BDM reset	Immediate	Flash unsecure	Enters debug mode with XCSR[ENBDM, CLKSW] set. The full set of BDM commands is available and debug can proceed. If the core is reset into a debug halt condition, the processor's response to the GO command depends on the BDM command(s) performed while it was halted. Specifically, if the PC register was loaded, the GO command causes the processor to exit halted state and pass control to the instruction address in the PC, bypassing normal reset exception processing. If the PC was not loaded, the GO command causes the processor to exit halted state and continue reset exception processing.
		Flash secure	Enters debug mode with XCSR[ENBDM, CLKSW] set. The allowable commands are limited to the always-available group. A GO command to start the processor is not allowed. The only recovery actions in this mode are: <ul style="list-style-type: none"> • Issue a BDM reset setting CSR2[BDFR] with CSR2[BDHBR] cleared and the BKGD pin held high to reset into normal operating mode • Erase the flash to unsecure the memory and then proceed with debug • Power cycle the device with the BKGD pin held high to reset into the normal operating mode

The processor's run/stop/halt status is always accessible in XCSR[CPUHALT,CPUSTOP]. Additionally, CSR[27–24] indicate the halt source, showing the highest priority source for multiple halt conditions. This field is cleared by a read of the CSR. A processor halt due to the PSTB full condition as indicated by CSR2[PSTH] is also reflected in CSR[BKPT]. The debug GO command clears CSR[26–24] and CSR2[PSTBH].

46.4.1.2 Background Debug Serial Interface Controller (BDC)

BDC serial communications use a custom serial protocol first introduced on the M68HC12 Family of microcontrollers and later used in the M68HCS08 family. This protocol assumes that the host knows the communication clock rate determined by the target BDC clock rate. The BDC clock rate may be the system bus clock frequency or an alternate frequency source depending on the state of XCSR[CLKSW]. All communication is initiated and controlled by the host which drives a high-to-low edge to signal the beginning of each bit time. Commands and data are sent most significant bit (msb) first. For a detailed description of the communications protocol, refer to [BDM Communication Details](#).

If a host is attempting to communicate with a target MCU that has an unknown BDC clock rate, a SYNC command may be sent to the target MCU to request a timed synchronization response signal from which the host can determine the correct communication speed. After establishing communications, the host can read XCSR and write the clock switch (CLKSW) control bit to change the source of the BDC clock for further serial communications if necessary.

BKGD is a pseudo-open-drain pin and there is an on-chip pullup so no external pullup resistor is required. Unlike typical open-drain pins, the external RC time constant on this pin, which is influenced by external capacitance, plays almost no role in signal rise time. The custom protocol provides for brief, actively driven speed-up pulses to force rapid rise times on this pin without risking harmful drive level conflicts. Refer to [BDM Communication Details](#), for more details.

When no debugger pod is connected to the standard 6-pin BDM interface connector ([Freescale-Recommended BDM Pinout](#)), the internal pullup on BKGD chooses normal operating mode. When a development system is connected, it can pull BKGD and $\overline{\text{RESET}}$ low, release $\overline{\text{RESET}}$ to select active background (halt) mode rather than normal operating mode, and then release BKGD. It is not necessary to reset the target MCU to communicate with it through the background debug interface. There is also a mechanism to generate a reset event in response to setting CSR2[BDFR].

46.4.1.3 BDM Communication Details

The BDC serial interface requires the external host controller to generate a falling edge on the BKGD pin to indicate the start of each bit time. The external controller provides this falling edge whether data is transmitted or received.

BKGD is a pseudo-open-drain pin that can be driven by an external controller or by the MCU. Data is transferred msb first at 16 BDC clock cycles per bit (nominal speed). The interface times-out if 512 BDC clock cycles occur between falling edges from the host. If a time-out occurs, the status of any command in progress must be determined before new commands can be sent from the host. To check the status of the command, follow the steps detailed in the bit description of XCSR[CSTAT].

The custom serial protocol requires the debug pod to know the target BDC communication clock speed. The clock switch (CLKSW) control bit in the XCSR[31–24] register allows you to select the BDC clock source. The BDC clock source can be the bus clock or the alternate BDC clock source. When the MCU is reset in normal user mode, CLKSW is cleared and that selects the alternate clock source. This clock source is a fixed frequency independent of the bus frequency so it does change if the user modifies clock generator settings. This is the preferred clock source for general debugging.

When the MCU is reset in active background (halt) mode, CLKSW is set which selects the bus clock as the source of the BDC clock. This CLKSW setting is most commonly used during flash memory programming because the bus clock can usually be configured to operate at the highest allowed bus frequency to ensure the fastest possible flash programming times. Because the host system is in control of changes to clock generator settings, it knows when a different BDC communication speed should be used. The host programmer also knows that no unexpected change in bus frequency could occur to disrupt BDC communications.

Normally, setting CLKSW should not be used for general debugging because there is no way to ensure the application program does not change the clock generator settings. This is especially true in the case of application programs that are not yet fully debugged.

After any reset (or at any other time), the host system can issue a SYNC command to determine the speed of the BDC clock. CLKSW may be written using the serial WRITE_XCSR_BYTE command through the BDC interface. CLKSW is located in the special XCSR byte register in the BDC module and it is not accessible in the normal memory map of the ColdFire core. This means that no program running on the processor can modify this register (intentionally or unintentionally).

The BKGD pin can receive a high- or low-level or transmit a high- or low-level. The following diagrams show timing for each of these cases. Interface timing is synchronous to clocks in the target BDC, but asynchronous to the external host. The internal BDC clock signal is shown for reference in counting cycles.

The following figure shows an external host transmitting a logic 1 or 0 to the BKGD pin of a target MCU. The host is asynchronous to the target so there is a 0–1 cycle delay from the host-generated falling edge to where the target perceives the beginning of the bit time. Ten target BDC clock cycles later, the target senses the bit level on the BKGD pin. Typically, the host actively drives the pseudo-open-drain BKGD pin during host-to-target transmissions to speed up rising edges. Because the target does not drive the BKGD pin during the host-to-target transmission period, there is no need to treat the line as an open-drain signal during this period.

Functional Description

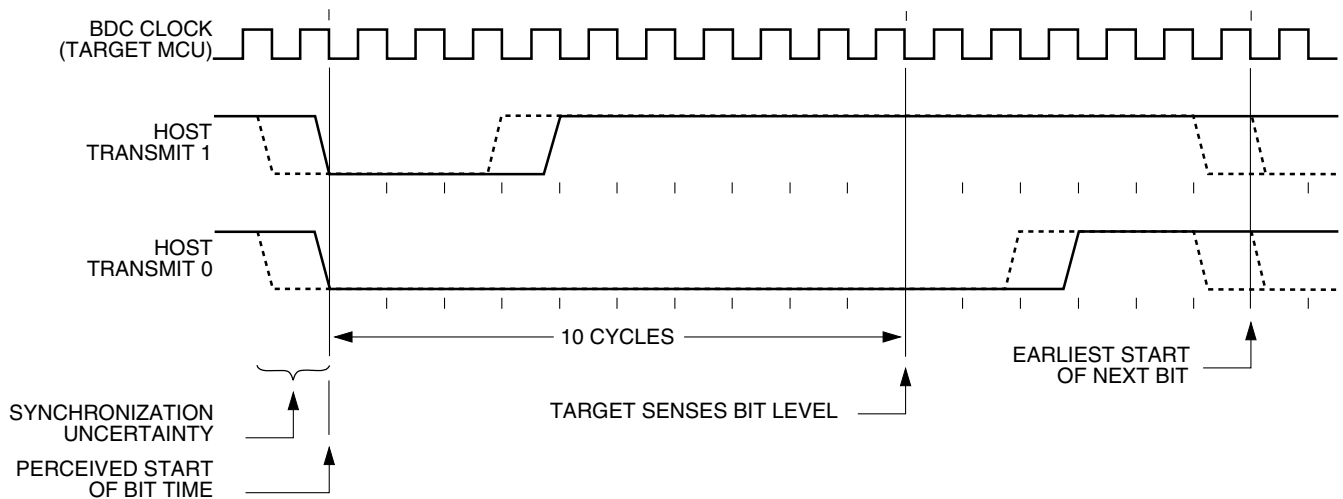

Figure 46-3. BDC Host-to-Target Serial Bit Timing

The following figure shows the host receiving a logic 1 from the target MCU. Because the host is asynchronous to the target MCU, there is a 0–1 cycle delay from the host-generated falling edge on BKGD to the perceived start of the bit time in the target MCU. The host holds the BKGD pin low long enough for the target to recognize it (at least two target BDC cycles). The host must release the low drive before the target MCU drives a brief active-high speedup pulse seven cycles after the perceived start of the bit time. The host should sample the bit level about 10 cycles after it started the bit time.

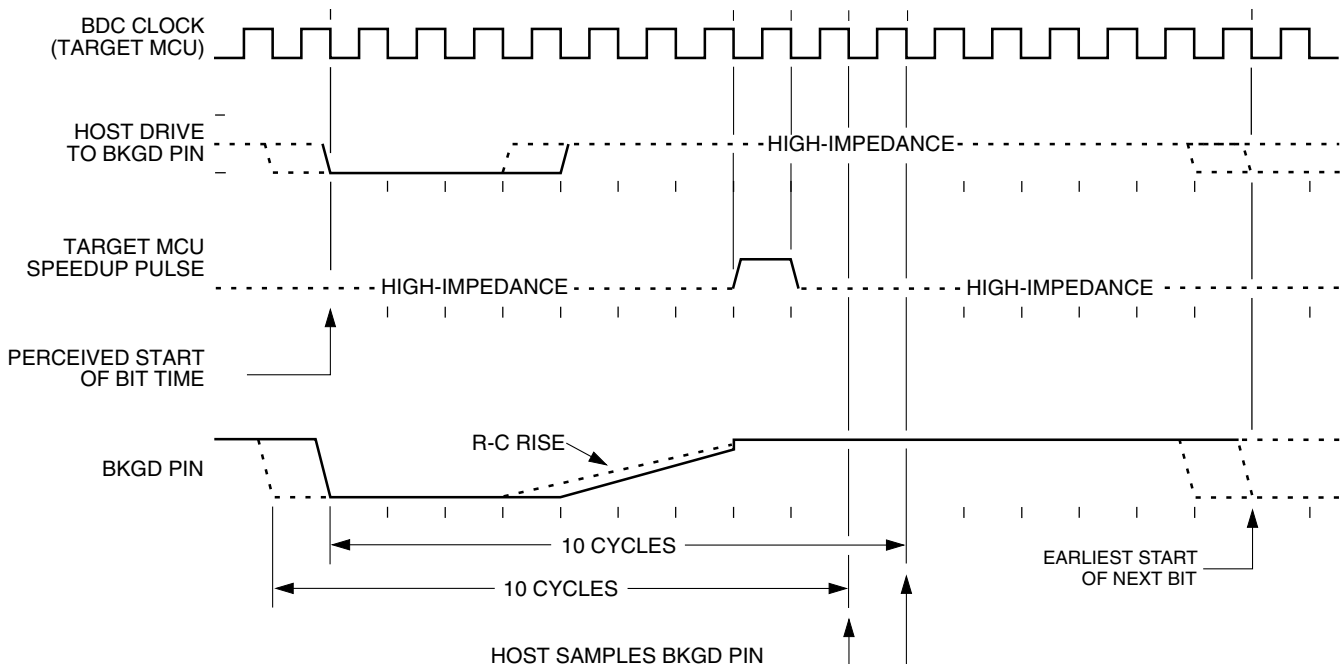

Figure 46-4. BDC Target-to-Host Serial Bit Timing (Logic 1)

The following figure shows the host receiving a logic 0 from the target MCU. Because the host is asynchronous to the target MCU, there is a 0–1 cycle delay from the host-generated falling edge on BKGD to the start of the bit time as perceived by the target

MCU. The host initiates the bit time, but the target MCU finishes it. Because the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 BDC clock cycles, then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 cycles after starting the bit time.

