

4Mb Ultra-Low Power Asynchronous CMOS SRAMs

256K × 16 bit POWER SAVER TECHNOLOGY™

Overview

The N04L1630C2B is an integrated memory device containing a 4 Mbit Static Random Access Memory organized as 262,144 words by 16 bits. The device is designed and fabricated using AMI Semiconductor's advanced CMOS technology to provide both high-speed performance and ultra-low power. The device operates with two chip enable ($\overline{CE1}$ and $\overline{CE2}$) controls and output enable (\overline{OE}) to allow for easy memory expansion. Byte controls (\overline{UB} and \overline{LB}) allow the upper and lower bytes to be accessed independently and can also be used to deselect the device. The N04L1630C2B is optimized for the ultimate in low power and is suited for various applications where ultra-low-power is critical such as medical applications, battery backup and power sensitive hand-held devices. The unique page mode operation saves operating power while improving the performance over standard SRAMs. The device can operate over a very wide temperature range of -40°C to $+85^{\circ}\text{C}$ and is available in JEDEC standard packages compatible with other standard 256Kb x 16 SRAMs.

1. When \overline{UB} and \overline{LB} are in select mode (low), $I/O_0 - I/O_{15}$ are affected as shown. When \overline{LB} only is in the select mode only $I/O_0 - I/O_7$ are affected as shown. When \overline{UB} is in the select mode only $I/O_8 - I/O_{15}$ are affected as shown.

2. When the device is in standby mode, control inputs (\overline{WE} , \overline{OE} , \overline{UB} , and \overline{LB}), address inputs and data input/outputs are internally isolated from any external influence and disabled from exerting any influence externally.

3. When \overline{WE} is invoked, the \overline{OE} input is internally disabled and has no effect on the circuit.

This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operating section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

1. Typical values are measured at V_{CC}=V_{CC} Typ., T_A=25°C and not 100% tested.

2. This parameter is specified with the outputs disabled to avoid external loading effects. The user must add current required to drive output capacitance expected in the actual system.

3. This device assumes a standby mode if the chip is disabled ($\overline{CE1}$ high or CE2 low). In order to achieve low standby current all inputs must be within 0.2 volts of either V_{CC} or V_{SS}.

Power Savings with Page Mode Operation ($\overline{WE} = V_{IH}$)

Note: Page mode operation is a method of addressing the SRAM to save operating current. The internal organization of the SRAM is optimized to allow this unique operating mode to be used as a valuable power saving feature.

The only thing that needs to be done is to address the SRAM in a manner that the internal page is left open and 16-bit words of data are read from the open page. By treating addresses A1-A4 as the least significant bits and addressing the 16 words within the open page, power is reduced to the page mode value which is considerably lower than standard operating currents for low power SRAMs.
