TABLE OF CONTENTS

Preface

Acronym for Register Type

R/W	Capable of both read and write access
RO	Read only
RC	Read only. After reading the register bank, each bit which is HIGH(1) will be cleared to LOW(0) automatically.
WO	Write only
W1S	Write only. When writing data bits to register bank, each bit which is HIGH(1) will cause the corresponding bit to be set to 1. Data bits which are LOW(0) has no effect on the corresponding bit.
W1C	Write only. When writing data bits to register bank, each bit which is HIGH(1) will cause the corresponding bit to be cleared to 0. Data bits which are LOW(0) has no effect on the corresponding bit.

1 System Overview

1.1 General Description

MT6573 is a highly integrated 3.75G baseband system-on-chip (SOC) platform which incorporates advanced features like HSPA R6 modem, 676MHz ARM11 CPU, OpenGL ES 2.0 3D graphics, 8M camera ISP, Programmable hardware video codec, and FWVGA (854x480) display. MT6573 can help phone manufacturers build high performance 3.75G smart phone with PC-like browser, 3D gaming, and cinema class home entertainment experience.

The chip integrates two ARM1176 MCUs and a powerful Dual MAC DSP processor with advanced system power management and multimedia capabilities. MT6573 interfaces to NAND flash memory and 32-bit LPDDR for optimal performance, while supporting booting from NAND to minimize overall BOM cost. In addition, an extensive set of interfaces and connectivity peripherals are included to interface to cameras, touch-screen displays, MMC/SD cards, and external Bluetooth, WiLAN, and GPS modules.

The Application Processor, an ARM1176JZFS which include a Vector Floating Point Coprocessor, offers the processing power necessary to support the latest OpenOS along with its demanding applications such as Web Browsing, Email, GPS Navigation, and Games. All while viewed on a high resolution touch screen display with graphics enhanced by the 2D and 3D Graphics OpenGL ES 2.0 acceleration. The MFlexVideo programmable multi-standard codec and an advanced audio subsystem are included to provide advanced multimedia applications and services such as Streaming audio and video, a multitude of decoders and encoders such as H.264 and MPEG-4. To enrich camera feature, MT6573 equips an 8M camera ISP with advanced features like auto focus, anti-handshake, continuous video AF, face detection, burst shot, optical zoom, panorama view and 3D photo. Other audio support includes FR, EFR, HR, and AMR vocoders, polyphonic ringtones, and advanced audio functions such as echo cancellation, hands-free speakerphone operation, and noise cancellation.

Modem subsystem built by An ARM1176JZS core, Dual MAC DSP, and EDGE/GPRS and HSPA coprocessors offers powerful capability to support Category 8 (7.2 Mbps) HSDPA downlink and Category 6 (5.76 Mbps) HSUPA uplink data rates, as well as Class 12 GPRS and EDGE.