Figure 46-5. BDM Target-to-Host Serial Bit Timing (Logic 0)

46.4.1.4 BDM Command Set Descriptions

This section presents detailed descriptions of the BDM commands.

The V1 BDM command set is based on transmission of one or more 8-bit data packets per operation. Each operation begins with a host-to-target transmission of an 8-bit command code packet. The command code definition broadly maps the operations into four formats as shown in the following figure.

Functional Description

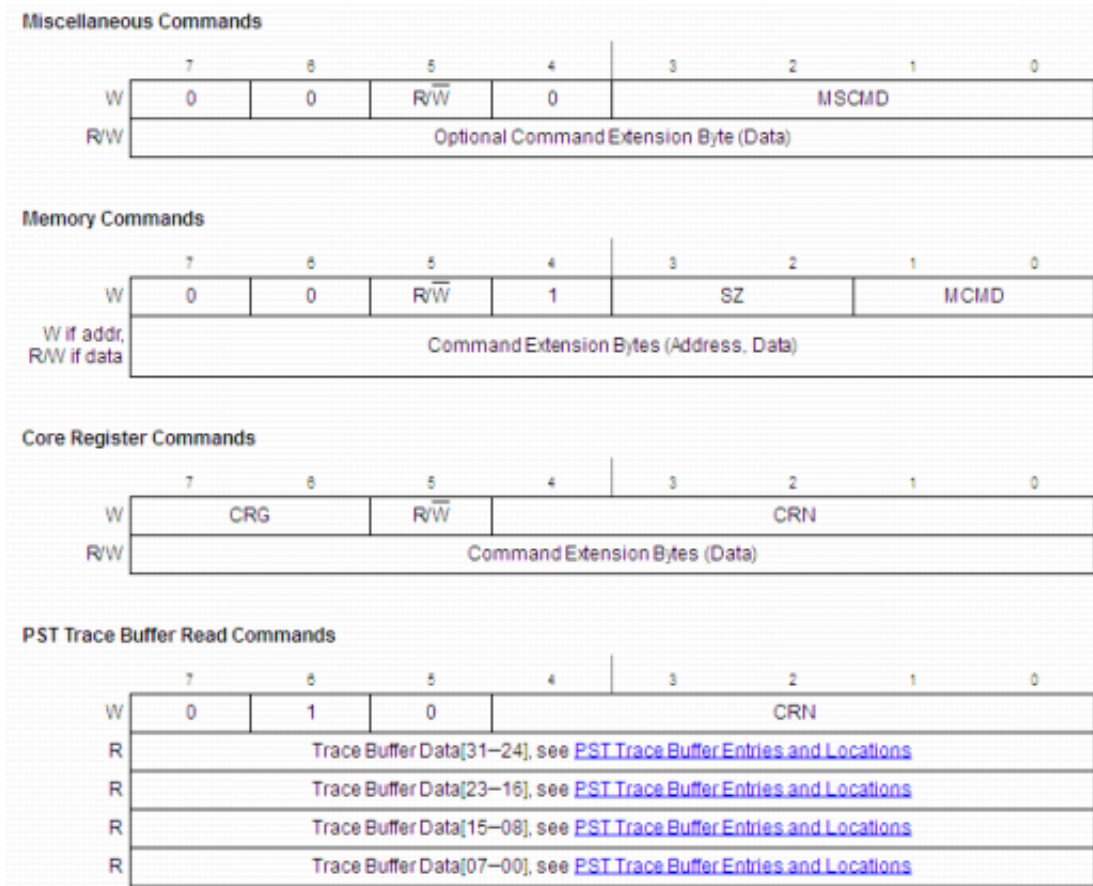

Figure 46-6. BDM Command Encodings

Table 46-39. BDM Command Field Descriptions

Field	Description
5	Read/Write.
R/W	0 Command is performing a write operation. 1 Command is performing a read operation.
3–0 MSCMD	Miscellaneous command. Defines the miscellaneous command to be performed. 0000 No operation 0001 Display the CPU's program counter (PC) plus optional capture in the PST trace buffer 0010 Enable the BDM acknowledge communication mode 0011 Disable the BDM acknowledge communication mode 0100 Force a CPU halt (background) 1000 Resume CPU execution (go) 1101 Read/write of the debug XCSR most significant byte 1110 Read/write of the debug CSR2 most significant byte 1111 Read/write of the debug CSR3 most significant byte

46.4.1.5 BDM Command Set Summary

The following table summarizes the BDM command set. Subsequent paragraphs contain detailed descriptions of each command. The nomenclature below is used in the following table to describe the structure of the BDM commands. Commands begin with an 8-bit hexadecimal command code in the host-to-target direction (most significant bit first)

/ = separates parts of the command
d = delay 32 target BDC clock cycles

Functional Description

ad24	=	24-bit memory address in the host-to-target direction
rd8	=	8 bits of read data in the target-to-host direction
rd16	=	16 bits of read data in the target-to-host direction
rd32	=	32 bits of read data in the target-to-host direction
rd.sz	=	read data, size defined by sz, in the target-to-host direction
wd8	=	8 bits of write data in the host-to-target direction
wd16	=	16 bits of write data in the host-to-target direction
wd32	=	32 bits of write data in the host-to-target direction
wd.sz	=	write data, size defined by sz, in the host-to-target direction
ss	=	the contents of XCSR[31:24] in the target-to-host direction
(STATUS)		
sz	=	memory operand size (0b00 = byte, 0b01 = word, 0b10 = long)
crn	=	core register number
WS	=	command suffix signaling the operation is with status

Table 46-40. BDM Command Summary

Command Mnemonic	Command Classification	ACK if Enb? ¹	Command Structure	Description
SYNC	Always Available	N/A	N/A ²	Request a timed reference pulse to determine the target BDC communication speed
ACK_DISABLE	Always Available	No	0x03/d	Disable the communication handshake. This command does not issue an ACK pulse.
ACK_ENABLE	Always Available	Yes	0x02/d	Enable the communication handshake. Issues an ACK pulse after the command is executed.
BACKGROUND	Non-Intrusive	Yes	0x04/d	Halt the CPU if ENBDM is set. Otherwise, ignore as illegal command.
DUMP_MEM.sz	Non-Intrusive	Yes	(0x32+4 x sz)/d/rd.sz	Dump (read) memory based on operand size (sz). Used with READ_MEM to dump large blocks of memory. An initial READ_MEM is executed to set up the starting address of the block and to retrieve the first result. Subsequent DUMP_MEM commands retrieve sequential operands.
DUMP_MEM.sz_WS	Non-Intrusive	No	(0x33+4 x sz)/d/ss/rd.sz	Dump (read) memory based on operand size (sz) and report status. Used with READ_MEM{_WS} to dump large blocks of memory. An initial READ_MEM{_WS} is executed to set up the starting address of the block and to retrieve the first result. Subsequent DUMP_MEM{_WS} commands retrieve sequential operands.

Table continues on the next page...

Table 46-40. BDM Command Summary (continued)

Command Mnemonic	Command Classification	ACK if Enb? ¹	Command Structure	Description
FILL_MEM.sz	Non-Intrusive	Yes	(0x12+4 x sz)/wd.sz/d	Fill (write) memory based on operand size (sz). Used with WRITE_MEM to fill large blocks of memory. An initial WRITE_MEM is executed to set up the starting address of the block and to write the first operand. Subsequent FILL_MEM commands write sequential operands.
FILL_MEM.sz_WS	Non-Intrusive	No	(0x13+4 x sz)/wd.sz/d/ss	Fill (write) memory based on operand size (sz) and report status. Used with WRITE_MEM{_WS} to fill large blocks of memory. An initial WRITE_MEM{_WS} is executed to set up the starting address of the block and to write the first operand. Subsequent FILL_MEM{_WS} commands write sequential operands.
GO	Non-Intrusive	Yes	0x08/d	Resume the CPU's execution ³
NOP	Non-Intrusive	Yes	0x00/d	No operation
READ_CREG	Active Background	Yes	(0xE0+CRN)/d/rd32	Read one of the CPU's control registers
READ_DREG	Non-Intrusive	Yes	(0xA0+CRN)/d/rd32	Read one of the debug module's control registers
READ_MEM.sz	Non-Intrusive	Yes	(0x30+4 x sz)/ad24/d/rd.sz	Read the appropriately-sized (sz) memory value from the location specified by the 24-bit address
READ_MEM.sz_WS	Non-Intrusive	No	(0x31+4 x sz)/ad24/d/ss/ rd.sz	Read the appropriately-sized (sz) memory value from the location specified by the 24-bit address and report status
READ_PSTB	Non-Intrusive	Yes	(0x40+CRN)/d/rd32	Read the requested longword location from the PST trace buffer
READ_Rn	Active Background	Yes	(0x60+CRN)/d/rd32	Read the requested general-purpose register (An, Dn) from the CPU
READ_XCSR_BYTE	Always Available	No	0x2D/rd8	Read the most significant byte of the debug module's XCSR
READ_CSR2_BYTE	Always Available	No	0x2E/rd8	Read the most significant byte of the debug module's CSR2
READ_CSR3_BYTE	Always Available	No	0x2F/rd8	Read the most significant byte of the debug module's CSR3
SYNC_PC	Non-Intrusive	Yes	0x01/d	Display the CPU's current PC and capture it in the PST trace buffer
WRITE_CREG	Active Background	Yes	(0xC0+CRN)/wd32/d	Write one of the CPU's control registers

Table continues on the next page...

Table 46-40. BDM Command Summary (continued)

Command Mnemonic	Command Classification	ACK if Enb? ¹	Command Structure	Description
WRITE_DREG	Non-Intrusive	Yes	(0x80+CRN)/wd32/d	Write one of the debug module's control registers
WRITE_MEM.sz	Non-Intrusive	Yes	(0x10+4 x sz)/ad24/wd.sz/d	Write the appropriately-sized (sz) memory value to the location specified by the 24-bit address
WRITE_MEM.sz_WS	Non-Intrusive	No	(0x11+4 x sz)/ad24/wd.sz/d/ss	Write the appropriately-sized (sz) memory value to the location specified by the 24-bit address and report status
WRITE_Rn	Active Background	Yes	(0x40+CRN)/wd32/d	Write the requested general-purpose register (An, Dn) of the CPU
WRITE_XCSR_BYTE	Always Available	No	0x0D/wd8	Write the most significant byte of the debug module's XCSR
WRITE_CSR2_BYTE	Always Available	No	0x0E/wd8	Write the most significant byte of the debug module's CSR2
WRITE_CSR3_BYTE	Always Available	No	0x0F/wd8	Write the most significant byte of the debug module's CSR3

1. This column identifies if the command generates an ACK pulse if operating with acknowledge mode enabled. See [ACK_ENABLE](#), for addition information.
2. The SYNC command is a special operation which does not have a command code.
3. If a GO command is received while the processor is not halted, it performs no operation.

