## 2.5V/3.3V Differential 2x10 Crosspoint Clock Driver with SDI Programmable Output Selects

The NB4L7210 is a Clock input crosspoint fanout distribution device selecting between one of two input clocks on each of the 10 differential output pairs. A 10 Bit Serial Data Interface programs each output MUX to asynchronously select either Input clock.

CLOCK inputs can accept LVCMOS, LVTTTL, LVPECL, CML, or LVDS signal levels and incorporate an internal 50 ohms on die termination resistors. SCLK, SDATA, and SLOAD input can accept single ended LVPECL, CML, LVCMOS, LVTTTL signals levels.

SCLK and SDATA inputs operate up to 20 MHz. SLOAD input loads and latches the output select data. The SDATAOUT pin permits cascading multiple devices. Outputs are optimized for minimal output-to-output skew and low jitter.

**Programming Application Information for the SDI**

To use the serial port, the SCLK signal samples the information on the SDATA line and indexes the data into a 10 bit shift register (See Figure 3). The register shifts once per rising edge of the SCLK input. The serial input SDATA bits must each meet setup and hold timing to their respective SCLK rising edge as specified in the AC Characteristics section of this document. (See Figure 4)

The SDATA Least Significant Bit (LSB), D0, is indexed in first and the Most Least Significant Bit (LSB), D9, is indexed in last. A Pulse on the SLOAD pin after the SHIFT register is fully indexed (10 clocks) will load and lock the MUX select data values into the Latch register (See Figure 4). For each MUX (Output Q[0:9], a “0” bit value selects CLK1 and a “1” bit value selects CLK 0 (see Figure 3, “C”).

As shown in Figure 4, the SLOAD pulse Low to HIGH level transition transfers the data from the SHIFT register to the LATCH register. The SLOAD Pulse HIGH to LOW level transition will lock the new MUX select data values into the LATCH register. An initial program load cycle is recommended since the 10 bit register will power-up in a random state.

SDATAOUT pin outputs the shift register LSB bit with each SCLK rising edge for porting to the SCLK of the next device in a cascade interconnect only. Cascade operation will require a complete data register loading of all devices to purge the shift registers of power up random state bits.