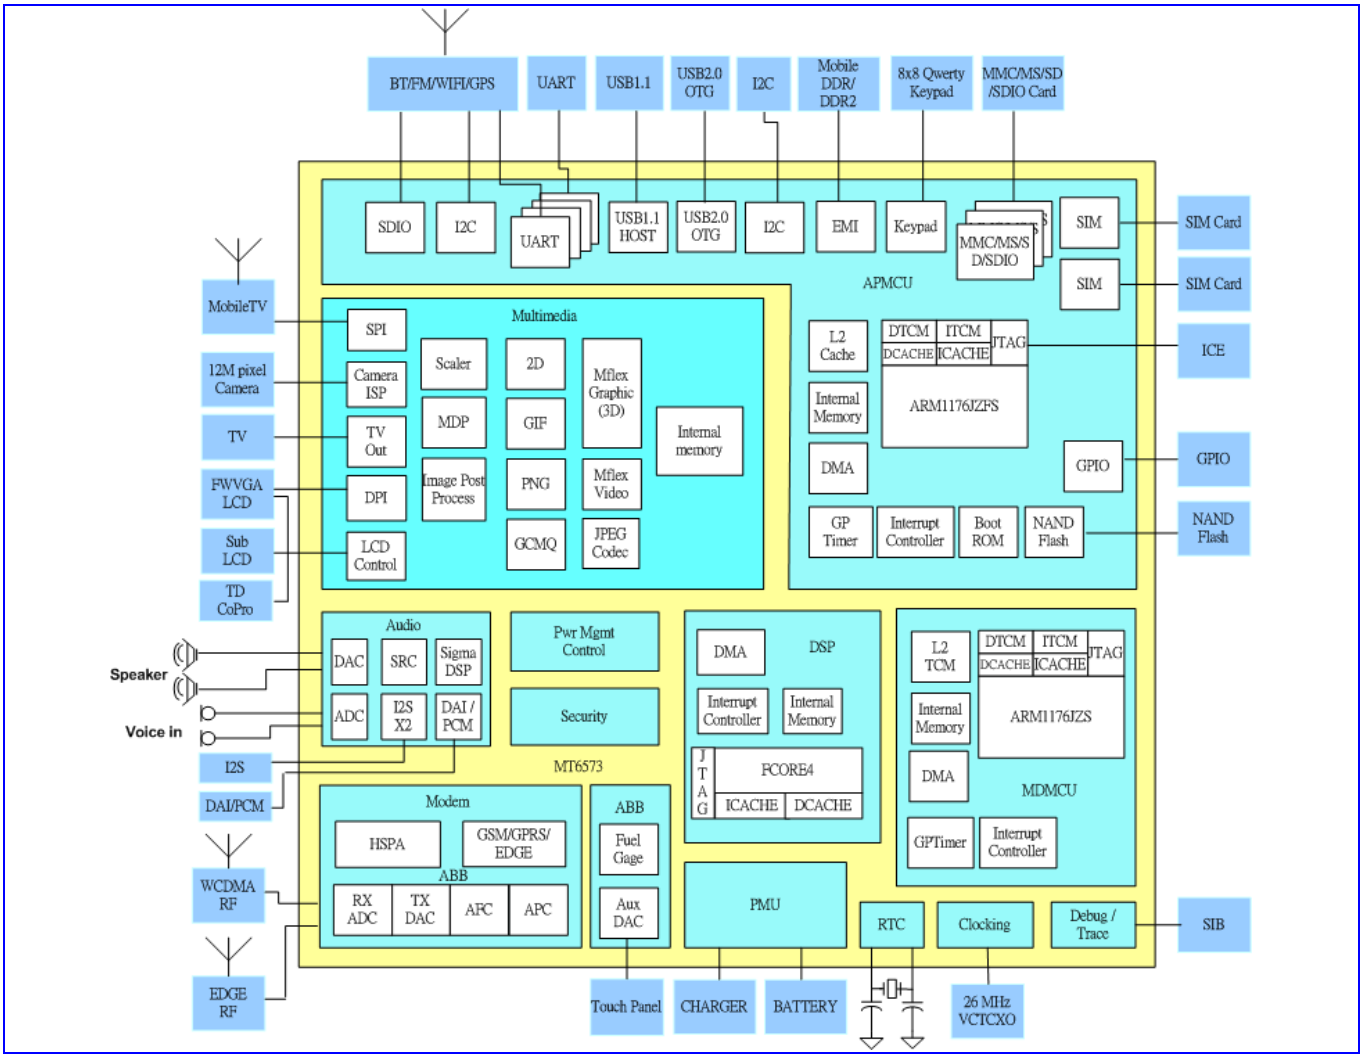

Figure 1 is the block diagram of MT6573.

Notation						

1. Any target VDD must be specified along with VDDIO combinations separately. Maximum operating frequency and operating temperature should be included for different VDD/VDDIO conditions.
2. Please specify different types of input logic level for differnet types of pins (Data/Clock/Address/Commands). Please try to converge (summary) all input logic level in one specification.
3. Leakage sensitive applications (RTC, crystal pads) senstive to this specification. Co-simulation is needed.
4. Dynamic IR drop on VDD versus IO design window must be checked before tapeout

2.4 Power on Sequence

The power-on/off sequence which is controlled by “Control” and “Reset Generator” is shown as follows,