46.4.1.5.1 SYNC

The SYNC command is unlike other BDC commands because the host does not necessarily know the correct speed to use for serial communications until after it has analyzed the response to the SYNC command.

To issue a SYNC command, the host:

1. Drives the BKGD pin low for at least 128 cycles of the slowest possible BDC clock (bus clock or device-specific alternate clock source).
2. Drives BKGD high for a brief speed-up pulse to get a fast rise time. (This speedup pulse is typically one cycle of the host clock which is as fast as the maximum target BDC clock.)
3. Removes all drive to the BKGD pin so it reverts to high impedance.
4. Listens to the BKGD pin for the sync response pulse.

Upon detecting the sync request from the host (which is a much longer low time than would ever occur during normal BDC communications), the target:

1. Waits for BKGD to return to a logic high.
2. Delays 16 cycles to allow the host to stop driving the high speed-up pulse.
3. Drives BKGD low for 128 BDC clock cycles.
4. Drives a 1-cycle high speed-up pulse to force a fast rise time on BKGD.
5. Removes all drive to the BKGD pin so it reverts to high impedance.

The host measures the low time of this 128-cycle sync response pulse and determines the correct speed for subsequent BDC communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the serial protocol can easily tolerate this speed error.

46.4.1.5.2 ACK_DISABLE

Disable host/target handshake protocol

Always Available

Disables the serial communication handshake protocol. The subsequent commands, issued after the ACK_DISABLE command, do not execute the hardware handshake protocol. This command is not followed by an ACK pulse.

46.4.1.5.3 ACK_ENABLE

Enable host/target handshake protocol

Always Available

Enables the hardware handshake protocol in the serial communication. The hardware handshake is implemented by an acknowledge (ACK) pulse issued by the target MCU in response to a host command. The ACK_ENABLE command is interpreted and executed in the BDC logic without the need to interface with the CPU. However, an acknowledge (ACK) pulse is issued by the target device after this command is executed. This feature can be used by the host to evaluate if the target supports the hardware handshake

Functional Description

protocol. If the target supports the hardware handshake protocol, subsequent commands are enabled to execute the hardware handshake protocol; otherwise, this command is ignored by the target.

For additional information about the hardware handshake protocol, refer to [Serial Interface Hardware Handshake Protocol](#) and [Hardware Handshake Abort Procedure](#).

46.4.1.5.4 BACKGROUND

Enter active background mode (if enabled)

Non-intrusive

Provided XCSR[ENBDM] is set (BDM enabled), the BACKGROUND command causes the target MCU to enter active background (halt) mode as soon as the current CPU instruction finishes. If ENBDM is cleared (its default value), the BACKGROUND command is ignored.

A delay of 32 BDC clock cycles is required after the BACKGROUND command to allow the target MCU to finish its current CPU instruction and enter active background mode before a new BDC command can be accepted.

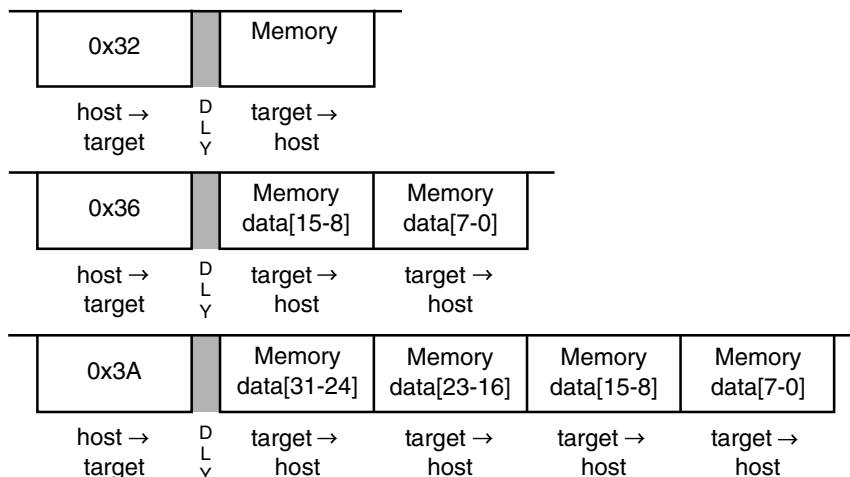

After the target MCU is reset into a normal operating mode, the host debugger must send a WRITE_XCSR_BYTE command to set ENBDM before attempting to send the BACKGROUND command the first time. Normally, the development host sets ENBDM once at the beginning of a debug session or after a target system reset, and then it leaves the ENBDM bit set during debugging operations. During debugging, the host uses GO commands to move from active background mode to normal user program execution and uses BACKGROUND commands or breakpoints to return to active background mode.

46.4.1.5.5 DUMP_MEM.sz, DUMP_MEM.sz_WS

DUMP_MEM.sz

Read memory specified by debug address register, then increment address

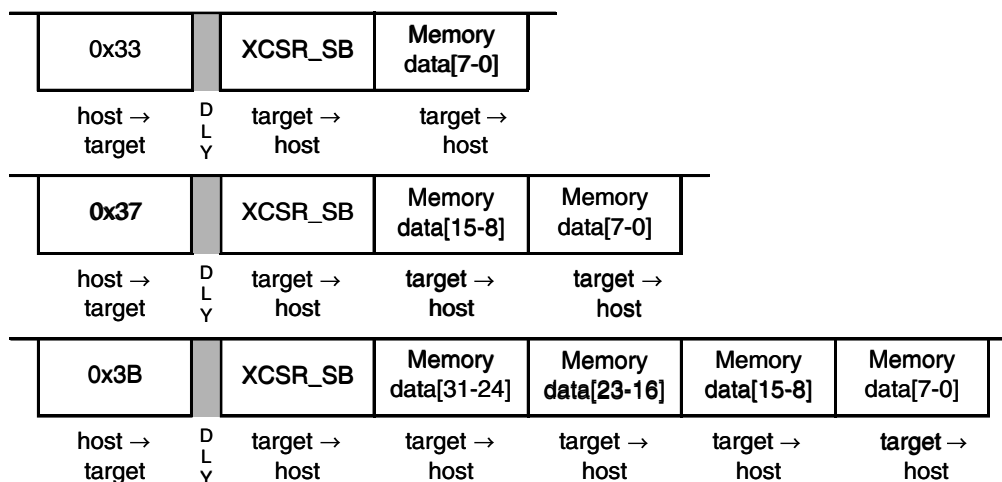

Non-intrusive

DUMP_MEM.sz_WS

Read memory specified by debug address register with status, then increment address

Non-intrusive

DUMP_MEM{_WS} is used with the READ_MEM{_WS} command to access large blocks of memory. An initial READ_MEM{_WS} is executed to set-up the starting address of the block and to retrieve the first result. If an initial READ_MEM{_WS} is not executed before the first DUMP_MEM{_WS}, an illegal command response is returned. The DUMP_MEM{_WS} command retrieves subsequent operands. The initial address is incremented by the operand size (1, 2, or 4) and saved in a temporary register. Subsequent DUMP_MEM{_WS} commands use this address, perform the memory read,

Functional Description

increment it by the current operand size, and store the updated address in the temporary register. If the with-status option is specified, the core status byte (XCSR_SB) contained in XCSR[31–24] is returned before the read data. XCSR_SB reflects the state after the memory read was performed.

Note

DUMP_MEM{ _WS } does not check for a valid address; it is a valid command only when preceded by NOP, READ_MEM{ _WS }, or another DUMP_MEM{ _WS } command. Otherwise, an illegal command response is returned. NOP can be used for inter-command padding without corrupting the address pointer.

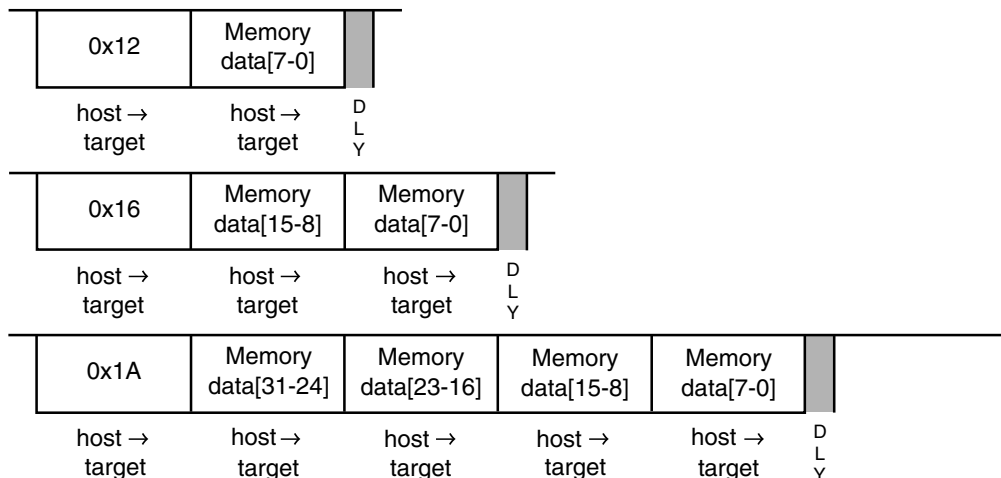

The size field (sz) is examined each time a DUMP_MEM{ _WS } command is processed, allowing the operand size to be dynamically altered. The examples show the DUMP_MEM.B{ _WS }, DUMP_MEM.W{ _WS } and DUMP_MEM.L{ _WS } commands.

46.4.1.5.6 FILL_MEM.sz, FILL_MEM.sz_WS

FILL_MEM.sz

Write memory specified by debug address register, then increment address

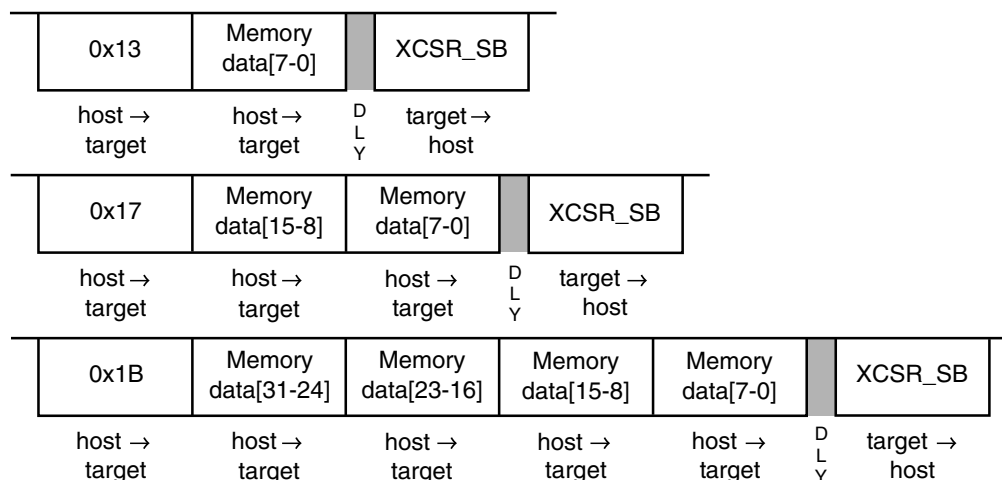

Non-intrusive

FILL_MEM.sz_WS

Write memory specified by debug address register with status, then increment address

Non-intrusive

FILL_MEM{_WS} is used with the WRITE_MEM{_WS} command to access large blocks of memory. An initial WRITE_MEM{_WS} is executed to set up the starting address of the block and write the first datum. If an initial WRITE_MEM{_WS} is not executed before the first FILL_MEM{_WS}, an illegal command response is returned. The FILL_MEM{_WS} command stores subsequent operands. The initial address is incremented by the operand size (1, 2, or 4) and saved in a temporary register. Subsequent FILL_MEM{_WS} commands use this address, perform the memory write, increment it by the current operand size, and store the updated address in the temporary register. If the with-status option is specified, the core status byte (XCSR_SB) contained in XCSR[31–24] is returned after the write data. XCSR_SB reflects the state after the memory write was performed.

