

NE555C

LINEAR INTEGRATED CIRCUIT

SINGLE TIMER

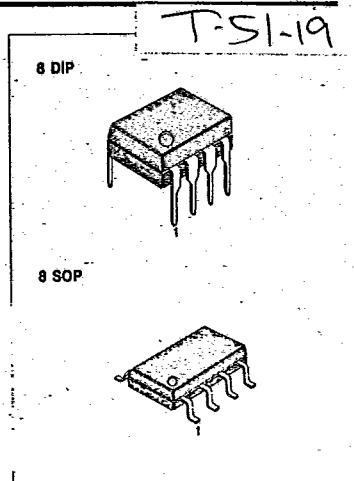

The NE555 is a highly stable controller capable of producing accurate timing pulses. With monostable operation, the time delay is controlled by one external and one capacitor. With astable operation, the frequency and duty cycle are accurately controlled with two external resistors and one capacitor.

FEATURES

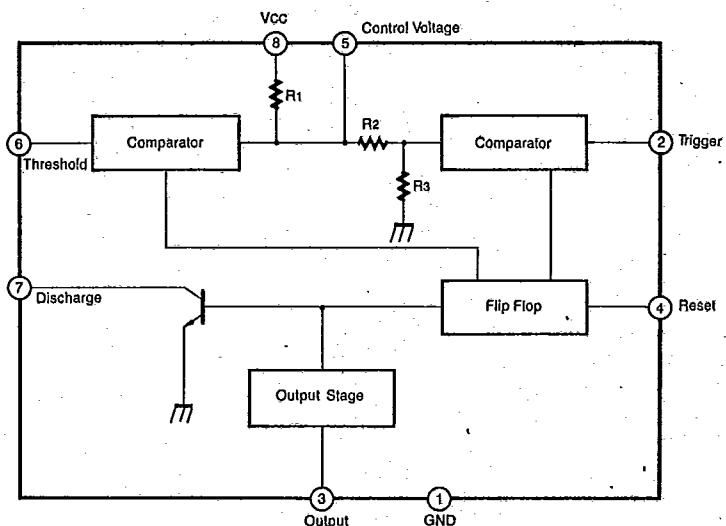

- High Current Drive Capability (= 200mA)
- Adjustable Duty Cycle
- Temperature Stability Of 0.005%/°C
- Timing From μ Sec To Hours
- Turn Off Time Less Than 2 μ sec

APPLICATIONS

- Precision Timing
- Pulse Generation
- Time Delay Generation
- Sequential Timing

Notes:

- Supply current when output is high is typically 1mA less at V_{CC}=5V.
- Tested at V_{CC}=5.0V and V_{CC}=15V
- This will determine the maximum value of R_A+R_B for 15V operation, the max total R=20MΩ, and for 5V operation the max total R=6.7MΩ.

APPLICATION NOTE

The application circuit shows astable mode.

Pin 6 (threshold) is tied to Pin 2 (trigger) and Pin 4 (reset) is tied to V_{CC} (Pin 8).

The external capacitor C_1 of Pin 6 and Pin 2 charges through R_A , R_B and discharges through R_B only.

In the internal circuit of the NE555 one input of the upper comparator is the $2/3 V_{CC}$ (* $R_1 = R_2 = R_3$), another input if it is connected Pin 6.

As soon as charging C_1 is higher than $2/3 V_{CC}$, discharge transistor Q_1 turns on and C_1 discharges to collector of transistor Q_1 .

Therefore, the flip-flop circuit is reset and output is low.

One input of lower comparator is the $1/3 V_{CC}$, discharge transistor Q_1 turn off and C_1 charges through R_A and R_B .

Therefore, the flip-flop circuit is set and output is high.

So to say, when C_1 charges through R_A and R_B output is high and when C_1 discharges through R_B output is low.

The charge time (output is high) T_1 is $0.693 (R_A + R_B) C_1$ and the discharge time (output is low) T_2 is $0.693 (R_B C_1)$.

$$(I_n \frac{V_{CC} - 1/3 V_{CC}}{V_{CC} - 2/3 V_{CC}} = 0.693)$$

Thus the total period time T is given by

$$T = T_1 + T_2 = 0.693 (R_A + 2R_B) C_1$$

Then the frequency of astable mode is given by

$$f = \frac{1}{T} = \frac{1.44}{(R_A + 2R_B) C_1}$$

The duty cycle is given by

$$D.C. = \frac{T_2}{T} = \frac{R_B}{R_A + 2R_B}$$

If you make use of the NE555 you can make two astable modes.