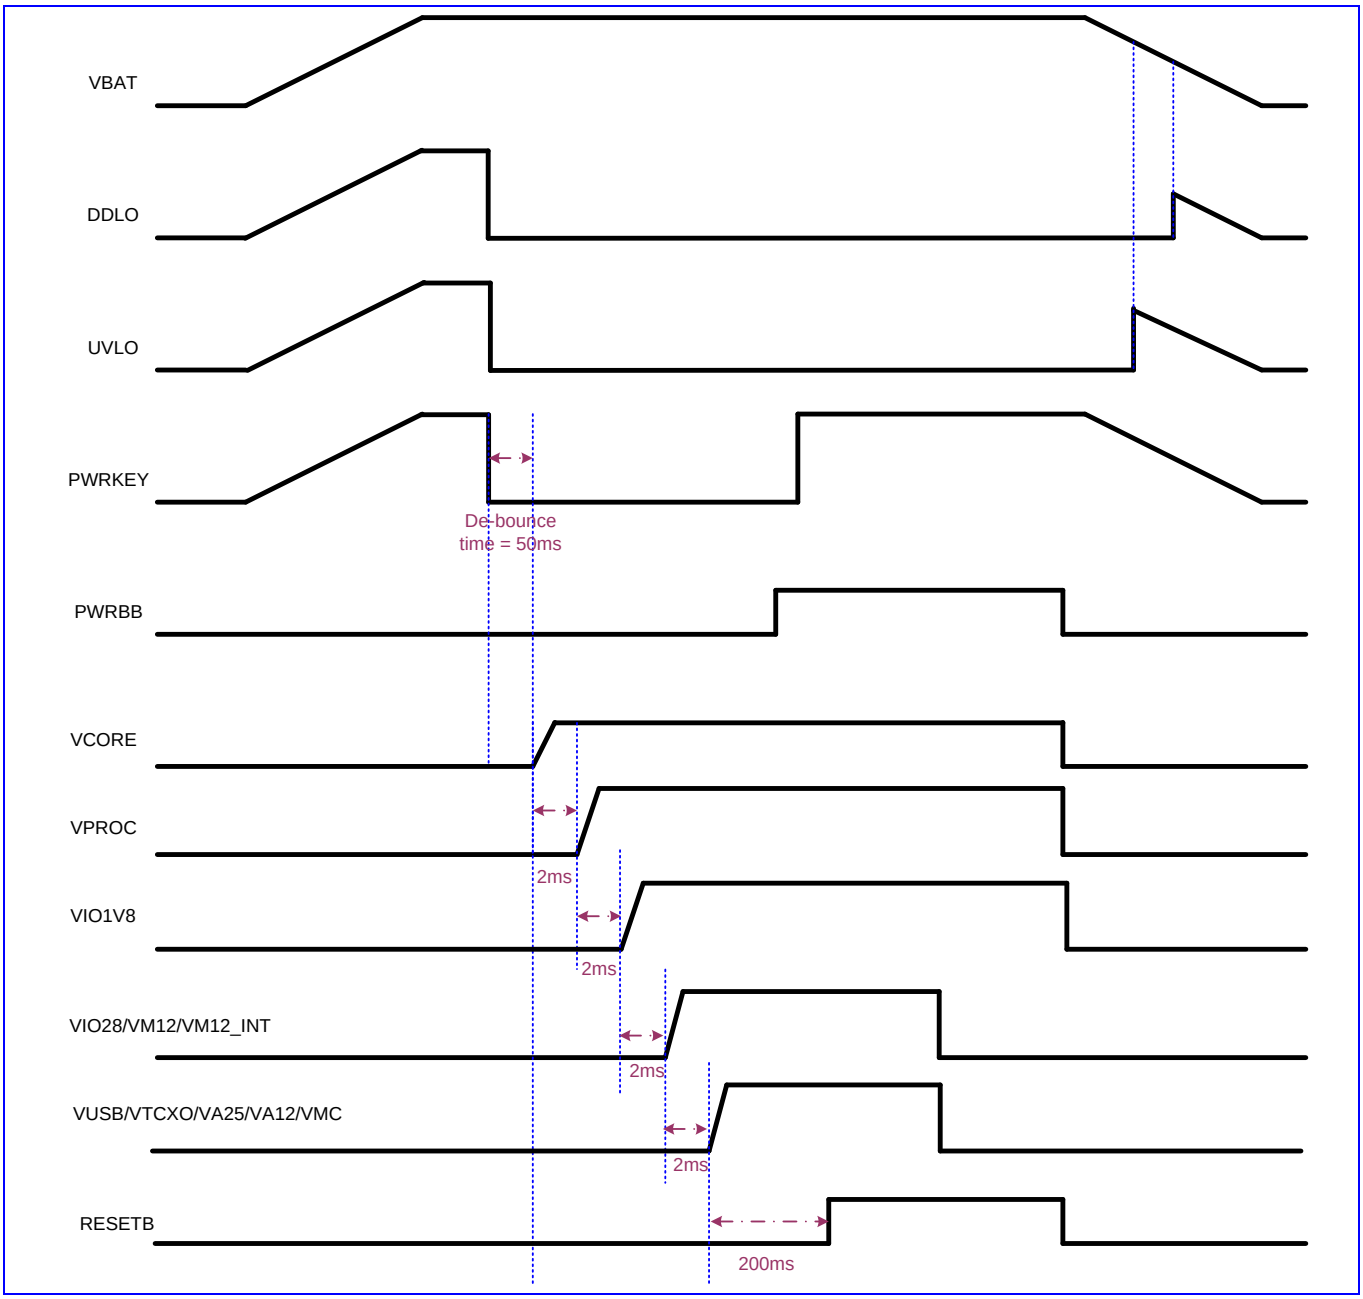

Figure 7 Power-on/off Control Sequence

Note that the above figure only shows one power-on/off condition. The MT6573 handles the powering ON and OFF of the handset. The following three different ways can switch-on the handset (When VBAT>=3.2V):

- Pulling PWRKEY low (User push PWRKEY)
- Pulling PWRBB high (Baseband BB_WakeUp)
- Valid charger plug-in

Pulling PWRKEY low is a normal way to turn on the handset. That will turn on VCORE, VPROC, VIO1V8, VIO28/VM12/VM12_INT and VUSB/VTCXO/VA25/VA12/VMC as long as the PWRKEY is kept low. The microprocessor then starts and pulls PWRBB high. After that PWRKEY can be released. Pulling PWRBB high will also turn on the handset. This is the case when the alarm in the RTC expires.

Besides, applying a valid external supply on CHRIN will also turn on the handset. However, If the battery is in UV state (VBAT<3.2V), the handset can't be turned-on in any way.

The UVLO function in the MT6573 prevents system startup when initial voltage of the main battery is below the 3.2V threshold. When the battery voltage is greater than 3.2V, the UVLO comparator switches and the threshold is reduced to 2.9V. This allows the handset to start smoothly unless the battery decays to 2.9V and below.

Once the MT6573 enters UVLO state, it draws very low quiescent current. The VRTC LDO is still active until the DDLO disables it.

2.5.3 Auxiliary ADC / Touch Screen Controller