Note

FILL_MEM{_WS} does not check for a valid address; it is a valid command only when preceded by NOP, WRITE_MEM{_WS}, or another FILL_MEM{_WS} command. Otherwise, an illegal command response is returned. NOP can be used for intercommand padding without corrupting the address pointer.

The size field (sz) is examined each time a FILL_MEM{_WS} command is processed, allowing the operand size to be dynamically altered. The examples show the FILL_MEM.B{_WS}, FILL_MEM.W{_WS} and FILL_MEM.L{_WS} commands.

46.4.1.5.7 GO

Go

Non-intrusive

This command is used to exit active background (halt) mode and begin (or resume) execution of the application's instructions. The CPU's pipeline is flushed and refilled before normal instruction execution resumes. Prefetching begins at the current address in the PC and at the current privilege level. If any register (such as the PC or SR) is altered by a BDM command while the processor is halted, the updated value is used when prefetching resumes. If a GO command is issued and the CPU is not halted, the command is ignored.

46.4.1.5.8 NOP

No operation

Non-intrusive

NOP performs no operation and may be used as a null command where required.

46.4.1.5.9 READ_CREG

Read CPU control register

Active Background

If the processor is halted, this command reads the selected control register and returns the 32-bit result. This register grouping includes the PC, SR, CPUCR, MACSR, MASK, ACC, VBR, and OTHER_A7. Accesses to processor control registers are always 32-bits wide, regardless of implemented register width. The register is addressed through the core register number (CRN). See [Table 46-39](#) for the CRN details when CRG is 11.

If the processor is not halted, this command is rejected as an illegal operation and no operation is performed.

46.4.1.5.10 READ_DREG

Read debug control register

Non-intrusive

0xA0+CRN		DREG data [31-24]	DREG data [23-16]	DREG data [15-8]	DREG data [7-0]
host → target	D L Y	target → host	target → host	target → host	target → host

This command reads the selected debug control register and returns the 32-bit result. This register grouping includes the CSR, XCSR, CSR2, and CSR3. Accesses to debug control registers are always 32-bits wide, regardless of implemented register width. The register is addressed through the core register number (CRN). See [Table 46-4](#) for CRN details.

46.4.1.5.11 READ_MEM.sz, READ_MEM.sz_WS

READ_MEM.sz

Read memory at the specified address

Non-intrusive

0x30	Address[23-0]		Memory data[7-0]			
host → target	host → target	D L Y	target → host			
0x34	Address[23-0]		Memory data[15-8]	Memory data[7-0]		
host → target	host → target	D L Y	target → host	target → host		
0x38	Address[23-0]		Memory data[31-24]	Memory data[23-16]	Memory data[15-8]	Memory data[7-0]
host → target	host → target	D L Y	target → host	target → host	target → host	target → host

READ_MEM.sz_WS

Read memory at the specified address with status

Non-intrusive

0x31	Address[23-0]		XCSR_SB	Memory data[7-0]			
host → target	host → target	D L Y	target → host	target → host			
0x35	Address[23-0]		XCSR_SB	Memory data[15-8]	Memory data[7-0]		
host → target	host → target	D L Y	target → host	target → host	target → host		
0x39	Address[23-0]		XCSR_SB	Memory data[31-24]	Memory data[23-16]	Memory data[15-8]	Memory data[7-0]
host → target	host → target	D L Y	target → host	target → host	target → host	target → host	target → host

Read data at the specified memory address. The reference address is transmitted as three 8-bit packets (msb to lsb) immediately after the command packet. The access attributes are defined by BAAR[TT, TM]. The hardware forces low-order address bits to zeros for word and longword accesses to ensure these accesses are on 0-modulo-size alignments. If the with-status option is specified, the core status byte (XCSR_SB) contained in XCSR[31–24] is returned before the read data. XCSR_SB reflects the state after the memory read was performed.

The examples show the READ_MEM.B{ _WS }, READ_MEM.W{ _WS } and READ_MEM.L{ _WS } commands.

46.4.1.5.12 READ_PSTB

Read PST trace buffer at the specified address

Non-intrusive

0x40+CRN		PSTB data [31-24]	PSTB data [23-16]	PSTB data [15-8]	PSTB data [7-0]
host → target	D L Y	target → host	target → host	target → host	target → host

Read 32 bits of captured PST/DDATA values from the trace buffer at the specified address. The PST trace buffer contains 64 six-bit entries, packed consecutively into 12 longword locations. See [Table 46-37](#) for an illustration of how the buffer entries are packed.

46.4.1.5.13 READ_Rn

Read general-purpose CPU register

Active Background

If the processor is halted, this command reads the selected CPU general-purpose register (An, Dn) and returns the 32-bit result. See [Table 46-39](#) for the CRN details when CRG is 01.

If the processor is not halted, this command is rejected as an illegal operation and no operation is performed.

46.4.1.5.14 READ_XCSR_BYTE

Read XCSR Status Byte

Always Available

Read the special status byte of XCSR (XCSR[31–24]). This command can be executed in any mode.

46.4.1.5.15 READ_CSR2_BYTE

Read CSR2 Status Byte

Always Available

Read the most significant byte of CSR2 (CSR2[31–24]). This command can be executed in any mode.

46.4.1.5.16 READ_CSR3_BYTE

Read CSR2 Status Byte

Always Available

Read the most significant byte of the CSR3 (CSR3[31–24]). This command can be executed in any mode.

46.4.1.5.17 SYNC_PC

Synchronize PC to PST/DDATA Signals

Non-intrusive

Capture the processor's current PC (program counter) and display it on the PST/DDATA signals. After the debug module receives the command, it sends a signal to the ColdFire core that the current PC must be displayed. The core responds by forcing an instruction fetch to the next PC with the address being captured by the DDATA logic. The DDATA logic captures a 2- or 3-byte instruction address, based on CSR[9]. If CSR[9] is cleared, then a 2-byte address is captured, else a 3-byte address is captured. The specific sequence of PST and DDATA values is defined as:

1. Debug signals a SYNC_PC command is pending.
2. CPU completes the current instruction.
3. CPU forces an instruction fetch to the next PC, generating a PST = 0x5 value indicating a taken branch. DDATA captures the instruction address corresponding to the PC. DDATA generates a PST marker signalling a 2- or 3-byte address as defined by CSR[9] (CSR[9] = 0, 2-byte; CSR[9] = 1, 3-byte) and displays the captured PC address.

This command can be used to provide a PC synchronization point between the core's execution and the application code in the PST trace buffer. It can also be used to dynamically access the PC for performance monitoring as the execution of this command is considerably less intrusive to the real-time operation of an application than a BACKGROUND/read-PC/GO command sequence.

46.4.1.5.18 WRITE_CREG

Write CPU control register

Active Background

0xC0+CRN	CREG data [31-24]	CREG data [23-16]	CREG data [15-8]	CREG data [7-0]	
host → target	host → target	host → target	host → target	host → target	D L Y

If the processor is halted, this command writes the 32-bit operand to the selected control register. This register grouping includes the PC, SR, CPUCR, MACSR, MASK, ACC, VBR, and OTHER_A7. Accesses to processor control registers are always 32-bits wide, regardless of implemented register width. The register is addressed through the core register number (CRN). See [Table 46-39](#) for the CRN details when CRG is 11.

If the processor is not halted, this command is rejected as an illegal operation and no operation is performed.

46.4.1.5.19 WRITE_DREG

Write debug control register

Non-intrusive

0x80+CRN	DREG data [31-24]	DREG data [23-16]	DREG data [15-8]	DREG data [7-0]	
host → target	host → target	host → target	host → target	host → target	D L Y

This command writes the 32-bit operand to the selected debug control register. This grouping includes all the debug control registers ($\{X\}$ CSR n , BAAR, AATR, TDR, PBR n , PBMR, AB x R, DBR, DBMR). Accesses to debug control registers are always 32-bits wide, regardless of implemented register width. The register is addressed through the core register number (CRN).

Note

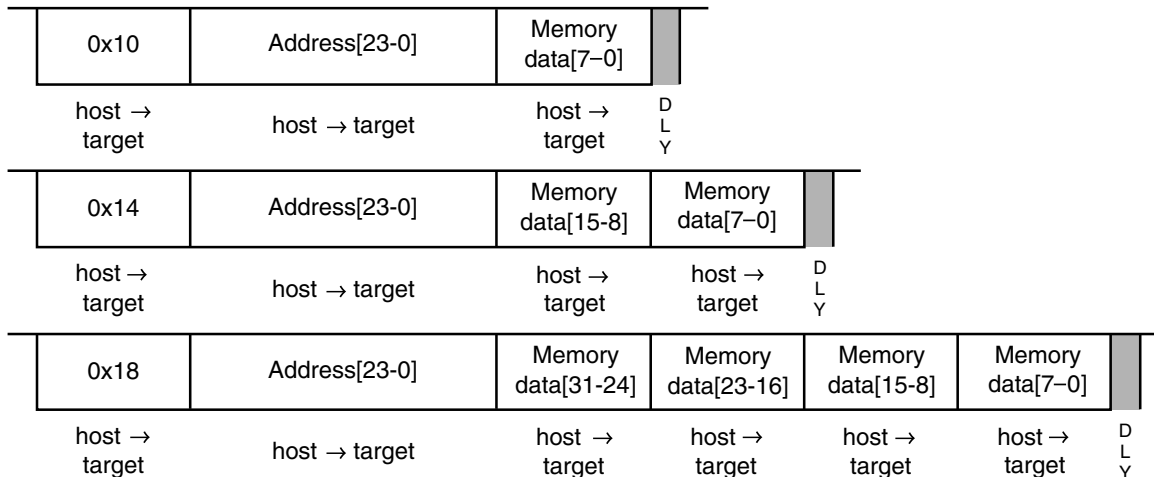

When writing XCSR, CSR2, or CSR3, WRITE_DREG only writes bits 23–0. The upper byte of these debug registers is only written with the special WRITE_XCSR_BYTE, WRITE_CSR2_BYTE, and WRITE_CSR3_BYTE commands.

