## NPN SILICON TRANSISTOR

### SWITCHMODE SERIES NPN SILICON POWER TRANSISTORS

■ DESCRIPTION

The **MJE13009-K** is designed for high-voltage, high-speed power switching inductive circuits where fall time is critical. They are particularly suited for 115 and 220V switch mode applications such as Switching Regulators, Inverters, Motor Controls, Solenoid/Relay drivers and Deflection circuits.

■ FEATURES

- \*  $V_{CE0}$  400V and 300 V
- \* Reverse Bias SOA with Inductive Loads @  $T_C = 100^\circ\text{C}$
- \* Inductive Switching Matrix 3 ~ 12 Amp, 25 and  $100^\circ\text{C}$   
 $t_c @ 8 \text{ A}, 100^\circ\text{C}$  is 120 ns (Typ.)
- \* 700 V Blocking Capability
- \* SOA and Switching Applications Information

■ SWITCHING TIME NOTES

In resistive switching circuits, rise, fall, and storage times have been defined and apply to both current and voltage waveforms since they are in phase. However, for inductive loads which are common to SWITCHMODE power supplies and hammer drivers, current and voltage waveforms are not in phase. Therefore, separate measurements must be made on each waveform to determine the total switching time. For this reason, the following new terms have been defined.

t<sub>sv</sub> = Voltage Storage Time, 90% I<sub>B1</sub> to 10% V<sub>CEM</sub>

t<sub>rv</sub> = Voltage Rise Time, 10–90% V<sub>CEM</sub>

t<sub>fi</sub> = Current Fall Time, 90–10% I<sub>CM</sub>

t<sub>ti</sub> = Current Tail, 10–2% I<sub>CM</sub>

t<sub>c</sub> = Crossover Time, 10% V<sub>CEM</sub> to 10% I<sub>CM</sub>

An enlarged portion of the turn-off waveforms is shown in Fig. 13 to aid in the visual identity of these terms.

For the designer, there is minimal switching loss during storage time and the predominant switching power losses occur during the crossover interval and can be obtained using the standard equation from AN-222:

$$P_{SWT} = 1/2 V_{CC} I_C (t_c) f$$

Typical inductive switching waveforms are shown in Fig. 14. In general, t<sub>rv</sub> + t<sub>fi</sub> ≈ t<sub>c</sub>. However, at lower test currents this relationship may not be valid.

As is common with most switching transistors, resistive switching is specified at 25°C and has become a benchmark for designers. However, for designers of high frequency converter circuits, the user oriented specifications which make this a “SWITCHMODE” transistor are the inductive switching speeds (t<sub>c</sub> and t<sub>sv</sub>) which are guaranteed at 100°C.

## TYPICAL CHARACTERISTICS

Fig. 1 Forward Bias Safe Operating Area

Fig. 2 Reverse Bias Switching Safe Operating Area

Fig. 3 Forward Bias Power Derating

There are two limitations on the power handling ability of a transistor: average junction temperature and second breakdown. Safe operating area curves indicate  $I_c - V_{CE}$  limits of the transistor that must be observed for reliable operation; i.e., the transistor must not be subjected to greater dissipation than the curves indicate.

The data of Fig. 1 is based on  $T_C = 25^\circ\text{C}$ ;  $T_{J(PK)}$  is variable depending on power level. Second breakdown pulse limits are valid for duty cycles to 10% but must be derated when  $T_C \geq 25^\circ\text{C}$ . Second breakdown limitations do not derate the same as thermal limitations. Allowable current at the voltages shown on Fig. 1 may be found at any case temperature by using the appropriate curve on Fig. 3.

$T_{J(PK)}$  may be calculated from the data in Fig. 4. At high case temperatures, thermal limitations will reduce the power that can be handled to values less than the limitations imposed by second breakdown. Use of reverse biased safe operating area data (Fig. 2) is discussed in the applications information section.