2.5.3.1 Block Descriptions

Auxiliary ADC serves as not only measuring ADC but also the resistive touch panel controller. The auxiliary ADC includes the following functional blocks:

1. *Analog Multiplexer:* The analog multiplexer selects signal from one of the auxiliary input channels. There are 16 input channels of AuxADC. Some are for internal voltage measuring and some for external voltage measuring. Real world message to be monitored, like temperature, should be transferred to the voltage domain.
2. *12 bits A/D Converter:* The ADC converts the multiplexed input signal to 12-bit digital data.

Touch Screen controller can drive external touch panel via Pads XP, XM, YP, and YM and AuxADC as a voltage meter can obtain X/Y-position of touched point on the external touch screen. Touch Screen Interface contains three main blocks. They are touch screen pads control logic, ADC interface logic and interrupt generation logic. Touch Screen Interface supports two conversion modes: separate X/Y position conversion mode and auto (sequential) X/Y position conversion mode.

2.5.5 Clock Squarer

2.5.5.1 Block Descriptions

For most VCXO, the output clock waveform is sinusoidal with too small amplitude (about several hundred mV) to make MT65xx digital circuits function well. Clock squarer is designed to convert such a small signal to a rail-to-rail clock signal with excellent duty-cycle. It provides also a pull-down function when the circuit is powered-down.