46.4.1.5.20 WRITE_MEM.sz, WRITE_MEM.sz_WS

WRITE_MEM.sz

Write memory at the specified address

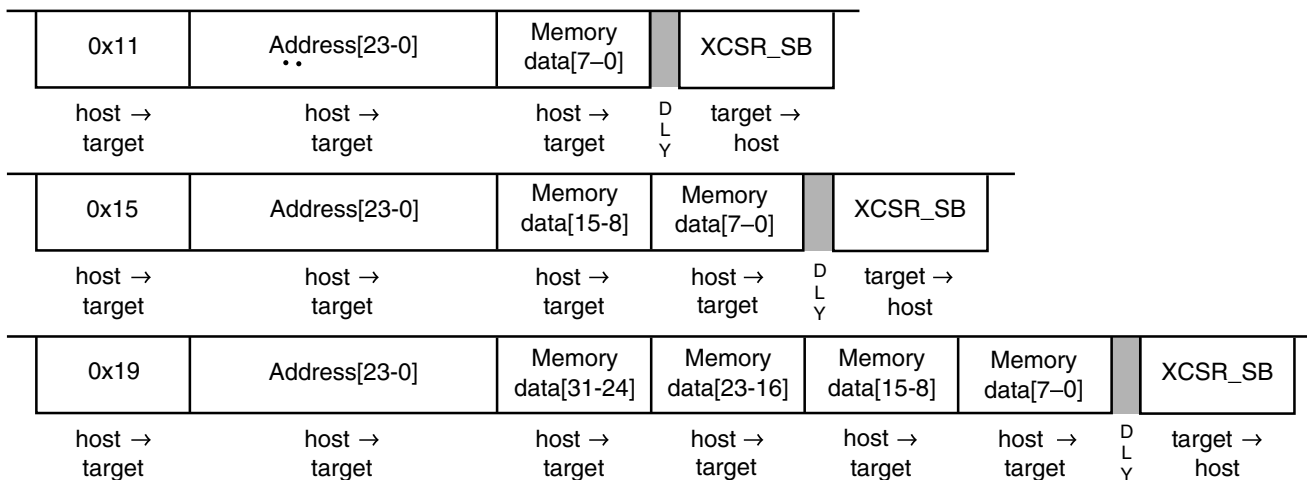

Non-intrusive

WRITE_MEM.sz_WS

Write memory at the specified address with status

Non-intrusive

Write data at the specified memory address. The reference address is transmitted as three 8-bit packets (msb to lsb) immediately after the command packet. The access attributes are defined by BAAR[TT, TM]. The hardware forces low-order address bits to zeros for word and longword accesses to ensure these accesses are on 0-modulo-size alignments. If the with-status option is specified, the core status byte (XCSR_SB) contained in XCSR[31-24] is returned after the read data. XCSR_SB reflects the state after the memory write was performed.

The examples show the `WRITE_MEM.B{ _WS }`, `WRITE_MEM.W{ _WS }`, and `WRITE_MEM.L{ _WS }` commands.

46.4.1.5.21 WRITE_Rn

Write general-purpose CPU register

Active Background

If the processor is halted, this command writes the 32-bit operand to the selected CPU general-purpose register (An, Dn). See [Table 46-39](#) for the CRN details when CRG is 01.

If the processor is not halted, this command is rejected as an illegal operation and no operation is performed.

46.4.1.5.22 WRITE_XCSR_BYTE

Write XCSR Status Byte

Always Available

Write the special status byte of XCSR (XCSR[31–24]). This command can be executed in any mode.

46.4.1.5.23 WRITE_CSR2_BYTE

Write CSR2 Status Byte

Always Available

Write the most significant byte of CSR2 (CSR2[31–24]). This command can be executed in any mode.

46.4.1.5.24 WRITE_CSR3_BYTE

Write CSR3 Status Byte

Always Available

Write the most significant byte of CSR3 (CSR3[31–24]). This command can be executed in any mode.

46.4.1.5.25 BDM Accesses of the MAC Registers

The presence of rounding logic in the output datapath of the MAC requires special care for BDM-initiated reads and writes of its programming model. In particular, any result rounding modes must be disabled during the read/write process so the exact bit-wise MAC register contents are accessed.

For example, a BDM read of the accumulator (ACC) must be preceded by two commands accessing the MAC status register, as shown in the following sequence:

```
BdmReadACC (
    rcreg    macsr;           // read current macsr contents and save
    wcreg    #0,macsr;       // disable all rounding modes
    rcreg    ACC;           // read the desired accumulator
    wcreg    #saved_data,macsr; // restore the original macsr
)
```

Likewise, to write an accumulator register, the following BDM sequence is needed:

```
BdmWriteACC (
    rcreg    macsr;           // read current macsr contents and save
    wcreg    #0,macsr;       // disable all rounding modes
    wcreg    #data,ACC;      // write the desired accumulator
    wcreg    #saved_data,macsr; // restore the original macsr
)
```

For more information on saving and restoring the complete MAC programming model, see <<create reference to "Saving and Restoring the EMAC Programming Model" section>>.

46.4.1.6 Serial Interface Hardware Handshake Protocol

BDC commands that require CPU execution are ultimately treated at the core clock rate. Because the BDC clock source can be asynchronous relative to the bus frequency when CLKS_W is cleared, it is necessary to provide a handshake protocol so the host can determine when an issued command is executed by the CPU. This section describes this protocol.

The hardware handshake protocol signals to the host controller when an issued command was successfully executed by the target. This protocol is implemented by a low pulse (16 BDC clock cycles) followed by a brief speedup pulse on the BKGD pin, generated by the target MCU when a command, issued by the host, has been successfully executed. See [Figure 46-7](#). This pulse is referred to as the ACK pulse. After the ACK pulse is finished, the host can start the data-read portion of the command if the last-issued command was a read command, or start a new command if the last command was a write command or a control command (BACKGROUND, GO, NOP, SYNC_PC). The ACK pulse is not issued earlier than 32 BDC clock cycles after the BDC command was issued. The end of the BDC command is assumed to be the 16th BDC clock cycle of the last bit. This minimum delay assures enough time for the host to recognize the ACK pulse. There is no upper limit for the delay between the command and the related ACK pulse, because the command execution depends on the CPU bus frequency, which in some cases could be slow compared to the serial communication rate. This protocol allows great flexibility for pod designers, because it does not rely on any accurate time measurement or short response time to any event in the serial communication.

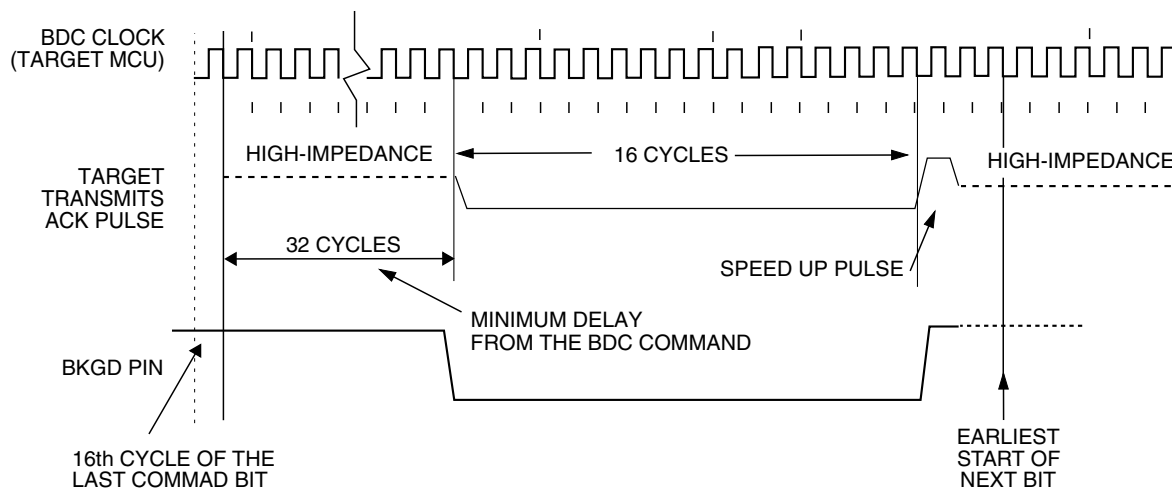

Figure 46-7. Target Acknowledge Pulse (ACK)

Note

If the ACK pulse was issued by the target, the host assumes the previous command was executed. If the CPU enters a stop mode prior to executing a non-intrusive command, the

command is discarded and the ACK pulse is not issued. After entering a stop mode, the BDC command is no longer pending and the XCSR[CSTAT] value of 001 is kept until the next command is successfully executed.

Figure 46-8 shows the ACK handshake protocol in a command level timing diagram. A READ_MEM.B command is used as an example:

1. The 8-bit command code is sent by the host, followed by the address of the memory location to be read.
2. The target BDC decodes the command and sends it to the CPU.
3. Upon receiving the BDC command request, the CPU schedules a execution slot for the command.
4. The CPU temporarily stalls the instruction stream at the scheduled point, executes the READ_MEM.B command and then continues.

This process is referred to as cycle stealing. The READ_MEM.B appears as a single-cycle operation to the processor, even though the pipelined nature of the Operand Execution Pipeline requires multiple CPU clock cycles for it to actually complete. After that, the debug module tracks the execution of the READ_MEM.b command as the processor resumes the normal flow of the application program. After detecting the READ_MEM.B command is done, the BDC issues an ACK pulse to the host controller, indicating that the addressed byte is ready to be retrieved. After detecting the ACK pulse, the host initiates the data-read portion of the command.

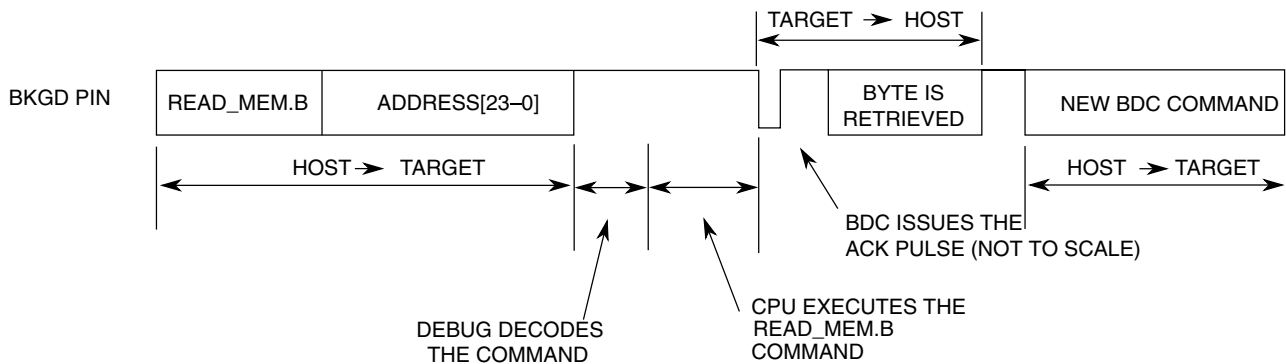

Figure 46-8. Handshake Protocol at Command Level

Unlike a normal bit transfer, where the host initiates the transmission by issuing a negative edge in the BKGD pin, the serial interface ACK handshake pulse is initiated by the target MCU. The hardware handshake protocol in Figure 46-8 specifies the timing when the BKGD pin is being driven, so the host should follow these timing relationships to avoid the risks of an electrical conflict at the BKGD pin.

The ACK handshake protocol does not support nested ACK pulses. If a BDC command is not acknowledged by an ACK pulse, the host first needs to abort the pending command before issuing a new BDC command. When the CPU enters a stop mode at about the same time the host issues a command that requires CPU execution, the target discards the incoming command. Therefore, the command is not acknowledged by the target, meaning that the ACK pulse is not issued in this case. After a certain time, the host could decide to abort the ACK protocol to allow a new command. Therefore, the protocol provides a mechanism where a command (a pending ACK) could be aborted. Unlike a regular BDC command, the ACK pulse does not provide a timeout. In the case of a STOP instruction where the ACK is prevented from being issued, it would remain pending indefinitely if not aborted. See the handshake abort procedure described in [Hardware Handshake Abort Procedure](#).