2.5.8 AFC DAC

2.5.8.1 Block Descriptions

As shown in the following figure, AFC-DAC is designed to produce a single-ended output signal at AFC pin. AFC pin should be connected to an external 1st-order R-C low pass filter to meet the 13-bits resolution (DNL) requirement[4].

[4] DNL performance depends on external output RC filter bandwidth: the narrower the bandwidth, the better the DNL. Thus, there exists a tradeoff between output setting speed and DNL performance

2.6.2 Buck Converter

2.6.2.1 Block Description

A BUCK is a step-down DC-DC converter which is capable of maintaining low power dissipation during input to output voltage conversion.

A BUCK consists of a reference, an error amplifier, a feedback voltage divider, comparators, power MOSFETs, slope compensation and PWM/PFM mode controller. A BUCK uses the fixed-frequency, peak current-mode PWM control architecture at medium to high loads, but shifts to a PFM mode control scheme at light loads to reduce the switching power losses and improve efficiency. When the devices operate in fixed-frequency PWM mode, output regulation is achieved by controlling the duty cycle of the integrated MOSFET. When the devices operate in PFM mode, the output voltage is controlled in a hysteretic manner with higher output ripple. In this mode of operation, the regulator periodically stops switching for a few cycles, thus keeping the conversion losses minimal to improve efficiency.