46.4.1.7 Hardware Handshake Abort Procedure

The abort procedure is based on the SYNC command. To abort a command that has not responded with an ACK pulse, the host controller generates a sync request (by driving BKGD low for at least 128 serial clock cycles and then driving it high for one serial clock cycle as a speedup pulse). By detecting this long low pulse on the BKGD pin, the target executes the sync protocol (see [SYNC](#)), and assumes that the pending command and therefore the related ACK pulse, are being aborted. Therefore, after the sync protocol completes, the host is free to issue new BDC commands.

Because the host knows the target BDC clock frequency, the SYNC command does not need to consider the lowest possible target frequency. In this case, the host could issue a SYNC close to the 128 serial clock cycles length, providing a small overhead on the pulse length to assure the sync pulse is not misinterpreted by the target.

It is important to notice that any issued BDC command that requires CPU execution is scheduled for execution by the pipeline based on the dynamic state of the machine, provided the processor does not enter any of the stop modes. If the host aborts a command by sending the sync pulse, it should then read XCSR[CSTAT] after the sync response is issued by the target, checking for CSTAT cleared, before attempting to send any new command that requires CPU execution. This prevents the new command from being discarded at the debug/CPU interface, due to the pending command being executed by the CPU. Any new command should be issued only after XCSR[CSTAT] is cleared.

There are multiple reasons that could cause a command to take too long to execute, measured in terms of the serial communication rate: The BDC clock frequency could be much faster than the CPU clock frequency, or the CPU could be accessing a slow memory, which would cause pipeline stall cycles to occur. All commands referencing the CPU registers or memory require access to the processor's local bus to complete. If the

Functional Description

processor is executing a tight loop contained within a single aligned longword, the processor may never successfully grant the internal bus to the debug command. For example:

```
label1:   align    4
          nop
          bra.b    label1
or
label2:   align    4
          bra.w    label2
```

These two examples of tight loops exhibit the BDM lockout behavior. If the loop spans across two longwords, there are no issues, so the recommended construct is:

```
label3:   align    4
          bra.l    label3
```

The hardware handshake protocol is appropriate for these situations, but the host could also decide to use the software handshake protocol instead. In this case, if XCSR[CSTAT] is 001, there is a BDC command pending at the debug/CPU interface. The host controller should monitor XCSR[CSTAT] and wait until it is 000 to be able to issue a new command that requires CPU execution. However, if the XCSR[CSTAT] is 1xx, the host should assume the last command failed to execute. To recover from this condition, the following sequence is suggested:

1. Issue a SYNC command to reset the BDC communication channel.
2. The host issues a BDM NOP command.
3. The host reads the channel status using a READ_XCSR_BYTE command.
4. If XCSR[CSTAT] is 000

then the status is okay; proceed

else

Halt the CPU using a BDM BACKGROUND command

Repeat steps 1,2,3

If XCSR[CSTAT] is 000, then proceed, else reset the device

The following figure shows a SYNC command aborting a READ_MEM.B. After the command is aborted, a new command could be issued by the host.

Note

In the following figure, signal timing is not drawn to scale.

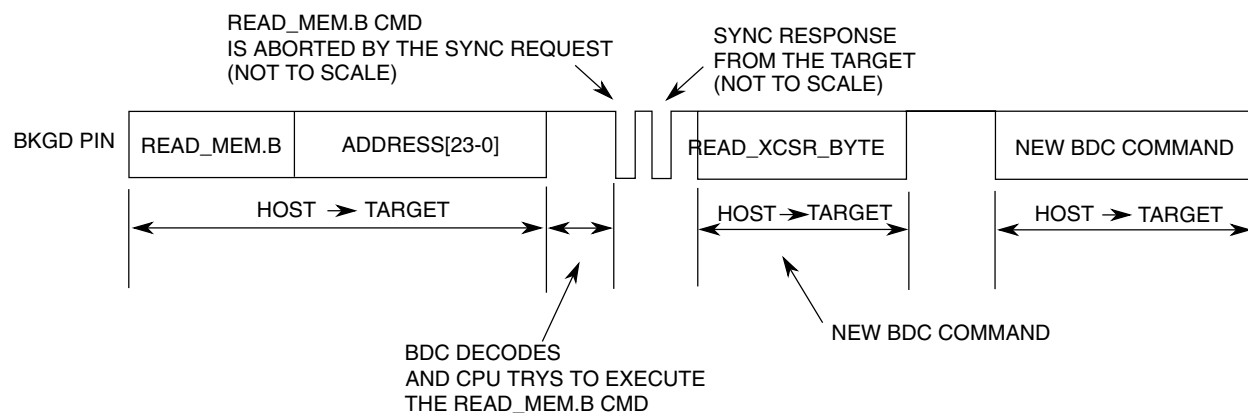

Figure 46-9. ACK Abort Procedure at the Command Level

The following figure shows a conflict between the ACK pulse and the sync request pulse. This conflict could occur if a pod device is connected to the target BKGD pin and the target is already executing a BDC command. Consider that the target CPU is executing a pending BDC command at the exact moment the pod is being connected to the BKGD pin. In this case, an ACK pulse is issued at the same time as the SYNC command. In this case there is an electrical conflict between the ACK speedup pulse and the sync pulse. Because this is not a probable situation, the protocol does not prevent this conflict from happening.

Figure 46-10. ACK Pulse and SYNC Request Conflict

The hardware handshake protocol is enabled by the `ACK_ENABLE` command and disabled by the `ACK_DISABLE` command. It also allows for pod devices to choose between the hardware handshake protocol or the software protocol that monitors the XCSR status byte. The `ACK_ENABLE` and `ACK_DISABLE` commands are:

Functional Description

- **ACK_ENABLE** — Enables the hardware handshake protocol. The target issues the ACK pulse when a CPU command is executed. The **ACK_ENABLE** command itself also has the ACK pulse as a response.
- **ACK_DISABLE** — Disables the ACK pulse protocol. In this case, the host should verify the state of **XCSR[CSTAT]** to evaluate if there are pending commands and to check if the CPU's operating state has changed to or from active background mode via **XCSR[31–30]**.

The default state of the protocol, after reset, is hardware handshake protocol disabled.

The commands that do not require CPU execution, or that have the status register included in the retrieved bit stream, do not perform the hardware handshake protocol. Therefore, the target does not respond with an ACK pulse for those commands even if the hardware protocol is enabled. Conversely, only commands that require CPU execution and do not include the status byte perform the hardware handshake protocol. See the third column in [Table 46-40](#) for the complete enumeration of this function.

An exception is the **ACK_ENABLE** command, which does not require CPU execution but responds with the ACK pulse. This feature can be used by the host to evaluate if the target supports the hardware handshake protocol. If an ACK pulse is issued in response to this command, the host knows that the target supports the hardware handshake protocol. If the target does not support the hardware handshake protocol the ACK pulse is not issued. In this case, the **ACK_ENABLE** command is ignored by the target, because it is not recognized as a valid command.

46.4.2 Real-Time Debug Support

The ColdFire family supports debugging real-time applications. For these types of embedded systems, the processor must continue to operate during debug. The foundation of this area of debug support is that while the processor cannot be halted to allow debugging, the system can generally tolerate the small intrusions with minimal effect on real-time operation.

Note

The details regarding real-time debug support will be supplied at a later time.

46.4.3 Trace Support

For the baseline V1 ColdFire core and its single debug signal, support for trace functionality is completely redefined. The V1 solution provides an on-chip PST/DDATA trace buffer (known as the PSTB) to record the stream of PST and DDATA values.

As a review, the classic ColdFire debug architecture supports real-time trace via the PST/DDATA output signals. For this functionality, the following apply:

- One (or more) PST value is generated for each executed instruction
- Branch target instruction address information is displayed on all non-PC-relative change-of-flow instructions, where the user selects a programmable number of bytes of target address
 - Displayed information includes PST marker plus target instruction address as DDATA
 - Captured address creates the appropriate number of DDATA entries, each with 4 bits of address
- Optional data trace capabilities are provided for accesses mapped to the slave peripheral bus
 - Displayed information includes PST marker plus captured operand value as DDATA
 - Captured operand creates the appropriate number of DDATA entries, each with 4 bits of data

The resulting PST/DDATA output stream, with the application program memory image, provides an instruction-by-instruction dynamic trace of the execution path.

Even with the application of a PST trace buffer, problems associated with the PST bandwidth and associated fill rate of the buffer remain. Given that there is one (or more) PST entry per instruction, the PSTB would fill rapidly without some type of data compression.

Consider the following example to illustrate the PST compression algorithm. Most sequential instructions generate a single $PST = 1$ value. Without compression, the execution of ten sequential instructions generates a stream of ten $PST = 1$ values. With PST compression, the reporting of any $PST = 1$ value is delayed so that consecutive $PST = 1$ values can be accumulated. When a $PST \neq 1$ value is reported, the maximum accumulation count is reached, or a debug data value is captured, a single accumulated

Functional Description

PST value is generated. Returning to the example with compression enabled, the execution of ten sequential instructions generates a single PST value indicating ten sequential instructions have been executed.

This technique has proven to be effective at significantly reducing the average PST entries per instruction and PST entries per machine cycle. The application of this compression technique makes the application of a useful PST trace buffer for the V1 ColdFire core realizable. The resulting 5-bit PST definitions are shown in the following table.

Table 46-41. CF1 Debug Processor Status Encodings

PST[4:0]	Definition
0x00	Continue execution. Many instructions execute in one processor cycle. If an instruction requires more processor clock cycles, subsequent clock cycles are indicated by driving PST with this encoding.
0x01	Begin execution of one instruction. For most instructions, this encoding signals the first processor clock cycle of an instruction's execution. Certain change-of-flow opcodes, plus the PULSE and WDDATA instructions, generate different encodings.
0x02	Reserved
0x03	Entry into user-mode. Signaled after execution of the instruction that caused the ColdFire processor to enter user mode.
0x04	Begin execution of PULSE and WDDATA instructions. PULSE defines triggers or markers for debug and/or performance analysis. WDDATA lets the core write any operand (byte, word, or longword) directly to the DDATA port, independent of debug module configuration. When WDDATA is executed, a value of 0x04 is signaled on the PST port, followed by the appropriate marker, and then the data transfer on the DDATA port. The number of captured data bytes depends on the WDDATA operand size.
0x05	Begin execution of taken branch or SYNC_PC BDM command. For some opcodes, a branch target address may be displayed on DDATA depending on the CSR settings. CSR also controls the number of address bytes displayed, indicated by the PST marker value preceding the DDATA nibble that begins the data output. This encoding also indicates that the SYNC_PC command has been processed.
0x06	Reserved
0x07	Begin execution of return from exception (RTE) instruction.
0x08–0x0B	Indicates the number of data bytes to be loaded into the PST trace buffer. The capturing of peripheral bus data references is controlled by CSR[DDC]. 0x08 Begin 1-byte data transfer on DDATA 0x09 Begin 2-byte data transfer on DDATA 0x0A Reserved 0x0B Begin 4-byte data transfer on DDATA
0x0C–0x0F	Indicates the number of address bytes to be loaded into the PST trace buffer. The capturing of branch target addresses is controlled by CSR[BTB]. 0x0C Reserved 0x0D Begin 2-byte address transfer on DDATA (Displayed address is shifted right 1: ADDR[16:1]) 0x0E Begin 3-byte address transfer on DDATA (Displayed address is shifted right 1: ADDR[23:1]) 0x0F Reserved
0x10–0x11	Reserved
0x12	Completed execution of 2 sequential instructions

Table continues on the next page...

Table 46-41. CF1 Debug Processor Status Encodings (continued)

PST[4:0]	Definition
0x13	Completed execution of 3 sequential instructions
0x14	Completed execution of 4 sequential instructions
0x15	Completed execution of 5 sequential instructions
0x16	Completed execution of 6 sequential instructions
0x17	Completed execution of 7 sequential instructions
0x18	Completed execution of 8 sequential instructions
0x19	Completed execution of 9 sequential instructions
0x1A	Completed execution of 10 sequential instructions
0x1B	This value signals there has been a change in the breakpoint trigger state machine. It appears as a single marker for each state change and is immediately followed by a DDATA value signaling the new breakpoint trigger state encoding. The DDATA breakpoint trigger state value is defined as $(0x20 + 2 \times \text{CSR}[\text{BSTAT}])$: 0x20 No breakpoints enabled 0x22 Waiting for a level-1 breakpoint 0x24 Level-1 breakpoint triggered 0x2A Waiting for a level-2 breakpoint 0x2C Level-2 breakpoint triggered
0x1C	Exception processing. This value signals the processor has encountered an exception condition. Although this is a multi-cycle mode, there are only two PST = 0x1C values recorded before the mode value is suppressed.
0x1D	Emulator mode exception processing. This value signals the processor has encountered a debug interrupt or a properly-configured trace exception. Although this is a multi-cycle mode, there are only two PST = 0x1D values recorded before the mode value is suppressed.
0x1E	Processor is stopped. This value signals the processor has executed a STOP instruction. Although this is a multi-cycle mode because the ColdFire processor remains stopped until an interrupt or reset occurs, there are only two PST = 0x1E values recorded before the mode value is suppressed.
0x1F	Processor is halted. This value signals the processor has been halted. Although this is a multi-cycle mode because the ColdFire processor remains halted until a BDM go command is received or reset occurs, there are only two PST = 0x1F values recorded before the mode value is suppressed.

46.4.3.1 Begin Execution of Taken Branch (PST = 0x05)

The PST is 0x05 when a taken branch is executed. For some opcodes, a branch target address may be loaded into the trace buffer (PSTB) depending on the CSR settings. CSR also controls the number of address bytes loaded that is indicated by the PST marker value immediately preceding the DDATA entry in the PSTB that begins the address entries.

Multiple byte DDATA values are displayed in least-to-most-significant order. The processor captures only those target addresses associated with taken branches that use a variant addressing mode (RTE and RTS instructions, JMP and JSR instructions using address register indirect or indexed addressing modes, and all exception vectors).

The simplest example of a branch instruction using a variant address is the compiled code for a C language case statement. Typically, the evaluation of this statement uses the variable of an expression as an index into a table of offsets, where each offset points to a unique case within the structure. For such change-of-flow operations, the ColdFire processor loads the PSTB as follows:

1. Load PST=0x05 to identify that a taken branch is executed.
2. Optionally load the marker for the target address capture. Encodings 0x0D or 0x0E identify the number of bytes loaded into the PSTB.
3. The new target address is optionally available in the PSTB. The number of bytes of the target address loaded is configurable (2 or 3 bytes, where the encoding is 0x0D and 0x0E, respectively).

Another example of a variant branch instruction is a JMP (A0) instruction. The following figure shows the PSTB entries that indicate a JMP (A0) execution, assuming CSR[BTB] was programmed to display the lower two bytes of an address.

PST/DDATA Values	Description
0x05	Taken Branch
0x0D	2-byte Address Marker
{10, Address[4:1]}	Address >> 1
{10, Address[8:5]}	
{10, Address[12:9]}	
{10, Address[16:13]}	

Figure 46-11. Example JMP Instruction Output in PSTB

The PST of 0x05 indicates a taken branch and the marker value 0x0D indicates a 2-byte address. Therefore, the following entries display the lower two bytes of address register A0, right-shifted by 1, in least-to-most-significant nibble order. The next PST entry after the JMP instruction completes depends on the target instruction. See [PST Trace Buffer \(PSTB\) Entry Format](#), for entry descriptions explaining the 2-bit prefix before each address nibble.

46.4.3.2 PST Trace Buffer (PSTB) Entry Format

As PST and DDATA values are captured and loaded in the trace buffer, each entry is six bits in size therefore, the type of the entry can easily be determined when post-processing the PSTB.

¹ Depending on which nibble is displayed (as determined by SDR[9:8]), Address [3:0] displays four bits of the real CPU address [16:1] or [24:1].

Figure 46-12. V1 PST/DDATA Trace Buffer Entry Format

46.4.3.3 PST/DDATA Example

In this section, an example showing the behavior of the PST/DDATA functionality is detailed. Consider the following interrupt service routine that counts the interrupt, negates the IRQ, performs a software IACK, and then exits. This example is presented here because it exercises a considerable set of the PST/DDATA capabilities.

```

_isr:
01074: 46fc 2700    mov.w    &0x2700,%sr        # disable interrupts
01078: 2f08         mov.l    %a0,-(%sp)         # save a0
0107a: 2f00         mov.l    %d0,-(%sp)         # save d0
0107c: 302f 0008    mov.w    (8,%sp),%d0        # load format/vector word
01080: e488         lsr.l    &2,%d0             # align vector number
01082: 0280 0000 00ff andi.l   &0xff,%d0          # isolate vector number
01088: 207c 0080 1400 mov.l    &int_count,%a0     # base of interrupt counters

_isr_entry1:
0108e: 52b0 0c00    addq.l   &1,(0,%a0,%d0.l*4) # count the interrupt
01092: 11c0 a021    mov.b    %d0,IGCR0+1.w      # negate the irq
01096: 1038 a020    mov.b    IGCR0.w,%d0        # force the write to complete
0109a: 4e71         nop                          # synchronize the pipelines
0109c: 71b8 ffe0    mvz.b    SWIACK.w,%d0       # software iack: pending irq?
010a0: 0c80 0000 0041 cmpi.l   %d0,&0x41          # level 7 or none pending?
010a6: 6f08         ble.b    _isr_exit          # yes, then exit
010a8: 52b9 0080 145c addq.l   &1,swiack_count     # increment the swiack count
010ae: 60de         bra.b    _isr_entry1        # continue at entry1

_isr_exit:
010b0: 201f         mov.l    (%sp)+,%d0         # restore d0
010b2: 205f         mov.l    (%sp)+,%a0         # restore a0
010b4: 4e73         rte                          # exit

```

This ISR executes mostly as straight-line code: there is a single conditional branch @ PC = 0x10A6, which is taken in this example. The following description includes the PST and DDATA values generated as this code snippet executes. In this example, the CSR setting enables only the display of 2-byte branch addresses. Operand data captures are not enabled. The sequence begins with an interrupt exception:

```

interrupt exception occurs @ pc = 5432 while in user mode
# pst   = 1c, 1c, 05, 0d
# ddata = 2a, 23, 28, 20

```

Functional Description

```

#           trg_addr = 083a << 1
#           trg_addr = 1074
_isr:
01074: 46fc 2700      mov.w   &0x2700,%sr      # pst = 01
01078: 2f08        mov.l   %a0,-(%sp)      # pst = 01
0107a: 2f00        mov.l   %d0,-(%sp)      # pst = 01
0107c: 302f 0008      mov.w   (8,%sp),%d0     # pst = 01
01080: e488        lsr.l   &2,%d0          # pst = 01
01082: 0280 0000 00ff  andi.l  &0xff,%d0        # pst = 01
01088: 207c 0080 1400  mov.l   &int_count,%a0  # pst = 01
0108e: 52b0 0c00      addq.l  &1,(0,%a0,%d0.1*4) # pst = 01
01092: 11c0 a021      mov.b   %d0,IGCR0+1.w   # pst = 01, 08c
#           ddata = 30, 30
#           wdata.b = 0x00
01096: 1038 a020      mov.b   IGCR0.w,%d0     # pst = 01, 08
#           ddata = 28, 21
#           rdata.b = 0x18
0109a: 4e71        nop                    # pst = 01
0109c: 71b8 ffe0      mvz.b   SWIACK.w,%d0    # pst = 01, 08
#           ddata = 20, 20
#           rdata.b = 0x00
010a0: 0c80 0000 0041  cmpi.l  %d0,&0x41        # pst = 01
010a6: 6f08        ble.b   _isr_exit       # pst = 05 (taken branch)
010b0: 201f        mov.l   (%sp)+,%d0     # pst = 01
010b2: 205f        mov.l   (%sp)+,%a0     # pst = 01
010b4: 4e73        rte                    # pst = 07, 03, 05, 0d
#           ddata = 29, 21, 2a, 22
#           trg_addr = 2a19 << 1
#           trg_addr = 5432
```

As the PSTs are compressed, the resulting stream of 6-bit hexadecimal entries is loaded into consecutive locations in the PST trace buffer:

```
PSTB[*]= 1c, 1c, 05, 0d, // interrupt exception
         2a, 23, 28, 20, // branch target addr = 1074
         1a,           // 10 sequential insts
         13,           // 3 sequential insts
         05, 12,      // taken_branch + 2 sequential
         07, 03, 05, 0d, // rte, entry into user mode
         29, 21, 2a, 22 // branch target addr = 5432
```

Architectural studies on the compression algorithm determined an appropriate size for the PST trace buffer. Using a suite of ten MCU benchmarks, a 64-entry PSTB was found to capture an average window of time of 520 processor cycles with program trace using 2-byte addresses enabled.

46.4.3.4 Processor Status, Debug Data Definition

This section specifies the ColdFire processor and debug module's generation of the processor status (PST) and debug data (DDATA) output on an instruction basis. In general, the PST/DDATA output for an instruction is defined as follows:

PST = 0x01, {PST = 0x0[89B], DDATA = operand}

where the {...} definition is optional operand information defined by the setting of the CSR, and [...] indicates the presence of one value from the list.

The CSR provides capabilities to display operands based on reference type (read, write, or both). A PST value {0x08, 0x09, or 0x0B} identifies the size and presence of valid data to follow in the PST trace buffer (PSTB) {1, 2, or 4 bytes, respectively}.

Additionally, CSR[DDC] specifies whether operand data capture is enabled and what size. Also, for certain change-of-flow instructions, CSR[BTB] provides the capability to display the target instruction address in the PSTB (2 or 3 bytes) using a PST value of 0x0D or 0x0E, respectively.

46.4.3.4.1 User Instruction Set

The following table shows the PST/DDATA specification for user-mode instructions. Rn represents any {Dn, An} register. In this definition, the y suffix generally denotes the source, and x denotes the destination operand. For a given instruction, the optional operand data is displayed only for those effective addresses referencing memory. The DD nomenclature refers to the DDATA outputs.

Table 46-42. PST/DDATA Specification for User-Mode Instructions

Table continues on the next page...