2.6.3 SIM Interface

2.6.3.1 Block Description

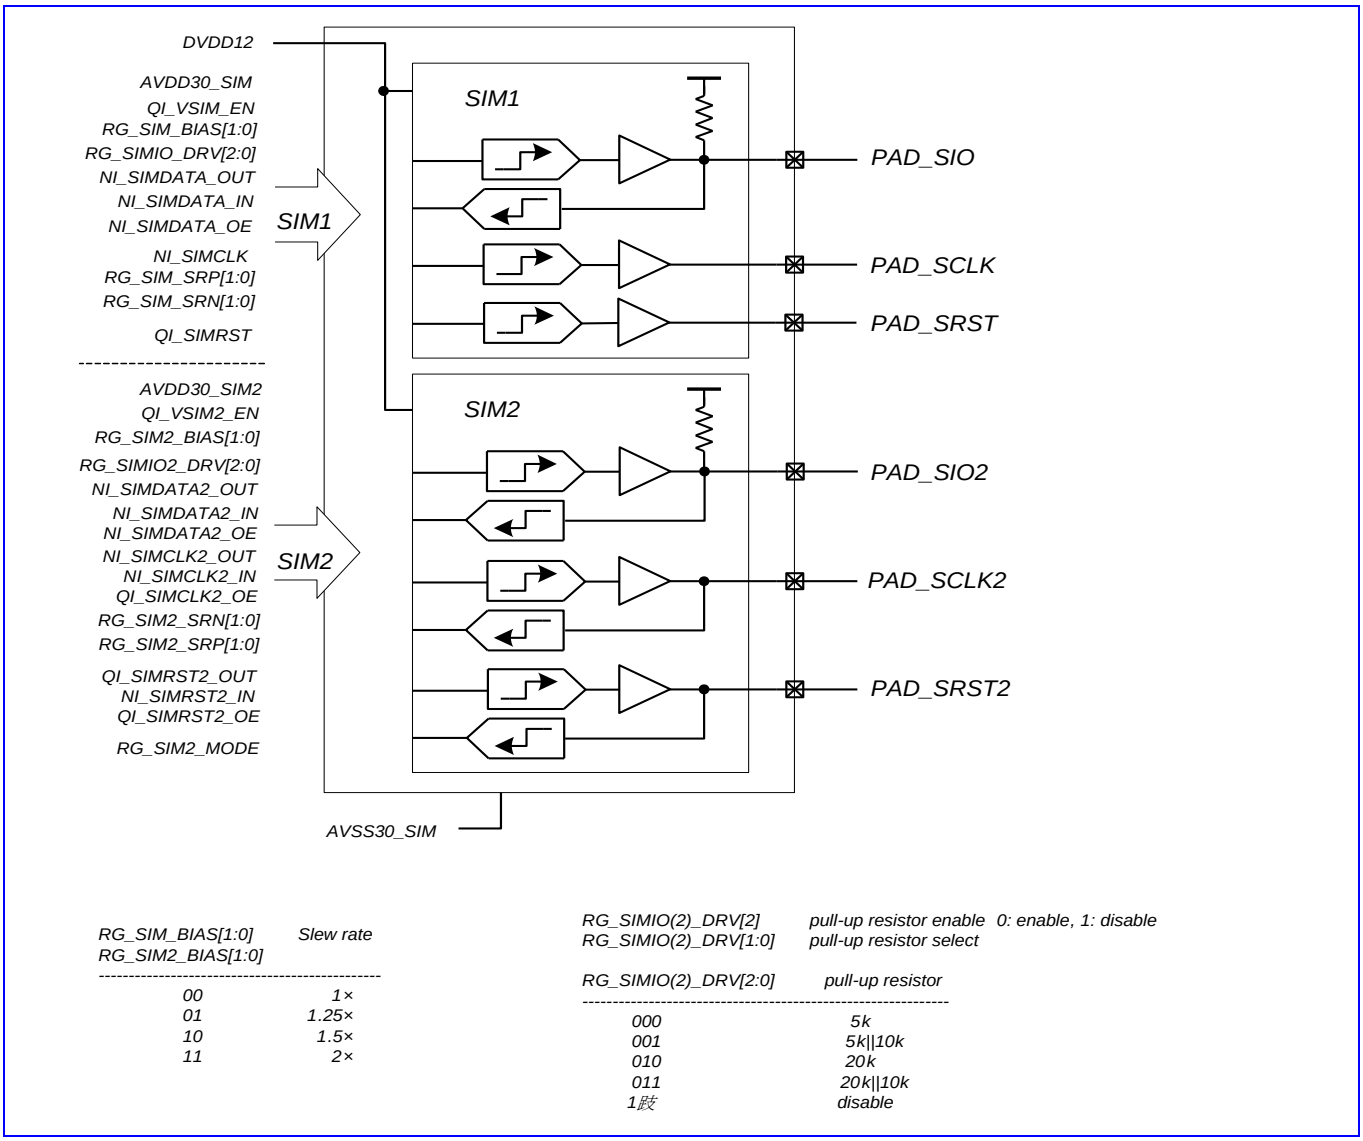

Figure 20 SIM interface block diagram

There are two SIM card interface modules to support two SIM cards simultaneously. The SIM card interface circuitry of PMU meets all ETSI and IMT-2000 SIM interface requirements. It provides level shifting needs for low voltage GSM controller to communicate with either 1.8V or 3V SIM cards. All SIM cards contain a clock input, a reset input, and a

bi-directional data input/output. The clock and reset inputs to SIM cards are level shifted from the supply of digital IO (Vio) of baseband to the SIM supply (Vsim). The bi-directional data bus is internal pull high to Vsim via 5KΩ resistor.

The 2nd SIM card interface can be used for supporting another SIM card or mobile TV. The interface pins such as SIO2, SRST2, SCLK2, can be configured as GPIO when there is no need to use the 2nd SIM card interface.

All pins that connect to the SIM card (Vsim, SRST, SCLK, SIO) withstand over 5kV HBM (human body mode) ESD. In order to ensure proper ESD protection, careful board layout is required.

2.6.4.2 Functional Specification

The Keypad LED connects its anode to VBAT and its cathode to the ballast resistor. The other terminal of the ballast resistor connects to the driver of MT6573. The Keypad LED driver is a low Ron switch which allows 150mA current.

The brightness of the Keypad LED can be controlled by changing the external ballast resistor or switching on/off the driver through dimming control. The dimming frequency and duty can be programmed by registers through I2C interface. For the details, please refer to the “dimming control” section.

2.6.5 Battery Charge

2.6.5.1 Block Description

The charger circuit in MT6573 is shown as follows.

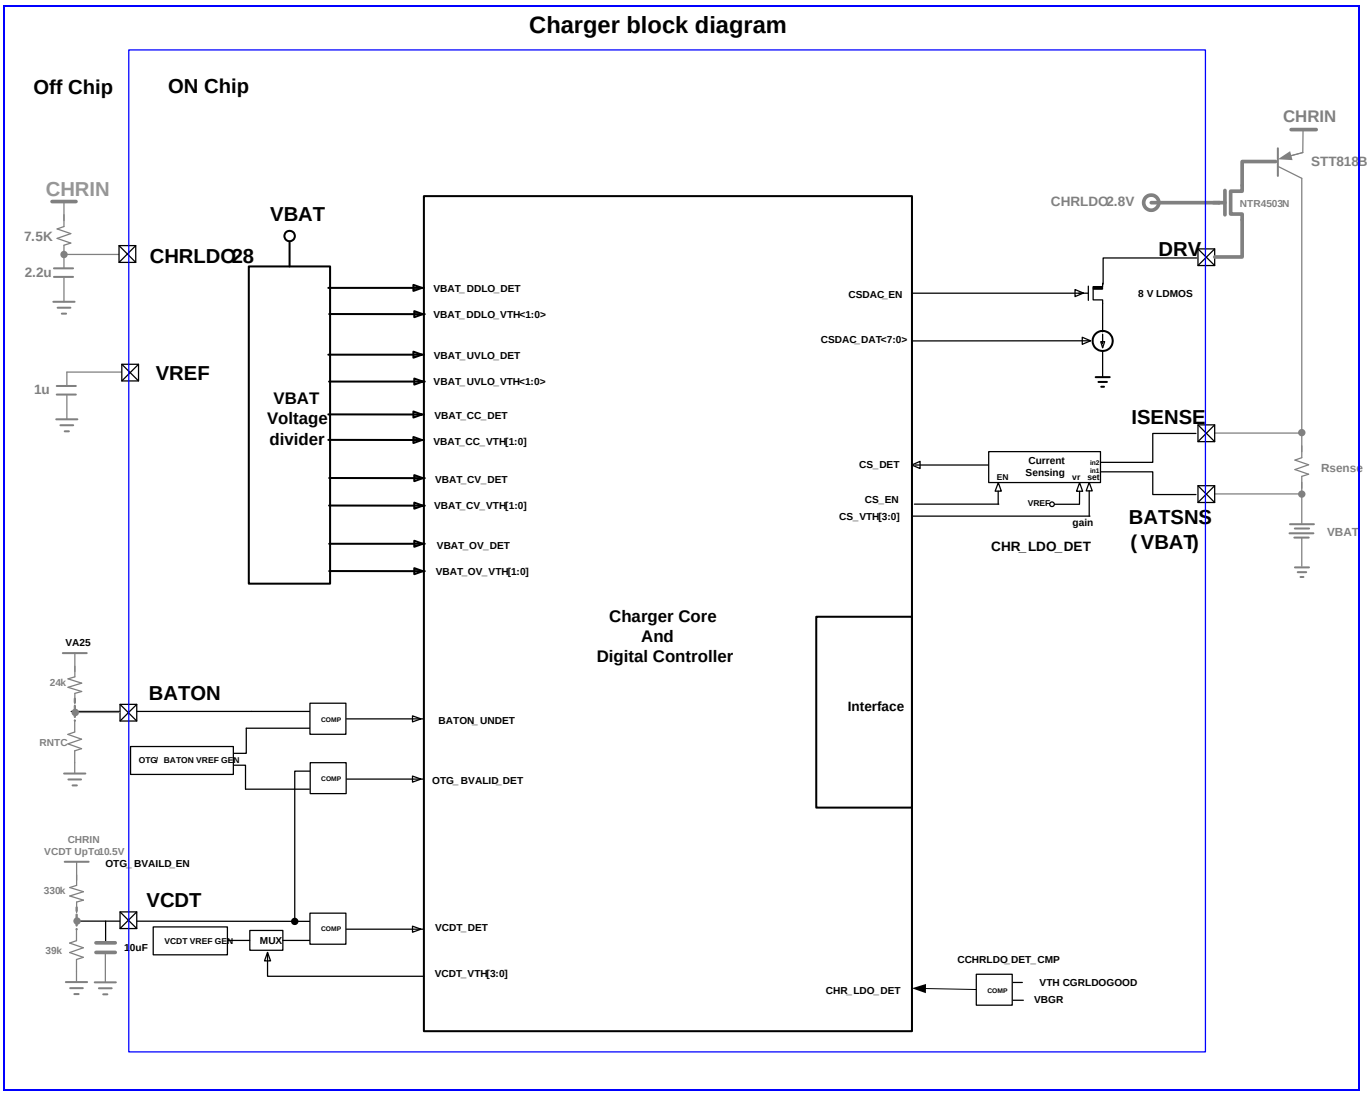

Figure 22 Battery charger block diagram

2.6.5.2 Functional Specification

The charger controller senses the charger input voltage (CHRIN) from either a standard AC-DC adaptor or an USB charger. When the charger input voltage is within a pre-determined range, the charging process is activated. This detector can resist higher input voltages than other parts of the PMIC. Therefore, if an invalid charging source is detected (> 7.0 V), the charger detector stops the charging process immediately to avoid burning out the chip or even the phone.

2.6.5.3 Charging Control

When the charger is active, the charger controller manages the charging phase according to the battery status. During the charging period, the battery voltage is constantly monitored. The battery charger in MT6573 supports pre-charge mode (VBAT<3.2V, switched-off state), CC mode (constant current mode or fast charging mode at the range of 3.2V<VBAT<4.2V) and CV mode (constant voltage mode) to optimize the charging procedure for Li-ion battery.

2.6.5.3.1 Pre-charge Mode

When the battery voltage is in the UV state, the charger operates in the pre-charge mode. There are two steps in this mode. While the battery voltage is deeply discharged below 2.2V, a IPRECC0 trickle charging current applies to the battery. When the battery voltage exceeds 2.2V, the closed-loop pre-charge is enabled. The voltage drop across the external Rsense is kept around 25mV (Typ.). The closed-loop pre-charge current can be calculated:

$$I_{PRE\_CHARGING} = \frac{V_{SENSE}}{Rsense} = \frac{25mV}{Rsense}$$

Symbol	Description	Condition	Min.	Typ.	Max.	Unit
	IPRECC0	VBAT<2.2V	30	50	80	mA
	Pre-charging current	VBAT<2.2V	5	10	30	mA

	Pre-charging off threshold	CHR_EN=L		3.3		V
	Pre-charging off hysteresis			0.4		V

Table 38 Pre-charge Specifications

2.6.5.3.2 Constant Current Mode

As the battery is charged up and over 3.2V, it can switch to the CC mode. (CHREN should be high) In CC mode, several charging currents can be set by programming registers or the external Rsense resistor. The charging current can be determined by Vch,ref/Rsense, where Vch,ref is programmed by registers. For example, if Rsense is selected as 0.2Ohm, the CC mode charging current can be set from 50mA to 800mA. It can accommodate the battery charger to the various charger inputs with different current capability.