Table 46-42. PST/DDATA Specification for User-Mode Instructions (continued)

Instruction	Operand Syntax	PST/DDATA
tst.l	<ea>y	PST = 0x01, {PST = 0x0B, DD = source operand}
tst.w	<ea>y	PST = 0x01, {PST = 0x09, DD = source operand}
unlk	Ax	PST = 0x01, {PST = 0x0B, DD = destination operand}
wddata.b	<ea>y	PST = 0x04, {PST = 0x08, DD = source operand}
wddata.l	<ea>y	PST = 0x04, {PST = 0x0B, DD = source operand}
wddata.w	<ea>y	PST = 0x04, {PST = 0x09, DD = source operand}

1. During normal exception processing, the PSTB is loaded with two successive 0x1C entries indicating the exception processing state. The exception stack write operands, as well as the vector read and target address of the exception handler may also be displayed.

```
Exception Processing:
PST = 0x1C, 0x1C,
{PST = 0x0B, DD = destination}, // stack frame
{PST = 0x0B, DD = destination}, // stack frame
{PST = 0x0B, DD = source}, // vector read
PST = 0x05, {PST = 0x0[DE], DD = target} // handler PC
```

A similar set of PST/DD values is generated in response to an emulator mode excetion. For these events (caused by a debug interrupt or properly-enabled trace exception), the initial PST values are 0x1D, 0x1D and the remaining sequence is equivalent to normal exception processing. The PST/DDATA specification for the reset exception is shown below:

```
Exception Processing:
PST = 0x1C, 0x1C,
PST = 0x05, {PST = 0x0[DE], DD = target} // initial PC
```

The initial references at address 0 and 4 are never captured nor displayed because these accesses are treated as instruction fetches. For all types of exception processing, the PST = 0x1C (or 0x1D) value is driven for two trace buffer entries.

2. For JMP and JSR instructions, the optional target instruction address is displayed only for those effective address fields defining variant addressing modes. This includes the following <ea>x values: (An), (d16,An), (d8,An,Xi), (d8,PC,Xi).

Table 46-43 shows the PST/DDATA specification for the MAC instructions if the optional MAC unit is present.

Table 46-43. PST/DDATA Values for Multiply-Accumulate Instructions

Instruction	Operand Syntax	PST/DDATA
mac.l	Ry,Rx	PST = 0x1
mac.l	Ry,Rx,<ea>y,Rw	PST = 0x1, {PST = 0xB, DD = source operand}
mac.w	Ry,Rx	PST = 0x1
mac.w	Ry,Rx,ea,Rw	PST = 0x1, {PST = 0xB, DD = source operand}
move.l	{Ry,#<data>},ACC	PST = 0x1
move.l	{Ry,#<data>},MACSR	PST = 0x1
move.l	{Ry,#<data>},MASK	PST = 0x1
move.l	ACC,Rx	PST = 0x1
move.l	MACSR,CCR	PST = 0x1

Table continues on the next page...

Table 46-43. PST/DDATA Values for Multiply-Accumulate Instructions (continued)

Instruction	Operand Syntax	PST/DDATA
move.l	MACSR,Rx	PST = 0x1
move.l	MASK,Rx	PST = 0x1
msac.l	Ry,Rx	PST = 0x1
msac.l	Ry,Rx,<ea>y,Rw	PST = 0x1, {PST = 0xB, DD = source}, {PST = 0xB, DD = destination}
msac.w	Ry,Rx	PST = 0x1
msac.w	Ry,Rx,<ea>y,Rw	PST = 0x1, {PST = 0xB, DD = source}, {PST = 0xB, DD = destination}

46.4.3.4.2 Supervisor Instruction Set

The supervisor instruction set has complete access to the user mode instructions plus the opcodes shown below. The PST/DDATA specification for these opcodes is shown in the following table.

Table 46-44. PST/DDATA Specification for Supervisor-Mode Instructions

Instruction	Operand Syntax	PST/DDATA
halt		PST = 0x1F, PST = 0x1F
move.l	Ay,USP	PST = 0x01
move.l	USP,Ax	PST = 0x01
move.w	SR,Dx	PST = 0x01
move.w	{Dy,#<data>},SR	PST = 0x01, {PST = 0x03}
movec.l	Ry,Rc	PST = 0x01
rte		PST = 0x07, {PST = 0x0B, DD = source operand}, {PST = 0x03}, {PST = 0x0B, DD = source operand}, PST = 0x05, {PST = 0x0[DE], DD = target address}
stldsr.w	#imm	PST = 0x01, {PST = 0x0B, DD = destination operand, PST = 0x03}
stop	#<data>	PST = 0x1E, PST = 0x1E
wdebug.l	<ea>y	PST = 0x01, {PST = 0x0B, DD = source, PST = 0x0B, DD = source}

The move-to-SR, STLDSR, and RTE instructions include an optional PST = 0x3 value, indicating an entry into user mode.

Similar to the exception processing mode, the stopped state (PST = 0x1E) and the halted state (PST = 0x1F) display this status for two entries when the ColdFire processor enters the given mode.

46.4.4 Freescale-Recommended BDM Pinout

Typically, a relatively simple interface pod is used to translate commands from a host computer into commands for the custom serial interface to the single-wire background debug system. Depending on the development tool vendor, this interface pod may use a standard RS-232 serial port, a parallel printer port, or some other type of communications such as a universal serial bus (USB) to communicate between the host PC and the pod. The pod typically connects to the target system with ground, the BKGD pin, RESET, and sometimes V_{DD} . An open-drain connection to reset allows the host to force a target system reset, useful to regain control of a lost target system or to control startup of a target system before the on-chip nonvolatile memory has been programmed. Sometimes V_{DD} can be used to allow the pod to use power from the target system to avoid the need for a separate power supply. However, if the pod is powered separately, it can be connected to a running target system without forcing a target system reset or otherwise disturbing the running application program.

Figure 46-13. Recommended BDM Connector

Appendix A

Release Notes

A.1 About This Document chapter changes

- No substantial content changes

A.2 Introduction chapter changes

- Removed references to discontinued QF and QH families

A.3 Chip Configuration chapter changes

- No substantial content changes

A.4 Memory Map chapter changes

- Added the new section "Read-after-write sequence and required serialization of memory operations"

A.5 Clock Distribution chapter changes

- No substantial content changes

A.6 Reset and Boot chapter changes

- No substantial content changes

A.7 Power Management chapter changes

- No substantial content changes

A.8 Security chapter changes

- No substantial content changes

A.9 Signal Multiplexing and Signal Descriptions chapter changes

- No substantial content changes

A.10 MXC changes

- No substantial content changes

A.11 V1 ColdFire Core changes

- No substantial content changes

A.12 EMAC changes

- No substantial content changes

A.13 SIM changes

- No substantial content changes

A.14 Crossbar switch module changes

- No substantial content changes

A.15 INTC V1 changes

- Removed the unnecessary section "Device-Specific Exception and Interrupt Vector Tables" because the information is not included in this chapter.
- In the "Interrupt Request Level and Priority Assignments" section, revised the description of the location of information.

A.16 LLWU changes

- No substantial content changes

A.17 RCM changes

- No substantial content changes

A.18 SMC changes

- For the RUN to VLPR transition trigger conditions in the "Power mode transition triggers" table, removed the specific maximum frequency numbers and made a reference to the chip-specific Power Management chapter.

A.19 PMC changes

- No substantial content changes

A.20 VREG changes

- Removed the number specified for the STANDBY regulator output load current.
- Corrected the figure "Ideal Relation Between the Regulator Output and Input Power Supply".

A.21 DMA Controller changes

- Reorganized the description of DSR_BCR[CE].
- Throughout: Changed "byte, word, longword" references to "8-bit, 16-bit, 32-bit" or "1-byte, 2-byte, 4-byte"
- In the "Programming the DMA Controller Module" section:
 - Clarified the cautionary note about programming the DMA module's registers during channel execution
 - Under the list item "TCD n is initialized": subordinated multiple subsequent list items
- In the "Advanced Data Transfer Controls: Auto-Alignment" section's example description: Reorganized the sample register/bitfield values as a list

A.22 MCG changes

- For the IRCST field in the MCG Status Register, changed references to the fast clock from "fast clock (2 MHz IRC)" to "fast clock (4 MHz IRC)".

A.23 OSC changes

- No substantial content changes

A.24 FMC changes

- No substantial content changes

A.25 FTFL changes

- Improved flash reliability specs per module certification results
- Fix Flash Command note to indicate that FlexRAM or Programming Acceleration RAM is used during PGMSEC command for all devices

A.26 Mini-FlexBus changes

- Minor editorial changes and reorganization of sections:
 - Many sections were divided into multiple subsections.
 - Changed “Overview” section name to “Definition.”
 - Moved data from signal description subsections into the signal description table.
 - Removed “Chip Select Operation” section.
 - Moved “Modes of operation” section to “Functional description” section.
 - Combined “Bus Cycle execution” and data transfer cycle states sections into the “Data transfer states” section.
- Changed the Note in the CSMR[V] bitfield description to say: "At reset, $\overline{\text{FB_CS0}}$ will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed."

A.27 EzPort changes

- No substantial content changes

A.28 CRC changes

No substantial content changes

A.29 ADC changes

- In ADC Signal Descriptions section: Added note to refer to chip configuration for inputs supported.

A.30 CMP changes

- Updated SE value in 'Sampled, Filtered (# 4B): Sampling point internally derived' diagram.

A.31 DAC changes

- No substantial content changes

A.32 VREF changes

- No substantial content changes

A.33 PDB changes

In the memory map, changed Channel n Status Register access to R/W.

A.34 MTIM changes

- No substantial content changes

A.35 LPTMR changes

Updated the following sentence: "If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set."

A.36 CMT changes

- No substantial content changes

A.37 FTM changes

- No substantial content changes

A.38 SPI changes

- No substantial content changes

A.39 I2C changes

<ul style="list-style-type: none"> • In description of F[ICR], added new final sentence and table containing examples of MULT and ICR field settings. • In description of C2[SBRC], added sentence describing an example of a "very fast" I2C mode. • In "Clock stretching" section, added new final sentence to clarify the effect of clock stretching.
<ul style="list-style-type: none"> • Clarified that the reserved bit 7 of the Programmable Input Glitch Filter register can be written but that writing it has no effect. • In the "SCL high timeout" section, removed references to detection of a HIGH timeout after a STOP condition appears on the bus. • Reorganized the "Address matching wakeup" section, and added in the final note the sentence "The main purpose is not communication."
<ul style="list-style-type: none"> • Reorganized the "Address matching" section, and clarified the sources of a 7-bit and 10-bit address, including the involvement of ADEXT and AD[10:8] in Control Register 2.
<ul style="list-style-type: none"> • In "Address matching wakeup" section: Combined the two notes and expanded the note text
<ul style="list-style-type: none"> • In the Status register: Added added a new note to the description of the RAM bit • In the "Address matching wakeup" section: Clarified the note text
<ul style="list-style-type: none"> • In "I2C divider and hold values" section: Added note preceding the table, and shaded table cells containing ICR values of 00h to 0Fh

A.40 UART changes

<ul style="list-style-type: none"> • No substantial content changes
--

A.41 RGPIO changes

<ul style="list-style-type: none"> • In "Initialization Information" section, revised sequence and text of list items.

A.42 EGPIO changes

<ul style="list-style-type: none"> • No substantial content changes
--

A.43 Port Control changes

<ul style="list-style-type: none"> • No substantial content changes
--

A.44 TSI changes

- No substantial content changes

A.45 IRQ changes

- In "Exit from Low-Power Modes" section: standardized references to low-power modes, and, in second sentence, changed "low" to "asserted"
- In "Stop modes" section: Changed "stop mode" to "stop modes," and revised first sentence

A.46 Debug changes

- In table of "Overview" section: added row for debug revision CF1_B+_no_PSTB
- In the "Program Counter Breakpoint/Mask Registers (PBR0–3, PBMR)" section: In the Note preceding the PBR0 diagram and table, simplified the final sentence