Due to process variation, the charging current may vary form chip to chip. To compensate for this variation, the offset registers can be set in MT6573. The PMIC reads this compensation value and applied the charging current offset when the phone is in the charging state. This compensation value could be obtained during the calibration process in phone production, or it could be constantly observed by the BB while the phone is charging.

Table 39 Constant Current Specifications

Note: SA should help to judge (1). which spec. items are required for our customers, (2). testing condition of each spec. items, and (3). which items should not release to our customers.

2.6.5.3.3 Constant Voltage Mode and Protection

If the battery voltage has reached the final value, said 4.2V, a constant voltage is applied to the battery and keeps it at 4.2V. After that, the charging current becomes smaller and smaller. When the charging current is less than a pre-determined threshold for a while, it enters the charge complete state. The charging process will be terminated by setting CHREN=0. The charge complete detection and CHREN control are managed by BB/SW.

Once the battery voltage exceeds 4.3V for any reason, the hardware over voltage protection (OV) will take action and turn off the charger immediately to prevent permanent damage to the battery.

When charging, the PMIC uses GATEDRV pin to control the current flow through the base of the external BJT. The charging current from the collect BJT of is sensed by the voltage drop across the external Rsense resistor (Typ. 0.2 Ω). Then the charging controller and the external components (NMOS,BJT, Rsense and battery) form a regulated charging loop.

During charging, the battery removal might cause the VBAT voltage to surge, damaging the chip before the over-voltage protection is enabled. Pin BAT_ON turns off the charger immediately if it goes high (> 2.205±0.1 V). This function is designated to stop CC or CV charging mode in case the battery is accidentally removed.
